For a better understanding of the difference between the averages of the quota and nonquota students, **Table 6** shows student performance in the 2005 vestibular, comparing the averages of the first and of the last student qualified in each of these groups, per chosen course. As previously observed, for the set of courses examined previously, in all courses at UFBA, a great difference is not observed between the average of the quota and nonquota students in the two positions evaluated, that is, in the first and in the last position for each group.

Performance in the Courses

The adoption of the quota system by public universities over the last 2 years allows analysis of the impact of the new system to enter the university. This fact is of extreme significance because there had only been data about students' entrance and performance in the vestibular. The hypothesis about course performance was based on facts relating to the other system, which was a classificatory one.

At UFBA, in 11 of the 18 courses of higher dispute (i.e., 61% of them), the quota students had a coefficient equal

or better than those who were not from the quota system (**Table 7**). Contrary to the expectations of those people who were resistant to the implementation of the quota system for fear of lowering the standard in education, the quota students' performance in the examination revealed very satisfactory results in courses from diverse areas.

This polarization is based on fragile arguments, principally the data concerning the student's performance in the vestibular and in the courses. In a recent paper, Barreto (2007) points out not only the good level of performance by students who receive scholarships in these programs but also their distinct perspective. Black students who entered the university through this system tend to positively affirm themselves as black as well as individuals (e.g., involvement in the black movement or non-black association, students' union, and political parties). Therefore, it is absolutely worth questioning: What is the meaning of racialization of Brazilian society, so feared and propelled by intellectuals against the quota system, if not the defense of points of view that translates the permanence of certain privileges and the exercise of power?

The result of this analysis characterized the quota policy, adopted by UFBA, as a very meaningful instrument to promote the democratization of access to higher education. The reservation of seats has shown to be not only capable of broadening the contingent of students who come from public schools, but it also permitted

students to enter the university to do courses of elevated competition so that they can have great social prestige. The racial segments (blacks and indigenous), who had shown the necessary performance, had earlier been systematically kept apart from this possibility, due to the reduced number of seats offered by the university as well as the classificatory system of their fulfillment.

Although it is recognized that the quota system has its own virtues, that its adoption is pertinent as a provisory policy within a context marked by the exclusion of a great number of social segments to the university, it is absolutely necessary not to lose sight of its limitations. The overall situation revealed by the present analysis signals an urgent educational policy

that might be able to broaden the offer of higher education in the state.

The participation of students, who had their educational background in public schools, must not be blind to what such institutions may offer. The research on the reality of Brazilian public schools does not leave room for doubt about the long road ahead for the state to offer adequate basic education. On the other hand, we must highlight that if affirmative action in higher education is considered in central countries or in the peripheral ones (United States (see Bowen and Bok, 1998; Allen, 1988), United Kingdom, China, Macedonia, and South Africa) and with strong emphasis on the minorities, the Brazilian experience suggests affirmative action directed to groups of minorities (indigenous and people with special needs) as much as to groups of high percentage representation, such as blacks, because they are almost 50% of the Brazilian people.

Another important difference in relation to these countries is the fact that most universities that adopted the quota system focus on students from public schools. The Brazilian uniqueness is due to a reformulation in the educational system over the last three decades and the subsequent lack of investment from the government in the public system of education. There had been an

increasing access of students to higher education coming from the private system, the majority of them belonging to middle classes and self-declared as whites. Therefore, the challenge in the universities is how to combine affirmative action policies directed both at race as well as at class (poor ones).

Black in White: Black Students at White and Black Colleges

L Evans and J R Feagin, Texas A&M University, College Station, TX, USA

© 2010 Elsevier Ltd. All rights reserved.

Obtaining a degree from an institution of higher education is a major goal for a great many Americans. In the US economy and the global economy, a college degree has moved beyond the scope of a reasonable individual goal and of status attainment to one of economic necessity. However, in US society, obtaining an adequate education has been a reality for only some groups, while educational aspirations have historically, as well as presently, remained only an unfulfilled desire for others.

African Americans, as a group, have historically faced significant racial obstacles to gaining entry into major institutions of higher education. Moreover, after legal segregation in the 1970s, once most major educational institutions became receptive to African-American students, the racial environments often told a different story. Several social science disciplines have studied the consequences of blocked access to educational opportunities for African-American students and other students of color, and we draw on them here. We also extend this area of research by adding contemporary examples of black student experiences at institutions that have been historically white as well as those that have been historically black.

Consider these reasons for examining student experiences in these often racially hostile environments. We need to push for a more diverse and multiracial curriculum not only in the area in which the research we cite has taken place, but also throughout this country, especially as more countries across the globe are experiencing multiracial and multicultural population changes. Indeed, going beyond the scope of a multiracial curriculum means that colleges and universities must do a more adequate job of recruiting and retaining not only African-American students but also students of color generally.

This article examines the historical significance of race, racism, and racist ideology as well as the challenges confronting black students and other students of color in their pursuit of higher education. Next, we chronicle the educational challenges, psychological consequences, and the everyday realities of African-American students within these white and black institutions of higher education. Finally, we introduce the agonizing dilemma faced by the parents of these students: African-American parents routinely have to make the tough decision of where to send or encourage their child to attend school. Although this article primarily focuses on US institutions of higher education, the implications may be extended to provide an understanding of issues facing students of color in various other contexts. First, we focus on the history and role of

systemic racism and its meaning for African-American students in education.

Education and the Role of Systemic Racism

In order to understand the current realities of many students of color and their experiences in higher education, a look at the role of systemic racism is needed. From this perspective, racism is and has been both foundational and systemic; it involves a material, social, and ideological reality that is both historically and presently entrenched in major US institutions (Feagin, 2006). Because of the persistence of racism well into the twentieth century, African Americans were often prevented from obtaining an education, or at best were allowed access to a very limited education. For instance, the 1890 census states that of the nearly 10 million students enrolled in public common schools in the United States, less than 1% of those students were then colored (US Census, 1890). Through the practices of institutional racism, not only were African-American students and other students of color prevented from obtaining an education at any significance, but also those whites in power used this lack of schooling as a means of continuing the vicious cycle of employment and other racial discrimination at most societal levels.

Understanding the historical background is of importance in considering the connection between past racial atrocities and current discrimination realities. Discrimination in educational opportunities throughout US history has not been limited to specific regions or sections of the country. Indeed, many educational institutions have institutionalized a variety of discriminatory practices, North and South (Feagin *et al.*, 1996). It was not until well into the twentieth century that African Americans were allowed to attend historically white universities in any significant numbers. In some cases, African-American students were only allowed to attend schools that were separate and unequal. For instance, in the state of Texas, the first African-American student admitted to a historically white college did not enter until 1954 due to segregation laws in place, restricting undergraduate admission of African-American students at such colleges. Moreover, when historically white institutions did finally allow entry of people of color, the experiences of these students were often very discriminatory and disheartening.

With institutional racism foundationally in place, the role of historically black college (HBCUs) and universities

early became paramount as a means of educating young black men and women. Because of the inability of students of color to attend historically white institutions, predominantly black universities became an intellectual haven for these students. Even today, these historically black institutions educate and provide degrees to nearly 25% of the African-American student population (Borden, 2005). Indeed, HBCUs have become more than an educational experience for students of color; they have become a safe haven from a racialized society that often marginalizes and discriminates against them. In the next section, we examine African-American students attending predominantly white universities, their relationship with faculty and peers, and their perceptions of the general campus climate.

Students Attending Predominantly White Universities

Presently, some African-American students find themselves attending a university that has been and remains a historically white institution. In this setting, African-American students often report experiences of white racism on and off campus. These experiences can range from blatant racist acts to instances of racial joking and subtle exclusion. Most of this behavior is indeed taken for granted by most white administrators, faculty, staff, and students, who view that the campus as “a ‘white’ place in which blacks are admitted, at best, as guests” (Feagin *et al.*, 1996: 13). In addition, African-American students in these majority-white settings must be able to deal with racial slurs, avoid becoming lost and isolated, and protect themselves from harm while enduring or confronting an often negative racial climate (Feagin, 1996; Stewart, 2008). In these predominantly white settings, African-American students often “have little choice but to accept the racist epithets as part of the heavy personal and psychological price they pay for securing certain societal opportunities that they consider important” (Picca and Feagin, 2007).

In a recent examination of African-American student experiences at predominantly white universities in the state of Texas, we questioned students about the significance of race and racism in their everyday lives. These black students often mentioned feeling as if they are not wanted, or as though they do not belong on these historically white campuses. This feeling can often carry over into the classroom, impacting the grades of the students as well as their interactions with their classmates. For instance, Sandy a senior at a predominantly white university stated, “I don’t have a relationship with the other [white] students in most of my classes. None of them really talk to me and if someone asks a question and I know the answer, they always turn their heads and ask someone else” (Evans, 2006). In many of the interviews, other African-American students attending this university

frequently echoed her sentiments. In cases such as these, we likely observe the long-standing belief in the minds of many whites about the inferior intellectual competence of African-American students. Indeed, considerable evidence exists showing that African-American students continue to have race-related experiences in classroom interactions with faculty and peers that can strongly influence their academic development and willingness to participate in class (Chavous *et al.*, 2004).

Important educational relationships in predominantly white settings between white faculty and students of color are in some senses lacking. For instance, when asked about her relationship with faculty at her university, one student commented:

In one example, I have one classmate and we really talk a lot. She was advised by the same advising professor. We both asked for independent studies. She got the independent study and all she has to do is write a paper. I asked for an independent study and I was told, “Well, give me a compelling reason and I’ll consider it”. Now, it could be anything but it didn’t feel that way. . . (Evans, 2006).

Other students in this type of environment shared similar racialized experiences with white faculty. In some cases, the perception of the interaction itself is seen differently by white faculty and black students. In recent research conducted on white faculty and African-American students, Gonsalves states that often faculty and students interact and the African-American students feel as though they and their comments are not taken seriously or are not respected by white faculty members. In this silent engagement, misunderstandings as well as actual discrimination can occur (Gonsalves, 2002). African-American students are thus not as likely as white students to interact with white faculty outside the classroom. These students are not as likely to be well integrated into campus life as white students (Guiffrida, 2005).

In the predominantly white setting, exclusion is not the only experience experienced by African-American students. Another everyday reality for African-American students attending predominantly white universities is facing stereotyped notions about what it is to be black. These imposed racial identities not only can be offensive but also can serve as a means of differential racial treatment. For instance, research in this area indicates that African-American students, particularly men, are often stereotyped as athletes and not as serious students. Several black students interviewed in a recent study suggest that the assumption by white students that African-American males are only attending universities for athletics or because of athletic ability seriously misrepresents their academic achievements. Several male students mentioned that they are approached and asked blatantly, “what sport do you play;” contributing to the existing stereotype of blacks as athletes at white colleges and universities

(Evans, 2006). This experience is not limited to men; several young women have recounted similar incidents in reference to their campus identities as something other than a serious student.

To continue our understanding of African-American students in higher education, we now turn to a discussion of black students at predominantly black universities.

Students at Predominantly Black Universities

Student experiences at HBCUs are often vastly different from student experiences at predominantly white institutions. The historically black university student, undoubtedly, experiences issues with gender, sexuality, and social class; however, in regard to racism in the classroom or on campus, students there report experiences that are quantitatively and qualitatively different. Social science research suggests that attending an HBCU contributes significantly to African-American student outcomes in reference to educational experiences and attainment (Laird *et al.*, 2007). In this environment, black students are unlikely to experience an educational environment where they feel unwanted, but rather an environment in which they feel generally welcomed.

African-American students there mention the atmosphere of the university as one of racial equality, not inequality. For instance, students often state that “it feels good to be here and see that we are all working toward the same goal” (Evans, 2006). In addition, HBCUs provide an environment rich in history and positive associations with the African-American community and culture. Students often find themselves empowered by their campus surroundings with other African-American students and faculty of color providing significant positive role models.

Students at historically black universities not only mention having a different academic experience than those attending predominantly white universities, but they also mention having a different type of relationship with administrators, faculty, and staff. As mentioned earlier, faculty relationships can have a significant effect on college student outcomes; some students at historically white institutions mention feeling as though faculty members do not care about their progress in their respective programs or at the university. Conversely, students attending black universities frequently mention having a positive relationship with their faculty members; specifically the African-American faculty members. Students often speak of faculty in a way that includes mentorship, encouragement, and assistance. For instance, one female student that had been attending an HBCU for 3 years mentions:

Most of my professors or better yet all my professors know our first and last names; they know where we are

from; they know our career goals. A lot of my professors just push us and instill in us the desire to do better. They talk about things that are in the news with us. It is like a parent-child relationship. Because not only do they teach us, they mentor us and help us view things in a bigger picture. Black professors are more interested in what you want to do and helping you achieve those goals. They understand you because they may have had some of the same or similar struggles (Evans, 2006).

In conjunction with better faculty relationships, students often mention faring better academically. Although HBCUs make up slightly over 2% of institutions of higher learning, they are awarding one in five baccalaureate degrees to African-American students (St. John, 2000). By reducing or nearly removing the racial tension perceived by African-American students at predominantly white universities, the atmosphere is more conducive to student learning in these cases. In other words, the experiences of African-American students at HBCUs are usually more beneficial educationally than the experiences of African-American students at predominantly white universities (Laird *et al.*, 2007). In order to benefit from the environment that colleges and universities have to offer, young African-American high school graduates and their parents are often faced with the agonizing dilemma of choosing a historically white college location for their children.

An Agonizing Dilemma

In recent research conducted at HBCUs, students reported making the decision to attend this type of university specifically as a means of avoiding institutions perceived to be predominantly white and overtly racist. Although most of the students interviewed had no prior experience attending predominantly white colleges, they mentioned that such advice to attend an HBCU often came from parents and peers with experience at institutions that are predominantly white. For instance, one student had a parent who obtained a 4-year degree from an institution that was historically white, while her father attended an HBCU. When it was time to apply for college, she noted that

Well I always knew it was a HBCU and that was the prime concern with my parents. My mother went to a predominantly white college and my dad went to a HBCU and there just seemed to be more of a connection with my father and his school. My mother even wanted me to go to a black school.

In research conducted at a major university, sociologists Feagin, Vera, and Imani found that there were occasions where students and parents compared the environments

and situations at predominantly white colleges with those of HBCUs. Feelings of not belonging or being surrounded by whiteness versus feelings of a sense of belonging and of worthiness can make a huge difference to parents and students of color (Feagin *et al.*, 1996). Moreover, African-American students fare typically better socially and academically at historically black institutions because of the fact that these institutions often emphasize a general educational and achievement philosophy similar to that accented in African-American communities (Chavous *et al.*, 2004).

African-American students often share the concerns of their parents when making the decision to go to college. When having these conversations, parents report talking to their children about being careful and being aware of their surroundings if attending a university that is predominantly white. Other parents suggested that their children attend a university with a large African-American student population in order to have an experience with college that allows them “to focus on academics and not on how people treat you” (Evans, 2006). Collectively, African-American parents are aware of the environment on white campuses and feel an agonizing dilemma when sending their children into this type of white environment. Nevertheless, many African-American students do attend a university that is predominantly white, and there are often severe consequences for them. In this next section, we examine some of the psychological consequences.

Consequences of Racism in Education

Stark differences in racial experiences are observed in research on African-American students attending predominantly black colleges and those attending predominantly white colleges. These differences can have vastly different consequences. When it pertains to predominantly white universities, racial discrimination and the racist ideologies spouted by some white students, faculty, and administrators often lead to undue stress for African-American students. The vast differences in racial climates can lead to distinct psychological consequences, depending on the type of school attended.

For African-American students attending a predominantly white university, the general campus climate can be one that is seen as racist and unwelcoming to students of color. Not only is this environment seen as one of whiteness to African-American students, but also white students, faculty, and administrators often do not perceive any racial hostility or discrimination in the campus environment. Because of this, to succeed African-American students must develop various ways to cope with the racialized stress produced on these historically white campuses. Moreover, experiences with racism can lead to psychological problems, excessive alcohol consumption, and problems with classes and grades (Bynum *et al.*, 2007).

In addition to the aforementioned factors, racialized stress at predominantly white universities can lead to feelings of inadequacy and poor classroom performance, which in turn can lead to decisions to leave their current university. Generally, the academic environment at historically white institutions can be a source of stress because of factors such as racial hostility and discrimination, and African-American students there often attribute their higher levels of stress and poor psychological well-being to such unwelcoming environments (Heppner *et al.*, 2004).

For African-American students attending predominantly black universities, psychological problems are mostly caused by factors outside the realm of racial discrimination. They may simply come from the nature of higher education, as for white students at historically white institutions. However, even at the HBCUs, the surrounding white-dominated environments may cause them educational problems. Thus, students at HBCUs often report no experiences with discrimination or racist ideologies on campus, but often note these negative experiences when off campus and not in this safe environment of the predominantly black campus. For instance, students attending one HBCU in Texas cited numerous examples of overt racial discrimination off campus. Yet, such students can often rely on the counsel of black peers and faculty in dealing with these off-campus issues. In such cases, the university can become a safe space for getting help in dealing with outside racism or avoiding that racism.

Conclusion

When it comes to higher education and African-American students, several factors affect their educational lives. First, the fundamental role of systemic racism in the experiences of these African-American students must be considered. At most predominantly white universities throughout the United States, the general campus racial climate can be very uncomfortable to African-American students. Due to the historically exclusive and often racist nature of these schools, this racial foundation can still manifest itself in the everyday campus climate. The consequences for African-American students can be detrimental to their futures in academia and their educational success.

Conversely, students attending an HBCU often have a different experience when it comes to the realities of a racist environment and to educational achievement. There are better relationships with faculty, administrators, and peers that take place in this environment in comparison to schools in which African-American students make up a minority of the population. At these historically black schools, students generally report greater social and academic integration because they do not face significant feelings of exclusion and disrespect.

In regard to the broader meanings of racist experiences on predominantly white college campuses, we should consider the significance of breaking down the hostile racial climate and increasing the multiracial curriculum in all areas. Educating students on cultural diversity and the importance in maintaining and accenting this diversity is a necessity if the United States is to prosper in the future. Understanding the role of systemic racism in historically white educational settings, thus, can contribute to the changes needed in recruiting and retaining students of color. By teaching the significance of respecting various racial and cultural differences, white racial hostility and discrimination on historically white college campuses and the negative consequences for students of color can perhaps be diminished.

Lisbon Strategy – The European Union (EU) Strategy that aims at making the EU the most competitive and dynamic knowledge-based economy in the world.

new dynamic to German universities by introducing the idea of a research university – ideas of freedom in teaching and learning (Rüegg, 1992/2004). This is the case, at present, in the Europe of the early years of the twenty-first century.

The last year of the twentieth century brought to public and professional attention a new concept describing the state of affairs in European higher education, which is the concept called the Bologna Process.

The purpose of this article is to look at the concept and meaning of the Bologna Process and to consider the strategies of European integration in the field of higher education. It includes an exploration of the definition and the meaning of the term and related notions, discussion of the rationales for the new plans, and policy actions called upon to transform higher education in Europe.

The primary objective is to construct a way of approaching the issues, to provide a framework for taking stock of what the appropriate paths are for establishing a common European higher education space, and to decipher what some of the challenges will be for European higher education following 2010, when the Bologna Process's ideas have to be implemented. Another important question involves how far the implementation of various policies in European higher education impacts the processes of tertiary learning in international perspectives.

Definition of the Bologna Process

The Bologna Process describes the active and comprehensive policy actions taken by European governments and universities leaders in order to modernize higher education structures in Europe and to create a Common European Higher Education Area (CEHEA). These actions commenced in 1999 and it was announced that activities of the process are to be completed by 2010.

The overall objective of the Bologna Process to create a CEHEA is detailed in the following action lines:

1. adopting a system of easily readable and comparable degrees;
2. adopting a system essentially based on two cycles (undergraduate and graduate);
3. establishing a system of transferable credits;
4. promoting academic mobility;
5. promoting European co-operation in quality assurance;

Introduction

The key concepts that have been dominant in professional literature on higher education in Europe have changed over time. Academic freedom and state, curriculum and methods of instruction, elite versus mass education, university governance, and funding have each, in turn, been examined in a series of debates and a plethora of reports, books, articles in professional journals, dictionaries, and encyclopedias (Rothblatt and Wittrock, 1993).

Philosophers, public thinkers, and political leaders have been involved in constant debates concerning the present state and the future of higher education in Europe (Bourdieu, 1996). This was, likewise, the case in the eleventh century when the idea of the university was introduced to Europe and to Western civilization. That was also the case in the nineteenth century when Wilhelm von Humboldt gave a

6. promoting the European dimension in higher education;
7. encouraging lifelong learning;
8. developing partnerships between higher education institutions and students;
9. promoting the attractiveness of the CEHEA; and
10. building programs in doctoral studies and the synergy between the CEHEA and the European Research Area.

The Bologna Process started as an initiative of European Ministers and European university leaders; however, it is not an official European Union (EU) project. Despite this, there is a great deal of overlap between policy actions in the framework of the Bologna Process and various official EU projects, including the EU's Lisbon Strategy that aims at making the EU "the most competitive and dynamic knowledge-based economy in the world" (Lisbon Strategy 2000). The reforms involved in this process attempt to address some of Europe's social and economic challenges by enhancing the quality of its education, research capacity, and graduate employability.

The Bologna initiatives stand for a comprehensive modernization of study programs and for internationally comparable degrees. They also entail a change in perspective toward learners and their development of competences. At the end of this path, European higher education leaders hope to find improvements in the quality of teaching for the sake of strengthening student's professional knowledge and skills.

The Set-Up and the Development of the Bologna's Initiatives

Universities have always reacted to environmental pressures for change, and – in the long run – they have done it quite successfully; that is why, at present, universities are among the oldest of structural organizations that are known in the world.

Much was heard in academic discourse with regard to reforming or restructuring, and concerning the reorganizing or modernizing that European countries have experienced in higher education since the mid-1980s. A great deal of academic research and writing was aimed at finding new ways to analyze the relationship between socioeconomic changes and higher education policies. All of this was sparked by perceptions of turbulent change

in contemporary Europe that has not been felt in centuries. The changes were most dramatically evident in the higher-learning institutions of Europe following the collapse of the old regimes in Eastern and Central Europe in the late 1980s, and the disintegration of the Soviet Union in 1991.

The field of education became most sensitive to simultaneously occurring revolutions: a political revolution that created new nation-states in Europe, an ideological revolution that ended the communist regimes, and an economic revolution that replaced state-administrative systems of production, distribution, and consumption with a market-driven economic order. Indeed, socioeconomic, political, and technological processes at the end of the twentieth century brought to the fore a completely new agenda for European education.

New national borders in Europe, new migration processes, and new structures in the labor market present new opportunities for higher education systems and international academic collaboration, while advances in communication technologies allow much faster exchanges and greater flexibility in the creation of joint-study programs. However, these exciting opportunities for international cooperation in higher education, at once, represent a host of challenges related to issues such as academic recognition, quality-assurance standards, and compatibility of qualification frameworks.

In June 1999, ministers of education from 29 European countries gathered in Bologna – the birthplace of Europe's oldest university – to sign the Joint Declaration of the European Ministers of Education (otherwise known as the Bologna Declaration). The policy actions proclaimed in the Declaration aimed at "increasing the international competitiveness of the European system of higher education" and at creating "the European area of higher education as a key way to promote citizen's mobility and employability and the Continent's overall development" (The Bologna Declaration, 1999). The Bologna Process had been started (**Figure 1**).

The Bologna Process has become the most important initiative in the field of higher education for contemporary Europe. Ministers of higher education from all country-signatories of the Bologna Declaration discuss policy actions, coordination efforts, and general strategies at biannual meetings (**Table 1**). The results of the Ministerial meetings are memorialized in documents called *communiqués*.

Figure 1 The Bologna Process.

Table 1 Country-signatories of the Bologna Declaration

Since 1999		Since 2001	Since 2003	Since 2005	Since 2006
Austria	Lithuania	Croatia	Albania	Armenia	Montenegro (as an independent State)
Belgium	Luxembourg	Cyprus	Andorra	Azerbaijan	
Bulgaria	Malta	Liechtenstein	Bosnia and Herzegovina	Georgia	
Czech Republic	Netherlands	Turkey	Holy See	Moldova	
Denmark	Norway		Russian Federation	Ukraine	
Estonia	Poland		Serbia and Montenegro		
Finland	Portugal		The former Yugoslav Republic of Macedonia		
France	Romania				
Germany	Slovak				
Greece	Republic				
Hungary	Slovenia				
Latvia	Spain				
Ireland	Sweden				
Italy	United Kingdom				
Iceland	Switzerland				

The *Communiqué* sets out recommendations for acceptance of new members, future priorities, and offers a working plan for the subsequent 2 years. The ideas of the *Communiqué* are to be implemented in the individual countries in accordance with their relevant legal contexts and national priorities.

The Bologna Follow-up Group (BFUG) was established in order to oversee the process between ministerial conferences. BFUG is composed of: (1) Representatives of all countries participating in the process of creating the CEHEA; (2) The European Commission as an additional full member; (3) Eight consultative members, namely – the Council of Europe, UNESCO's European Centre for Higher Education, the European University Association, the European Association of Institutions in Higher Education, the European Students' Union, the European Association for Quality Assurance in Higher Education, the Education International Pan-European Structure, and Business Europe. The BFUG meets at least once every 6 months and is chaired by the country holding the Presidency of the EU.

Economic, Social, and Academic Rationales for Unified European Higher Education

The Bologna Process should not be viewed in isolation from global processes – it is an example of a response to the internationalization of higher education and global integration; it is determined by economic, social, and academic rationales. The Bologna Process initiatives should also not be viewed in isolation from the sociopolitical processes in contemporary Europe.

European higher education structures are undergoing a substantial, comprehensive change as part of the international higher education system. The scope of this change is as great, or even universal, as the change that higher education systems experienced at the end of nineteenth century (Slaughter and Leslie, 1997), when vast advances in the industrial mode of production and an overwhelming transformation of social relationships fundamentally reshaped the mission, structure, and practices of higher education. At present, the expansion of markets and market relationships, globalization, and the further development of technology entail higher education-transformation processes in three major interrelated directions: the marketization of higher education, structural modification, and the establishment of new forms of learning at advanced levels. The market dominance and sharp decrease of government spending on higher education in contemporary European societies necessitates greater reactivity in higher education systems to market signals; especially those that come from the labor market. Higher education institutes (HEI) are forced to adjust to market conditions, and they do so by developing new organizational structures and altering the preceding structures, policies, and practices. The end of the twentieth century in Europe was marked by the emergence of a new type of HEI that has been recently referred to as an innovative, for-profit, or entrepreneurial university (Clark, 1998; Ruch, 2001). Finally, the introduction of new forms of higher education also provides evidence of the ongoing process of transforming traditional patterns of higher education: e-Learning, distance learning or distance education, life-long education, and nonuniversity forms of tertiary education. Europe is confronted with the reality of change when knowledge is vital to the welfare of its countries.

The scope, diversity, and contradictory nature of the aforementioned changes characterize the great interest of policymakers in terms of the pathways and mechanisms of transformation, its driving forces, determinants, and agents. The socioeconomic realities of contemporary Europe determine the necessity for concrete policy actions and projects that will help with the realization of an efficient and performing knowledge enterprise that generates increasing output with decreasing input.

It has also to be taken into account that the forming of the EU as a new sociopolitical unit now accounts for about 500 million citizens and about one-third of the world's gross domestic product (GDP). Although it arguably constitutes a technical process, the complexity of uniting the diverse cultural regions and ethnic and national traditions in common socialization processes, at the same time, requires active policy actions for creating a new European identity. Educational policy is the most direct means to foster an environment for developing, in the young generations, a feeling of unity in diversity.

Thus, a specific approach was needed to create a new European educational model that would value a variety of countries and nations and yield the maximum possible results for establishing the new EU. A shared long-term vision and the objectives of universities in European society as agents for constructing a united Europe in the global context came to the political agenda.

Globalization Effects on European Higher Education

How does globalization affect higher education policy and academic structures in Europe? Social analysts disagree on the essence and critical features of globalization and even whether it was unique historically, although most agree on certain basic ideas with respect to the relations between globalization and higher education and on the factors that shape the realities of the tertiary education systems in the twenty-first century.

Among the most important are the assumptions that the driving force for higher education in the time of globalization are the market and commercialization. The factors that influence the dynamics of higher education systems include new ways of financing higher education, new managerial techniques, and new rules of the game for people who make up the schools, unprecedented mobility for students and professors, the role of English as the *lingua franca* for higher education and science, advanced information, and communication technology (Altbach, 1998).

In Europe, education, in general, and higher education, in particular, were the great agents of nation-state building. Eugene Weber – in a classic account of nation building – has documented how people in France were molded into a

nation. The most important element that sped this process was a national educational system (Weber, 1976).

Ernest Gellner's study of nations and nationalism further stressed the relationship between nation building and education (Gellner, 1983). As Richard H. Robbins points out, "Gellner went so far as to suggest that education became the ultimate instrument of state power, that the professor and the classroom came to replace the executioner and the guillotine as the enforcer of national sovereignty, and that a monopoly on legitimate education became more important than the monopoly on legitimate violence to build a common national identity" (Robbins, 2005).

Thus, European academic systems and structures that – back in history – were closely related with nation-states and grew within national boundaries, in the time of globalization, find themselves competing internationally. The national languages that were major factors for comprising educational systems compete with English even within national borders.

Globalization poses exciting new opportunities for policymakers. Despite the fact that policymakers worry that they are losing yet more of their control over their own higher education systems, they are, nevertheless, turning increasingly to regional or international institutions in the hope that coordinated solutions will provide some new dynamics.

Globalization as a concept and analytical instrument – while used for understanding processes of change in higher education – focuses on the power relations between nation-states and global and regional actors, on the economic and social interactions between HEIs, governments, business enterprises, and nongovernmental organizations (NGOs).

The current debates on higher education and globalization in Europe have two distinct tendencies that might be called positive and negative. One group of scholars, political leaders, and educational practitioners praise globalization for opening new opportunities for higher education through trade liberalization, global competition, and commercial interactions. They put forward an argument that globalization serves as a means to eliminate the effects of national isolation. In the time of significant public cuts to systems of higher education, globalization is viewed by this group as a kind of new wind for the canvases of educational ships. Another group of academics argues that economic globalization is strictly alien and even conflicting with traditional goals and fundamental values of higher education. Globalization, in their view, makes the Humboldtian/European university model obsolete. The university may well survive as an educational corporation pushed forward by globalization, yet – in such a case – it would no longer be the university as it was known throughout European history (Higher Education in Europe, 2001).

The implementation of the Bologna Process's ideas demanded a strong governmental influence on higher

education. Thus – on the one hand – globalization brings to Europe the idea of a declining role of the state in university life. Yet, on the other hand, the government – irrespective of whether it is federal or unitary, centralized or decentralized – is in constant demand as a leading actor in facilitating the Bologna policy actions to modernize its higher education system by setting new parameters and providing financial support and legal regulations.

A strange symbiosis of globalization processes and the mounting role of nation-states for modernizing higher education systems throughout Europe tends to reinforce the fears of those who are concerned about the increasing homogenization and standardization of higher learning.

There are other challenges of globalization that have direct and profound effects on higher education in Europe: technological change and environmental threats, global risks and threats to the well-being of society, migration, and the security of the population (i.e., terrorism).

The Bologna Process is an attempt to meet these challenges, to answer the question of how higher education can become an active part in shaping the future of European societies.

The Bologna Process in the International Setting

The European higher education-reform model has created considerable interest in other parts of the world. In some countries, it generated public debate concerning the possibilities of implementing Bologna-like reforms in domestic higher education. A number of professional higher education associations around the world have acknowledged the significance of the emerging CEHEA, and have decided to undertake a course of action to address the implications of the Bologna Process for the development of their national universities (AUCC, 2008).

There are international initiatives aiming to facilitate the convergence of higher education systems at a regional (supranational) level. The inaugural Asia-Pacific Education Ministers' meeting was held in Brisbane, Australia, in April 2006. The Ministers signed a Brisbane *Communiqué* and agreed to promote regional student and academic mobility.

The Bologna Process has also stimulated a discussion between European and international partners with regard to the mutual recognition of qualifications. In the USA, for example, the Institute for Higher Education Policy (IHEP), which is based in Washington DC, has launched an initiative to create a new understanding of the rapidly changing global context for higher education learning and credentialing and the impact of these changes on US higher education.

While the Bologna initiatives are geared toward endorsing Europe's own competitiveness and attractiveness to non-European students and faculty, stakeholders within

Europe are becoming increasingly aware of the need to look beyond Europe's borders to broaden cooperation with other regions of the world. In the most recent years, country-signatories of the Bologna Declaration have also commenced to actively promote the ideas of the Bologna Process throughout the globe. In 2007, at the Ministerial conference in London, The European Higher Education Area in a Global Setting strategy was adopted. It encompasses the following five core policy areas:

1. improving information on the CEHEA;
2. promoting European higher education to enhance its worldwide attractiveness and competitiveness;
3. strengthening cooperation based on partnerships;
4. intensifying policy dialog; and
5. furthering recognition of qualifications.

Problems in the Implementation of the Bologna Process

The Bologna Process only provides the administrative framework for reforms, yet there is no homogeneous situation throughout Europe with regard to the implementation of strategic policies. The starting point for each country-signatory of the Bologna Declaration was different. Some countries already had a two-cycle (undergraduate–graduate) structure or a credit system in place while others did not have it. Countries also started at different times and with different economic potentials. The countries that joined the Bologna Process after 2003 are not yet advanced in implementation of the announced objectives. The former Soviet Union countries face multiple economic, social, and political problems in their attempts to incorporate Bologna's ideas into the reality of the legacies of the former centrally planned type of society and ideology-based education (Rezaev, 2005).

Following several years of Bologna Process activities aimed to transform European higher education, most European universities are still not competitive on a global scale with the HEIs of its major competitors; neither in access for students not from Europe, nor in attractiveness for students around the world, nor in the excellence of education and research. It is a general perception that the productive reforms cannot be accomplished within the current levels and patterns of investment in European higher education. The total (public and private) spending on higher education in the EU, in 2002, was 1.3% of GDP, compared to 2.8% in the USA. To close the spending gap with the US, the EU would have to commit an additional 140 billion Euro per year – securing, in particular, substantial investment from the private sector. One of the remedies to improve the situation in European higher education will be to diversify financial incomes and investments.

The major higher education initiatives that have been undertaken in the framework of the Bologna Process,

in Europe, in recent years have had different assessments. The optimists look at CEHEA as a real step toward constructing a new society based on common European ideas and values. The pessimists see the Bologna Process as an obstacle for real modernization of the national systems of higher education. Then a camp of pragmatists assesses CEHEA as a response to globalization processes and Europe's need for self-improvement and to make the higher education system more dynamic under market constraints. The latter group argues that CEHEA is the only way for European universities to become a real alternative to the American educational system – which takes in more and more students from around the world, including Europe.

Whatever view characterizes the current status – great success, success, partial success, or failure – nonpartial observers agree that implementation of Bologna's objectives is a complex process and that it needs more energy and constructive actions.

What Lies Ahead?

The actual problems for European higher education leaders to successfully establish CEHEA are quite numerous. To name a few that are most obvious: (1) Higher education systems in European countries continue to be a responsibility of national governments. The major portion of funding still comes to HEIs from national governments. (2) Most European HEIs are provincial, oriented toward training graduates from a specific region for a specific regional labor market. (3) The large majority of students – specifically from Central and Southern Europe – do not study abroad and could not effectively study in English but only in their native language. (4) The European labor market for graduates is not open to all professional fields but to relatively few. (5) European higher education continues to be highly Eurocentric, causing real problems for students from Muslim countries such as Turkey or Azerbaijan. (6) Foreign students are unevenly spread in European HEIs – with the UK, Germany, and France hosting the majority of international students. Other countries, particularly the member states of Eastern and Southern Europe, are highly underrepresented.

The realities of creating the new European system of higher education manifest the necessity to make this system open to real diversification. Five elements will constitute and determine the world of diversity in European higher education following 2010:

1. diversity of funding base;
2. diversity of curricula and programs;
3. diversity of methodology and teaching techniques;
4. diversity of departments and departmental periphery (interdisciplinary centers and professionalized organizational units to work with outside organizations and groups); and

5. diversity of faculty and students in terms of ethnicity, gender, cultural, and sub-cultural milieu.

Summary

The Bologna Process, aiming to create CEHEA by 2010, is an ambitious project that is complex and subtle. It is a project that answers objective economic, social, political, and academic challenges. The CEHEA is a significant challenge for the EU and for the unity of countries that share national borders, citizens, or values. It requires cooperation and collaboration among units that are often self-interested instead of focused on communal activity.

What is possible in the coming years will be achieved only through ambitiously tackling the obstacles to coherent growth and through self-sacrifice to the common goals. The Bologna Process has gained the allegiance of 46 countries, including those like Russia and the former Soviet Union countries that are not formally part of the EU and are struggling with the Soviet legacies. The opportunity of improving interactivity between HEIs through joint projects, research and development, scientific cooperation, and sharing of resources is already evident. How much unity can be found in the diversity and whether or not modern higher education will be fundamentally altered as a result of new technologies, systems, and programs are still debatable questions in Europe. In some senses, CEHEA redefines the meaning of university and seeks to establish a multiversity wherein diverse voices are represented on their own sovereign and independent terms.

The Bologna Process is a specifically European answer to global issues; it is obvious that the Bologna Process also contributes to international public goods. Despite this, the necessity for more institutional and conceptual cooperation with the rest of the world is of great importance. It is almost obvious that there is a necessity to open much wider the doors of the European higher education labor market to the rest of the world.

The year 2010 is the year when the Bologna Process is scheduled to be fully implemented and it appears that Europe will meet yet another process rather than a final event.

Critical Race Theory in Education Research

R Vue and C B Newman, University of California, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Colorblindness or colorblind ideology – Refers to a worldview that disregards race or racial characteristics. In practice it is a method of disregarding race as a criterion used for selection of participation or receipt of services.

Jurisprudence – Refers to the theory or philosophy of law. In this article it primarily refers to the dominant legal thought which excludes and marginalizes racial minorities in the United States.

Meritocracy – Refers to a system of rewards based on the ability and talent of individuals, leaving unaccounted for the structural advantages and disadvantages conferred to different groups in society.

Positivism – As it concerns social reality and knowledge is the notion that both exist objectively and independently of social actors.

Race – Refers to a socially constructed classification used to categorize people into groups based on phenotype and characteristics assumed to be inherently shared.

Critical race theory (CRT) is an evolving movement formalized in the legal field during the 1970s in order to grapple with the nexus between race, racism, and American jurisprudence, in a better manner. CRT's emergence represents a response to the retrenchment of civil rights reform. This accounts for critical race scholars' critique of civil rights doctrine (which espouses equal treatment) and dissatisfaction with traditional legal reform; Both legal ideals viewed as inadequate for the emancipation of people of color and susceptible to discourses supporting neoconservative agendas to reinstate racial subordination. Accordingly, CRT was formulated by scholars whose primary concern was advancing a theory and method for examining race and overcoming racial inequality through critical analysis of legal doctrines. While CRT is largely used in the legal field, the theory has been adopted by scholars in fields like sociology and education. Scholars in these fields continue to utilize and advance CRT's core tenets – most notably the centrality of race and experiential knowledge. This article discusses CRT as a theoretical framework for education research.

Although an exhaustive list of the theoretical elements and arguments of CRT scholars is beyond the

scope of this article, the key principals presented provide a basic understanding of theoretical underpinnings. First, a brief summary of CRT's emergence is provided; we then describe two central features of CRT and address how CRT has evolved. Finally, a description of its application to education presents examples of scholarship where CRT is employed to understand issues in the field of education. We conclude with implications for the future of educational research as it relates to a critical race framework.

Though critical race theorists vary in the scope of their study, at least five central tenets guide its use in education (theory, research, pedagogy, curriculum, and policy): "Centrality of race and racism and their intersectionality with other forms of subordination, the challenge to dominant ideology, the commitment to social justice, the centrality of experiential knowledge, and the transdisciplinary perspective" (Solórzano, Ceja and Yosso 2000, p. 63). The use of CRT in education is appropriate for several reasons; however, the main justification extends its emergence out of critical legal studies (CLS); both in its points of alignment and departure. Thus, before addressing CRT in education some discussion of its emergence merits attention.

Critical Legal Theory

CRT is considered to have its origins in a departure from the theorizing of CLS. While the critical race movement's inception is marked by critiques of legal scholars, most of whom were scholars of color (such as Derrick Bell, Richard Delgado, Allan Freeman, and later scholars such as Kimberly Crenshaw, Angela Harris, and Mari Matsuda) within the legal studies movement, the formulation of CRT is inherently informed by a myriad of previous movements – including (among others) feminism and the spirit of the civil rights movement encompassing a long legacy of resistance to racial subordination (Delgado and Stefancic, 2001) – and literature across multiple disciplines (Yosso, 2005). However, legal scholars were instrumental in informing the constructs that ultimately have come to define the critical race movement and theory.

The emergence of CRT is more than simply an extension of CLS: it serves as a critique. Although critical race theories and critical legal theories are separate and in contention with one another, they share some notions about how law operates in society. Broadly, the critical

legal movement emerged to counter presumptions that the law operates in a neutral and objective manner (Hunt, 1986). Specifically, it advocates notions of realism, a movement “developed out of the dissatisfaction with tenets of classical legal thought that cast judicial decision as the product of reasoning from a finite set of determined rules” (White, 1972 as cited in Tate 1997, p. 207). Thus, CLS provides an analytical lens to critically examine legal ideology and discourse as a mechanism to socially reproduce and legitimate inequality within society (Hunt, 1986; Tate, 1997). In alignment with this tradition, Tate’s (1997) review of CRT origins notes that critical legal theories provide two important critiques that would ultimately inform CRT; these include a critique of formalism and objectivism. The first is characterized by “impersonal purposes, policies, and principles that serve as the foundation for legal reasoning” while the latter assumes the legal system provides an intelligible moral order (Tate, 1997, p. 208). Therefore, critical legal theorists offer a critique of law which acknowledges legal ideology and legal structures of authority as producing and maintaining social inequality, as opposed to functionalist views viewing social inequality as natural. This critique has served critical race theorists in their interrogation of inconsistencies within legal doctrines, specifically explanations of the contradictions and therefore negative consequential effects of civil rights law on progressive racial reform (i.e., Bell, 1976; 1980; Freeman, 1995). For these reasons, Matsuda (1995) describes, “[t]he willingness to at least consider the utopian prospect and the passionate criticism of existing conditions of racism and poverty attract non-white readers to CLS” (p. 64). Given the legacy of racial inequality within the United States, largely maintained through the construction of laws, critical legal theories share an important perspective with the critical race theorist, which is necessary for understanding the nexus between law and oppression.

Despite its utility, critical race theorists point to limitations of critical legal theories, which render them inadequate for understanding experiences of populations of color. Dalton (1995) writes, as scholars of color within the CLS movement they “are always invited in for tea, but rarely invited to stay for supper, lest we use the wrong intellectual fork” (p. 80), specifically speaking to the limits and determinism that CLS’s hegemonic view of rights doctrine poses for people of color. The collective response to sentiments of disempowerment and intellectual differentiation resulted in CRT; a movement which foregrounds the lived experiences of people of color in order to both acknowledge their marginalization in American jurisprudence but also enable a vision of law that holds the potential for social justice in terms of equal rights, status, and material outcomes. While there are multiple theoretical discontents, including inability to offer structures for social change, a central critique that

critical race theorists have of critical legal theories is the assumption that racism is the same as other forms of oppression (Delgado and Stefancic, 1993). Utilizing legal theorists’ critiques of legal doctrine as a foundation for their own work, critical race theorists brought the racial dimension to the forefront of the analysis: race, they assert, is crucial for understanding and ultimately overcoming inequality given racial saliency in the United States.

Grounded in traditions of the critical legal theorist, Bell’s early writings (including Bell, 1976; 1980) have been identified as “the intellectual starting point of Critical Race Theory” (Crenshaw, Gotanda, Peller, and Thomas, 1995: 3). Crenshaw and colleagues believe that while Bell’s critiques of civil rights discourse represent critical legal critiques of the time, his use of a race-conscious perspective that (1) focused specifically on the effect on Blacks and (2) presented legal decisions as reflective of White racial interests, was a departure in perspective, marking the development of CRT. Specifically, Bell’s (1980) concept of interest convergence – the argument that basic rights are provided only when they meet the shared interests of and do not harm the benefits of Whites – was significant in propelling forward the critical race movement, especially as scholars of color worked to construct a theory in which race centered as an important, necessary basis of analysis.

Centrality of Race

The centrality of race is one of the distinguishing factors of CRT (Delgado and Stefancic, 1993; Solórzano *et al.*, 2000). Crenshaw (1988), points to the importance of race as a basis of analysis, given the legacy of racial oppression in the United States. She argues to ignore that race is illogical, especially when race has become so deeply embedded in how institutions operate to produce social inequality. For that reason, critical race theorists argue that race is significant and excluding race from the analysis merely veils rather than halts its influence in research, policy, and practice. By bringing race to the forefront of the analysis, critical race theorists explicate the presence use of race. Therefore, revealing race consciousness will illuminate what has traditionally been ignored or hidden in past analysis.

When applied specifically to education, the issues of race often fall into the colorblind discourse (Crenshaw, 1988). Colorblind rhetoric and rationale is misleading because although it follows civil rights doctrine, it is often used by conservatives to garner support for repealing race-based initiatives aimed at addressing race inequities. By evoking principals of equality while ignoring the cumulated effects of race reification in material conditions, the concept of colorblindness is deployed to eliminate progressive gains of racial minorities. A well-known and debated contemporary example of this is present in

debates over the issue of affirmative action in United States higher education. Opponents of affirmative action argue that race-based sanctions are unjust, because it betrays a fair approach by privileging people of color over Whites. To ground their arguments, opponents call forth the contradictions that affirmative action poses to treating all people as equal. Embedded within this discourse is the notion of a meritocracy, which is a system of rewards believed to be based on demonstrated talent and ability of an individual. Both simultaneously work to undermine social reform addressing race inequities. The use of colorblind ideology to dismantle affirmative action policies exemplifies critical race legal scholars' critiques of civil rights doctrine, and more broadly liberalism, which is ambiguous and potentially serves to disarm progressive efforts toward social justice. In principle alone, arguments grounded in colorblind discourses may appear to adhere to moral reasoning; however this rationale leaves accounted for the historical and sociocultural contexts that justify the need for affirmative action practices.

Crenshaw (1988) addresses the notion of equality by framing it in terms of equal process and equal outcomes. Using the terms restrictive and expansive equality Crenshaw argues that equal processes are not always indicative of equal outcomes. In accord with the earlier work of Freeman (1995), who uses the competing concepts of perpetrator and victim perspectives of racism to explicate race (and consequently non-neutral nature) in law, Crenshaw points to the absence of historical continuity in rationalizing colorblind approaches to equality. The notion of equality as used to support the elimination of race-based initiatives fails to acknowledge the presence of different opportunities, erroneously positioning Whites as the true victims. As such, race as used in the case of explaining affirmative action, and more generally law in the United States is important because it explicates the presence of race and the role of racism in ideology, structures, and practices.

Similarly, Tate (1997) raises the issue of race as critical for understanding law, education, and society. Arguments for including race are based on the premise that a colorblind approach requires a consciousness of race to be able to reject its consideration (Aleinikoff, 1991 as cited in Tate 1997: 203). In this regard, ignoring race merely disguises rather than eliminates its significance to debates. In citing Justice Blackmun's dissenting opinion in the *Bakke* decision, this argument is exemplary of critical race thought, "In order to get beyond racism [to color blindness], we must first take into account race. There is no other way" (*Regents of the University of California vs. Bakke*, 1978: 407 as cited in Tate, 1997: 203). More importantly, recognizing that race exists unveils the construction of whiteness as normative. Critical race theorists put forth race as a strong analytical tool for understanding and overcoming racism. Therefore, CRT's advancement in the legal field serves to further deconstruct the law,

which was formed (and evolved) to maintain racial privileges of one group and consequently legalize the oppression of another; all factors which betray the objectiveness it presupposes.

Although race is a central feature of CRT critical race scholars recognize the role of multiple forms of subordination including class, gender, and sexuality operating in society and law. Therefore, embedded within the critical race framework is a rejection and critique of essentialism (Delgado and Stefancic, 2001). Anti-essentialism is the notion there is no singular experience for people of color, Blacks, or any other socially constructed group. To further advance the anti-essentialism thesis, critical race feminist scholars proposed intersectionality to more meaningfully account for the unique ways in which multiple forms of oppression interact to shape the lived experiences of those with multiple identity. Intersectionality does not merely suggest that multiple identities are additive, but that their intersectional nature create a unique social location of marginality as well as the potential for ground breaking social and political empowerment. For example, Crenshaw (1995) describes how both feminists and antiracist discourses have failed to adequately consider women of color's intersectional identities. Therefore, the centrality of race is not to minimize the role of these other forms of oppression, but instead to recognize its social construction largely through legal processes (among other means), such as the formation of the constitution, which continue to influence society. Critical race scholarship works under the notion that racial subordination is intricately linked to other forms of oppression; thus dismantling racial inequity is a step towards achieving social justice.

The Centrality of Experiential Knowledge

Within the CRT movement is the commitment to voice scholarship, which centers experiential knowledge as important. Critical race scholars emphasize the importance of localized narratives, which helps to contextualize and provide understanding. This incorporates a methodological and theoretical approach of perspective taking that requires "looking to the bottom," – the oppressed of society – to effectively elucidate and appreciate the complexities of their struggle, both material and ideological (Matsuda, 1995). Further, Delgado (1989) argues that a method of including the experiential knowledge of people of color counters the way traditional legal scholarship conducts analysis. Given that many legal scholars embrace universalism over particularity, the perspective tends to minimize anything that is historical, contextual, or specific with the unscholarly descriptors of literacy or personal (Tate, 1997: 220). Critical race theorists argue for the inclusion of these factors in helping to explain the realities of people

of color, which are often marginalized in the presentation of law and society generally.

Bringing attention to whose voice is included and reflected in the dominant narrative points to the larger issue of what is considered legitimate knowledge in scholarship. Bringing radicalized lenses to the discussion not only gives voice to marginalized communities, but also offers a critique of the dominant ideology of what is understood as valid knowledge. The inclusion of narratives of people of color in understanding and reforming law counters the dominant discourse and challenges the racial construction of whiteness as the norm by which standards and merit are judged. Universal truths and methods of reasoning as they have been constructed in law are inherently biased toward privileging the dominant group. This is exemplified in Freeman's (1995) analysis of court decisions on civil rights cases of the past century, asserting that the court often adopted a perpetrator perspective of racial discrimination – viewing “racial discrimination not as a social phenomenon but merely as the misguided conduct of particular actors” (p. 30) – a process that consequently negates the victim perspective of discrimination which names the inequities in outcomes and conditions. Accordingly, CRT scholars emphasize subjectivity in experiences, which account for the differences in reality (Delgado, 1989). Thus, where they previously have been silenced, centering on the lived experiences of people of color, voice is a crucial concern of analysis and methodology, both for legal policy and for educational research.

Related to this concept of voice, as it involves inclusion of people of color, is the role of the scholar and researcher. This aspect has been addressed by critical race scholars, who find themselves as outside scholars, marginal within their fields of study (Delgado, 1984; 1992). Specifically, scholars like Delgado (1984) have called attention to how the ethos of academia perpetuates dominant narratives and inadvertently work to de-legitimize and silence scholars of color, particularly in discussions concerning minority rights (i.e., civil rights). Additionally, this critique has led to employing methodology which includes reflexive processes of self-interrogation (particularly for White scholars), interrogating how scholars' worldviews inform, understand, and contextualize the textual product. These aspects of theory and methodology are at the heart of CRT.

Narratives, Stories, and Counterstories

Within the construct of voice for CRT is the application of storytelling. The critical race movement was founded on the works of scholars like Derrick Bell and Richard Delgado, who employed and established a narrative tradition, which departed from mainstream legal scholarship and was more commonly found in literature. These include the use of “parables, chronicles, stories, counterstories, poetry,

fiction, and revisionist histories” (Ladson-Billings and Tate, 1995). These narrative forms enable scholars to challenge dominant discourses that propagate stereotypes and distorted images of people of color. Appropriately termed counterstories, they exist as a method for conveying the untold experiences of marginalized groups, and also function as a tool for analyzing dominant narratives presumed to be reality. Among the reasons for utilizing counterstories include (1) community building; (2) challenging the perceived wisdom of the those at the center of society; (3) self-preservation for marginalized groups; (4) constructing a richer description of issues and stories that reality alone may be unable to provide; and (5) provide a context for understanding and challenging established belief systems (Delgado, 1989; Lawson, 1995 as cited in Solórzano and Yosso, 2002). While stories are a critical part of the critical race tradition, their use is highly contentious and is not universally accepted as appropriate for the academy. Still, CRT scholars argue that this method is valid and critiques originate from a positivist paradigm which privileges the normative nature of whiteness as the status quo. Further, they argue that counterstories are necessary particularly since reality is socially constructed and therefore stories from people of color's lived experiences can illuminate their circumstances, since the experiences of Whites are privileged in the dominant or majoritarian narrative. (Delgado, 1989).

Branches of CRT and Related Literature

Although CRT originated in the legal field, the theory has made its way into multiple fields including sociology and education. It has also been advanced to offer new insights and innovative critiques of previous theories as well as issues within these fields. Likewise, along with its growing use, CRT as a theoretical construct has expanded to incorporate the experiences of women (FemCrit), Latinas/os (LatCrit), Native Americans (TribalCrit), Asian Americans (AsianCrit), sexualities, genders, and other social identities that fall outside normative identities (QueerCrit) and even White scholars (WhiteCrit), which consists of studies of Whiteness and critically examines White privilege. These branches of CRT move beyond the Black/White binary that CRT critiques tended to follow understandably as their critiques were originally focused on civil rights legislation (Yosso, 2005). Yet, just as each of these expansions represents the varied issues and priorities within and between communities of color and socially marginalized groups, CRT scholars acknowledge, “the institution of slavery is foundational in American racism” and instructive for the struggle against multiple oppressive isms beyond the Black–White paradigm (Matsuda, 2002: 397). Therefore, CRT has become more nuanced as it is applied to multiple experiences of people of color. Finally, due to the

interdisciplinary focus, CRT literature overlaps with literature from fields such as women studies, ethnic studies, history, law, and sociology.

CRT in Education

CRT is used in education to frame how institutions maintain racism, sexism, and classism through structures, processes, and discourses. Ladson-Billings and Tate (1995) initially introduced CRT to the field of education, arguing that race has gone virtually untheorized in understanding issues of education. Together, they put forth CRT as a theory for understanding and overcoming school and educational inequity. Since then, a growing number of scholars began employing CRT in education to elucidate how educational practices and widely accepted theories minimize the importance of race and/or perpetuate a system which oppresses, subordinates, and marginalizes African-American, Latino(a), Asian-American, and Native-American students. Solórzano and Yosso (2001) contend that stereotypes and deficit frames used in elementary and secondary educational practices reproduce social inequities. Educational practitioners, who subscribe to these stereotypes, suggest that students of color are intellectually inferior, lack motivation, and are destined to become engaged in criminal activity. Additionally, educational practitioners have used deficit-framed perspectives to explain the academic underachievement of students of color. These frameworks often put the onus of blame on student and/or his or her culture for poor academic performance. For example, deficit frame employers may state, "African Americans (or Latinos) do not perform academically because African American (or Latino) culture does not emphasize education." Clearly, the unequal resources, the quality of education, and societal inequities are not considered in these deficit frames. As a result, these educational inequities may be manifested in low expectations for African-American, Latino(a), and Native-American students, tracking, remediating the curriculum, and limiting access to high-level or advanced placement courses (Solórzano and Yosso, 2001; Darling-Hammond, 2001).

Reframing Dominant Educational Theory through a Critical Race Perspective

CRT is used to reconceptualize dominant educational theory, which has been framed around European American cultural values. A noteworthy example is Yosso (2005), who uses CRT to reframe the Bourdieuean theory of cultural capital, which is a narrowly defined theory based on "White, middle class values, and is more limited than wealth – one's accumulated assets and resources" (p. 77). Yosso expands this view to include cultural capital more

representative of communities of color, which include aspirational capital (maintain hopes and dreams), familial capital (cultural knowledge and community history), linguistic capital (skill gained from communicating in more than one language), social capital (networks and community resources), navigational capital (negotiate social institutions), and resistant capital (knowledge and skill gained from opposing inequality). Collectively, Yosso refers to this new cultural capital frame as a community of cultural wealth.

Similarly, Patton *et al.* (2007) use a critical race frame to problematize racelessness (p. 43) in prevailing college student development theories. An example of a raceless college student development theory is in Chickering and Reisser's (1993) *Education and Identity*, which gives limited treatment to the role of race in identity development. Additionally, Patton *et al.* point out that some scholars have used homogeneously White samples to inform the theories they developed. Subsequently, these theories are applied to college students in general and do not account for the experiences of college students of color. Patton *et al.* suggest "Color-blind racism and racial indifference must consistently be challenged through exposing the manner in which racial advances often come at the cost of promoting or feeding into White self-interests" (p. 43).

Exemplified through the works reviewed, CRT can aid scholars in reshaping the discourse around students of color in educational research. Previously, the norms and values of dominant cultural groups were juxtaposed with those of communities of color, resulting in an assimilationist approach to dealing with students of color. This approach suggests that students must discard cultural values not aligned with the dominant frame in order to succeed. As a result, students' (of color) culture is to blame for their academic underperformance and not the system maladaptive to multiple points of view. CRT has given scholars and practitioners the tools to reevaluate theoretical perspectives and educational practices from multiracial and multicultural perspectives.

CRT in Empirical Educational Research

Educational researchers have effectively utilized CRT to frame empirical research. For example, CRT-based research has been used to explain educational inequities in K-12 schooling, to evaluate how educational policies shape the educational pipeline from primary education through graduate school, the importance of family and culture in education, and the role of racial micro-aggressions in the perceived college-campus climate of students of color. In these contexts, CRT goes beyond simply describing a problem or challenges associated with educational outcomes; it explicates the sources of persisting problems, which is very often grounded in systemic racism and oppression.

In examining educational policy and educational pipeline Solórzano and Ornelas (2004) use CRT as a lens to investigate enrolment patterns of advanced placement (AP) courses generally in the top 50 California high schools and specifically in four Los Angeles Unified School District high schools. The findings suggest Latino and African-American students are disproportionately underrepresented in these AP classrooms. Solórzano and Ornelas apply CRT to suggest that AP courses reproduce societal inequities because Whites and some Asian Americans are afforded advantages in college admissions due to the boost that AP courses give to grade point averages. As a result, African-American and Latino students, who are underrepresented in AP courses, are less competitive in the college-application process. Solórzano and Ornelas are encouraged by the fact that African-American and Latino families are demanding better educational opportunities and have filed lawsuits against school districts and the University of California regents.

The disparities found in AP course enrolment is further investigated in the study by Solórzano *et al.* (2005) study, which employs CRT to examine how educational structures, policies, and practice impact Latino (a) students' educational attainment in the United States. The quantitative analysis shows that for every 100 Latino(a) students who begin primary education, only 48 graduate from high school and only 10 graduate from a 4-year college or university. Solórzano *et al.* (2005) focus the inquiry on California, which has had clear policy changes in anti-affirmative action legislation. In California, for every 100 Latino(a) high school graduates, only 40 continue on to public 4-year institutions with 30 attending 2-year community colleges. Using CRT as a lens, Solórzano, Villapando, and Oseguera suggest that policies designed to eliminate race-based-admissions decisions and emphasize merit are in fact still emphasizing race. For instance, persistent inequities in the educational and social system make Latino(a) students more likely to drop out of high school – and if they graduate, to be diverted to 2-year community colleges. In this regard, presumably race neutral policies and approaches perpetuate the achievement gap between Whites and underrepresented racial minorities.

Focusing on ethnographic studies of Latino families and education, Villenas and Deyhle (1999) use CRT to position schools' and larger society's negative perceptions of cultural differences in family socialization and education within a framework of power relations and the castification of Latinos in the United States. They find that Latino families play key roles resisting assaults on Latino culture. The history of Latinos as taught from the dominant White ideology, propagates views of Latinos as illegal immigrants and foreigners. The ethnographic studies demonstrate how Latino families can take collective action to transform the schooling of their children. Clearly, CRT can be used to identify counternarratives that "challenge

dominant culture's 'stock stories' which legitimize the world views of White, upper-class United Statesians" (p. 441).

Finally, A CRT perspective can also elucidate the atmospheric nature of racism in educational institutions as hostile climates for students of color. Solórzano *et al.* (2000) use CRT to describe the experiences of African American students attending predominantly White research universities. Participants in this study shared their experiences with everyday subtle forms of racism and stereotypes (micro-aggressions). Examples of these micro-aggressions include feeling invisible as one of only a few African Americans in a particular college classroom, faculty having low expectations, challenges in joining study groups with non-African American students, and feeling a sense of hyper-surveillance because of perceived criminality. Micro-aggressions created a negative campus racial climate, which led to feelings of frustration, isolation, self-doubt, and exhaustion. Many students in this study coped with the negative campus racial climate by creating counterspaces where they could be surrounded by supportive peers and collectively reject the notions of intellectual inferiority and stereotypes of deviance or criminality.

Implications of CRT for Future Educational Scholarship

While CRT has emerged as a powerful framework for understanding educational issues, it is yet to be fully realized. Scholars who employ a CRT framework most notably utilize the concept of permanence of racism and voice scholarship through counter-storytelling. For example, voice scholarship has included examining the experiences of students of color as well as the inclusion of scholars of color in theorizing space. However, the presence of an internal struggle over the materialist concerns of CRT has pressing implications for CRT scholars. Namely, it points to CRT inquiry, which has transcended from its material origins to its ideological concerns. Yet, these two forms of inquiry are inextricably connected, merely posing as two sides of the same coin. For example, while Crenshaw (1995) acknowledges identities as ideological in nature, she argues their consequences on lived experiences necessitate their consideration, in order to explicate and positively change ones marginalized condition by embracing and enacting on ones identity. In other words, although race is socially constructed and not a social fact in and of itself, the material consequence of race convey its social significance. Therefore, challenging both the social construction of race and the enactment of power based on race is significant. Still, the concern that scholarship in which CRT engages in may never reach those who are most affected, the very populations for which CRT is meant to account for (Ladson-Billings, 1999), exists as a valid concern which scholars must consciously engage

themselves in. One challenge then is in examining and asserting how ideological struggles are linked to material consequences. Harris' (1995) concept of Whiteness as property, further articulated by Ladson-Billings and Tate (1995), presents the opportunity to identify (ideological and structural) processes that consequently result in concrete differences in schooling opportunities. Yet, it has been underutilized, presenting a gap for future work to fill.

Additionally, Bell's (1980) concept of interest convergence also has important implications for understanding numerous issues, including the discourse centered on Asian Americans, especially within the context of affirmative action debates. A CRT approach which recognizes and examines how discursive practices construct, impose, and empower identity as well as shape definitions of minority, diversity, or social justice are important for understanding contemporary debates over the allocation of college-admission slots. First, it can challenge the social construction of race and further examine how particular definitions of race are privileged in certain instances and used to inform a limited definition and application of diversity that ultimately support conservative agendas (Omi and Winant, 1994). A CRT perspective can also elucidate the larger social context in which education issues are understood, explicating how foreign relations often shape experiences of Asian Americans and people of color in the US that ultimately support conservative agendas (Omi, 2008). For example, the peril of Asian Americans as invading and overrunning higher education institutions requires a critical race approach to elucidate that they mirror the larger societal sentiments seen in foreign relations. Finally, CRT and interest convergence can further aid, particularly in understanding how, despite these sentiments, Whiteness can be thrust upon Asian Americans (Omi, 2008) when it aids in the larger social and political interests of Whites. The case of Asian Americans serves as just one example of how CRT theoretical constructs can elucidate and explicate how ideologies of race and discursive practices have real consequences and are directly connected to material interests.

Methodologically, in part due to its role in advancing voice scholarship, CRT is less often applied to examining quantitative data. This is understandably so as quantitative research, until recently, was viewed as the only legitimate scientific method. The struggle over legitimate scientific inquiry and use of qualitative research has a tradition of giving voice to the experiences of marginalized populations. While CRT can be a useful framework for understanding educational inequity, the underutilization of CRT to examine quantitative work presents a glaring gap. The above-reviewed work of Solórzano and Ornelas (2004) and Solórzano *et al.* (2005) serve as examples of how CRT can be used to understand the hard facts of inequalities. We appreciate the epistemological struggle to legitimize qualitative research; therefore application of CRT to quantitative data must be approached cautiously. It is

imperative to include continuous interrogation of how numbers can be construed and recognize inherent biases in how numbers are collected, categorized, and understood. Such can be seen in the aggregation of Asian Americans as a monolithic group, which presents the misguided notion that they are outwhiting Whites in higher education (CARE Report, 2008). However, coupled with a narrative tradition, the continued use of CRT to examine quantitative data can further elucidate education issues.

To conclude, education scholars employ CRT to understand school inequity and educational issues while advancing the evolution of CRT in significant ways. Given its origins in and departure from critical legal theories, aimed at understanding the interplay of race, racism, and the law, a critical race analysis is appropriate for the field of education on both philosophical and historical grounds. When considering that law was used to, first, ban African Americans and other marginal groups from obtaining education; then, institute segregation and later, repeal initiatives like affirmative action aimed at addressing the legacy of racism, the use of CRT in education is logical if the ultimate goal is to overcome societal inequity. While these reasons alone represent a compelling case for CRT, the need for a theory which advances race as an analytical tool for understanding issues in education treads much deeper. It calls into question the ideologies and jurisprudence which informs and sustains these laws. Much like the legal scholars of color who were instrumental in creating a CRT framework, the allure of CRT for scholars in education is the possibility for liberation. Specifically, we are drawn to idea that although schools and schooling practices (curriculum, instruction, pedagogy, etc.) are sites and tools of social reproduction, we remain hopelessly optimistic in achieving a transformative education: one that is grounded in our experiences, inclusive of our cultural knowledge, and intentionally fosters social praxis for the emancipation of marginalized communities. For these reasons, scholars of color in education find solace in the discontent, struggle, and discourse of legal scholars of color within their field, (not merely in their collective identity as people of color, but more principally) in their criticisms, yet unyielding commitment in the ideals of and belief in the very institution in which they hope to transform (theoretically, methodologically, and practically). Finally, and perhaps most importantly, CRT challenges scholars to interrogate their own socialization into the academy and confront their possible roles in reproducing dominant discourses. Therefore, CRT has far-reaching implications for theory, research, and practice in education.

Cultural Diversification and Japanese Education: Social Constructions of the New Diversity

R Tsuneyoshi, The University of Tokyo, Tokyo, Japan

Social Constructions of Ethnic Differences in the Japanese Context

Research on ethnicity suggests that what societies define as ethnic differences are socially constructed, not a given reality (Barth, 1969; Jenkins, 1997). The arrival of newcomers often pressurizes existing social boundaries to change, and provides opportunities to observe the social reconstruction of difference at work. Kaplan (2001) shows how the Jewish Ethiopians, newcomers in a predominantly white society, Israel, are depicted as black or non-black, or whiter than other groups but not quite white, depending on who the object of comparison is and who is doing the comparison. Studies on American immigration have also suggested that successive waves of immigration have forced the reconstruction of what it means to be white or black (Fass, 1989; Oakes, 1985).

Japan provides an interesting case in this sense, since it has often been seen as one of the most homogeneous-minded societies in the world, and yet from the 1980s, it has experienced its largest postwar influx of new foreigners which challenge this image of homogeneity. One does not have to go far back to find an assumption of homogeneity in the Japanese official discourse (e.g., the former Prime Minister Nakasone's comment that "Japan is a mono-ethnic nation" in 1986), a discourse that has its counterparts in other nation-states (Hickman and Walter, 2001).

Indeed, needless to say, Japan has never been totally homogeneous. In the northern districts, there are the indigenous populations, the Ainu, and though ethnically Japanese, the descendants of Japan's feudal outcaste population have constituted one of Japan's largest minorities. A title of a representative work on this population, *Japan's Invisible Race* (DeVos and Wagatsuma, 1966) captures the nature of invisibility and discrimination of this minority status in Japan. The colonization of Korea in 1910 also brought many Koreans into Japan as forced labor, or as voluntary entrants.

A characteristic of Japanese cultural diversity has been that the visible indicators of difference (e.g., skin color) has tended to be more subtle than many other visibly diverse societies, since the major ethnic/racial minorities in Japan, such as the Koreans and Chinese, are not visibly distinguishable from ethnic Japanese, and adhere to relatively similar cultural heritages (e.g., Confucianism, Buddhism). Indeed, for a large part of the postwar period,

foreigners were in large part identified with a single ethnic group, the Koreans in Japan (see Figure 1).

As recent as the late 1980s, those of Korean nationality comprised almost 70% of the registered foreigners residing in Japan. These foreigners were mainly the descendants of the Koreans who came, either voluntarily or by force, because of the colonization of Korea in 1910. With the end of World War II, Koreans lost their Japanese nationality, though a significant number were led to remain in Japan. Since Japanese nationality is gained either through naturalization or through one's Japanese parent (previously it was limited to the male parent; the nationality law was revised in 1985 to make it possible to acquire citizenship from either parent), this led to a situation in which there are a number of Korean nationals within Japan, who were born and raised in Japan, and who are the counterparts of later-generation immigrants in other countries, but who are foreign in nationality. This population has been called sociologically Japanese by Kajita (1998) since they look like Japanese, speak Japanese, and behave Japanese, but are foreign in nationality.

Since the Koreans in Japan cannot be distinguished by the color of their skin from the majority Japanese, and nationality is hidden in daily life, what signals that one is ethnically Korean is a Korean name. However, with the pressure to assimilate, since the vast majority of Koreans use their Japanese names instead of their Korean names, there is often no visible indicator differentiating the later-generation Koreans in Japan from the majority ethnic Japanese. Ethnicity in Japan is thus often concealed on the surface, visible on a daily basis only in those areas where there is a concentration of a certain population. It is thus not a surprise that the Korean movement has tended to emphasize the importance of using one's real Korean name. Where visible indicators of ethnicity are scarce, the use of an alien name is a powerful indicator of ethnic pride.

Due to the situation above, being ethnically different in Japan has tended to be identified with being foreign, not with being an ethnic minority. Nationality is identified with ethnicity, and although the majority of Japanese are aware of differences based on nationality, ethnicity is assumed to be a reflection of nationality. This paradigm, however, is highly problematic when applied to ethnic minorities living for generations in Japan.

Yet, since many Koreans in their third, fourth, and later generations, whose daily language is Japanese, are

Figure 1 Number and distribution of registered foreigners by nationality and the region of origin. Source: Immigration Bureau, Ministry of Justice, Japan.

still foreign nationals (though an increasing number are Japanese nationals through naturalization and as children of intermarriages between Koreans and Japanese), they are, in the Japanese mind, foreigners. Such reasoning can be seen everywhere, not the least in governmental documents which refer to these populations as foreigners and count the ethnically different populations based on nationality (e.g., based on the assumption that Korean nationality means Korean ethnicity). School statistics are the same, recording by nationality, thus there is no recognition of an ethnic Japanese (e.g., Korean-Japanese); the categories available are Japanese and foreigners (foreign nationals). This dichotomous understanding of ethnicity as nationality, as well as the invisibility of Japanese ethnicity, was the background against which the Japanese returnees in the 1970s and the new foreigners in the 1980s emerged on the cultural diversity scene.

The Japanese Returnees

Where visible differences are not stark, subtle differences can become a major issue as seems to be the case of the Japanese returnees. These are children of Japanese living abroad temporarily (e.g., children of businessmen stationed abroad), who spent part of their school age in another country and returned to Japan. These children were Japanese in nationality, but if they were brought up in a local school abroad, they often had internalized parts of the culture of the host country and thus acted non-Japanese or were able to speak a foreign language, and were different from the majority Japanese.

Around the 1960s, Japanese companies moved out into various parts of the world, stationing their employees in foreign countries. More Japanese school-age children started to grow up abroad, and they returned and were called the *kikokushijo* (the Japanese returnees). The number of school-age children at the compulsory-education

level who were residing in another country for 3 months or more (and who were not the children of Japanese permanently residing abroad), was a mere 6662 in 1971, shooting up above 20,000 in less than a decade, and leveling out near 50,000 from around 1990. In 2007 April, there were 58,304 such children abroad. When these children come back to Japan, they become the *kikokushijo*, more than 10,000 in a school year.

The returnees quickly became a social problem. Despite the fact that they came from middle-class (often elite) business-person families, and were quite Japanese in the regular sense of the word (nationality), many *kikokushijo* came home to find that Japanese society was not ready for them (e.g., forced to attend a grade lower than their age). Although schools in districts with a concentration of the Koreans in Japan or other historically discriminated-against groups had experience with issues of cultural diversity and human rights issues, this was not the case for most other areas. While the *kikokushijo* were undergoing a personal cultural shock upon (re)entry to Japan, the emergence of a different type of Japanese child presented a cultural shock for many educators and researchers. The Intercultural Education Society (*Ibunkakan Kyoiku Gakkai*), for example, started in 1981 with many of its members researching *kikokushijo*. Today, the research themes have diversified as the new foreigners have arrived, and more interest has turned to other populations such as foreign students. The *kikokushijo* provided an inspiration for educators in international understanding education as well.

This also coincided with the increasing efforts of the government to emphasize internationalization. Various measures were institutionalized to meet the needs of Japanese children abroad. For example, schools following the national curriculum were erected in developing countries, and Japanese teachers were sent by the government, exporting Japanese compulsory education abroad. These teachers came back and practiced international understanding education; the Association of Japanese

Returnees (*Zenkoku Kaigaishijyo Kyoiku Kenkyu Kyogikai*) was established in 1974, and today it has added international understanding education to its title (*Zenkoku Kaigaishijyo Kyoiku Kokusairikai Kyoiku Kenkyu Kyogikai*) reflecting a widening of focus from its original narrow focus on returnees (the organization is a nonprofit organization (NPO) since 2005). Schools started to adopt special admission procedures for returnees (*kikokushijyo waku*) at various levels. Special schools were erected to focus on returnee education. In public schools, Japanese-language classrooms were erected and provided pull-out instruction for returnees who required assistance in Japanese.

The 1970s–1980s was the era of increased internationalization, and the term seemed to acquire instant media popularity. Government policies called for the internationalization of Japan, the expansion of foreign student exchange, the teaching of communicative English, and the strengthening of international understanding. The national rhetoric surrounding the *kikokushijyo* shifted from *kikokushijyo* as objects to be assimilated and saved, to *kikokushijyo* as pioneers of internationalization, and assets for international understanding education. As children of Japanese businessmen who had led Japanese society to its economic recovery, these *kikokushijyo* had powerful agents lobbying for their cause. Goodman (2003: 177) argues that “no other group’s image and status have changed as rapidly.” Once problems, some members of the *kikokushijyo* group were now looked up to as champions of internationalization, though behind these privileged few were many more who could not fully adjust to Japanese society.

The New Foreigners

The *kikokushijyo*, despite the fact that they are Japanese both in terms of ethnicity and nationality, have served as a reference point in conceptualizing education for the new foreigners. On the one hand, these new foreigners are foreigners like the Koreans in Japan before them. Yet, in other contexts, they are put together with the Japanese returnees as agents of internationalization. The manner in which the concept of the new foreigners shifts, is one indication of how the majority society is struggling to define the emerging cultural diversity.

The new foreigners were very diverse in terms of their purpose and country of origin. They came as foreign laborers, Chinese returnees, Indochinese refugees, and spouses of Japanese. From around the 1980s onward, certain districts became associated with a concentration of a certain group of new foreigners. Most famous perhaps are the districts with Latin American of Japanese descent, who are Japan’s largest new-foreigner group, and who typically come as foreign labor. For example, Oizumi and Ota in the northern Gunma prefecture, and Hamamatsu City in Shizuoka are well known (Matsuo, 1997;

Noyama, 1997). Certain public housing too, such as the prefectural public housing Ichō Danchi in Kanagawa prefecture, relatively near the former refugee-placement center, is now known to have high concentrations of the Indochinese as well as the Chinese returnees (Shimizu and Shimizu, 2001). There are, of course, the Ainu in northern Japan, and the children of international marriages of US army persons in Okinawa, or urban areas with concentrations of Asian workers (Okuda and Tajima, 1991, 1993), and rural communities with Asian brides (Shibata, 1997). Research on such districts is starting to accumulate (Ebashi, 1993; Watabe, 1995; Komai and Watodo, 1997; Shiramizu, 1996).

Compared to the existing cultural minorities, these new foreigners tended to be more visible at first sight. First of all, if they came straight from their country, there were language differences. In some cases, as in Southeast Asians, the skin color immediately signaled a difference. The Islamic residents constitute a small but visible population, whose religious customs and clothing tend to be very alien from the majority Japanese. At the same time, the new foreigners, as were the Koreans and Chinese in Japan before them, are predominantly from Asia. In the case of Latin Americans, because of the Japanese governmental policies that placed preference on Japanese descent, there were many who were difficult to distinguish by their skin color. Due to this invisibility, there are observations that reinstituting markers of difference was one reaction to dealing with Japanese expectations of homogeneity. For example, Brazilian youth have been observed to deliberately exhibit their Brazilian-ness by the way they dress and act, in order to avoid the expectations that would be imposed on them if people assumed they were Japanese (Tsunda, 2000).

The inflow of new Koreans also resulted in a diversification of the Korean category. There were not only the existing Koreans in Japan, but the new Koreans. The same held true for Chinese. The Koreans in Japan were in their later generations, born and raised in Japan. The new foreign Koreans were foreign laborers, spouses of Japanese, and foreign students, among others. Attempting to distinguish the differences among foreigners, researchers began calling the existing cultural minorities the old-comers (*orudo kama*) and contrasted this group to the new foreigners by calling them the newcomers (*nyukama*) based on the period of their entry, which was linked to the reason of their residence in Japan. However, this meant that Latin American children, a child of an intermarriage between a Japanese and foreign national, and a foreign worker from the Middle East are all together in the same category. It also meant breaking up members of the same ethnic group into different categories, such as the case with newcomer Koreans and oldcomer Koreans. Other attempts include distinguishing between permanently residing foreigners and the others, the permanently residing foreigners including the Koreans in Japan.

Another attempt at distinguishing between the foreigners was to link the concept to Japanese as a second language in education. The Japanese government started to compile statistics on the education of the children of the new foreigners since the revision to the Immigration and Refugee Registration Law in 1990, after which there was an increase in the number of Latin Americans of Japanese descent. Since this group was more likely than others to bring their children with them, there was an increase in the number of Latin American (mother tongue Spanish or Portuguese) children in Japanese public schools (see Figure 2). The government devised a term, foreign pupils and students who require instruction in the Japanese language and defined it as “those pupils or students who cannot sufficiently manage daily conversations in Japanese, or who can hold daily conversations, but who lack grade-level instructional vocabulary, and thus have difficulty in participating in learning activities, and who require instruction in the Japanese language.” In 2006, this population totaled to 22,413 students from elementary to high school. The hidden contrasts are those that do not require instruction in Japanese language, which presumably refers to the oldcomers as well as the Japanese.

Yet, reality seems to be outpacing the utility of this categorization as well. Though at one point, these figures were used to capture the number of newcomer children in Japanese public schools, there is an increasing number of newcomers who are raised in Japan and whose Japanese at a daily level is not a problem, and who do not appear in these statistics. Like the ethnic Korean who acquires a Japanese nationality and becomes Japanese, this concept creates an area where certain children fall through the gaps and disappear from the social categories of difference.

All of these experiments in conceptualizing the new diversity seem destined to change. For example, even if

the initial waves of immigration in the 1980s could be called the newcomers in contrast to existing ethnic minorities, albeit in a very gross way, what should the society call the migrants who are entering Japan today? The new newcomers? Many of the newcomer children are now not that new, since as in the example of Indochinese refugees, there is a generation that is now born and raised in Japan.

Internationalization as an Umbrella Term

If the categories of newcomers and oldcomers were terms that tried to distinguish between foreigners, there have also been attempts to categorize the newcomers using the label of internationalization. Needless to say, Japanese returnees and the newcomers are different in many ways, not the least because of differences in nationality and ethnicity. Japanese returnees are mainstream in both these factors. Yet, ironically, the newcomers are often placed under the same category as the Japanese returnees using the umbrella term of internationalization. For example, the 1974 May Central Council for Education (Japan’s main governmental committee for reform) report on International Exchange in Education, Academics, and Culture (*Kyoiku, gakujutsu, bunka ni okeru kokusai koryu nitsuite*) called for fostering Japanese who can become part of the international community. The report referred to the promotion of international understanding education, strengthening foreign-language (in effect English) education, and addressing issues seen as relating to internationalization, including the treatment of Japanese returnees and Japanese schoolchildren abroad, foreign-student education, assistance to developing countries, and Japanese-language lessons to foreign students. Since those foreigners who require instruction in the Japanese language are the

Figure 2 Numbers by mother tongue from 1999 to 2006. Yellow, Spanish; light green, Chinese; dark green Portuguese; and brown, others. Results are from the 2006, September Survey on the Acceptance, etc. of Foreign Pupils and Students Who Require Instruction in the Japanese Language (*Nihongo shido ga hitsuyona gaikokujin jidoseito no ukeire jokyō nado nikansuru chosa* (H18) *no kekka*). Japan: Ministry of Education, Culture, Sports, Science and Technology.

newcomers, it is this group of foreigners that is being associated with internationalization in this context.

This line of thinking has persisted. For example, the 1996 July report of the Central Council for Education on *The Education of Our Country Towards the 21st Century* (21 seiki o tenboshita waga kuni no kyoiku no arikata nitsuite) contained sections on international understanding education, English, Japanese returnees and Japanese schoolchildren abroad, and the Japanese language instruction of foreigners staying in Japan as related to internationalization. Now, if there is a similarity between the Japanese returnees and the new foreigners, it is the experience of growing up in another culture. Of course, this does not hold for the newcomer foreign children who grew up in Japan, but even in this case, if the parent(s) is from another country, he/she/they would be able to talk about their culture. The common image is someone coming from abroad. Thus, the models that have been used to understand Japanese returnees, in other words, acquisition of Japanese language (*nihongo shido*), learning Japanese ways (*tekio shido*), and respecting the traits that the child acquired in another culture as assets for international understanding, have all been applied to the newcomer education (Mabuchi, 2002: 92).

The link between the two categories can be seen in another aspect. The unit overseeing the returnees took charge of the foreigners requiring Japanese-language assistance. In 2001, when the organization of the ministry of education was restructured, the overseas and returnee unit (*Kaigai shijyo kyoiku ka*) was restructured and became part of the international-education unit (*Kokusai kyoiku ka*). Correspondingly, the designated schools formally labeled the cooperative schools for returnee education (*kikokushijyo kyoiku kenkyu kyoryoku ko*) was restructured as the districts that promote the internationalization of education with the returnees and foreign pupils and students (*kikoku/gaikokujin jido seito to tomoni susumeru kyoiku no kokusaika suishin chiki*) to include foreigners (Mabuchi, 2002). The national intracollege center for international education was formally established to research Japanese children abroad and returnees. Founded in 1978, its previous name was the Center for Japanese Returnee Education (*Kaigai shijyo kyoiku senta*). With the internationalization of Japanese society (from its homepage, it was renamed the Center for International Education (*Kokusai kyoiku senta*) in 2002, a unit was erected for the education of foreign children. As mentioned previously, the association for returnees (*Zenkoku Kaigaishijyo Kyoiku Kokusairi Kyoiku Kenkyu Kyogikai*) that gathers international-understanding-education-oriented educators, which formally referred to only the Japanese children abroad and returnees, added international understanding education to its title to enlarge its focus to the foreigners.

Although understanding foreigners using this internationalization framework works relatively well for the

newcomers who come from another country, what it has trouble incorporating is the oldcomers who have lived in Japan preceding the waves of the so-called internationalization. Japanese international understanding education continues to be criticized for its inability to incorporate the oldcomers (Nakajima, 1988). These latter groups are more strongly associated with human-rights education, emancipation education (*kaibo kyoiku*), or other practices that have a strong human-rights focus. In comparison, newcomers are more easily incorporated into the above-stated framework.

At the same time, though Japanese returnees and the newcomers are often placed under the same category of internationalization, there is a clear status difference between the two in terms of nationality and social class, which also has its counterpart in people's perceptions. Sekiguchi (2003: 92–93) compares the image Japanese have of Japanese returnees and the Latin American of Japanese descent, and notes that though both are linked to Japanese roots, the former is identified more with a first-world image, English, and an international elite (e.g., active, smart, progressive), while the latter is identified with the image of a developing country, Portuguese, and foreign worker.

Conclusion

In another paper, the author did a content analysis of how foreigners were portrayed in the latest version of the elementary school social studies textbook (2006 version) of the company which has more than half the national market share (Tsuneyoshi, 2007). There was an association between the type of foreigner being discussed in the unit, and the concept that was associated with it. The newcomer foreigners were linked to an image of internationalization and basically seen as people who came and left. On the other hand, when the foreigners discussed were the oldcomers, they tended to appear in sections which dealt with welfare, peace, human rights, and discrimination. These were the foreigners that stayed in Japanese society, and were associated with human-rights issues.

The entry of the new foreigners into the Japanese cultural diversity scene has brought about changes in how cultural boundaries are drawn. The ways in which the new foreigners are sometimes foreigners based on their nationality, and sometimes agents of internationalization together with a segment of the majority Japanese population, shows how such categories can cut across ethnic, racial, religious, and even nationality divisions. In a society where ethnicity or race tends to be the dominant dividing factor between culturally different groups, such as the United States, it may be hard to conceive of a category that cuts across the same ethnic/racial group, for example, as in the case of the newcomer Koreans and

the oldcomer Koreans. It may also seem absurd to put together two groups together, when the only thing they seem to have in common is their experience in another culture. However, this is the logic that places the newcomers in the same internationalization category as Japanese returnees, despite the fact that they differ in their nationality, ethnicity, and social positions in Japanese society.

Such social differentiation by the Japanese society can be seen as one example of how definitions of difference are socially constructed. At the same time, they also reflect existing views of how diversity has been understood in Japan.

Education in War Countries: A Disempowerment of Society

J L Nkata, Makerere University, Kampala, Uganda

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Education has been a central and leading instrument that has assisted humans, from the very beginning, to prepare and guarantee his survival through innovativeness and development. The creation of knowledge, skills, attitudes, and values, as central psychological and social precepts of any tribe, society, or country, is supported by educational constructs and systems that are underpinned by social goals and purpose, proven and reliable. In this respect, education – whether informal or nonformal – possesses psychological and social liberating potential that underlies life development and sustainability. This is possible when society moulds its activities around a cherished social philosophy that is informed by a salient value premise and goals, destining to improve the intensity of knowledge, skills, values, and social attitudes. It is a social responsibility of a society to sustain education because education upholds social values, perceived morality, ethics, economics, culture, and politics leading to the preservation of the environment in society and outside society.

To achieve this, society needs to be organized and controlled through viable systems and structures that are both open and porous to entertain innovation, creativity, and strategic interventions. This is the ideal environment for systematic formal education systems and cultures; it allows the enrichment of values to enable such society to remain relevant in national and international aspirations. The nature of planning and management should be organic and should strive to achieve effectiveness and efficiency. Unfortunately, many countries are far from realizing such environment because they are constantly in war times, and this threatens their continued survival, global peace, and mutual coexistence. Such environment is not favorable to enable planned education to carry out its central role of empowering people to becoming more purposeful to development initiatives and to instinctively live on. Wars are pollutants to the utopia because they contaminate only meaningful viability for people to carry out activities that would redeem them to be self-supportive regarding food, health, education, security, democracy, and other areas. They become less empowered.

In this article, education is an organized entity or enterprise with definite goals, especially goals of redemption of human efforts, geared toward their survival and relevance. Education is further seen as an organization with structures and systematic programs whose effectiveness and efficiency are redeemed by corporate efforts of

the internal environment and outside factors. War, therefore, is seen as a constituent of both the intra- and extra-environments whose causes and prevalence affect the integrity of society and the environment.

This thought is supported by the systems literature that puts emphasis on systematic and effective management of organizations if goals and values that support them are to be achieved (Nkata, 2004). It underscores the rationale and importance of effective performance of substructures of the larger organization and their subsequent translation as effective constituents of the organization into its success, viability, and development (Kaufman, 1972; Etzioni, 1975; Mullins, 2002; Simon, 1964). In this respect, a country is understood in terms of its complexity and as an organized entity whose activities are assumed to be systematic and focused to social perceived goals.

This article examines the theoretical underpinnings of wars and the impact of wars on educational systems in those countries that have continued strife and armed confrontations, Uganda and Iraq in particular. It highlights the possible causes of war, its effects to education structure and systems, and the consequent disempowerment of societies and countries. Finally, recommendations are proposed via the path of possible solutions as mitigating measures to prevent occurrence or to subside war intensity across the globe.

Theoretical Considerations on the Causes of Wars or Conflicts

The central precept and agency in conflicts, it is agreed across disciplines, involves the role of human as an individual and humans in groups. In this respect, humans are seen as a leader or a participant in programs, issues, assignments, and agenda. Several schools of thought advance the genesis of conflicts as a possible missing link between what ought to be and what is or was. They see conflicts as being sparked by anxieties as a result of fear of extinction, denial, hatred, segregation, social ambiguity, terror, hidden truth, and confusion. Wars and conflicts are a result of a mismatch between people's aspirations and what is given to them or what they receive.

Psychologists

Psychologists such as Sigmund Freud, Erik Erikson, Harry Stack Sullivan, Alfred Adler, and Carl Jung

advanced theories that emphasize the role of individuals as leaders and participants in conflicts and aggressions (Vinacke and Reinhold, 1968). They see survival of the individual and the group as being causal and effective in flagging off social and psychological conflicts. This also implies, in part, that humans have two sides of the self: the bright side and the dark side (Jung, 1956). When everything is fine, the bright side shines but when there is deprivation of psychosocial needs, the dark side of human nature shadows the bright side. In such cases, the Freudian school of thought believes that gratification and survival are derived from aggression. Human being is essentially instinctive, and his/her survival instinct will lead him/her to anything when his/her harmony, freedom, and tranquility are threatened. It is now very clear that war is a reinforcement replacing the positive side to signal society that survival and esteem are being trampled upon. Finally, psychologists believe that pressures on self-esteem tend to reduce the individual's motivation and identity, yielding to aggression (Adler, 1998) for social dominance. Therefore, in order to uphold the individual's identity, emphasis should be placed on issues that reduce social ambiguity in society.

Brown (2001) identifies major classifications of variables that may lead to conflicts and wars in some regions or locations in the world: (1) structural variables (e.g., weak states, intrastate security systems, ethnicity, and geography); (2) political variables (e.g., discriminatory political institutions, exclusionary national ideologies, intergroup politics, and elite politics); (3) economic and social variables (e.g., economic problems, discriminatory economic environment, social dualism, and modernization); and (4) cultural/perceptual variables (e.g., patterns of cultural discrimination and problematic group histories). All these variables tend to underpin ethnic and identity domains of social behavior. Ratzburg (2000), however, observes that wars and conflicts can come by as a result of communication failure, value differences, goal differences, substandard performance, lack of cooperation, differences regarding responsibility, competition over resources, and noncompliance with rules.

All of these theoretical considerations confirm the presence of two parties in a conflict situation, that is, the happy and the unhappy, the satisfied and the unsatisfied, the oppressor and the oppressed, and so on.

Sociologists

Social psychologists emphasize the role of individuals (people) in groups (formal or informal), observing that groups can bring out the best as well as the worst in people. Group contagion can translate into uncertainty, panic, mindlessness, and collective maladjustment with misjudgment (Milgram, 1994). This theory is in line with the psychological assertion of Jung (1956) in relation to

the original and essential nature of people whose image is perceived as bright or dark, good or bad, righteous or evil. The implicit translation is that people can be good or bad, peaceful or war-like, depending on the nature of their environment and how they operate.

Biological Theories

Aggression is essentially in human beings for their survival as living things. It is like animals that have natural instincts and endowments for their protection from danger. It is unfortunate that humans do not apply homogeneous means of aggression. With developing technology, human survival can turn out to be very destructive and violent to others and to the environment. Humans invent weapons that can be used during communal aggression (Lorenz and Wilson, 1966). He/she does this to defend himself when confronted or when his/her psychological integrity and esteem are subjected to danger. However, according to Barbara Ehrenreich, anxieties and fears were naturally hardwired into prehuman species during the times when wild beasts feasted on the *Homo sapiens* to inherit such fears, and these fears were transferred to the humans.

Social Scientists

Some political scientists, such as Karl Marx, believe that the nation is the cause of war. That is, the nation and the people (masses) are in constant struggle for the ever-limited resources. Other social scientists believe that inflexibility and weak leadership can also lead to situations of conflicts and wars (Tuchman, 2004). However, Emmanuel Wallerstein observes that there is a strong diametrical opposition between the center and periphery, cities and villages, leaders and the led, employers and employees – the center exploiting the resources of the periphery, causing imbalances. In such cases, conflicts are rife and consequently, wars. On the other hand, violence results when human communities are under economic, social, and environmental stress or when they engage in ethnic and other social competitions such as religiosity.

Researchers on Stability and Peace

The New International Economic Order (NIEO) that led to globalization is also criticized on the premise that it created and is continuing to create imbalances and epitomizing exploitation, inequality, and aggravated syndromes of dependence. Groups and societies find themselves belonging to the wave of globalization. In attempts to emancipate themselves, conflicts and violence remain but a necessary imperative (Galtung, 1997). This also

implies that transformations on policies, regulations, and goals become incongruent to individual and social values as a result of the bandwagon effect.

Impact of War on Education

Educated people are those whose states of mind and behavior exhibit knowledge and understanding. However, they are not born this way and neither do they become this way through a process of maturation; they achieve it through learning. Often the teaching of others stimulates this learning (Peters, 1980). If the environment of teaching is turbulent, then the importance of learning is ruined or undermined. It will be very difficult to establish schools, train teachers, and enrol students. This is increasingly becoming a global concern due to issues of social and economic interdependence. This article cites Uganda and Iraq as representatives of countries that have been in persistent wars, whose effects on the youth, who are the majority and future generation, threaten local and global interdependency and socioeconomic sustainability.

Uganda

Two decades of armed conflict between the Lord's Resistance Army (LRA) and the Ugandan government in Northern Uganda has caused nearly 2 million civilians to be displaced from their homes. Ordered into so-called protected camps, internally displaced persons (IDPs) face heightened insecurity, appalling living conditions, and lack of means for subsistence. Abuses against these communities are rampant; the LRA has committed war crimes and gross violations of human rights, including the abduction of over 20 000 children; widespread maiming, rape, and murder against the civilian population. These attacks have led to secondary displacement in which up to 40 000 children commute nightly from the camps to sleep in the relative safety of town centers.

While the LRA has been the perpetrator of these crimes, the Ugandan People's Defense Forces (UPDF), the national army, has also committed human rights violations against civilians that include arbitrary detention, extrajudicial killing, torture, and rape. The UPDF, whose mandate is to protect civilians, has not only failed to prevent attacks and abductions by the LRA but has also perpetrated grave abuses against civilians in a climate of impunity (Between Two Fires, *Torture and Displacement in Northern Uganda*, Human Rights Focus-HURIFO). The impact of armed conflicts on children and youth development, in terms of their appropriate health, nutrition, security, psychological and sociological esteem, and integrity, has so far remained a dream beyond the periphery for the over 30 000 young children of this area. The International Rescue Committee (IRC Report, 2006)

notes that more than 30 000 children were kidnapped to serve as soldiers and slaves by the LRA. Boys in captivity were forced to loot, torture, and kill neighbors. Abducted girls were routinely raped and became sex slaves or wives of rebel commanders. Since 2006, efforts to reconcile and reach a peaceful resolution between the LRA and the Ugandan government have been slow to resettle over 1.8 million displaced people, who have been in protected villages. Unfortunately, much damage was done on the psychosocial dimension of their lives besides other facets of economics, culture, morality, and ethics.

There is insufficiency in terms of teachers who can handle the normal school curriculum, as well as assist with rehabilitation lessons and programs. This is why the Africa Education Initiative (AEI) has so far trained over 9000 teachers in conflict-affected areas in this region. This claim is supported by what the National Assistant Minister of Education and Sports found on ground when he recently visited some schools in the area (The Monitor Newspaper, 11th February 2008) to get firsthand information. At Orum Primary School, only two teachers were at the school during class hours. Over 80% of the staff (teachers) were absent or missing. Hon. Peter Lokeris who arrived at 11:00 a.m. also saw loitering students, yet this was already a month since schools opened for the first term in January. He was shocked to learn that out of the 28 pupils who had registered for Primary Leaving Examinations (public examination), no one had passed! He also learned that primary six students expected for term one, 2008, were 58 in number but only 21 had reported for the new term and year. This appears to be the reality in the war-torn northern region of Uganda where virtually every physical and social infrastructure and human resources including schools, roads, and teachers were either destroyed, displaced, or mismanaged, therefore calling for emergency assistance and resuscitation. As a result of the war, the region has failed to meet national set targets of education performance. For example, if one applied the Education For All (EFA) goals and targets of the Jomtien Declaration of 1990 (Education For All by the year 2000) to judge the performance of education, via the 18 indicators that underpin EFA targets, they would be appalled. The National Ministry of Education and Sports, on comparing the regional gross enrolment ratios (GERs) of 1991 and 1995, found out that whereas the GER of eastern, central and western regions of the country were progressively rising, that of the northern region was appallingly, reduced from 71.8% to 56.3% (see **Table 1** and **Figure 1**).

Again, the Ministry of Education admitted that standards fell in this region where turbulence has been going on for the last two decades. This was reached after a survey on performance of pupils in science and social studies, on a comparative basis by region, conducted in 1997 to establish reference points for Universal Primary Education (UPE), which was launched in this same year.

Northern region performed poorest among the four regions of the country. One of the outstanding reasons adduced to this phenomenon is armed insurgency (see Table 2).

Insecurity in this part of Uganda has lent to massive diversion of resources (financial and otherwise) to contain the situation and this is a great opportunity cost to the social, political, and economic performance of the country.

Table 1 Regional gross enrolment rates

Region	1991	1995
Northern	71.8	56.3
Eastern	78.5	86.4
Central	76.7	88.9
Western	78.8	86.0
Total	76.5	79.4

From Educational statistical abstract (ESA).

Figure 1 Regional gross enrolment rates. Looking at the regional gross enrolment ratios for 1991 and 1995, we note from Table 1 and Figure 1 that GER for the Northern region, which was as high as 71.8% in 1991, had significantly reduced to as low as 56.3% by 1995. One of the possible causes of this fall is the insurgency that has been in the region for many years now. This insurgency has forced many children out of school. For all the other regions, the gross enrolment ratio has increased over the same period (ESA).

This has been reflected in national budgets where the vote for defense is still leading other sectoral expenditure. In addition, international donor agencies, community-based initiatives, nongovernmental organizations and nonprofit-making bodies have continually come in to provide various interventions.

Through United States Agency for International Development (USAID), support is extended to the following areas to intervene into the wanting social-service sector:

- Improving policing in the north of the country through strategic functional training programs to civil police to reduce crime incidence and occurrence, such as illicit trafficking in conventional arms. The intention is to increase security and reduce intensity of criminal lawlessness, creating a safer environment for social and economic services/activities such as education.
- Supporting the reintegration of ex-combatants – majority of who are children and youth, through deliberate programs to increase their awareness and potential for greater coexistence, morality, and ethics.
- Distributing emergency assistance in collaboration with the World Food Programme and other private voluntary organizations. Over 64 000 metric tons of food aid has been provided to more than 270 000 returnees in the region; in addition, USD 19 000 000 for health and agro interventions has so far been provided.

Besides the USAID assistance to the northern districts of Uganda, many projects have been started with hope that the environment will be revamped, to enable the region stand again on its feet to support social structures such as those of formal education. These include (among others):

- Uganda Girls' Education Initiative Project, established by Acholi Education Initiative (AEI) and being funded by Pindof Project of Canada.
- World Council of Churches (WCC), through the local AEI supports child mothers with scholarships, uniforms,

Table 2 Overall performance of pupils in science and social studies by region

Class	Grade	North	West	Central	East	All
Science						
P6	Distinction	7 (2%)	25 (8%)	40 (15%)	22 (8%)	94 (8%)
	Pass	66 (22%)	109 (36%)	57 (21%)	82 (30%)	314 (27%)
	Fail	230 (76%)	171 (56%)	172 (64%)	168 (62%)	741 (65%)
Social studies						
P6	Distinction	46 (15%)	136 (45%)	99 (38%)	88 (32%)	369 (32%)
	Pass	82 (27%)	86 (29%)	62 (23%)	66 (24%)	296 (26%)
	Fail	173 (57%)	80 (27%)	109 (40%)	120 (44%)	482 (42%)

From: National Assessment of Progress in Education (NAPE), 1998.

books, and pens for their secondary period of 4 years. These girl mothers are given access to psychological counseling services and other support to meet healthcare and other basic needs in form of food, shelter, and clothing. Funds for their rehabilitation are also given to them through assortments of out-reach programs.

- Northern Uganda Child Legal Defense Project operates in the districts of Kitgum and Gulu with the sponsorship of the Association of Women Lawyers and Human Rights Focus, under the Legal Project of the Uganda Law Society.

The surest way of restoring order is to resuscitate the structure of education in the region, to enable its pivotal role of empowerment and awareness to take place among people – majority being youth and children. Education assists society to hand over the desired skills, knowledge, values, and attitudes to young generations, for its development and sustainability. It is therefore a tool that can be used to prevent and stop such insurgency.

Iraq

From the 1970s to 1980s, Iraq was a leading and fast-growing country in the Middle East, with per capita income of up to USD 3600. The successive wars, among other factors, have now stifled growth and development, debilitating basic social services such as education. By 2003, gross domestic product (GDP) per capita lowered to a mere USD 480–630. The most recent war that ousted Saddam Hussein just aggravated the situation and as a result the social sector, including education was affected. United Nations Educational, Scientific and Cultural Organization (UNESCO) reports indicate that before the First Gulf War in 1991 Iraq's education system and performance was one of the best in the Gulf region, with a GER of 100%, and literacy rates were significantly high. As a result of wars the education system and structure has suffered severely, sanctions and instability have complicated the situation, and yet the key asset of the country lies in its educated and experienced personnel. Unlike Uganda and many other countries emerging from war conflict or crisis, Iraq is well endowed with natural resources. The immediate challenge will be to restore its self-confidence and recover a sense of normalcy. The resumption of educational services is a prerequisite for all initiatives aimed at promoting national reconciliation, policy dialog, and the democratization process.

Education is a necessary social tool that can help society maintain its order. To do this its structure and that of the environment in which it operates must be mutually systematic and interactive. This supports their existence as vibrant entities. In the case where the environment is

hostile and nonsupportive, social development is not guaranteed. Countries should endeavor to prevent situations and circumstances that can lead them to war because war is destructive. In the face of its prevalence, in many countries across the globe something must be done.

Way Forward

Since war affects both the internal and external environments of warring countries, it should be observed that corporate global efforts should be concerted as much as possible to stabilize the environment of educational operations, performance, and development. This is possible by:

- Putting in place revised controls as much as possible to prevent wars. Such controls can be in form of regional cooperations with sufficient and genuine awareness programs – these stand out to empower the leaders and masses as privileged choosers of their destiny.
- Warring groups should be compelled by the global fraternity to become more accountable to their people to the extent of enabling simple but progressive core subjects, relevant to war situation such as empowerment lessons. The people, besides knowing why they are in war, should by right, be involved in resolutions that can lead to its end. Failure by war leaders to enable this right to be realized should be punishable by competent courts after the war. It should be taken as an abuse of fundamental right to humanity.
- With advanced technology, hi-tech researchers should evolve gadgets in form of microcomputers with programs that can facilitate learning during war times. A small computer like a matchbox is more convenient than a walkie-talkie to a soldier. People should not be kept in ignorance and information blackout.

Finally, all formal classes, during the good days when there is no war, should involve Development and Liberal Education (DLE) programs, across all levels of education to impart ideals of development, morality, ethics, and desired discipline to the learners. Currently in many countries in the world, emphasis is put on academic excellence. Development education is ignored and yet it would assist to produce reliable, upright, and responsible focused personalities who would contribute to the reduction of conflicts and wars. Formal education should also endeavor to provide quality basic education and training; reduce adult illiteracy, thereby increasing the acquisition by families and individuals of developmental knowledge, skills, values, and attitudes required for better living; and improve learning achievements. It is hoped that with the ever-increasing quality of education among countries, wars will be prevented due to its empowerment potential.

Educational Attainments of U.S. Black Males and Females: 1971 to 2003

F B Bonner, M-C Jipguep-Akhtar, and R J Harrison, Howard University, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The participation and progress of females in higher education in the United States has been followed closely for more than three decades. Debates over closing the gender gap in postsecondary education continue. Several arguments have been put forward advancing the proposition that women are succeeding at the expense of males. In the US, concerns have been greatest for the growing gap in college enrolment and completion between black men and women. While black women comprised 55% of all blacks enrolled in 4-year institutions in 1971, they constituted 60% of the black students enrolled in 4-year institutions in 2004 (Allen *et al.*, 2005). The gap is even larger in all degree-granting undergraduate institutions, where 64.3% of all blacks enrolled in 2004 were women.

The female to male differential in enrolment and graduation rates has been reported to be as high as 6:1 in some historically black colleges and universities (HBCUs; Kaba, 2005), creating a gap that some find alarming. The black gender differential has often been couched in the wider context of several indicators on which the relative status of black males is poor or deteriorating, including employment, health, and incarceration measures (Sum *et al.*, 2007). A common inference is that special programs or policies are needed to target young black males, and to address specific barriers or dysfunctions to which they are presumed to be subject (Sum *et al.*, 2007).

Our research tracks the enrolment of males and females in higher education over a 30-year period in an attempt to shed light on the problem. This article notes that the gender gap in college enrolment and completion among African Americans is consistent with – though much larger than – similar gaps among all major race and ethnic groups in the United States, and is thus – in important senses – not solely just one more socioeconomic or cultural problem that is specific to African Americans or African-American males. We demonstrate that for African-Americans and other major race and ethnic groups, the gender gap – as measured by undergraduate fall enrolment – is larger than the gap measured by the percentages of all 18- to 24-year-olds and of 18- to 24-year-old high school graduates who entered or completed college. This would strongly suggest that differential retention is important to explain the gap, and that,

policymakers and educational institutions may need to focus more on identifying and addressing issues that might affect retention – including academic and financial resources, social support issues, and competing employment needs or opportunities.

A Glance into Black Male–Female Participation in Higher Education

Since the 1970s, both black females and males in the United States have made substantial gains in postsecondary education, but the gains of females have clearly been greater. The belief that females have benefited more from educational gains in recent years and are outperforming males at all levels is widespread (Association of Teachers and Lecturers, 2004). Historically, more black women have attended college than black males, and these women tend to achieve higher grade point averages (GPAs) and receive more academic honors than black men (Jackson, 1986). In 1976, nearly 54% of black undergraduate enrollees were female. Since 1976, the number of both males and females in undergraduate programs has increased. By 1980, the percentage of all females enrolled as undergraduates had surpassed that of all males. The largest difference between male and female enrolment was for black students. In 2002, the percentage of women with high school degrees surpassed the percentage for men, and in 2005 slightly more females (84.6%) than males (83.6%) reported they had earned a high school diploma (American Community Survey (ACS), 2005). Black females continued to enrol in degree-granting institutions in larger numbers than black males, and in 2004, females accounted for 64% of all black enrollees (Kewal Ramani *et al.*, 2007). This trend continues (Crissey *et al.*, 2007).

A Note on Gender, Race, and Educational Attainment in the United States

In global and national contexts, education has become increasingly important as a means of improving societal well-being through its role in increasing understanding and skills development as well as improving social cohesion and reducing social inequalities (Power, 2007). In the last 30 years, there has been increasing awareness of the

relationship between gender, race, and ethnicity and educational inequalities (Power, 2007). Existing studies have posited that involuntary minority groups with a history of oppression in the United States, specifically African Americans, are more likely to resist educational goals in opposition to the values of the dominant society. Such arguments have been used to explain the lack of congruence between black students' high educational aspirations and poor school performance (Ogbu, 1978; Ainsworth-Darnell and Downey, 1998; Hirschman and Lee, 2005). Early work on the educational attainment of US blacks also focused on females compared to white males; but, another debate emerged in the black feminist literature. This debate focused on the disaggregation of data to provide a clearer picture of the participation and progress of women of color compared to white males and white females.

Until recently, there has been little examination of the participation and progress of black males compared to females in these data. This changed with the publication of a few obscure articles, in 2003, on the disproportionate number of females to males enrolled at HBCUs. Research showed that, in many instances, the ratio of US female-to-male participation in higher education was as high as 6:1. However, most early studies ignored the fact that females outnumbered males in post-secondary education in nearly every country of the world. The alarm was sounded and the debate raged on – fueled, at that time, by the struggle over the reaffirmation of Title IX. Recent research on gender equity in education from the American Association of University Women (AAUW) posits that girls' successes have not come at the expense of boys' (Corbett *et al.*, 2008). The AAUW's (2008) comprehensive assessment of girls' and boys' educational progress during the past 35 years concludes that a boys crisis in US schools may be a myth and that both sexes have stayed the same or improved on standardized tests in the past decades (Strauss, 2008). This conclusion challenges the notions that the subgroup with the most persistent lag in education is black males, and stands in stark opposition to education statistics that consistently reveal that black males cluster at the bottom of the distribution of virtually every indicator of school failure such as enrolment and dropping out (Jordan and Cooper, 2002).

Educational Attainment and Black Males

The relative educational status of black males in the US has been characterized as problematic, with disparities evident across many educational metrics, including graduation rates and skills (Levin *et al.*, 2006). While the extant literature on gender differences in educational attainment among African-Americans suggests that males have deplorable high school graduation and dropout rates (Weatherspoon, 2006), statistics show that the percentage of black males

completing high school has increased at a rate comparable to the percentage for black women, and both have dramatically closed the high school completion gap with whites since 1965. At that time, only about one-half of all black women (50.3%) and black men (50.2%) in the age range of 25 and 29 years had completed high school, compared to nearly three-quarters of white women (72.8% and 72.7%). By 2007, high school completion was almost universal among Asians (97.2%) and whites (93.5%), and African Americans (87.4%) were not far behind. The female-to-male high school completion ratio among African Americans, in 2007 (1.01), was comparable to those for whites (1.02) and Asians (1.03), and none statistically differed from unity. The female-to-male high school completion ratio for African Americans has fluctuated over the years, reaching 1.06 as recently as 2006, as well as back in 1967 and 1970, and 1.12 in 1971. However, it has also dropped as low as 0.87 in 1967, 0.92 in 1968, and 0.93 in 1974 and 1977, and the average ratio in the past decade (1998–2007), the past 20 years (1988–2007), and the past 30 years (1978–2007) does not statistically differ from parity.

The data thus suggest that black males have made similar advances in their rates of completing high school as black females, and that both have dramatically closed the gaps with whites in high school completion. *The Journal of Blacks in Higher Education* (2006) notes that 758 400 black males were enrolled in institutions of higher education in 2004. They represented 10% of all male enrollees and 4.4% of all enrollees in higher education. In 1990, 484 700 black males were enrolled in higher education, and they comprised only 6.4% of all male enrollees and 3.5% of all enrollees in institutions higher education. In 1976, of the 1 033 000 black students enrolled in higher education institutions, 563 100 were women. The enrolment figure of black women in higher education institutions increased to 917 800 and, in 1999, of the 1 640 000 black students enrolled in institutions of higher education, 1 037 700 were women (National Center for Education Statistics (NCES), 2002; Kaba, 2005). Thus, not only black females, but also black males, have posted substantial gains in college enrolment in recent decades.

Enrolment in Degree-Granting Institutions

Enrolment statistics seem to tell a sharply different story, however. Black males have fallen from 45.7% of black enrolment in 1976 to only 35.7% in 2004 (see **Figure 1(a)**). In 2004, there were 1.8 black females in degree-granting institutions for every black male. This ratio was far higher than that for whites (1.27) and Asians (1.16), but did not statistically differ from the ratios for Hispanics (1.41) and Native Americans (1.56).

Figure 1 (a) Percent male of fall undergraduate enrolment in degree-granting institutions, by race and ethnicity, 1976–2004. (b) Ratio of female to male enrolment in degree-granting institutions, by race and ethnicity, selected years, 1976–2004. From US Department of Education, National Center for Education Statistics, Digest of Education Statistics, 2005 (NCES 2006-030), table 205 'Fall enrollment in colleges and universities'.

The female-to-male enrolment ratio grew by over 50% (51.4%) among blacks (see **Figure 1(b)**). However, it is worth noting that the ratio grew as rapidly among Hispanics (68.1%) and Native Americans (55.4%), and that the growth for blacks did not statistically differ from the growth among whites (39.2%) or Asians (35.5%). The trend among blacks thus seems to represent developments

common to all major race and ethnic groups, and is no stronger than those in the other minority populations – Hispanics and Native Americans – with lower educational attainments than whites and Asians.

One might, nevertheless, ask: does the much higher female-to-male college enrolment ratio among blacks (1.8 females per male) not confirm that the problem is at least

Figure 2 Ratio of female-to-male 18–24-year-olds enrolled in degree-granting institutions by race and ethnicity, 1967–2006 (3-year moving average). From US Census Bureau, current population survey, 1967–2006.

more severe in the black population, even though the gap is substantial in the major racial and ethnic populations, and also grew within them between 1976 and 2004? In the remainder of this article, we present evidence that suggests that the higher female-to-male ratios for blacks reflects at least two additional factors that have received too little attention and merit further analysis. First, a larger part of the gender differential among blacks seems attributable to enrolments of black women older than 25 years in institutions of higher learning: enrolment ratios are substantially lower for black 18–24-year olds. Second, the ratios seem even lower when one examines percentages of 14–24 and of 25–29-year-olds who attended or completed college. This suggests that some of the gender gaps in the stock of black females and males enrolled at any point in time may reflect differences in the flows of black women and men into and out of degree-granting institutions. Both more rapid completion of degrees and higher attrition could contribute to black men entering and leaving degree-granting institutions more rapidly than black women, contributing to a higher stock of black women at any given point in time.

18–24-Year-Olds Attending or Having Attended a Degree-Granting Institution

The statistics cited above indicate that in 2004, for every black male enrolled in a degree-granting institution there were 1.8 black females. However, among 18–24-year olds, only 1.34 black women were enrolled in degree-granting institutions for every black male, and 1.33 in 2006 (**Figure 2**). This suggests that more than half of the gap between black males and females reflects much higher enrolments of

black women than black men who are older than 24 years, either because they are in graduate or professional schools, or are returning to school – in all likelihood after some break in their education – or because they taking more years to complete their degrees – perhaps as part-time students. In contrast, the female-to-male enrolment ratio for whites of all ages (1.27) did not statistically differ from that for 18–24-year-olds (1.17) in 2004 (**Figure 2**).

The differences in enrolment for all ages compared to 18–24-year-olds in 2004 were also not statistically significant for Hispanics (1.41 and 1.46) or for Asians (1.16 vs. 0.93). Much of the unique dominance in the enrolment of black women over black men in degree-granting institutions thus seems to reflect a uniquely large enrolment of black women older than 24 years. The ratio of female-to-male enrolment among 18–24-year-olds for blacks (1.34), in fact, was not statistically higher than that for whites (1.17) in 2004 (**Figure 2**). The problem – in the light of these statistics – seems to lie less in the enrolment rates or behavior of young black men than in what one must infer is much higher enrolments among black women over 25 years still completing or returning to their education.

The statistics cited here on black female and male enrolment are drawn from fall enrolment in degree-granting institutions – a measure of the stock at each point in time. The percentage of 18–24-year-olds and of 14–24-year-old high school graduates who – in a given year – were enrolled in or had completed some college provides an indicator that reflects flows as well as stocks. The black female-to-male ratio for enrolment in or completion of college was only 1.20 in 2004, and remained below 1.25 until 2006 when it surged to 1.29 (**Figure 3**). This was statistically identical to the corresponding ratio for whites,

Figure 3 Female-to-male ratio of 14–24-year-old high school graduates who attended or completed college, by race and ethnicity, 1967–2006 (3-year moving average). From US Census Bureau, current population survey, 1967–2006.

which was 1.12 in 2004, and 1.09 in 2001 – when the ratio for blacks was 1.20 (**Figure 3**). The black female-to-male ratios for enrolment in or completion of some college are comparable for 14–24-year-olds and for 18–24-year-olds – remaining below 1.20, except in 2001 and in 2006, when the ratio climbed to 1.26. The female-to-male enrolment and completion ratios for 18–24- and for 14–24-year-olds both indicate that the behavior of young black male and female high school graduates do not differ greatly from those of their white counterparts, or, in most years, from Hispanics either.

College Completion

The fact that the percentages of 18–24-year-old black men who were enrolled in or had completed some college seems closer to the corresponding percentages for black women in most years than their enrolment rates, at any given point in time, suggests that black men may spend fewer years on campus than black women. This might arise from lower retention rates (higher college-dropout rates) for black males, or because black males take less time, on average, to complete their degrees. If college dropout rates were notably higher for black men than for black women, one would expect that the ratio of black females to black males with bachelors' degrees would be considerably higher than the corresponding ratio for those who enrolled in or completed at least some college.

There is no strong evidence of this in the percentages of 25–29-year-old black women and men with BAs. The 3-year moving average of the ratio was 1.29 in 2004 (and in 1997), and reached 1.46 in 2005 before falling to only 1.11 in 2007. With the exception of a few years adjacent to these

peaks, the ratio of black female to male BAs in this cohort has seldom exceeded 1.20 since the mid-1970s, and, in fact, briefly fell below 1.00 between 1988 and 1991. These ratios are well within the same range as those for the black female-to-male ratios for those enrolled in or having completed some college in the 14–24-year-old and the 18–24-year-old cohorts. The ratios, since the 1990s, for blacks may look high in comparison with the period from 1974 to 1984, during which the ratio remained under 1.10. However, the female-to-male BA ratios for black 25–29-year-olds, although higher, have also remained well within the range of those for whites, which have steadily risen from unity in 1990 (when the ratio for blacks was 0.94), to 1.23 in 2007 – a ratio seemingly higher than the 1.11 female-to-male BA ratio for blacks in 2007. Indeed, the black and white female-to-male college-completion ratios did not statistically differ from one another between 1989 and 1992, and between 2000 and 2003.

College-dropout rates may well have been higher for black men than for black women during some of these years, and this must certainly be an item of high priority for research on gender differentials in college enrolment and completion in recent decades. However, the comparability of the ratios of black 25–29-year-old women and men holding BAs to ratios of those who enrolled in or completed some college suggests instead that black women may be taking longer to complete their degrees. Any slower flow of black women through the institutions while completing their degrees would contribute to their higher enrolments, and might also help explain why the ratio of black female-to-male enrolment in college is higher than the corresponding ratio for young black adults (25–29-year olds) who have completed college. This too should be high on the research agenda.

Discussion and Conclusion

The fact that nearly two-thirds of all black students enrolled in degree-granting institutions in 2004 were women, and that there are approximately 1.8 black women for every black man on campuses in the United States has frequently been presented and discussed as yet another indicator where black men seem to lag far behind men and women in most major racial and ethnic groups in their educational achievements and attainments. We have presented evidence here that the largest factor in the differential enrolment of black men and women might lie in uniquely high enrolment by black women over 25 years old: the black female-to-male ratio among 18–24-year-olds is 1.40:1 – only half the ratio for blacks of all ages. The ratio falls even further, to – at most – 1.30:1 and usually 1.20:1, when one compares black males and females in the 18–24-year-old and 14–24-year-old cohorts who have enrolled in or completed some college. The ratios for enrolment and completion could be lower than those for enrolment alone if black men were dropping out of college at higher rates than black women, or if they were completing their degrees in less time. The ratios of black women to black men in the 25–29-year-old cohort who have completed a bachelor's degree also fall within the same range as the ratios for enrolment and completion. This suggests that higher dropout rates probably contribute less to the differential in most years than would faster completion of the degree by black men. Once these factors are considered, the gender differentials in the college enrolment and completion rates for blacks – and Hispanics – (usually no more than 1.30:1 and usually less than 1.20:1) do not differ dramatically from the differentials for whites (no more than 1.25:1 and usually above 1.10:1).

The gender differentials in enrolments might be telling us much more about women, and especially black women, than about black men and their lower educational attainments. In 2006, the mean earnings of a female black (\$22 643), white (\$23 805), Asian (\$25 696), or Hispanic (\$20 608) high school graduate falls short of or barely reaches the mean earnings range of a white, male high school drop-out (\$26 100). Completing some college or an Associate Arts degree barely raises the mean earnings of black (\$28 706), white (\$28 322), Asian (\$29 415), and Hispanic (\$26 260) women above the mean earnings of the white male dropout (\$26 100). Black (\$44 326), white (\$43 473), Asian (\$44 932), and Hispanic women (\$38 825) can roughly double what they would earn with a high school degree by completing college (even though this only gives them mean earnings comparable to those of white males with some college or an associate arts degree – \$43 589).

One might hypothesize that as social and cultural changes have greatly increased the likelihood that women – even those raising children – will work for most of their

adult years, they have also seen completing at least some college or earning an associate's or bachelor's degree as essential to making work worthwhile. In contrast, with only a high school degree, even black (\$30 122), Asian (\$32 528), and Hispanic (\$32 148) males can earn more than minority women who have completed some college or an associate arts degree (\$26 000–\$29 500). Many of these men might think it better – or might feel pressed by family responsibilities – to enter the labor market and begin earning wages that a woman could not expect to earn without completing some college or a degree. One might also hypothesize that the need to increase earnings potential may have led black women – who have had historically higher rates of single parenthood and contributed higher shares to family income when married – to increase their efforts (compared to males) to attend and complete some college before women in other racial and ethnic groups did so. The necessities of attending or completing college while working – and, for others, of returning to school to improve earnings – might be examined as factors that might help explain the much higher college enrolment rates of black women over 25 years of age.

Educational Preparation: Fostering the Self-Efficacy and Resilience of Urban Adolescent Youth

M B Spencer and B Tinsley, University of Pennsylvania, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Guaranteeing that a society's youth are prepared to take on adult tasks, through educational preparation and appropriate socialization opportunities, represents an important duty deserving substantial attention and support. The preparatory content may be framed and implemented with degrees of variation given the unique cultural traditions. However, it is universally understood that adolescence is a pivotal period of academic, social, and emotional adjustment. These anticipated changes arise in response to normative sets of challenges accompanying youths' preparations for transitioning into adulthood.

As detailed elsewhere, all humans are vulnerable (i.e., embody both risk and protective factors) (see Spencer, 2006, 2008). As a social minority, particular youths' normative experiences and, thus, vulnerability specific to the adolescent period of development, are intensified. Furthermore, belonging to a specific group that is perceived by the majority (or those in power) as inferior, in some manner, matters. For example, living in a family with few social and economic resources worsens the normative development-linked risks and their expression as myriad challenges in need of coping responses during this period. Additionally, although not often discussed, the potential impact may be moderated by adequate levels of protective factors manifested as supports. That is, resiliency is possible (i.e., the achievement of good outcomes in the face of significant challenge) as a function of the availability of and access to significant levels of support; the resources serve to offset the cumulative and significant levels of risks encountered. However, a question infrequently posed is whether one might have access to excessive and unacknowledged protective factors and, accordingly, too many supports?

Group membership and the availability of resources as supports and assets, as suggested, matter. Consequently, significant resource availability may either serve as protective factors which balance out normative risks or, on the other hand, exacerbate the risk level. With the exception of Luthar and colleagues (e.g., Luthar and Becker, 2002; Luthar and Latendresse, 2002), this theme is infrequently addressed; nonetheless, significant and unacknowledged social, emotional, or economic opportunity and asset access (e.g., as group status associated entitlements or privileges) may further complicate youths' healthy transition into

adulthood and compromise self-efficacy efforts. Simply stated, an overprotection against risk exposure and normative youth experience may contribute to inadequate learning opportunities, ordinarily afforded by confronting challenges.

For example, affluence and socially bestowed entitlements obscure learning opportunities obtained from instances requiring the confrontation of challenges and appropriately responsive and in-the-moment positive-reactive coping. Confronting and coping with normative developmental challenges contribute to (1) coping-skill development, (2) nurturing of competence (given successful results), and (3) establishing positive self-efficacy beliefs. On the other hand, the diminishment or absence of coping opportunities may result in maladaptive responses (e.g., drug use, suicide, and an inaccurate self-concept) when effective coping is most beneficial. In such circumstances, proactive learning opportunities are denied or sheltered against by disproportionate access to socially situated, significant, and unearned privilege (see Luthar and Becker, 2002; Luthar and Latendresse, 2002) (**Figure 1**). As described in **Figure 1**, habitually low-risk experiencing youth, although having a significantly high presence of protective factors or supports, are described as untested and having undetermined vulnerability. On the other hand, individuals with high risk but possessing high and significant levels of protective factors, are viewed as resilient (i.e., they obtain good outcomes in the face of significant challenge) (see Spencer, 2006, 2008; Spencer *et al.*, 2006).

As indicated, all humans experience some level of danger, represented as different levels of vulnerability with varying outcomes (see **Figure 1**) thus, the character and content of socialization and training opportunities is critical. In fact, the role of preparing youth for the future is an especially vital function that requires patience, commitment, and adequate knowledge. It is a responsibility that cannot be taken lightly given the many and varied societal challenges that exist. Accordingly, adolescents developing in exceptionally challenging neighborhoods may find it especially difficult to focus on issues of consequence (e.g., school achievement) that are critical for adult success. Not surprisingly, varying contextual obstacles may present difficulty for financially disadvantaged youth, and particularly, those of minority status. Considered collectively, adverse factors, such as a lack of personal

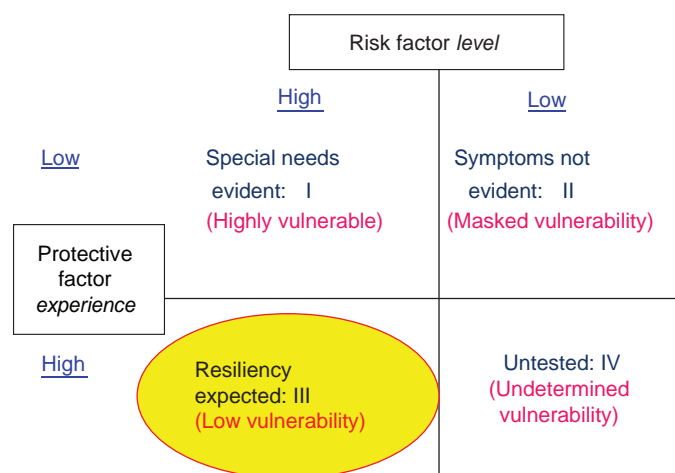

Figure 1 Phenomenological variant of ecological systems theory (PVEST)-linked vulnerability level and resiliency-prediction quadrant model. From Spencer, M. B. (2006). Phenomenology and ecological systems theory: Development of diverse groups. In Damon, W. and Lerner, R. (eds.) *Handbook of Child Psychology*, 6th edn, vol. 1, pp 829–893. financial resources, awareness of the inequality of opportunity, along with low-quality schooling, and harsh neighborhood contexts, reinforce persistent achievement gaps (Spencer, 1999, 2001).

The prevalence of an achievement gap between affluent and financially disadvantaged students is well documented (Hilliard, 2003). There is substantial evidence that students of color from low-socioeconomic backgrounds are disproportionately taught by less-qualified teachers and attend deteriorated schools that are racially and socioeconomically isolated (Darling-Hammond, 1997). In comparison with the college campus-like educational facilities provided by many affluent suburban communities, the attendant risks associated with economically strained urban schools and contributed to by teaching inadequacies and physical plant character, are obvious (see Spencer *et al.*, 2004; Spencer and Harpalani, 2004, 2008).

Accordingly, youth who develop in exceedingly challenging social contexts require attention that may look different from the mainstream. In order to address this issue, practitioners and researchers alike may benefit from understanding the distinctiveness of schooling experiences and therefore, adjust their actions. In this way, teachers, administrators, and parents can promote and make use of supportive strategies, which produce positive and productive youth development in the face of hardship by affording the necessary level and specific character of social supports. The specification is important given that all support, in fact, may not be experienced as supportive, given the history of undervalued American minorities (see Harpalani and Spencer, 2005; Spencer, 2005, 2008). Consistent with White's (1959, 1960) competence theorizing and explanation of

effectance motivations, adolescent students may positively and appropriately respond to the multitude of challenges and exhibit resiliency (i.e., obtain positive outcomes in the face of challenge) (refer to **Figure 1**). This most often occurs when young people believe that their efforts have a positive impact on the environment (i.e., manifested effectance motivation) (see White, 1959, 1960). Consequently, the level of academic and social resiliency of youth relies upon preparation and the quality and character of support offered to them by significant others in the varied settings transected by youth. Thus, the school environment should not be merely reproductive of traditional academic norms and standards but, instead, be transformative in the manner in which youth are taught and competence is achieved.

Accordingly, this article focuses on what factors contribute to a functional support system. The following ideas offer a theoretical perspective on how adolescents may best develop a sense of competence given any number of burdening factors. In particular, we consider how youth, particularly low-resource and minority-status youth of color, obtain and experience educational preparation as a source of support given the goal of academic self-efficacy and resilience. The solidification of these concepts endows youth with a sense of power and status, and facilitates a sense of competence. Fundamentally, educators benefit from understanding that learning is a developmental process and a risk-taking exercise. The context should provide a setting which communicates a sense of trust for engaging in learning as risk taking. Additionally, in order to serve youth more adequately, educators and school administrators would be wise to consider the perception-based cognitive dynamics around the formation of adolescent beliefs

about power, equity, and status. If not adequately informed by the insights described, seemingly proactive administrative and teaching efforts may waste resources, that is, and as suggested, intended supports may not be experienced as such and, instead, actually result in feelings of greater challenge due to unintentional systems injury (Spencer, 2006, 2008).

Background

Despite what has come to be the general public's perception of African-American children's desire to achieve (see review by Spencer and Harpalani, 2008), Black youth in America set high academic goals for themselves (see Spencer *et al.*, 2003). Yet, these socialized values and aspirations may be disputed as a function of matriculating through an educational system that, among other things, may neither financially nor socially support youth's academic intentions and, instead, communicate low expectations. The dilemma continues to be particularly acute for African-American males (Spencer, 2002; Youngblood and Spencer, 2003).

In 1990, Simmons and Grady reported that in a southern Maryland suburb located just outside of Washington, DC, Black males and females performed equally as well as their white counterparts in both mathematics and reading until the third grade. However, during the fourth grade year, a sharp decline in criterion-referenced mathematics and reading tests results were reported. Additionally, the percentage of Black males in the top reading groups dropped significantly (from 23% to 12%) from grade four to grade six (Lewis *et al.*, 2006; Simmons and Grady, 1990).

Unpacking and determining the causes of such findings is an imperative. Hypotheses about the most salient contributing factors include the examination of the school environment, inadequate self-reflection opportunities, and limited identity-exploration opportunities available to students. The implementation of strategies that take into account the factors noted, are thought to have implications for enhanced self-concepts and the development of increasingly positive attitudes and behaviors toward education. Support, experienced as positive change, can lead to broadened intellectual interests, improved self-regulated learning, greater commitment to education, and the framing of specific vocational plans and long-term aspirations (Fournet *et al.*, 1998). As proposed, greater specification and exposure to supports, overall, have implications for resilient outcomes in spite of the persistence of socially constructed risk factors.

In fact, contrary to common public perception, African-American boys wish to complete school and many actually desire classes that are academically challenging. In a survey of 2250 African-American males in New Orleans, 95% reported an expectation to graduate from high

school. Forty percent stated that they believed their teachers did not set high goals for them and 60% expressed a desire for their teachers to have higher expectations for them (Lewis *et al.*, 2006). Yet, despite these findings, unfortunately, low teacher expectations are inferred by youth and begin to take shape at startlingly early ages. Garibaldi (1992) reported that of 318 teacher respondents, 60% of whom taught in elementary schools, approximately six in ten stated that they did not believe their Black male students would go to college. Strikingly, 70% of these teachers had taught for 10 years or more and 65% of these teachers were African American. These detrimental biases are also evident as a function of the rate at which Black males are excluded from the classroom. In particular, African-American male-student statistics indicate that they are disproportionately suspended and/or expelled, show poor scholastic performance, avoid academic engagement, and represent decreasing rates of college attendance (Garibaldi, 1992).

Children are undoubtedly perceptive, conscious and aware of many of the biases that surface in the classroom. As a result, they are unavoidably sensitive to their central placement within the social dynamic. Thus, experiencing these hardships may be detrimental to positive youth development. Experiencing the noted biases while entering into and navigating through adolescence may be even more salient for such youth. That is, the outcomes lay the groundwork for additional critical-developmental tasks to be achieved for successful transitioning into late adolescence and early adulthood.

As previously noted, adolescence is a difficult stage to navigate due to the constant changes in one's physical and cognitive development. It is a time of heightened sensitivity to the many changes occurring both internally and externally. Consequently, adolescence may also bring about negative changes, including increased anxiety about school performance, social comparisons as a basis for assessing ability, confusion about the causes of one's academic outcomes, and declines in intrinsic motivation (Zimmerman *et al.*, 2000).

The negative psychological and behavioral outcomes noted may be exacerbated, while sources of protective factors, such as acknowledging youths' strengths, abilities, and cultural traditions, often go ignored. The lack of attention to cultural variations and opportunities to utilize them as strengths and sources of support may, in fact, cause their value or inferred relevance to a particular cultural context to wane. When Black youth are socialized to devalue the experiences of their own culture and ignore the historical and contemporary significance of issues facing their own ethnic groups, their psychological and behavioral well-being is affected (Baldwin *et al.*, 1987; Lewis, 2001).

For a better understanding of the phenomena of adolescent self-efficacy and resilience as it relates to perceived

competence, invoking a theoretical perspective is useful. In this instance, Spencer's phenomenological variant of ecological systems theory (PVEST) (Spencer, 1995, 2006, 2008) is useful when assessing how adolescents perceive, interpret, and act upon the stimuli that form their educational context. Given the task at hand, PVEST is beneficial due to its emphasis on meaning making as a potential contributor to youths' vulnerability as well as resiliency. Additionally, the systems theory views the self-system processes as dynamic, as well as recognizes the bridge between the individual's actions and societal context.

Taking into account that all humans are vulnerable, the PVEST framework consists of five components linked by bi-directional processes (Figure 2) (see Spencer, 1995, 2006, 2008), forming a cyclic, recursive model that explains identity development throughout the life course. The first component, net vulnerability level, represents the relationship or potential balance between risk factors versus protective-factor presence (e.g., protective factors as cultural capital). For urban minority youth, risks may be exacerbated by low socioeconomic conditions or sociocultural factors such as race and sex stereotypes. The second component, net stress level (i.e., challenges vs. supports), mediates between net vulnerability level and component three (i.e., reactive coping responses). The latter represents the state of balance between in-the-moment responses of maladaptive as opposed to adaptive strategic responses to confronted challenges. Particularly important at adolescence,

an individual's patterned reactive coping response (i.e., either maladaptive or adaptive), over time, becomes an internalized emergent identity (i.e., component four of PVEST). As illustrated in Figure 2, the emergent identifications can be either negative or positive. It is the consistent identity-linked set of behaviors that lead to component five (i.e., either unproductive or productive outcomes). Component five represent patterned sets of outcomes which have life-course implications. That is, as a productive or unproductive pattern, given the sets of developmental tasks associated with each developmental period of the life course, outcomes at one stage contribute to the subsequent period's status of vulnerability (i.e., risk vs. protective factors) (refer to component one of PVEST in Figure 2). As suggested by its cyclic character, the PVEST framework recycles and recurses through the lifespan as individuals balance new risks against protective factors, engage new stress levels, given challenges potentially offset by supporters, try different coping strategies, and redefine how they and others view themselves. Throughout the process, as individuals navigate across time and place, new developmental tasks are presented, which require responses. Thus, in many ways, the theory postulates an unchanging state of human coping. As noted, vulnerability (i.e., both protective and risk factors) is consistently a part of human development across the life course. Adolescence, in and of itself, holds rather fascinating challenges given pubertal changes and the

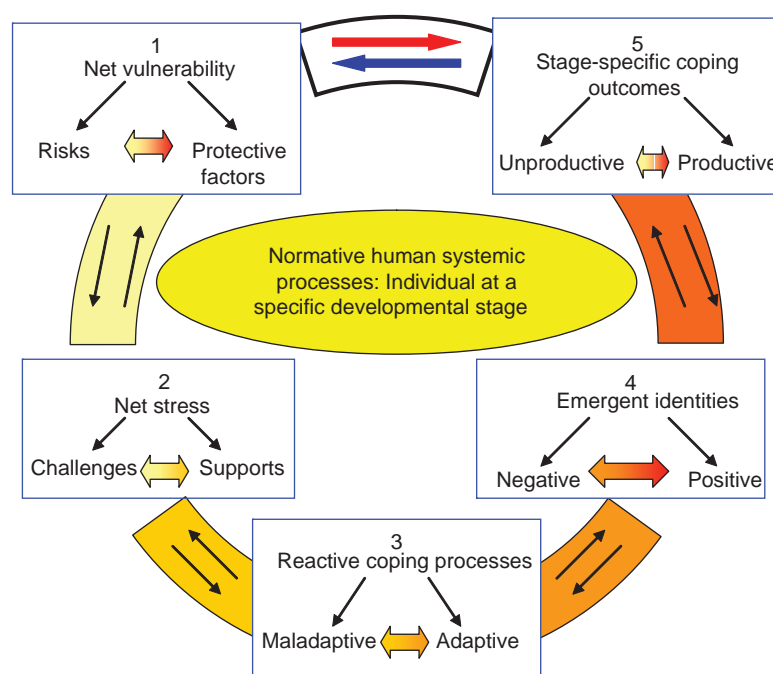

Figure 2 Phenomenological variant of ecological systems theory (PVEST). From Spencer (1995); (2004) Rev; Spencer, M. B. (2006). Phenomenology and ecological systems theory: Development of diverse groups. In Damon, W. and Lerner, R. (eds.) *Handbook of Child Psychology*, 6th edn., vol. 1, pp 829–893. New York: Wiley Publishers; and Spencer, M. B. (2008). Phenomenology and ecological systems theory: Development of diverse groups. In Damon, W. and Lerner, R. (eds.) *Child and Adolescent Development: An Advanced Course*, pp 696–735. New York: Wiley Publishers.

period's critical transitional role in preparing youth for the longest period of the life course – adulthood. Self-efficacy is an important protective factor that promotes the process.

Self-Efficacy

A number of factors, including stress and anxiety, may decrease one's level of self-efficacy. Particularly for socially marginalized youth (e.g., minority youth of color, immigrant, and special-needs young people), the additional social and financial barriers frequently encountered can heighten levels of anxiety and stress, which may interfere with academic performance and thus, the development of positive perceptions of self as a learner.

Cultural dissonance, which is understood to be the cognitive and emotional stresses resulting from conflicting cultural values or norms confronted by individuals in culturally salient situations, are hypothesized to be linked with unavoidable social cognitive processes (Spencer, 1982, 1984, 1985; Spencer and Markstrom-Adams, 1990). That is, one's cognition-based awareness of inequalities contributes to experienced cultural dissonance given personal values, desires, and interests.

A prominent hypothesis used to describe the discontinuity or discontinuity between inferred-context character and individuals' goals and desires has been described by Steele (1995) as a stereotype threat. This occurs when an individual of a socially stigmatized group is aware of certain task-related negative perception(s) held about their group. This consequently influences their ability to effectively conceive of themselves as able to successfully perform particular tasks. Otherwise stated, competing assumptions contribute to self-questioning about one's inferred level of efficacy.

In order to establish a sense of competency, adolescents' feelings of self-worth must remain intact and is associated with a belief that their efforts make a difference (see White, 1950, 1960). Hence, an undermining of confidence interferes with the ability to sustain a sense of power and/or control in a given situation; particularly those that are related to the development of academic self-esteem (see Hare and Castenell, 1985). This sense of authority over the direction of one's life trajectory and the various elements that may arise as daily hassles, often referred to as locus of control, endows youth with an important sense that they can enact change, or as classically described by White (1959, 1960), suggests effectance motivation. Accordingly, youth realize that they have the ability to function as active agents in their own lives, rather than existing as passive beings without a sense of agency. As indicated, past research has established academic self-efficacy as a fundamental adolescent coping mechanism used to navigate the educational system. Coping methods result in specific

products that may then be defined as demonstrations of competence (Anthony, 1987; White, 1959). Successful outcomes are often underacknowledged when associated with significant risk conditions and social challenges; that is, resiliency is underacknowledged. However, resiliency is a normal aspect of life for many successful young people.

Resiliency

As suggested, although resilience characterizes the daily experience of many lower-income minority adolescents (i.e., good outcomes are achieved in the face of significant challenge), for highly vulnerable youth, the stress that accompanies poverty, ethnicity-related social inequities, and chronic unchecked violence, may undermine self-efficacy beliefs and achievement efforts (Chestang, 1972; Hacker, 1992). Still, relatively little research has been conducted that focuses on the underlying processes of resiliency as observed among minority-status children of color. However, protective factors are also present and certainly a matter for offsetting the risks described (see Spencer *et al.*, 2006). Spencer *et al.* (1998) found that one's in-group cultural-identity processes support greater resilience of youth during periods of unusual stress. Their findings indicate that both academic and mental-health outcomes were positive and significantly higher for middle childhood and early adolescent youth who valued their own ethnic heritage as opposed to identifying with the dominant group.

Educational Preparation

Undoubtedly, education is one of the most influential tools for shaping and replicating a number of societal dynamics, namely, cultural norms and attitudes. Schools are one of the most prominent institutions for promoting mainstream ideology by contributing to students' development of a sense of organization and expectation. In fact, they are determined by the curriculum and structure of the school, as well as, the character of interactions experienced among students, teachers, and parents (Adler *et al.*, 1992).

The notion of educational preparation is concerned largely with the process of meaning making. Fundamentally, the manner in which individuals make meaning of the world is linked to their experiences with education, preparation, and competence. There has been relatively little research conducted in the area of educational preparation of urban-minority students. Furthermore, the research produced is not without flaws.

Essentially, educational preparation consists of the development of skills, knowledge, and the characters of youth. The formation of these elements enables adolescents

to create an environment in which they play a role in the planning, implementation, and modification of their own learning processes. Thus, while serving in diverse educational roles, they can reflect on their growth and, in turn, respond proactively to what they deem as societal needs.

Accordingly, socializing agents as individuals in position to influence outcomes should (1) seek to develop a knowledge base that is comprehensive and directed to the individual's needs; (2) identify and enact dispositions which enable them to be perceived and experienced as understanding, respectful, and inclusive in their creation of nurturing learning environments for diverse learners; and (3) hone skills which enable them to plan, implement, and assess appropriate instruction (Gagne *et al.*, 1988). Therefore, it is critical that educators prepare to be effective instructors who are responsive to the needs of ethnically diverse learners (e.g., including students of color). This requires sustaining students' sense of competency and enhancing resiliency outcomes. The process is facilitated by providing youth with supportive experiences, which produce a sense of personal causation (De Charms, 1953) or a belief that they can have a constructive impact on their environment.

Too often, there is a lack of understanding of cultural context. The patterned failure to appreciate the cultural components of the lives of young people contributes to misunderstanding about their outward expressions of self-hood (i.e., behaviors and attitudes). Furthermore, behaviors and struggles that result in success are often overlooked by authority figures since too many adults, specifically responsible for youth socialization, remain ill-equipped to recognize strengths as well as challenges. This significant shortcoming contributes to a failure to accurately assess these populations of students. The identification of influential and positive factors and their incorporation into the implementation of constructive interventions continue to be underrecognized albeit pivotal for the positive development of minority and highly vulnerable adolescents more generally.

Specifically, providing and teaching from a culturally relevant text is essential for the positive development of African-American youth. Education is aided when youth are provided with philosophical and academic material that is grounded in historically accurate content, which then facilitates the transmission of African and African American culture (e.g., see Spencer, 1990; Spencer and Dornbusch, 1990; Spencer and Markstrom-Adams, 1990; Spencer *et al.*, 2003). Teaching students to think critically and to understand their place in history can aid in the acquisition of skills and the accomplishment of this goal. In this way, children are able to recognize in a better manner, the importance of African heritage and the group's accomplishments under conditions of patterned adversity. Therefore, all of the above are important elements in developing socially responsible and engaged youth.

Overall, the goals of educational settings may well benefit from perspectives that recognize and enhance communal orientation, increase youths' sense of school connectedness, increase their motivation to achieve, increase their involvement in positive social change, and thus, improve their academic achievement. Although the noted values are frequently acknowledged, unfortunately, themes such as communalism frequently remain unacknowledged and are infrequently addressed.

Communalism, according to Lewis *et al.* (2006), refers to "attitudes and beliefs that one maintains concerning the significant and meaning of communal world experience and how one defines oneself in relation to one's community" (p. 5). Individuals with a communal orientation act in ways which communicates the notion that duty to one's social group is more important than individual rights and privileges (Boykin and Bailey, 2000). School connectedness refers to the extent to which one feels personally accepted, valued, supported, and encouraged by peers, teachers, and other adults in the school social environment (Goodenow and Grady, 1993). Additionally, an individual's degree of connectedness refers to the extent to which one feels a part of or aligned with the activity of one's context. For youth, the overwhelming majority of their context includes the classroom setting. As a function of their perceived and dynamic sense of synchrony, a young person's feelings of high connectedness correlates with open communication, high expectations from teachers, positive peer interactions, and motivation to achieve academic excellence (Arroyo and Zigler, 1995).

Accordingly, those students who feel alienated, are less likely to be motivated to achieve. Logically, they may demonstrate their sense of alienation by inserting their presence in other ways that are misunderstood or inferred to communicate disinterest in learning (e.g., acting out in class) (see Spencer, 1999, 2001, 2006).

Academic motivation refers to one's desire to learn and excel (Donohue and Wong, 1997).

Student motivation to achieve is among the top quartile of variables having strong effects on student achievement outcomes (Hudley, 1997; Weiner, 1990). Heightened motivation to achieve is of particular salience for Black adolescents in traditional mainstream educational environments (Hudley, 1997).

Knowledge as Power and Status

Understandably, the involvement of adolescents in some amount of change (e.g., social, educational, and emotional) in their environment may serve to fuel their desire to learn. The idea that one can alter the dynamics of a specific entity may serve as a fuel for one's desire for knowledge. Youth may have a stronger desire to achieve if they perceive their efforts and accomplishments to have

a significant impact on the world around them. Too frequently and as a function of marginalization, minority youth in particular, may feel that the efforts they put forth have no impact on the world around them, thus feeling that these efforts are in vain. Hence, endowing youth with the sense that their knowledge and efforts can generate positive change, can potentially increase their willingness to participate in the learning process.

Additionally, knowledge can be viewed as an indication of social position and, thus, a tool for altering one's status. As stated previously, this can be accomplished, in part, through the structure of school programming. One of the ways speculated for carrying out the task of providing cultural competence is via emancipatory education (Freire, 1998), generally described as African-centered education (see Madhubuti and Madhubuti, 1994). As referred to in the literature, both emancipatory and African-centered schooling involve a process of training that is intended to liberate underrepresented groups from racist ideologies and social institution in contemporary society (Lewis, 2004). Emancipatory schools attempt to connect African-American culture with Africa through the introduction and infusion of Afro-centric cultural approaches into curriculum and training (Akoto, 1992).

Emancipatory education, specifically, has been shown to increase communal orientation, school connectedness, motivation, and social-change involvement (Lewis *et al.*, 2006). However, participants in the program also felt more individualistic and competitive, which are prominent characteristics of mainstream American society and, when adopted, show utility for obtaining success in and beyond the classroom. Thus, adolescents who adopted either of these values more readily excelled in school when compared against those who are more collectivistic and communal in their work habits.

Conclusion

Teachers and parents should encourage youth to engage in self-appraisals regarding their academic competence and efficacy. The strategy has been shown to be positively related to achievement motivation and academic persistence (Bandura, 1977). As described, teachers and administrators obtain greater success when they adopt the use of strategies that are supportive of culturally responsive pedagogy. The strategy described facilitates the awareness of students' cultural needs while enhancing youths' interests and experiences. The suggested strategy builds trust and facilitates the achievement of core competence and critical competencies (i.e., particularly through the use of effective questioning strategies), thus, increasing opportunities for engagement in constructive dialog around student needs (Villegas and Lucas, 2002).

The adoption and integration of the several ideas espoused by emancipatory-education pedagogy may serve to bridge the achievement gap. The perspective offered counters the long-term void between the mainstream norms that schools continue to practice and also acknowledges the culturally specific and contextual needs of minority students (see Lee *et al.*, 2003; Rogoff, 2003).

As put forth by Spencer (2001), conceptual models are needed for a better understanding of the benefits of resiliency-promoting factors from a contextually and developmentally sensitive perspective. Spencer (2001) states that individual behavior is guided not only by opportunities but also by the perceptions of those opportunities. Thus, resilient outcomes can be achieved in spite of barriers if one perceives those barriers to be surmountable.

HIV Education for Low-Literate People: Transforming Students and Communities through Paulo Freire's Praxis and the Pedagogy of Action

N Z Haniff, University of Michigan, Ann Arbor, MI, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Activism – To become advocates of a cause related to social justice.

Consciousness – To be aware of the complex systems and ideas that drive social injustice in people's lives and the awareness that overcoming these injustices requires your own participation.

Empowerment – Ensuring that the least privileged is provided with the skills and knowledge that they can own and use to improve their lives.

Exoticism – To reduce a culture to essentialist caricatures, for example, one does not really see Africa unless one sees animals, or all Africans live in huts.

Low literacy – Population which is literate but only functionally literate.

Pedagogy – A method of teaching which facilitates the learners engagement in the teaching.

Praxis – Putting theory into action.

Introduction

This project asks some key question relating to transformation of students and communities: How young men and women can be conscientized about social injustice (race and gender) and translate that consciousness as a core principle of their own transformation as activists? How can a teacher who is a gender and human immunodeficiency virus (HIV) activist in South Africa, the Caribbean, and the United States use the nexus between privileged students and the community to develop consciousness in these communities to see themselves not as victims but as participants who can solve the problems faced by their communities if given the right tools? How can empowerment be achieved not as an academic exercise but as an act of human rights advocacy for the least literate and most marginalized?

The response to this question has been a three-course curriculum lasting a year. The first part of this curriculum is the course Pedagogy of Empowerment: Activism in Race, Gender, and Health, which educates the student about the HIV menace among African-Americans. There are four very important objectives for this class. First, the

student must become fully informed about HIV and African-Americans. Second, this information provides the context for a lively discussion on race and gender. Third, the students must be theoretically grounded in both race and gender in the HIV epidemic in the African community. Finally, from this process, the students become involved in praxis through teaching the low-literate module on HIV to communities outside the university.

The module was developed in the Caribbean when the author was engaged in creating low-literacy modules to teach women about their bodies. The women in Guyana asked to be taught about HIV. At the heart of this methodology is the philosophy that people can take responsibility for themselves if given the right tools, and that literacy was not a requirement for education. This module was then taught in Guyana, St. Lucia, Grenada, Dominica, St. Vincent, and Jamaica with great success. At that time, the epidemic was beginning to emerge as a great threat in Africa, and South Africa was then on its way to becoming the country with the largest number of infections (today there are 5 million HIV-infected persons in South Africa). The author is of the opinion that this module could have had some impact in South Africa, since there were large numbers of people who were not literate and needed HIV prevention education. Through her teaching at the University of Michigan, the author intends to create cadres of student activists from among the students who took her classes and who then would learn this pedagogy and then go into these communities.

To a certain extent, many of the students would embark on a kind of peer education where they would not only teach their peers the module but any community or organized group that would listen. This perception of community engagement or community involvement is often presumed to be simply a matter of acquiring skills. Campbell and MacPhail (2002) argue that "Peer education has been described as a method in search of a theory." They then further discuss a conceptual framework of community and peer education based on the work of Paulo Freire, whose conceptualization of empowerment adds a more cognitive intellectual dimension, focusing on people's intellectual analyses. He argues that a vital precondition for positive behavior change by marginalized social groups is the development of critical consciousness. Freire's book *The Pedagogy of the Oppressed* is the theoretical text used in all of the three courses of this project.

The students must first be conscientized by examining their own education and by challenging their perception of activism, including their own privileged status. Who and what is their community? How do they define community? Do they have a community? The class itself is not structured in the traditional didactic educational style but through dialogs about race, HIV, and gender. The issues Freire raises drive the theory of their ultimate project, teaching the HIV module to their own communities. These discussions are sometimes difficult but they happen nonetheless. This is the backbone of the pedagogy of action. Freire's conceptual framework is used in all three of the courses building layers of understanding that enhance the students own critical consciousness and their own emerging awareness of the intrinsic value of this consciousness in teaching their own communities and communities outside the United States.

The reflection on conscientization and its role in teaching the module provides an important insight into the student's own inability to depart from systematic education. It is here that the concept of praxis, putting theory into action, becomes critical. The student no longer sees teaching the module as an act of charity but as an act of building democracy, allowing the silenced to have a voice and to own knowledge rather than become a receptacle of that knowledge. Here, HIV work is transformed into human rights work, making both the beneficiaries and the educators, human rights activists. The act of teaching HIV prevention is inextricably linked to empowerment of the community and their ownership of the information.

The module is oral in nature and requires very little writing, and it is resource independent, there is nothing to read, no handouts, and no literature. At the most it lasts 20 min and takes about 3 days to learn and become teachers for those who are totally illiterate and about 2 h for those who are educated. The groups must be small with no more than 10 persons. A normal session of teaching would last 3 half-day sessions lasting 2–3 h. During that time, the student will learn the module and teach it back to their peers first in English and then develop the module in their own language when it is done in South Africa. Through this methodology, thousands of people have been taught by first- and second-generation teachers.

The HIV Module

On paper the module looks like this.

Science Lesson

As this module was developed to help low-literate people teach HIV prevention, it really has no meaning as a written text. To write about this module is to write about the pedagogy of these five simple lines. It is elementary in nature – it is like looking at the alphabet – structured

in such a way that the least-literate person can do it. A is for apple, H is for human, I is for ink or I is for a big long word immuno-deficiency, and V is for virus. First you begin with a story. Let us say I am in the kitchen and I am cutting cabbage and I accidentally cut my finger; what will I see? Blood. If you take a big glass and look at your blood, you will see that your blood is made up of little dots. These dots are called cells. There are two kinds of dots: red dots called red blood cells, and white dots called white blood cells. The red cells nourish your body and send oxygen throughout your body. To demonstrate this, we have to ask everyone to breathe in and out saying that we are breathing in oxygen and exhaling as it travels around our body. The white cells protect one's body. Here, we draw soldiers and explain how the white cells protect our bodies. We say, for example, if you fall and cut your knee then the white blood cells would rush to that area and form a scab, which means that it is now protecting that area from further harm, and begin the process of healing the cut. We now go to HIV (Figure 1).

H is for human, which means us, not dogs or cats or goats but us, humans. I stands for a big long word, immuno-deficiency, which means that all those white dots or soldiers who form a wall of protection against any disease or illness our bodies acquire, get together and fight it off so we can defeat the illness. So immuno is the white blood cells – the soldiers protecting one's body. Deficient simply means that the wall is now weakened – its not working well, something is wrong with the white blood cells.

At this point, we will show that a soldier has lost an arm or another one has lost a leg, demonstrating deficiency. The V in HIV stands for virus. The virus is explained as bacteria that have entered the body (Figure 2).

The Four Ways of Transmission

Here, we discuss the four ways in which one can contract HIV:

H	1	A	F	L
I	2	I	A	U
V	3	D	C	C
	4	S	T	K
			S	

Figure 1 The immune system: The soldiers (white blood cells).

Figure 2 Immune deficiency: The soldiers (white blood cells) are compromised.

1. The first way is through sex. Depending on the audience we are speaking to, we describe sex as friction. During this time, we ask participants to put their hands together and rub them together. This is known as friction, which represents the process that facilitates the cuts and tears that can occur during sex. Since we are not able to see them, fluids, including blood from one partner, can enter the small cuts and openings in the other partner and HIV can be transmitted this way.

2. The second way is through needles. We ask them to make a cylindrical tube while joining their two hands (as a fist) together. We explain that the needle is a tube, in which blood can remain, which if it is shared can transmit blood and other fluids.

3. The third way is mother to child. Although there have been preventative measures to reduce this, we still discuss it as a way of transmission. An HIV-infected mother can give her child the virus through breast-feeding. Breast-feeding is very important because it is the best nutrition a child can receive; therefore, it is important that mothers are tested so that they can breast-feed their child without fear of transmitting any infection. The child can contract HIV from the mother in the womb, if there is any kind of disruption in the womb, before delivery. The other way a mother can transmit HIV to a child is through labor. The infection occurs when the child is being delivered. The child can exchange fluids from the mother through the child's tender skin and openings such as the eyes, mouth, and nose. This is very important from a woman's point of view, so that she knows how to protect herself and her baby during pregnancy.

4. Finally, we discuss the fourth way, namely blood transfusion. Although this is very rare too, if blood is not screened for HIV, transmission can be facilitated. In a hospital, blood transfusion is done to patients, at times, in a life-or-death situation. If that blood is not tested then the person receiving the blood can become infected that way. Nowadays, this is not such a big problem because, in most places, the blood is tested for the HIV virus.

AIDS

Next, we link HIV with AIDS. The acronym can be explicated as:

- A in AIDS stands for acquired; the word, acquired, means that something is given from one person to another person.
- I in AIDS stands for immunodeficiency, just like in HIV, and we break it into two parts. The immune part stands for immune system and the deficiency in AIDS means that one's soldiers are not only losing an arm or leg but they are dying all together. Here, we wipe out all the soldiers we draw, except one or two, explaining the

soldiers cannot fight the virus anymore, which accounts for deficiency that is now more extreme.

- D is for deficient, which means the white blood cells are defeated. Some people can fight the disease for a very long time and some cannot. If one's soldiers can no longer fight the HIV virus, then one contracts AIDS.
- S in AIDS stands for syndrome, meaning a collection of all the illnesses that the person begins to experience – diarrhea, losing weight, rashes, and many other illnesses, which can eventually cause death since the body can no longer resist infections. No one really dies of AIDS but they die from one of these illnesses, such as a cold, which can turn into pneumonia and cause death, sores that cannot heal, weight loss, or constant diarrhea.

FACTS – Prevention of HIV

FACTS are some things one can use to protect themselves, and can be defined as follows.

- F stands for faithful, which means staying faithful to oneself and to others. This is a feminist interpretation of faithful. We say the first act of faithfulness is to oneself; if life's dream involves going to school, getting into university, or being employed in a good job, then it is important to be faithful to this dream. In this way, one is faithful to oneself by making his/her life better and by making good decisions about one's priorities. If your partner wants to have sex without protection or wants you to have a child before you are ready then if you make the wrong decisions you will put your future and your life in danger. If you have one partner then you must stick with one partner as well. This might mean–
- A abstaining, having no sex until you are ready, not when your partner is ready. This is especially important when talking to young people but does not exclude adults who want this as a choice.
- C stands for using a condom or, in South Africa, condomise. If you are ready then you should use a latex condom.
- T stands for testing, which means get tested for HIV. It also means to get tested for STDs like gonorrhea and syphilis, which cause open sores on one's private parts, which can help in the transferring of HIV. Finally, S stands for 'stay away from drugs and alcohol'. These substances can cause inhibitions to be lowered, causing one to possibly make the wrong judgment. If one plans to participate in these activities, we encourage the person to always have a trusted friend who will help you make right decisions.

Then if you know a person who is HIV positive you must be a source of LUCK to them. This is a critical part of the module since it deals with stigma which is still affecting

HIV-positive people and preventing others from seeking help because of fear of rejection.

LUCK – Stigma Reduction

- L is for love; show love to the infected person. Sit with them, talk to them, if you loved them before they had HIV, you should love them after they have HIV – they are still the same person. Do not reject them or turn your back on them.
- U is for understanding. Understand what the disease is, be educated about it, and educate others about it. Know that you cannot get HIV from touching or caring for them, that you cannot get it from drinking from the same cup or sitting on the bed or toilet. You can hug them and talk to them. The virus cannot live very long outside the body and so it is important you understand all of this, the ways you cannot get HIV. Understand also what they are going through, how they must be feeling having HIV or AIDS.
- C and K are for caring and kindness. Take the time to show them love, take them to church, take them for a drive, visit with them, and help in any way you can to make their lives more comfortable and show other people they should not be rejected but accepted. Show them love understanding caring and kindness.

Today there are many drugs, herbs, and foods to help your white blood cells fight this virus. Therefore, it is important that you get tested as soon as possible. To get tested does not mean that you are going to die, but that you are going to live because now there are many ways to manage this virus than before. So know the facts and be the bearer of LUCK. And be a role model who will stand up for an HIV-positive person.

Teach-Back Methodology

Students who take The Pedagogy of Empowerment course must then teach this module to a community outside the university and have at least two people teach it back. There have been many problems with this component of the class. Many students do not have a community they can go to and are afraid to do this. Many times they teach their peers within the university. Others try to teach youth groups in their churches, often being disappointed because they cannot teach sex in the church. Students also try to teach in their high schools and find it is complicated, because the schools also cannot teach about sex unless there is a long procedure that entails getting each parent to sign off or the school board has to decide. What seem apparently easy turns out to be very complicated.

The teach-back component of this methodology is critical to its success. It is here that didactic education is

most challenged. When the students in the class first learn the module, all of them must teach it back. They cannot use notes; they must look at their audience and teach the same way they were taught, that is without writing or turning their backs to the audience to write on the board. Students are so unfamiliar with this kind of presentation without notes that they intuitively want to write the acronyms out. Thus, for example, the F in FACTS they will write out facts on the board. This is strongly discouraged since for low-literate audiences this communicates that they too must write on the board. We discourage this because it slows down the story, the orality of the module, and diminishes their ability to feel empowered to teach this module. The transformation for the farmer, for example, when he/she gets up to teach is that they have taken on the role of the teacher and this act alone is empowering. That they could teach such information is, for them, the first act of egalitarianism the module facilitates. Most important, however, is the almost universal reticence to get up and teach even among the very literate. After two or three times of hearing the module, everyone thinks they can teach this, but when they are asked to do so very few actually get up. It is at this point that Freire's idea about the educational system becomes a living testimony. The hierarchy of the teacher as banker and the student as depositary is an idea so intractable in education that students become resentful and afraid when they are asked to become owners of knowledge rather than receptacles. They are often afraid and this is exactly the same when community members are asked to teach. This reticence is seen equally among the educated as well as the illiterate.

The peasant feels inferior to the boss because the boss seems to be the only one who knows things and is able to run things. They call themselves ignorant and say the "professor" is the one who has knowledge and to whom they should listen. The criteria of knowledge imposed upon them are the conventional ones. "Why don't you" said a peasant participating in a culture circle, "explain the pictures first? That way I'll take less time and won't give us a headache" Almost never do they realize that they too, "know things." (Freire, 2002)

This process provides a pivotal teaching moment for the Pedagogy of Empowerment. It is at this point that the students examine their own education. Are they being educated for themselves or to serve their communities? Why do they have few contacts with their communities other than church and high schools? The Freirean methodology and the theory of this pedagogy become apparent for now the limits of the didactic educational system and the illiteracy of their own social justice skills are exposed.

Only by working with the people could I achieve anything authentic on their behalf. Never had I believed that the

democratization of culture meant either its vulgarization or simply passing on to the people the prescription formulated in a teacher's office. I agreed with Mannheim that "as democratic processes become widespread it becomes more and more difficult to permit the masses to remain in a state of ignorance". Mannheim would not restrict his definition of ignorance to illiteracy, but would include the masses' lack of experience at participating and intervening in the historical process. (Freire and Macedo, 2000)

There are schools dedicated to interactions with the community, but the agenda is to teach the student to become a professional person in that community, to be a social worker, to be a clinician, a nurse, a teacher, etc. Many classes require community participation where the community provides the reality context for the student's education. The greatest beneficiary of all these 'projects' is the student ("remember you are part of a system, the field placement system which uses a variety of actors to accomplish the educational mission of the school") (Gorbman, 2002). Supervision and time for the student who is being placed to 'help' the community is done at the largesse of the community organization, which is not, as a general rule, paid to do this work, that they are getting a 'university student' to work with them is seen as payment enough (Barton *et al.*, 2005). Many workers in these organizations feel burdened by this; often the students themselves are left to muddle through simply because teaching them requires time, which organizations under stress do not have. This does not mean that the experience is not successful for many but, as a political commentary, it is important to note that the students leave, complete their education at the university, get their degree, and become professionals.

Discussions with students who volunteer in many humanitarian and nongovernmental organizations reveal that many are often loath to consider themselves beneficiaries at all. They feel they are good people and that the Freirean methodology of the class challenges their good work. It is not that their good work is not valued, but one must be able to distinguish the difference between charity and development. This is not an easy pill to swallow for young people who are caring and want to make a difference. The difference between criticism and challenge often becomes blurred. Even though it is emphasized that they should not stop their charity work because it has intrinsic value, it is still difficult, because the intent of the challenge is to make them see how their privilege still makes them beneficiaries even when they are giving. This in part is what Freire refers to as "problem posing education." It is about reflection on action and then again action and reflection. The process of conscientization begins with problem posing education. And it is this that is at the core of the class on the pedagogy of empowerment.

Before the class on the pedagogy of empowerment, they had no idea of the level of the HIV crisis in the

African-American communities. This information was shocking to them. They felt HIV was the disease of the 'other' in Africa. They raised money for Africa and felt that because they were Americans this had been addressed. It had not. At the 2008 Aids International Conference, the CDC MMWR (2008) reported the HIV epidemic was much larger in the African-American community than they had thought.

The new estimates show that MSM (men who have sex with men) of all races and ethnicities, and African-American men and women, are the groups most affected by HIV. Fifty-three percent of all new infections in 2006 occurred in MSM. African-Americans, while comprising 13% of the US population, accounted for 45% of the new HIV infections in 2006, with an annual infection rate seven times higher than whites and almost three times higher than Latinos (CDC MMWR, 2007).

This information confirms what those of us who have been working in this field for many years knew. The numbers were high but few people were paying attention on a national scale. The CDC notes that the new estimate does not represent an actual increase in the number of new HIV infections. Analyses conducted by the agency indicate the annual number of new infections has remained fairly stable over the past decade, albeit significantly higher than was originally thought (CDC MMWR, 2008).

Still the HIV epidemic has not reached a tipping point in the African-American community, and these issues were the center of many dialogs in the class. The greatest significance of this awakening was the realization "going to Africa to work on HIV" is not more important than working on HIV in the United States. The first principle of the Pedagogy of Action is that HIV in South Africa is not to be seen as a site for charity. The commitment to addressing HIV should be in the United States as well as in Africa. HIV has been exoticised as an "African disease" and the cultural politics of the racialization of disease has led to its marginalization in the United States as an African-American or American problem. This has clearly contributed to the ongoing perception that Africa is a place which must be rescued.

Preparation for the Field

Before students could embark on the culmination the Pedagogy of Action course, they had to first enroll in the class entitled 'Preparation for the Field'. This was a critical class because, once the students had been conscientized about HIV, race, gender, health, and empowerment in the United States, they had now to confront the hegemony of the United States and its image in the world. Readings and discussions about the issues, ideas, culture, and politics of the young American student engaged in communities abroad were rigorously addressed. What and where is South Africa?

What are the myths and perceptions of this African country? Is Africa a place to be exoticised or to be taken seriously as a site of cultural significance, a place of ideas and learning? What does it mean to be an American in the world today? How do South Africans see Americans? What kind of American do you want to be and present to the world?

Although the majority of the students would have taken the basic The Pedagogy of Empowerment class, a few will have applied to the 'study abroad' program and this class with those who had already taken the Pedagogy of Empowerment class will then form a cohort to bring the other students up to speed. They will also have to learn the module and teach it in the United States before they left for South Africa. The readings covered the latest information on the epidemic and its history in South Africa. The political life stories and struggles of Nelson Mandela and Bishop Desmond Tutu were required texts. The ideal number of students in this group was 10, most were undergraduates in their last 2 years and a graduate student who worked as an assistant. They ranged from engineering students to the social sciences and humanities.

A critical examination of the United States was essential in a pedagogy in which American students go into the developing world to see the world and to engage in projects. The questions they must examine were the following: Is anything or anyone better than America? If you have been told all your life that the United States is the greatest country in the world and that you are the greatest, is it possible then for you to see anyone or anywhere else as your equal? (Haniff, 2008). These questions formed the ideological basis of the preparation for the field.

The Pedagogy of Action

The Final semester is spent on the project in which the students put all these ideas into action in South Africa. The student who is now more thoughtful and reflecting is now taken into an environment that is even more radical. To teach HIV prevention, for example, in the townships in South Africa is both a frightening and exciting possibility. On the one hand, to presume that privileged American students can actually come to South Africa and teach people who speak in many different languages was a kind of arrogance or naiveté. On the other hand, it was such a challenge as to achieve it would itself be an act of supreme transformation for the student and maybe the community. Since the fall of apartheid, the universities have been developing ways to include service as a part of academic education. The tension between learning as knowledge in academia and learning as knowledge grounded in the community is at the nexus of education for all developing countries, especially in newly emerging democracies like South Africa. The Pedagogy of Action is an example of this praxis, that responsibility to one's community does not

exclude theoretical rigor or academic excellence. This is why the University of Witwatersrand and the University of Zululand were keenly interested in the Pedagogy of Action. The numbers have increased every year from 60 graduates in the HIV module the first year to a 110 the following year at the University of Zululand. At the University of Witwatersrand, students developed the module in 10 different languages, which include Sotho, Zulu, Xhosa, Yoruba, Lingala, and so on. In 2007 we met 10 of 60 students who graduated in our program in 2006 – out of their own commitment to act, they taught over 4000 people in their home villages in Kwa-Zulu Natal. This is how education can be a force for true citizenship and democracy.

Transformation

The impact of the pedagogy of action can be looked at through the evaluations conducted at various phases of the pedagogy. Evaluations of this pedagogy have been done in the Caribbean and in South Africa. The difference is that in the Caribbean evaluation represents the voices of community activists who had used the pedagogy over 4 years at the time of the evaluation (Haniff, 2004). The South Africa component was evaluated a year after the students had taught the module in their communities and reflects the voices of the teachers and not the communities who were taught. The transformation of students is expressed in their project papers where they recollect and analyze incidents pivotal to their new thinking and awareness.

The Community Activist

The early development of the module when it was taught by the author and two facilitators directly to communities did not include the capacity-building component. The sustainability of the module was left directly in the hands of the communities themselves through activists, nurses, teachers, and the outreach workers. However, this was found to have limited appeal since these activists could not go out of the communities and were not in a position to train others. They could, however, continue to teach. It was after these experiences with the module that we decided to train, for example, university students in South Africa – who were basically peers of my students who were the first-line teachers. The ideas and analyses of the impact of the pedagogy on the community as a part of the evolution of the pedagogy provide an important voice in the power of the pedagogy of action.

Although revolutionary leaders may have to think about the people in order to understand them better, this thinking differs from that of the elite; for in thinking about the people in order to liberate (rather than dominate) them the leaders give of themselves to the thinking of the

people. One is the thinking of the master; the other is the thinking of the comrade. (Freire, 2002: 132)

It is good because going to other workshops where they give you handouts and the speaker get up then I say I have everything already so you don't pay attention, but this workshop you had to listen so you had to take in what was said. You could always jot down whatever you wanted but whatever was being said, it had to remain in your head. It also develops your listening skills, so you can listen carefully. I think that method was very good. Too many times we are given handouts and after the workshop we chuck it there and then we don't have time to go back to it and whatever knowledge was said in this workshop it remain with us because we were given the facilities to give it back and it remains with you rather than a handout.

You see when I tell people what I know they say how I know that and I am not a doctor, not even a nurse because you know what happen. Because in learning to know about health I learn to know about my own self. I learn that nobody is higher, we at the same level. I can do whatever any other person can do.

Having to go up (to teach the module first time) you always feel a little nervous, in fact in truth you always feel a little shaky. Another thing that made us able to do it like we were on one level. Like you and the facilitator came, make yourself at the same level, like we were one, but sometimes you go to workshops where you have people of different height, (class) but it is for them (the education is for them) but you are not them because you are a different class. So you feel you are not comfortable among these people, so you not open up to receive, to grasp much. But you all come and make yourself part of us, just like us so we felt much more comfortable with you so therefore we were able to grasp and to learn faster that keep people back when you go to a workshop and they rank you (look down on you) and they don't take heed of you.

The New Teachers at the University of Zululand

These are the voices of the students who were taught by the University of Michigan students in South Africa. They were not community activists but were the peers of the University of Michigan students, at the University of Zululand. These new teachers taught in their villages and field placements in the rural areas of Kwa-Zulu Natal. The module was developed by these students into Zulu and then taught to their communities using their own language.

One cannot expect positive results from an educational or political action program which fails to respect the

particular view of the world held by the people. Such a program constitutes cultural invasion, good intentions notwithstanding. (Freire, 2002: 95)

Well, I already know about HIV, but what I learned was the simplest way to make HIV seem not as bad and not as complex as it is. It gives me, a teacher, like an imagination, even when I explain it to little kids. You know, kids imagine what HIV is. You don't know how to explain, but this just gives me a picture of HIV. And it's not as complex.

Also, again, I would really love, especially, foreigners or donors to make it a point that when they come to Africa, assisting people, they should empower people, not let people be in a position that they will fold their arms and just receive whatsoever. It could be information, but foreign people, they must empower people to be effective.

You are now even free to tell the whole community-you are positive. They won't, even, like, maybe hit you or do something or hate you. I mean, this program or this module has made people realize that the fact that you're HIV-positive, it doesn't mean that you are a bad person in the community. Maybe they thought you are unacceptable within the people or you are different from other people. Now people are learning to accept one another.

The Students

This is an excerpt from a student's writing on the topic 'faith', which was assigned to examine whether students really trusted that their 'low literate' audience could be empowered to teach.

The generosity of the oppressors is nourished by an unjust order, which must be maintained in order to justify that generosity. Our converts on the other hand, truly desire to transform the unjust order; but because of their background they believe that they must be the executors of the transformation. They talk about the people, but they do not trust them; and trusting the people is the indispensable precondition for revolutionary change. A real humanist must be identified more by his trust in the people, which engages them in his struggle than by a thousand actions in their favor without that trust. (Freire, 2002, 60)

A lot of things changed with a man named Timothy "Teaspoon" Zulu. On the first day of teaching, Teaspoon was the man that had said to us that he would "never wear a condom" because he was an "African man," and a real African man cannot wear a condom. As soon as I heard this, I lost any faith in him that I had in the first place, which probably was not much to begin with. How was I going to change his mind? Nevertheless, after a couple of days, he would become the most phenomenal teacher I have seen to emerge from our work using the module.

I use the term “emerge” to purposefully denote the fact that the teacher inside of him was always there, but it had now been finally given a chance to come out. Teaspoon taught the module in a way I have never seen anyone teach it before or since. He had charisma, confidence. And he knew what he was talking about. If someone would have told me on the first day that Teaspoon would be the one to get up in front of the executive board—a room full of white men, and teach them the module so perfectly that it brought tears to my eyes, I would never have believed them. When I saw Teaspoon do this, I had two feelings: pride and surprise. Pride because I was so proud of what he was accomplishing, and surprise because I had such little faith in him to begin with that I was surprised at what he accomplished. Nevertheless after the feeling of surprise had left, a little bit of faith came to take its place. Teaspoon had proven me wrong, and shown me that I should have had faith from the beginning.

Through these experiences, I have come to see that faith is not a matter of science or religion, it is a matter of choice. I can choose to have faith in the people I work with, and it will help them and me in the long run. When I met Mr. Ahmed Kathrada the other day, he said some of the most [profound words that I have ever heard: “there is no such thing as defeat if you are fighting for a just cause”. I believe this means that there is absolutely no harm, but only good, in believing in people, trusting them, and putting your faith in them. It is a just cause to educate, and especially to empower, and thus no defeat may come from any endeavor to do so. In addition, I have learned from these experiences that I should not need proof to have faith in something. It is quite arrogant to not believe in something that cannot be proven, for who am I to decide what “proof” is? And I know that as a white person, I have been socially trained to be doubtful of black people and their capabilities. However, I never knew, or possibly wanted to believe, how much this social training really manifested itself in my daily life. I now see it is my responsibility to overcome this, and to have faith in people, for as Freire has so poignantly said, the person who works for the liberation of an oppressed group but continues to regard them as totally ignorant, is doing nothing but false generosity.

HIV AIDS and Impact of the Pedagogy of Action

These voices articulate the impact of the pedagogy of action. It is the immediate response to problem posing education, which is a method not only for the community but also for those in higher education. To challenge the acquisition of knowledge at the university level is particularly important for those coming from marginalized communities and those who are unconscious of the

consequences of the didactic form of education. It is an ideological position that premises education as praxis rather than education as careerist. Whose responsibility is it to transform the world and to ensure those locked out of literacy and formal education not become victims of their circumstances but rather empowered to act? It is the educated who must do this and it is the institution of education which must develop pedagogies that provide tools to equip the actors for social justice.

Many nongovernmental organizations have been struggling on the front lines with illiterate and functionally literate populations, predominantly the female. The victims of HIV are growing increasingly female and people of color. We cannot wait until these populations become literate. There have been innovative methodologies of empowerment that have addressed the immediate issues of poverty, education, and health. The Barefoot College championed by ‘Bunker Roy’ is one example.

The philosophy of Mahatma Gandhi is reflected in the work style and lifestyle of the College. Traditional knowledge, village skills and practical wisdom are given greater respect than paper qualifications, and reading and writing are not seen as essential. “Just because someone cannot read or write does not mean he or she is uneducated,” Roy points out. The barefoot approach clearly works, and there are now 20 such colleges in 13 states in India. Plus the college is now involved in training villages from other countries, including Afghanistan, Ethiopia, Bhutan, Senegal and Sierra Leone. “But the real achievement,” says Roy, “is the process rather than the result.” (Milnes, 2006)

The microcredit movement, which started in Bangladesh, also wrestled with dehumanizing poverty by developing methodologies that empowered the very poor to sustain and support themselves ensuring that their integrity was not compromised by systems that undermined their autonomy. Yunus (2001), the catalyst of the Grameen Foundation, has said:

It is not microcredit alone which will end poverty. Credit is one door through which people can escape from poverty. Many more doors and windows can be created to facilitate an easy exit. It involves conceptualizing about people differently; it involves designing a new institutional framework consistent with this new conceptualization.

The Pedagogy of Action has attempted to change not only the uneducated but more importantly the educated by teaching them the basic principles “of conceptualizing about people differently.” They must first respect the uneducated and be given new eyes to see the value in traditional knowledge and practical wisdom. “Just because someone cannot read or write does not mean he or she is uneducated” (Roy). The Freirean theoretical principles used in the Pedagogy of Empowerment, and the Pedagogy

of Action were developed to create a body of students who would not only become actors for good in the world but actors on the world stage where these American students must manage the hegemony of their nationality. Problem posing education as a methodology in developing 'HIV education for low-literate people' transformed both students and the communities. It is a pedagogy that has attempted to address the problematics of the privileged who must construe their responses to inequality and social injustice in their own communities and in the world.

How Are Discussions of Interdisciplinary Studies Linked to Diversity Discourse?

C N Spence, Spelman College, Atlanta, GA, USA

© 2010 Elsevier Ltd. All rights reserved.

The introduction to varied ways of knowing and seeing the world is lauded as the cornerstone of the liberal arts learning environment. Throughout the academy, interdisciplinary and multidisciplinary scholarship and research are recognized as progressive academic initiatives. These initiatives are tailored to encourage understanding and respect for the healthy tensions that exist among the various disciplines. It is clear that recognition of the value of embracing diverse ways of knowing and seeing the world through the examination of academic disciplinary lenses is a priority within the higher education community. What remains a challenge is an equal priority to expose students to voices of difference represented by faculty, students, and senior administrative staff.

While most institutions of higher education are not required to welcome all who seek admission or to acknowledge the experiences and opinions of all who would be considered different, it is expected that the academy will be a place where diversity is represented and elevated as an institutional goal. Many institutions of higher education profess to share a common goal to be agents of intellectual, personal, and social transformation for those who inhabit their walls. The challenge for many of these institutions is how to accurately define, construct, and implement initiatives that are inclusive and responsive to the particulars of their institutional history, setting, and culture. Second, institutions of higher education are charged with ensuring that inequities that exist outside the walls of the academy are not replicated within their teaching and learning environments. Implicit in the interdisciplinary and diversity language rests an assumption that the optimal teaching and learning environment is a space for free-flowing ideas that are representative of a collection of ideas and students and faculty representing varied personal, social, and cultural experiences.

It is assumed that the exchange of sometimes similar and many times dissimilar voices serves to enrich the teaching and learning environment. Such an opinion was expressed by Supreme Court Justice Sandra Day O'Connor in the opinion of the *Grutter v. Bollinger*, 539 US 306 (2003) case when she asserted that the contested plan implemented by the University of Michigan law school met the compelling state interest test applied in instances where intentional preferences based on race or some other protected category are operative. In her opinion, she cited the research and assertions of others who found that there

are instructional benefits associated with diversity in the classroom. (A number of *amicus* briefs were reviewed by the Supreme Court. Briefs prepared by the military and representative of Corporate America spoke the benefits of having a diverse workforce.) The cited benefits included breaking down of racial stereotypes and increasing cross-cultural understanding (539, US 306). It is assumed that the classroom becomes a safe space for diverse views and life experiences as represented in course content and student composition. The classroom supports the necessary tensions that develop as difference is accounted for and accepted. The classroom can become a social laboratory where difference becomes the common denominator as diverse ideas, theories, and individual perspectives and experiences frame the teaching and learning environment.

The Legal and Social Context

Various amendments to the Constitution have provided clear legal standards for the equitable treatment of persons regardless of race, class, or gender. While these standards continue to be legally acknowledged, the day-to-day realities of persons of color and women operate within personal, social, and political spaces that reflect what Hooks (2004) refers to as "imperialistic white supremacists capitalistic patriarchal culture." Such recognition requires us to remain ever vigilant in our quest to demand race, class, and gender equity. Those of us who hold positions of influence within the academy must not shy away from discussions that interrogate racist and sexist ideas, social policies, and behaviors. We must enlighten others to the realization that the absence of blatant discrimination does not in any way suggest that marginalization and disenfranchisement based on difference is not present. Bonilla-Silva (2006) speaks very specifically about the absence of honest discussions about the existence of racism within society. His assertions can easily be transferred to the absence of honest discussions about sexism. This absence of discussion is supported by those who would suggest that the most significant indicators of a racist and sexist society have disappeared or at least substantially dissipated. This presumption is based on a number of social indicators and number counting that denies the institutionalized systems of racism and sexism in our society. Uplifting all those who have made it

obscures the reality of those who remain on the margins of society and asserts a false sense of color and gender-blind ascension for those who hold coveted places within narrowly constructed windows of opportunity.

Institutions of higher education can in many ways become complicit in this false sense of progress. The creation of an elite class of educated individuals, whose opportunities for status mobility far exceed their parents,' suggests to some that things have really changed. The challenge for the academy is to create a space where these realities are celebrated but are not seen as clear and convincing evidence that such critiques are irrelevant. Many classrooms across this country become the forums for critical discussions of the existence of systemic racial, class, and gender inequities that permeate all sectors of society, inform dominant discourse, and serve as a lens through which the day-to-day life experiences of persons of color and women are evaluated. The scholarship of teaching and learning provides the canvas for the active engagement of students in this process of societal evaluation and self-discovery that is anchored in a very intentional reliance upon interdisciplinary analysis of issues of race, class, and gender.

The task then of the academy is to help students not only to understand race, class, and gender discrimination law and how it impacts their individual and social lives, but also to empower students to see education as a tool for social transformation. Many scholars and theorists point to what they consider the obligation of higher education to make individuals become active agents in the learning process (Freire, 1993; Hooks, 1994). A second task of the academy is to create a setting where patterns associated with patriarchy, racism, sexism, classism, and heterosexism are not modeled and reinforced. The classroom must become a safe space for the interrogation of these systems of oppression and subordination. Such a belief is not shared throughout the academy.

Interdisciplinary Studies and Diversity Discourse

While interdisciplinarity is lauded within the academy as a way to embrace the various ways of seeing and knowing afforded by diverse disciplinary lenses, the reality of the richness afforded by differing racial, ethnic, class, and sexual preference realities is not given the same accolades. Even within the context of the discussion of the benefits of interdisciplinary teaching and learning environments, preference is assigned to those disciplinary thinkers who do not necessarily represent the mosaic of ideas and theories espoused by scholars of color or women. Thus, interdisciplinary knowledge is often narrowly confined to the ideas of those who have informed dominant discourse within their particular disciplinary field of study. Many

see the structure and methods of the US higher educational system as a mirror of existing societal systems based on hierarchy wedded to capitalist ideological perspectives that are Darwinian at best and are marked by vacuous discussions of diversity that merely reflect a commitment to increasing numbers of brown and black faces only. Such a system denies the importance of not only discussing but also advancing race, class, and gender equity in the context of the classroom. This denial and/or delayed response to discussions of race, class, and gender equity are fueled by the historical commitment to the exclusion of blacks and women in higher education. Contexts, however, change either voluntarily or involuntarily. The presence of minority-serving institutions, including women's institutions, and the current reality of the imbalanced ratio of males to females attending institutions of higher education call for a reexamination of the ways institutions of higher education can demonstrate a commitment to racial, class, and gender equity in structure, content, and process and within the teaching and learning environment.

The Women's College Context

The question of how best to educate women presents particular challenges as considerations are made regarding how to prepare students for their role in a society that does not necessarily reflect a commitment to gender equality. How functional is it to create what Maher and Tetreault (2001) refer to as a feminist classroom? A feminist classroom is women centered and engages students in discussions that provoke introspection and external inspection of social systems that dominate and constrain the lives of women and girls. A feminist classroom creates a safe space for women to engage theory in ways that are specifically meaningful in the context of the designated discipline, and even more importantly, in the context of their lives. Issues of gender equity are at the center of all classroom explorations.

Classrooms that mirror society replicate and reinforce dominant societal norms, values, and beliefs. The subordination and disenfranchisement of women and persons of color inform and frame most of our social institutions, including the higher education community. Thus, paying particular attention to the voices of women and persons of color becomes a priority within classrooms committed to individual and social transformation. Empowering students to challenge the *status quo* becomes an intentional progressive revolutionary tactic inside of some classrooms. Bell Hooks refers to this form of pedagogy in *Teaching to Transgress* (1994) as "the practice of freedom." She suggests that a progressive classroom is one where students are taught to challenge established boundaries and to push beyond them in an effort to find truth. Is it important to create a classroom space that is women

centered in pedagogy and context? If so, how does one construct this environment in a way that emphasizes the significance and value of epistemologies that are framed by what Foucault refers to as power/knowledge? The sharing of knowledge that is empowering and that changes the student to examine the origins of dominant thought.

The creation of a feminist classroom is antithetical to the dominant model of higher education. One must remember that the education of women was not the primary goal of higher education. This reality continues to influence classroom dynamics across the country, particularly within some specialist professional areas. Guinere (1997), when examining the law school classroom, found it to be a sometimes hostile space for women students. In describing the law school setting, she found that it was a male-dominated space. The structure, pedagogy, culture, and general patterns of interaction ran counter to what she felt were reflections of the commitment to gender equity. Law school classrooms have historically been disproportionately male spaces until the most recent decade.

A recent American Association of University Professors report points to the fact that women represent 39% of university faculty (Gender Equity Report, 2006). One assumes that the face of the professoriate will inevitably change as the number of females attaining PhDs continues to outnumber the male turnout. However, the increase in the number of females receiving PhDs does not fully address concerns related to the achievement of racial equity in society in general and within the academy. The percentage of persons of color attaining a PhD remains below 7%.

The academy has not necessarily been seen as a space where students would critique systems of inequality and to dismantle the compound effects of patriarchy, racism, sexism, and heterosexism for the decade or more, discussions focusing on diversity in the higher education community have taken on increased significance. Most of these discussions have been framed by questions of access and accommodation primarily for students of color, with particular emphasis on African-American students. The development of and the challenging of special initiatives and programs to ensure the presence of students of color have dominated campus discussions and have resulted in the creation of some diversity initiatives and the dilution and dissolution of others. These discussions have not paid particular attention to gender equity. This reality may be attributable to the fact that when discussions of affirmative action have been raised, the impact upon gender equity in higher education has been a secondary discussion.

A Ford Foundation white paper, summarizing deliberations with diversity scholars and higher education diversity leaders, found several criteria that should be evident within institutions sincerely committed to a diversity agenda. (A white paper written by Cynthia Neal Spence, PhD, titled 'Reframing the diversity narrative: Achieving

social justice within the academy' was prepared for the Ford Foundation project, Diversity, Inclusion, and Institutional Change.) First and foremost, the commitment to diversity must be communicated from the top. The senior leadership of the institution must not only articulate a diversity agenda, but also provide tangible evidence of the institutional commitment. Second, the institutional mission statement must reflect and/or provide room for interpretation that includes an institutional commitment to actualize inclusion and diversity. Third, institutions of higher education must tangibly acknowledge the importance of diversity through the development of core curriculum initiatives that challenge the *status quo* Western civilization paradigm and force students and faculty to step outside conventional notions of how to situate themselves in a world community. A fourth consideration is one focusing on the equity of outcomes for underrepresented students, faculty, and staff. Not only must their representation be increased, but they should also flourish and succeed at the institution at the same rate as whites within the academy. (Access to honors, tenure and promotion, fellowships and scholarships, research opportunities, and significant committee leadership for underrepresented populations should mirror the access and accomplishments of white students, faculty, and staff.) Finally, and most significantly, institutions of higher education must move beyond providing mere access to the university to diverse groups, and must address climate issues that provide greater guarantees that diverse groups' experiences within and outside of the classroom will be conducive to learning and succeeding in the academic environment. This final criterion speaks to the institution's demonstrated commitment to recruitment and retention of diverse faculty, administrative staff, and students.

It is these two final criteria that colleges and universities find most challenging. Institutional promotional materials often exhibit the faces of diversity. Many can speak of the number of students of color and women admitted to their institutions. The Ford Foundation report suggests that mere numbers and faces are not enough. Persistence rates and the quality of the educational experience are equally important to those institutions that are sincerely committed to diversity. Thus, the recruitment and retention of faculty, students, and administrative staff of color must be matched by an equal commitment to ensure a welcoming and supportive environment. Strategic initiatives must be developed and implemented that include outreach, recruitment, and retention of faculty, administrative staff, and students of color.

The nation's top-tier institutions operate in a competitive environment as each seeks to attract the best and brightest faculty, students, and staff. This competition among the nation's top-tier institutions has a profound impact upon the ability of second tier and small liberal arts colleges as they seek faculty, staff, and students from

the same small pipeline of potential applicants. The shared goal of all institutions that enter this competition is to create an institutional environment that is reflective of the demographics of the larger society.

The language of diversity, while symbolically representing a shared meaning that is very much situated in race and ethnicity discourse, takes on a particular contextual significance through institutional history, programming, and implementation. Often, left out of the conversations or rendered secondary are discussions of other identity markers, including faith traditions, sexual preference, disabilities, and other life experiences and choices that may serve to marginalize particular segments of the population. The dominant diversity discourse is consistent with the US Constitution's affirmation of protected classes within society. This language of protected classes includes those who would be discriminated against on the basis of race, ethnicity, sex, and religion. Thus, diversity language and practice are often more attentive to ensuring that blatant discrimination cannot be found against faculty, staff, and students because of their race, ethnicity, sex, or religion. It is important to note that gender is not a protected class but is addressed by the language of protection based on sex discrimination. Of the specified protected classifications, racial discrimination and discrimination of groups based on ethnicity have been the most dominant consideration in diversity discussions, particularly when discussed within the historically white colleges and university context. The sociohistorical significance of race and racial discrimination within the American context continues to take precedence over other identity markers.

Discrimination based on sex, which is also very deeply rooted in American society, receives almost equal consideration in discussions about diversity. One must note, however, the increasing gender imbalance nationwide within undergraduate student populations, with more than 50%

women and, in some instances, particularly historically black institutions, more than 60% female population. This phenomenon even has some institutions and special higher education programs considering affirmative action plans for men. Creating a diverse environment is often translated into making sure that persons of color with specific intent to include African Americans and other persons of color are present in the institutional mix. Some recent research reports, however, indicate that at many of the more elite institutions, racial diversity is manifested by a student body who are blacks, who are foreign born, or are the children of foreign-born parents. The faculty diversity numbers are also influenced by foreign-born blacks and other persons of color. According to US Census data, more than 12% of all black undergraduate students enrolled at US colleges and universities were born in a foreign land. Among black graduate students, 18.7% are foreign born. Most recently, a commitment to diversity is materializing through special initiatives that focus on the socioeconomic status of potential students. Thus, social class becomes the dominant consideration for persons who would not ordinarily be represented in the student body. The question that is at the center of most diversity discussions is: What is the impact upon the institutional climate and teaching and learning environment?

Identifying Patterns of Doctoral Attrition Across Academic Fields

A James, Loyola Marymount University, USA

K J Fosnacht, E B Stolzenberg and D Thirumalai, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Background/Purpose

As individual students are the most affected by doctoral attrition (Lovitts, 2001), in the past, university leaders were not necessarily concerned with the role the institution played in the students' decisions to leave their programs. However, economic constraints are forcing institutions to (re)evaluate all facets of the higher education enterprise, including doctoral education. In this era of perpetual fiscal crisis, institutional leaders are realizing that doctoral education is one of the most expensive areas of higher education due to the costs of recruiting and enrolling top students, maintaining small classes, expensive equipment, and facilities, and the individualized attention provided by faculty (Baird, 1993). Consequently, attrition from doctoral programs becomes a question of the efficient use of a university's scarce resources (Kluever, 1997; Lovitts, 2001).

When talented doctoral students leave before graduating, institutions fail to benefit from the significant roles noncompleters would have played in furthering research and educating undergraduates in their respective fields (Haynes, 2004). In addition to the negative effects of doctoral attrition on institutions, society also suffers when qualified doctoral students leave before completing the degree. While society can benefit tremendously when students' research sheds light on a problem (Katz, 1997), society also loses out when the social and scientific perspectives, questions, and ideas of noncompleters are not pursued (Lovitts, 2001).

Literature

Researchers agree that the program, department, and discipline are all central to the persistence of doctoral students. Benkin (1984) found that after controlling for demographic and academic factors, the student's field of study was the most significant predictor of doctoral degree completion. Bowen and Rudenstine (1992) also demonstrated that differences in completion rates are most typically associated with the field of study than any other factor. Various studies have shown that completion rates are lower in the humanities and social sciences and that completion rates are higher in engineering and the natural sciences (Baird, 1997; Bowen and Rudenstine, 1992; Ferrer de Valero, 2001; Haynes, 2004; Hodgson and Simoni, 1995; Nerad and Cerny, 1993; Nerad and Miller, 1997; Smallwood, 2004).

In addition, certain characteristics of academic fields play a role in doctoral persistence, such as the nature of research and the dissertation, funding traditions/opportunities, relationship and amount/type of contact with the advisor and other faculty, and individual characteristics that lead students toward graduate study in a particular field (Bair and Haworth, 2004). For example, women and non-Asian minority students tend to be more represented in programs that have lower completion rates, such as those in the social sciences and humanities (Nerad and Cerny, 1993). Further, women, minority students, and American students drop out at higher rates than men, White students, and international students, respectively (Bowen and Rudenstine, 1992; Lovitts, 2001; Smallwood, 2004).

The structure of the discipline shapes both the academic and social interactions of its members and is also responsible for the long-term patterns of attrition across academic disciplines (Bowen and Rudenstine, 1992). For example, the sciences are highly structured disciplines, advisers are selected early, funding is more stable, and there is frequent contact between the student and the faculty and among students (Bowen and Rudenstine, 1992). On the other hand, the humanities and many of the social sciences are more loosely structured, research can be isolating, students select advisers later on in the process, and there is not much social and academic support from faculty and other students.

Past research has shown that failure to complete the doctoral degree is not solely a function of intelligence, academic preparation, or finances (Baird, 1991, 1993; Ferrer de Valero, 2001; Lovitts, 2001; Smallwood, 2004; Tinto, 1993). Students with fellowships do not complete the degree at a higher-than-average rate, as National Science Foundation fellowship recipients complete at a rate of only 75%, comparable to nonfellowship recipients in the sciences (Smallwood, 2004). Types of financial assistance can have differential effects on student outcomes depending on the student's stage of doctoral study. For example, when beginning doctoral study, an assistantship may be more beneficial for persistence than a fellowship, as a research position can facilitate both academic and social integration. However, during the dissertation stage, a research assistantship may not allow the student enough time dedicated to completing the dissertation (Tinto, 1993).

With respect to academic preparation, Lovitts (2001) found that completers and noncompleters enter their doctoral programs with comparable undergraduate grade-point

averages (GPAs), but women had higher GPAs, with female noncompleters reporting the highest grade-point averages. She also found that those who did not complete the doctorate appear to be as professionally qualified, if not more so, at time of entry (with respect to prior socialization experiences, such as being mentored by faculty and subscribing to journals).

The relationships between students and faculty are crucial in the doctoral-education process. The adviser is often the most influential person throughout the doctoral-education experience. Students learn the nature of the academic profession from their adviser, and the adviser plays a key role in the students' socialization into the roles of researchers and teachers. The dissertation topic, scope, and its quality are also shaped by the students' relationship with the adviser. Subsequent job placement can also be affected by the nature of this relationship: "Affiliation with the proper adviser can often spell the difference between completion and noncompletion" (Lovitts, 2001: 131).

Theoretical Frameworks

Three theoretical frameworks underlie this study – doctoral persistence, graduate-student socialization, and disciplinary/department culture. Tinto (1993) believes that due to disciplinary differences and differences in the stages of the doctoral process, persistence at the graduate level cannot be described by any one developmental model. Factors that are significant at one stage may not be significant at the next stage.

Graduate-student socialization is not a linear, predictable process, and no two students are socialized in the same way (Wulff and Austin, 2004). Doctoral-student socialization is a dynamic process in which students influence, and are influenced by, their environment (Austin, 2002). Socialization in graduate school is the process through which students gain the necessary knowledge, skills, and ideals to enter a career that requires advanced knowledge and specialized skills (Weidman *et al.*, 2001). The socialization process is affected by the chosen discipline, the institution in which it takes place, and the structure of the graduate program (Weidman *et al.*, 2001). The point of reference for integration for undergraduates is the institution or campus community; however, doctoral students associate more closely with the academic department or program (Golde, 2000).

Finally, academic disciplines have distinct cultures that affect faculty and student beliefs and behaviors, such as values, faculty work, training of students, the nature of research (types of research questions and research methods), and faculty–student interaction (Austin, 2002; Golde and Dore, 2004; Lovitts, 2001; Smart *et al.*, 2000;

Turner *et al.*, 2002). Knowledge of distinct disciplinary settings is fundamental to understanding and improving key aspects of doctoral education, such as student retention and satisfaction (Golde and Dore, 2004; Smart *et al.*, 2000).

Research Questions

The aforementioned literature and theoretical frameworks guided the development of these research questions:

1. During what years are doctoral students most likely to depart?
2. What individual and department factors help predict doctoral attrition?
3. Do departments vary in their patterns of doctoral student departure?

Data Sources/Sample

To address these research questions, this study utilizes institutional records from a large, public research university in the western United States. The institution is divided into 14 broad academic fields, housing more than 80 doctoral programs. The university frequently participates in national studies of doctoral-student outcomes. The data set includes all students pursuing a doctoral degree (PhD, Dr.PH, DMA, or DEnv.) who entered the institution between the 1992–93 and 2004–05 academic years. Excluded from the study are students enrolled in interdepartmental programs and programs not administered by the graduate school. The institutional records comprising the data set include data from admissions, enrolment, degree, financial support, and employment records, combined with student-survey data. Faculty demographic data will also be included.

On average, about 782 doctoral students enter each year, resulting in a total sample of 10 166 students. These students are spread among 59 academic departments. **Table 1** contains the list of academic departments by broad field. About 44% of the sample is female. Over a quarter (28%) are international students, and about 11% are domestic underrepresented minority students (as designated by the institution, which includes Black/African American, Native American, Chicano/Mexican American, Latino, and Filipino students).

Methods

As doctoral attrition is an event that occurs over time, we first examined life tables and graphs of the student-departure process for the campus and each academic field.

To preserve confidentiality, departments have been renamed to generic descriptions and the departments within the schools of Engineering and Public Health have been removed.

The tables and graphs were subsequently compared to investigate when students are most likely to depart and if these patterns vary by academic field.

However, conducting the multivariate analyses on student attrition presents two methodological challenges. First, student attrition is an event that occurs not at a static moment in time, but rather over time. The failure to control for the time will result in biased estimates (Allison, 1984). Additionally, the students attending the university are nested in academic departments and not a random sample. The nesting of students violates the assumptions of traditional multivariate methods such as logistic regression (Raudenbush and Bryk, 2002).

Taking these concerns into account, we decided to conduct a discrete-time hazard analysis in a multilevel framework (Barber *et al.*, 2000). (Hazard analysis is also commonly referred to as survival analysis, event history modeling, and duration analysis, see DesJardins, 2003, for an overview of its application in education research.) This study represents the first application of this analytic technique to student attrition at either the undergraduate or graduate level. Discrete-time hazard models avoid the assumption of cross-sectional models that assume statistical equilibrium exists over time and allow for the inclusion of time-varying regressors leading to less-biased results (Allison, 1984; Singer and Willett, 1993). The models also allow for the investigation of when doctoral students are most at risk for departure. Additionally, in the study of student persistence and attrition, a discrete-time model is preferable to a continuous-time model, such as the Cox model, because the exact time of departure within a semester or year is unknown (Yamaguchi, 1993).

This study uses the academic year as the unit of time. To conduct the multilevel hazard model, the initial data set was converted to person-period form, where each observation represented one academic year. The first time period for all students is their first year of enrolment. A central concept behind hazard models is the risk set – the set of individuals who may experience the event of interest. Consequently, three types of observations were then deleted from the sample. First, observations occurring after departure were removed as the student was no longer at risk to drop out of the institution again. Additionally, two classes of observations were excluded due to right censoring. After receiving their doctoral degree, the student is no longer at risk, and these future time periods are right censored. Similarly, for students currently enrolled with observation periods not yet observed, the unobserved periods are also right censored. No observations were left censored as students cannot depart from college before enrolling. After the deletion of the censored observations, the study yielded a final sample of 44 962 person-year observations from 10 130 students.

The multilevel component of the analysis satisfies the assumption of independence for hazard models and provides an opportunity to investigate if doctoral-student attrition varies between academic departments. We employed a two-level random-intercept model using logistic regression.

The general form of the model can be expressed as

$$\text{logit}(p_{nij(y=1)}) = \beta_{0j} + \beta_1 \lambda_r + \beta_2 (X_{ij} - \bar{X}_{\cdot j}) + \beta_3 (X_{tij} - \bar{X}_{\cdot j}) + \beta_4 X_{\cdot j} + \beta_5 X_{tj} + \varepsilon \quad \beta_{0j} = \beta_0 + \mu_j \quad [1]$$

where β_{0j} is the intercept term for department j , β_1 is the coefficient associated with a vector of dummy variables representing the hazard function, β_2 is the coefficient associated with a vector of time-invariant group mean-centered variables for individual i in department j , β_3 is the coefficient associated with a vector of time-varying group mean-centered variables at time t for individual i in department j , β_4 is the coefficient associated with a vector of time-invariant variables for department j , β_5 is the coefficient associated with a vector of time-varying variables at time t for department j , μ_j is the random effect for department j , and ε is the error term.

Analysis Strategy

To begin the study, we first examined the life table for the sample, which summarizes the patterns of attrition by observation period. Derived from the life table is the hazard rate, which forms the basic concept behind the hazard model. The hazard rate or more commonly, the hazard, is the probability that “an event will occur at a particular time to a particular individual, given that the individual is at risk at that time” (Allison, 1984: 16). For this study, the hazard refers to the probability that a student will depart from the institution without receiving his/her doctoral degree in a particular academic year, provided he/she is at risk for attrition. From the life table, the survivor function, which is the proportion of the sample that has not yet departed and is at risk to depart in an academic year, is also derived.

Our data-analysis strategy proceeded to build a final model by level. First, we fitted an initial model with just the hazard function and the random intercept. Next, we added a number of student-level variables to the first model. Subsequent models were fitted to include the context the student experienced while enrolling, the academic field of the department, and a number of interaction effects. Finally, a subset analysis of students in departments requiring the Graduate Record Examination (GRE) for admission was conducted.

Dependent Variable

As stated above, the dependent variable is a dichotomized variable indicating student attrition in a given academic

year. This study uses the institutional definition of attrition, which is when a student does not enrol or file for a leave of absence for two consecutive years without receiving the doctorate.

Independent Variables

A full list of the independent variables examined in this study and their coding schemes can be found in **Table 2**. Variable selection was guided by previous research and the availability of data. In addition to variables indicating the hazard function, student-level variables such as demographic traits including gender, age, ethnicity, and citizenship were included in the analyses. Additionally, data on the student's prior history were assessed by including variables indicating baccalaureate institution type and prior graduate-degree achievement. The total amount of net financial support (after deducting mandatory tuition and fees) received by the student per year was included in the analysis. These values were adjusted for inflation to the 2000 calendar year using the consumer price index (CPI) measure for the local metropolitan area. Moreover, dichotomous variables indicating whether the student was a teaching or research assistant during the observation period were included. All student-level variables were centered at their department's mean.

We also included variables reflecting the department/program environment, such as the demographic make up of the department's ladder rank, faculty, and student body. In addition, student satisfaction with the quality of instruction was examined. The analysis included department means for a number of the student-level variables to examine contextual effects. Finally, GRE percentile scores at the individual and department level were examined in the subset analyses described above.

Results

Descriptive Statistics

Table 3 contains the life table for the total sample, and **Figure 1** demonstrates the survival function over the sample's time period. The median life span for the sample is 11 years, indicating that half of all students fail to finish their doctoral degrees by year 11. This statistic is similar to the national average for all doctoral students (Bowen and Rudenstine, 1992; Lovitts, 2001).

The hazard function can be found in the last column of **Table 3** and graphically represented in **Figure 2**. The risk of drop out in the first year is 6% and rises to 9% in the second year. Then, the hazard rate gradually declines until year 8, when it begins to rise again. The hazard peaks in year 13; however, this rate should be interpreted with caution as only 35 students were observed during this

time period. Nonetheless, the hazard rate indicates that doctoral students at this institution are most likely to depart in their first 3 years and 9 years after entry.

Figure 3 contains the survival-function graph by broad academic field. The survival functions demonstrate differences in student departure across the academic fields. The survival curves for the humanities, health science professional, professional schools, and the social sciences appear to have similar, linear slopes. In contrast, the graphs for the life and physical sciences have a downward curve that

levels off after year 6. (The drop in attrition during year 9 for the physical sciences is based on a sample of just 46 and is within the standard error compared to year 8.)

Multivariate Results

A multilevel model was created to explore the impact of various factors on doctoral students' attrition at different time periods. The first model includes the baseline hazard of leaving the doctoral program at different time periods

Table 3 Life table of doctoral attrition, 1992–2004 entering cohorts

compared to year 1 of doctoral study. Subsequently, additional models added several student-level characteristics presented at the time of admission to the doctoral program, departmental-level characteristics, broad field-level characteristics, and interaction effects to the baseline hazard model. The study results are contained in **Table 4**.

The baseline hazard of leaving doctoral study is highest at year 13 followed by years 2 and 3 compared to the reference group, which is year 1 of doctoral study. The odds of attrition drop down by year 4 and increase again after year 8. Students at year 13 are 3.4 times more likely to drop out than the reference group, but as mentioned earlier, only 35 students were observed during this time period. Hazards of attrition at years 2 and 3 remain significant after accounting for the effects of student, department, and field characteristics and interaction effects to the baseline model. In all levels of the model, students are less likely to depart at years 6 and 7 as compared with year 1.

The second model includes group-centered mean variables for individuals based on their departmental affiliation. Taking group-centered mean values by department accounts for the clustering effect of the variables by department. Foreign students and students with a previous graduate degree are predicted to have a lower probability of attrition across all models at $p < 0.001$. There is no significant difference in the probability of attrition between students who received baccalaureate degrees from top-tier schools compared to other less-prestigious schools. The probability of attrition for domestic under-represented minority students (URM) is higher than other students holding all else constant. In the second model that contains the students' basic demographic and academic characteristics, the older the student was at the beginning of doctoral study, the more likely he/she was to

Figure 3 Survival curves for doctoral students by broad academic field, 1992–2004 entering cohorts.

depart before completing the degree. However, after accounting for the amount of student support received and the departmental context, the direction of the effect changed, and the older the student was at the start of doctoral study, the less likely he/she was to leave before completing the degree.

The third model includes the baseline, department- and student-level variables. Not surprisingly, the more total financial support the students received, the less likely they were to drop out. Interestingly, the total amount of loans received had the same effect, perhaps a reflection of the students' commitment to, and investment in, their education. Students who are enrolled in departments with higher student-rated levels of instructional quality are less likely to drop out of their doctoral studies. However, this effect becomes significant only after controlling for the broad academic fields, indicating that instructional quality varies between academic fields.

The next model includes dichotomous variables indicating the broad academic field in addition to the other independent variables discussed above. Using the life sciences as the reference group, students in all other fields, except for the professional health sciences, are predicted to be more likely to drop out, holding all else constant. Students in the humanities and social sciences are approximately 65% more likely to drop out of their doctoral program compared to life-science students. On the contrary, students from the professional health sciences field are 25% less likely to depart from their program, but the difference is not statistically significant.

The full model includes all the variables from the previous models and interaction effects. The results indicate that the impact of financial support varies across time periods. The interaction effects indicate that financial support plays a greater role in doctoral student departure during the third, fourth, and seventh year of enrolment. The other significant interaction effect observed was between females and the percentage of female students in the program. As the percentage of female students increases in a department, females become less likely to withdraw from their doctoral study.

Across all models, inclusion of the random effect was significant at $p < 0.001$. Consequently, we can conclude that doctoral-student attrition varies between academic departments.

In addition, we fitted a subset model that included the full model plus individual and mean department GRE percentile scores (for departments that required the GRE for admission). The results indicate that both individual and mean department GRE quantitative scores have no significant effect on doctoral-student attrition. However, individual GRE verbal percentile scores are positively related to doctoral-student attrition, indicating that students with higher GRE verbal percentile scores were more likely to drop out before completing the degree.

Discussion and Conclusion

This study applied multilevel hazard analysis to examine doctoral-student attrition at a university in the western

United States. The results indicate that the point at which doctoral students depart varies. While it is commonly understood that the doctoral process in all fields involves stages of degree progress (coursework, exams, candidacy, and dissertation), the timing of these stages is highly variable. Utilizing academic year as the unit of time instead of stage-of-degree progress adds another level of clarity to the analysis.

Not surprisingly, the study also found that student support is critical to doctoral-student success. One difference from past research is the finding that the sum of student loans seemed to be a predictor of student commitment to degree obtainment, rather than a reflection of the burden of student debt. The finding that the impact of financial support changes over time requires further analyses, though Tinto (1993) believed this to be true as well.

The fact that there is more variability between academic departments than academic fields highlights the need to understand department and doctoral program culture better, including the nature of student–faculty relationships, mentoring, and relationships among students. Additionally,

the results suggest that female students are less likely to drop out before completing the doctorate in departments with higher percentages of female students. This is an important contextual effect that needs to be examined more closely, especially as it relates to fields in which women are underrepresented.

Implications for Policy and Practice

The results contain a number of findings that can be used to inform policy and practice on graduate-student issues. First, most doctoral students at the institution studied are at the highest risk for departure during their second and third years. After declining between years 3 and 7, the risk of drop out subsequently increases again during year 8. Increased focus on retaining students should occur during the second and third years of study when students are making the transition from the coursework to dissertation phase of their doctoral studies and after 8 years of enrolment, when students have completed all but the dissertation.

The results support previous research indicating that adequate student support is critical to student success (Bair and Haworth, 2004). Apart from the effect of time, financial assistance was the most significant factor in the model. Financial support appears to play an even more critical role during the third and fourth year of enrolment. These years represent the time when many students are beginning the dissertation process; consequently, when students fail to receive adequate financial support during the transition from class work to candidacy, they are more likely to drop out.

The present study both supports and contradicts what has been found in previous studies: that women, minority students, and American students drop out at higher rates than men, White students, and international students, respectively (Bowen and Rudenstine, 1992; Lovitts, 2001; Smallwood, 2004). Across all models in this study, foreign students are less likely to depart compared with majority domestic students. Initially, domestic URM students are not predicted to depart more than their majority counterparts; however, after taking into account the departmental context, the model predicts that URM students will be more likely to leave before completing their doctoral studies. Finally, gender was not a significant predictor of attrition; however, as mentioned below, gender does come into play with respect to the structural characteristics of the department.

The results support the previous research indicating that the structural characteristics of the department have little relationship to doctoral-student attrition. From the faculty-to-student ratio to the percentage of underrepresented students in the program, the basic observable characteristics appear to be unrelated to drop out. The exception is the finding that female students are less likely to drop out in departments with higher percentages of female students.

The study also suggests that academic credentials of applicants are not the best predictors of student success, confirming previous research (Bair and Haworth, 2004). While having a previous graduate degree is consistently associated with a declining probability of student departure, GRE quantitative scores at the individual and department levels appear to be unrelated to doctoral-student attrition. However, individual GRE verbal scores are modeled to be positively related to doctoral-student attrition, indicating that students with higher verbal scores are more likely to not complete their studies. This finding raises questions about the validity of GRE scores as a predictor of graduate-student success.

Glossary

Hegemonic masculinity – Refers to the belief in the existence of a culturally normative ideal of male behavior.

Summarizing academic research relevant to the decline of male academic performance in education is an important step toward understanding why males appear disengaged, uninterested, and failing at high rates (Sutherland, 1999). To this end, it is critical that education scholars and practitioners gain better understanding of current research and use it to closely analyze and identify explanations for the male educational crisis. Without this understanding, how could we realistically address this problem? Arguably, more so than any other time in history, human capital is one of society's most precious commodities. Countries, such as the United States, Canada, England, and France, can no longer stand on the sidelines watching certain demographic groups underachieve or low achieve in their educational systems.

Today's knowledge-based economy mandates continuous investment in education to ensure that countries are able to compete in the new global market. Increasingly, the government and business leadership of countries around the world realize that they must improve their educational systems and address the issue of underachievement or low achievement among certain demographic groups, including males. These countries also recognize that they must invest more resources in science, technology, engineering, and mathematics (STEM). Nations, such as China and India, once seen as poor, antiquated, and underdeveloped, are now viewed as major players in the twenty-first century.

Over the last decade or so, these two countries have invested major financial resources in improving their educational system, particularly in the STEM areas. In this short span of time, the two countries have reaped major benefits from these investments. More specifically, they have allowed China and India to transform themselves from struggling, poor nations to global economic engines, where other countries want to partner with them.

In these countries, men and boys are front and center and are the primary reasons for the transformation. As in most parts of the world, there are gender disparities; however, the biggest difference is that boys are leading the way educationally, which is the complete opposite for other countries, such as the United States and England. Instead, in the United States and England, girls are outperforming boys (Jha and Kelleher, 2006). The former pattern, not the latter, is evident for other countries that have "achieved universal access and have high participation rates for both girls and boys, at least at the primary stage of schools (including a number of Commonwealth countries in the Caribbean, Europe, East Asia, and the Pacific, and some sub-Saharan Africa and South Asia)" (Jha and Kelleher, 2006: 4).

To ensure that countries have a place at the table in the global market, it is important that their social scientists, educators, and policymakers take note of the educational trends for males and equally work to understand them better. Similar to Jha and Kelleher (2006) in *Boys Underachievement in Education: An Exploration in Select Commonwealth Country*, we framed this article on participation and performance. Based on our review, these two points were the most salient issues for males as it relates to their underachievement or low achievement.

Establishing the Problem

Scholarly journal entries (e.g., Jackson and Moore, 2006, 2008) and popular media excerpts (e.g., Patterson, 2006) present a compelling argument regarding the academic decline of males in education. These arguments are largely based on national standardized test scores, high dropout rates, disciplinary rates, disproportionate numbers in special education, and falling college enrolment (Weaver-Hightower, 2003). In order to interpret the male underachievement concept, a synopsis of the research literature depicting the shift in concern toward the educational experiences of males across the world is undertaken. Of particular interest are the perceptions of this phenomenon as a crisis directly related to the performance of the girls and women. By exploring this specific contrast, we are able to find inconsistencies across the

literature when attempting to characterize and interpret the nature of what is defined as male underachievement.

The Boy Concern

The shift toward the study of the educational performance of males emerged as a global concern only in the mid-1990s, when a focus on the schooling experiences of boys took the central stage of educational debate (Weaver-Hightower, 2003). Preoccupation, within the United States, was echoed by concerns in countries, such as England and Australia, where this issue acquired the label of a national crisis. In particular, national anxiety in England occurred because girls surpassed boys at A level for the first time on the General Certificate of Secondary Education (GCSE) examinations in 2000 (Myhill, 2002).

The practice-based focus on boys was accompanied by an empirical research component. Weaver-Hightower (2003) defines this transition toward the study of males as the boy turn. He acknowledged that shifting attention from girls to boys could be seen as unwelcomed, but it also provides a space for policy and research to face the current academic struggles of this population. Concurrently, despite the relatively nascent nature of research on males, most of the current research in this area is dominated by the study of the experiences of black/African-American males. In certain London districts, the black expulsion rate is 15 times that of whites. Unfortunately, less than 25% of British secondary schools had a specific policy to address low black student educational achievement (*Journal of Blacks in Higher Education*, 2002).

Studying the experiences of the black/African-American male student population is also occurring in the United States. Cross and Slater (2000) assert:

It is true that men of *all* races are increasingly earning smaller share of all degrees awarded in the United States. In large part this is the product of a society that has rather recently opened up employment and professional opportunities to women generally. But the declining performance of men in higher education in relative terms took hold much earlier for [B]lack men than it did for [W]hite men. (p. 82)

Further supporting and perhaps explaining the reasons for a particular interest in the underachievement of black/African-American males, it is necessary to acknowledge that the black/African-American male college completion rate has dropped from 35% to 31% since 1995 (Cross and Slater, 2001).

This decline coincides with the time period (i.e., mid-1990s) when educational research started focusing on the experiences of males, and it is not difficult to suspect that some relationship could be drawn between the low academic performance of black/African-American males and

their current struggle in other social domains. For example, in 1999 it was reported that 25% more black/African-American men were in prison than enrolled in higher education (*The Journal of Blacks in Higher Education*, 2003). This occurrence could be an indication of the implications of low academic performance and its broader repercussion in a world that continuously places a higher value on postsecondary academic preparation. Data on the experience of black/African-American males in education worldwide are troublesome. It seems as if black/African-American males are edified by male underachievement.

Problematising the Label of Male Underachievement

It must be noted that there are challenges to the current perception and applicability of the label male underachievement. It is highly suggested that current definitions be reviewed, and in turn, alternative interpretations of the phenomenon considered. It is believed that focusing on the underachievement of boys' obscures differences within genders by social class and ethnicity (Tinklin, 2003). Likewise, Smith (2003) found that the term is largely used by politicians, journalists, academics, and practitioners to describe relatively poor academic performance. Nonetheless, a review of scientific and popular literature does not yield a consensus on its definition and measurement. He further states that "gender accounted for less than 1% of the variance in examination outcome," which has deep implications for "commentators who place gender, and the underachievement of boys in particular, at the heart of the standards debate and should provide a cautionary note for all those who perpetuate the binary notion of boys versus girls" (Smith, 2003: 585).

This statement, in particular, voices a powerful criticism of the current notion of underachievement. A specific focus on understanding what the underachievement is in relation to and the use of more appropriate terms such as low achievement, or differential achievement, to describe the male performance, ought to be considered. It appears evident that redefining how the gender gap is currently conceived and studied is imperative to move into a deeper exploration of this phenomenon, particularly avoiding a shortcoming where previous research may have been attempting to explain differences whose nature was incompletely understood. This compels researchers to further explore the potential socioeconomic, classroom, and individual determinants of these gender gaps (Gorard *et al.*, 2001), while also moving away from a surge of media interest positing a number of interpretations as a cause of the gender gap (Renold, 2001).

For that reason, in the following section, we offer a review of important evidence across five themes within

the literature that could offer valuable clues to understand the various aspects related to the educational performance of males and reasons for their current academic predicament.

Identified Reasons of Male Underachievement

Scholarly research examining topics, such as social identity, parent involvement, peer influence, classroom behavior, lack of engagement, and school curriculum, among other themes are scrutinized as potential underlying reasons contributing to male underachievement. Our exploration of the research literature – focused on academic performance of the male population – opens new avenues for understanding this challenge.

Family Composition

A body of academic research explores family composition and its impact on behavior problems of inner-city boys. Florsheim *et al.* (1998) found that boys in single-mother families were at greater risk of developing problems than boys in two-parent families. However, the risks associated with single motherhood were offset by a structured family environment, an effective disciplinary strategy that allowed for some degree of adolescent autonomy, and the positive involvement of a male family member. In addition, it is necessary to note that they also found that higher economic status among these single-mother families did not deter negative behaviors. This finding contrasts with previous findings that suggest underachievers are mainly working-class boys.

These findings are relevant in relation to male underachievement, because it is imperative to understand that there are multiple family risk factors that play a role in the development of such problems. Stated differently, the accumulation of risks elevates the likelihood that behavior disorders will occur. This understanding offers an approach to better interpret and draw connections among the current reasons for male underachievement.

Identity Development

A student's identity development is influenced by the environment in which they interact. Further, current conceptions of masculinity influence attitudes across various individual and social contexts. In these contexts, students are continuously attempting to fit in with common stereotypes that guide their behaviors within the school setting. Dumais (2002) proposes that researchers should consider both one's resources (capital) and the orientation one has toward using those resources (habitus) to truly understand the academic potential of students. This differentiation is

important considering that male students continuously attempt to downplay, or disguise these attributes, fearing that their peers will label them as sissies, in turn, preventing these boys from transforming their cultural knowledge skills into success in the classroom. Stereotypes are structured upon concepts of masculinity that dominate the educational experiences of boys. Therefore, understanding the context of these interactions could explain why male identity is guided through a path that is in opposition to academic success, dedication, and hard work.

Hegemonic masculinity

The concept of social identity is introduced as a predominant factor with potential to explain the roots of male underachievement. More recent concepts of masculinities and femininities are often constructed in opposition to each other (Renold, 2001). Renold's (2001) ethnographic study explores the interactions of students in a rural, white middle-class town in England, where for a boy being academically oriented is often devalued and denigrated because it is equated with femininity which conflicts with conventional forms of hegemonic masculinity. From these notions, and framing male identity development within the context of hegemonic masculinity, it is easy to observe aggressive behavior as a key trait for male students to protect and reassure their male identity. An increasing number of high-achieving boys are "strategically dissociating from the activities of their nonhegemonic peers and investing heavily in dominant masculine practice such as fighting, rule-transcending and football" (Renold, 2001: 377). Foney and Cunningham (2002) argue that males' status may be increased when they express violence that encourages boys to recreate these types of behavior, while females are the recipients of rejection at the expression of their aggression.

Racialized perspectives of masculinity

Foney and Cunningham (2002) also identified race as a significant factor affecting the male academic performance. In particular, they explored the connection between concepts of hegemonic masculinity and the experience of black/African-American students. Relevant to student behavior, they note as follows: "Although the 'daring' behaviors may not ordinarily be labeled 'aggressive behavior' in majority cultures, in Black/African American males, these daring behaviors may be viewed as antisocial and aggressive" (Foney and Cunningham, 2002: 145). Therefore, their interpretation, among other cultures, produces a negative impact that triggers attitudes within this population such as the development of maladaptive coping mechanisms which are linked to behavior that affect academic performance.

Wright *et al.* (1998) focused on black Caribbean males and recognized that current perceptions of their masculinity are constructed and influenced by other male peers and white teachers. However, they emphasize that these

expressions of black male masculinity triggering exclusion from the educational system should not be interpreted as an inability to attain white concepts of masculinities. These particular findings are in direct opposition to what Horvat and Lewis (2003) assert in their analysis of factors that inhibit academic excellence. Horvat and Lewis rely upon Fordham and Ogbu's (1986) work, *Black Students' School Success: Coping with the Burden of Acting White*, and conclude that black/African-American students continue to underperform in school because of their cultural opposition to acting white, particularly believing that they do not receive comparable returns for their hard work in school relative to whites.

Classroom Behavior

From acting cool to acting dumb

Linked to the process of identity development, student's behaviors and practices in classroom settings are important factors to consider when exploring academic achievement. Tinklin (2003) notes that key factors that help to explain gender differences in attainment is that girls take school more seriously than boys. This finding is related to previous research that suggests: "[w]hile academic success was valued by girls, doing too well at school could disadvantage some boys among their peers" (p. 321). As a result, poor classroom behavior could be seen as a way of compensating for losing popularity or being at risk of negative labels associated with strong academic performance. This opens doors for debate regarding the correlation of classroom behavior and the decline of male academic performance.

Moreover, Martino's (2000) research on adolescent boys in a Catholic coeducational school in Australia affirms that boys develop versions of masculinity for themselves through specific social practices such as mucking around in class, giving crap, and acting cool. In turn, these practices themselves establish norms for fashioning a desirable heterosexual cool masculinity reinforced by a system of verbal abuse and put-downs which establishes a hierarchy of masculinities (Frank, 1987). Martino (1999) also found that the cool boys act dumb to establish a hegemonic form of masculinity through which they can demonstrate their opposition to the values embodied in the aims of formal education. Osborne (1999) further elaborates and reflects upon these notions of being cool as opposition to academic achievement from a psychological aspect. He refers to the adoption of a cool pose in opposition to the stigmas attached to good academic performance as central matter that explains black/African-American male disengagement with school.

Student engagement

Educators play an important role in a classroom, impacting on students' learning and influencing their attitudes

toward achievement (Moore, 2006; Moore *et al.*, 2008). One would expect that teachers treat their students equitably and their teaching methods are structured in such a way that will provide equal treatment to both male and female students. However, referring to the implicit gender difference illustrated within the literature, Younger *et al.* (1999) state:

Research in this broader context suggests that most teachers believe that they give equal treatment to girls and to boys, particularly in support of their learning, but focus group interviews with students and classroom observation suggest that this is rarely achieved; in most schools, boys appear to dominate certain classroom interactions, while girls participate more in teacher-student interactions which support learning. (p. 325)

Therefore, student engagement must be analyzed as a central theme when referring to academic achievement. However, making adequate differentiations among types of positive and negative engagement is necessary to comprehend current evidence that highlights difference patterns and levels of engagement between genders. Marks' (2000) work states, "Female gender (at all grade levels) contributes positively to engagement, although the effect is attenuated in the orientation toward school and forms of social support models" (p. 171). In contrast, males are associated with patterns of engagement dominated by disruption. This results in animosity between students and instructors, and as a consequence, teachers' attention toward boys is dominated by a negative connotation, and they start to perceive girls as their ideal students. That is, girls embody characteristics such as confidence, self-learning, and articulation and are more inclined to take initiative in promoting their own learning (Younger *et al.*, 1999).

Educator's Perceptions

Younger *et al.* (1999) note that the idea of teacher's negative attention toward male students is rooted in teachers' interpretation of boys' behavior. That is, boys are more vocal, boisterous, less advanced for their years, more easily distracted than girls. This in turn, is seen as a direct challenge to their authority and efforts to create a learning environment. Consequently, this translates in to direct frustration and anger toward male students reinforcing teachers' perceptions that male students have other interests above and more important than school work (Younger *et al.*, 1999).

This particular negative perception of male students is also evident when referring to black/African-American males. Teachers interpreted the behavior of black/African-American males within a sinister and intentional context, punishing them as adults, while judging the rule-breaking attitudes of white boys as childish and innocent

acts (Ferguson, 2000; O'Connor, 2001). Along these lines, Hubbard (1999) argues that teacher's low expectations are particularly prevalent for the black/African-American male student population. These beliefs are part of a cycle of disengagement where teacher's low expectations will diminish student involvement that further caused teachers to have even lower expectations regarding the student's ability creating a self-fulfilling prophecy of failure. The reverse must also be considered regarding the negative connotations of student engagement and teacher's expectations. It is worth recognizing that classroom interactions and boys' (negative) participation in classrooms could be framed in a context where positive contribution to student learning is possible.

Myhill (2002) concluded that there are relationships between underachievement and levels of interaction and response in whole-class teaching episodes. Myhill recognized that there are exceptions within each gender, where "Whilst it appears to be true that boys do dominate calling out, high achievers dominate positive learning interactions whilst underachievers dominate the more negative classroom interactions" (p. 347). Therefore, dominance of high achievers, particularly males, offers hope for school reform that will acknowledge the potential of canalizing boys' energy and learning styles in classroom settings. In turn, this presents the opportunity to develop teaching styles that acknowledge learning and behavior differences among each student and contribute to the overall student's social and intellectual achievement.

Curriculum and Class Structure

A concern with the apparent underachievement of boys had led schools to review the potential benefits of single-sex classes and gender-specific curriculum as interventions to improve the performance of students. However, it is essential to mention that in countries such as England, the debate about the merits of single-sex education has focused on girls and less so on boys (Warrington and Younger, 2001). For that reason, considering the current concern for the performance of males, it is imperative to understand the benefits and limitations of class composition and the type of curriculum that is employed. "Curriculum-as-usual boys' classes do nothing to challenge the problematic macho male cultures inherent in schools; indeed, it may be the case that they actually exacerbate them" (Jackson, 2002: 37).

From a curriculum perspective focusing on school literacy and masculinity, Young and Brozo (2001) levied two arguments. One is arguing for the benefit of finding "boy books for boys and girls books for girls," and the other one stating the benefits of exposing all students to multiple kinds of texts, helping boys and girls to analyze the implicit notions of masculinity and femininity embedded in the literature. Despite this discrepancy, these authors

acknowledge that it might be beneficial to develop and start a curriculum that does not pit boys against girls. This notion was based on the recognition of the social construction of gender and its implications on current literacy practices in schools.

This notion also advanced the discussion regarding the benefits of single-sex versus coeducational schools for boys and girls. Findings across many countries appear to echo the criticism of the benefits of single-sex school for boys. Wong *et al.* (2002) examined the gender differences in educational achievements and concluded that, "after controlling for initial ability, that girls benefited from studying in single-sex schools whereas boys benefited from co-educational schools" (p. 827). These assertions raise a question of the potential effectiveness of school reforms that focused on single-sex class environments.

However, it must not be ignored that most studies have shown no advantage for boys of all-male classrooms. In turn, no studies have documented that coeducational schooling is any better for males than single-sex classes (Singh *et al.*, 1998). As a result, understanding the implications beyond class structures will help to better comprehend the learning process of students, stepping away from research paradigms that ignore implicit connections of class composition with other student and teacher characteristics that must be factored to understand student performance.

Conclusion and Proposed Solutions

Currently, we are venturing into a field of research where discrepancies, different criteria, and uncertainty create a conflictive scenario. Consequently, approaching male academic performance as a multilayer issue is problematic, especially when it is not studied from different academic perspectives. Likewise, attempting to understand each of its components as a smaller part of a bigger and interrelated matter raises many eminent concerns. Therefore, understanding this phenomenon of male underachievement is a difficult task, because it evolves around ideas, such as "one of relative rates of improvement for both sexes" (Younger *et al.*, 1999: 326). It is quite likely that this could help to better comprehend why some males have failed in their quest to conquer academic excellence, while others have succeeded.

It is also worth asking if we are currently improperly labeling the experience of all males in education as a crisis, ignoring that for policy and educational research to effectively target the specific needs of identified student populations, we must consider unique aspects of the experience of each group, and variances within its own population. From this literature review, it is undeniable that male students face various challenges that currently

affect their academic performance. However, placing all these male underachievement indicators under one category constitutes a fatal error when attempting to provide solutions to low academic performance.

O'Connor (2001) affirms that current research and structural theories dealing with achievement: "have failed to account for within-group variation in achievement because they are rendered as if class or race unilaterally positions people in the social world. But people are not simply raced or classed. They are raced and classed and gendered" (p. 164). This reasoning provides us with a valuable alternative to the current approach to this problem, where future research must start examining internal group variation within each academic cohort of students, acknowledging that "in explaining achievement outcomes, we have to attend to the fact, for example, that being black in a public school is different from being black in a Catholic school, being black in a low-ability group is different from being black in a high-ability group, and being black in one family is different from being black in another" (O'Connor, 2001: 164).

Considering the current concern about boy's performance and its many implications of hegemonic masculinity in the identity development process of this population, it is imperative for schools to create environments that positively engage, offer learning opportunities, and challenge "the impact and effects of hegemonic masculinities in school" (Martino, 1999: 259). Drawing upon the themes that emerged as potential reasons that trigger current academic decline among the male population within this literature review could be seen as a solid point to redirect current research, where each theme is explored and placed into the context of a specific population (e.g., black/African American) under analysis, attempting to find evidence of each category represented in the experience of male students that live, study, and go through a process of social, cultural, and educational development that complicates current notions of male underachievement as a single-tier problem. Tinklin (2003) suggests that "a more complex definition of the problem of underachievement is needed" (p. 323).

We do not posit that this review of the literature is exhaustive; however, we do believe that it is one of the most comprehensive examinations of male underachievement or low achievement found in the research literature that goes beyond the borders of the United States. In closing, we hope that this article provides the reader with a starting point to further explore the topic of male underachievement or low achievement. That is, we desire to instigate research that will deepen our knowledge on this topic. Likewise, we hope educational practitioners and policymakers will look at this article as a challenge to develop new strategies and improve the current ones to address education outcomes for males across the globe.

Noncognitive Measures for Higher Education Admissions

W E Sedlacek, University of Maryland, College Park, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Noncognitive variables – Noncognitive is used here to refer to variables relating to adjustment, motivation, and student perceptions, rather than the traditional verbal and quantitative (often called cognitive) areas typically measured by standardized tests.

Nontraditional students – Those with cultural, racial, and gender-related experiences different from 18 to 22 year olds with white middle and upper-middle class Euro-centric experiences.

Variance – A statistical term referring to variability on a measurable dimension.

Introduction

We appear to have forgotten why tests were created in the first place. While they were always considered to be useful in evaluating candidates, they were also considered to be more equitable than using prior grades because of the variation in quality among preparatory schools. The College Board has long felt that the Scholastic Aptitude Test (SAT) was limited in what it measured and should not be relied upon as the only tool to judge applicants (Angoff, 1971).

In 1993, the verbal and mathematical reasoning sections of the SAT were lengthened and the multiple-choice Test of Standard Written English was dropped. The name was changed from Scholastic Aptitude Test to Scholastic Assessment Tests, while retaining the SAT initials. Currently, it is just called the SAT-I. In 2003, the College Board announced that an essay would be added and the analogies item type removed as of 2005. Despite various changes and versions over the years, the SAT in essence measures what it did in 1926, verbal and math ability; it is basically still a general intelligence test (Sedlacek, 2003, 2004).

However, we have come to the point where the Big Test has become the focal point in our schools (Lemann, 2000). It has become the standard by which we judge ourselves and others. Many assume that if an individual has high SAT scores, or if a school has high mean SAT scores, the students must be learning something, and the school must be good. To cite that common metaphor, the tail is wagging the dog.

Test results should be useful to educators, student service workers, and administrators, by providing the basis to help students learn better and to analyze their needs. As currently designed, tests do not accomplish these objectives. Many teachers tend to teach to get the highest test scores for their students, student service workers may ignore the tests, and too many administrators are satisfied if the average test scores rise in their school. We need some things from our tests that currently we are not getting. We need tests that are fair to all and provide a good assessment of the developmental and learning needs of students, while being useful in selecting outstanding applicants. Our current tests do not do that.

Keeping Up with Change

The world is much different than it was when the SAT and other tests were developed in the last century. International students, women, people of color, gays, lesbians, and bisexuals, among others, are participating in higher education in more extensive and varied ways (Knapp *et al.*, 2002). Commonly employed tests have not kept up with these changes (Sedlacek, 2004).

We need a fresh approach. It is not good enough to feel constrained by the limitations of our current ways of conceiving of tests. Instead of asking, "How can we make the SAT and other such tests better?" we need to ask, "What kinds of measures will meet our needs now and in the future?" The purpose of this article is to present the underlying logic and research supporting a method that yields such measures. We do not need to ignore our current tests, we need to add some new measures that expand the potential we can derive from assessment.

Noncognitive Variables

Noncognitive is used here to refer to variables relating to adjustment, motivation, and student perceptions, rather than the traditional verbal and quantitative (often called cognitive) areas typically measured by standardized tests (Sedlacek, 1998a, 1998b, 2004). While noncognitive variables are useful for all students, they are particularly critical for nontraditional students, since standardized tests and prior grades may provide only a limited view of their potential. Below is a discussion of the eight variables recommended to be included in admissions assessment systems (see **Table 1**).

Table 1 Description of noncognitive variables

Variable #	Variable name
1	<i>Positive self-concept</i> • Demonstrates confidence, strength of character, determination, and independence.
2	<i>Realistic self-appraisal</i> • Recognizes and accepts any strengths and deficiencies, especially academic, and works hard at self-development. Recognizes need to broaden his/her individuality.
3	<i>Understands and knows how to handle racism (the system)</i> • Exhibits a realistic view of the system based upon personal experience of racism. Committed to improving the existing system. Takes an assertive approach to dealing with existing wrongs, but is not hostile to society, nor is a “cop-out”. Able to handle racist system.
4	<i>Prefers long-range to short-term or immediate needs</i> • Able to respond to deferred gratification, plans ahead and sets goals.
5	<i>Availability of strong support person</i> • Seeks and takes advantage of a strong support network or has someone to turn to in a crisis or for encouragement.
6	<i>Successful leadership experience</i> • Demonstrates strong leadership in any area of his/her background (e.g., church, sports, noneducational groups, and gang leader).
7	<i>Demonstrated community service</i> • Participates and is involved in his/her community.
8	<i>Knowledge acquired in or about a field</i> • Acquires knowledge in a sustained and/or culturally related ways in any field.

Positive Self-Concept

There is evidence that the way students feel about themselves is related to their adjustment and success in college (Sedlacek, 2003, 2004). A strong self-concept is particularly important for students of color, students with disabilities, and women returning to school.

A number of studies have shown that a positive self-concept correlates with college grades, retention, and graduation, particularly the later two, for regularly admitted African-American students. O’Callaghan and Bryant (1990) found self-concept important for the success of black American students at the US Air Force Academy. A positive self-concept has also shown to be important for Asian and Pacific Islanders, Latinos, international students, and women, among others (Ancis *et al.*, 2000).

Realistic Self-Appraisal

Realistic self-appraisal is the ability to assess one’s strengths and weaknesses and allows for self-development. Realism in self-appraisal by nontraditional persons does not connote cultural, racial, or gender deficiency or inferiority.

White students may do well pursuing their own interests (internal control) in a society designed to meet their needs, while students of color need to also be aware of the external control on their lives which requires them to negotiate the racism in the system (Sedlacek, 2003, 2004, 2005). Perceived intrinsic interest in a field has been shown to be a major barrier to achieving career goals for whites and Asian Americans, while African-Americans, Latinos, and Native Americans cited personal finances as their major barrier.

Realistic self-appraisal has been found to correlate with college grades, retention, and graduation for students of all races, but the relationships were particularly strong for African-Americans. Women who are able to make realistic self-appraisals have been shown to get higher grades in a university than those who have difficulty with such assessments (Sedlacek, 2004).

Understands and Deals with Racism

The successful nontraditional student is a realist based on a personal experience with discrimination, is committed to fighting to improve the existing system, and is able to handle a racist system. Institutional racism is defined as the negative consequences that accrue to a member of a given group because of the way a system or subsystem operates in the society (e.g., college admissions), regardless of any other attributes of the individual (Sedlacek, 2003, 2004). Racism can take many forms and is used here to cover all types of ‘isms’ (e.g., sexism, ageism, and athleticism). While racism can be individual rather than institutional, the primary concern here is for dealing with the policies, procedures, and barriers, intentional or not, that interfere with the development of people.

For traditional students, the variable takes the form of handling the system without the addition of racism (Sedlacek, 2003, 2004, 2005). How one learns to handle the circumstances with which they are confronted tells us much about their ability and potential.

Steele’s (1997) work on stereotype threat supports the importance of the psychological set with which examinees approach a test. If African-Americans are told that they do

not usually do well on a test, they do less well than if a more positive set is given. Therefore, for African-Americans, the act of taking a test probably involves dealing with the racism that may have been involved in helping to create a stereotype threat in the first place. Hence, part of the variance that is being measured when an African-American takes the SAT is likely to relate to how that person handles racism.

Prefers Long-Range Goals

Having long-range goals will predict success in college for students. Since role models often are more difficult to find, and the reinforcement system has been relatively random for them, many nontraditional students have difficulty in understanding the relationship between current efforts and the ultimate practice of their professions (Sedlacek, 2003, 2004, 2005).

A significant relationship has been found between setting long-range goals and grades and retention for international students, including international community college students (Boyer and Sedlacek, 1988).

Availability of a Strong Support Person

Students who have done well in school tend to have a person of strong influence who provides advice to them, particularly in times of crisis (e.g., Sedlacek, 2003, 2004, 2005). This individual may be in the education system, but may be a relative or a community worker. Evidence is available for women, athletes of all races, and international students (Bennett and Okinaka, 1990). This variable involves having someone beyond a role model, although that may be part of the relationship. A strong support person takes an active role in advising and directing someone.

Successful Leadership Experience

Students who are most successful in higher education have shown an ability to organize and influence others. The key here is that nontraditional students may show evidence of leadership in different ways than their white counterparts (Liu and Sedlacek, 1999).

Asian-American students have unique and culturally related ways of expressing their leadership. If an applicant succeeds in his or her culture and is now ready to take on college, there is evidence that the student has the potential to succeed. There is evidence of the value of leadership in the retention of Latinos and Native Americans, and African-Americans in undergraduate and medical school programs (Webb *et al.*, 1997). Leadership has also been identified as a correlate of success for women and for female and male international students (Sedlacek, 2004).

Community

Having a community with which students can identify, and from which they can receive support, is critical to their academic success. For white students, there tend to be a number of opportunities to find a community, in or out of school. The community for nontraditional students often is based on racial, cultural, or gender-related variables. Students of color, women, and other persons with nontraditional experiences who are active in a community learn how to handle the system, exhibit leadership, and develop their self-concepts in such groups. For example, it has been found that African-American students who used campus athletic facilities and certain student union programs were more likely to stay in school than those who did not (Mallinckrodt and Sedlacek, 1987).

Identification with a community has been shown to be important for Asian-American, Latino, and Native-American success in school, and for male and female athletes of all races. Community also has been shown to be a correlate of success for undergraduate women, teachers in training, and international students (Sedlacek, 2004).

Nontraditional Knowledge Acquired

The ability of someone to learn from experiences outside the classroom correlates with their success in school. Persons of color are more apt to learn and develop using methods that are less traditional and are outside the education system. The methods may be culture or gender-related, and the field itself may be nontraditional students and women (Sedlacek, 2004). This learning should be demonstrated in an admission or scholarship application, rather than just listed as a job or internship. Several schools and programs use this method of assessment as discussed below.

Measuring Noncognitive Variables

The Noncognitive Questionnaire (NCQ) was designed to assess the eight noncognitive variables discussed above and shown in **Table 1** (Sedlacek, 1996). Several forms of the NCQ have been developed and employed in different selection contexts 2-week test-retest reliability estimates on NCQ scores ranging from .74 to .94, with a median of .85 (Sedlacek, 2004). Interrater reliability on scores from the three open-ended NCQ items ranged from .73 to 1.00.

The variables shown in **Table 1** have been successfully assessed in ways other than a version of the NCQ. In the Gates Millennium Scholars program, a review of an entire application is scored on the noncognitive variables, and makes up about 80% of the weight used in selection. The application includes short-answer questions based on each of

the noncognitive variables shown in **Table 1**, a personal statement by the applicant, letters of recommendation by the nominator and another person, and demographic, background, and activity questions. Raters were trained to identify and consider all this information in scoring each of the eight noncognitive variables. The raters were educators of color, familiar with multicultural issues in education, and in working with the kinds of students that were applying. Inter-judge reliability was estimated at .83 for a sample of raters in the first year (Sedlacek and Sheu, 2004). More than 11 000 Gates scholars have attended more than 1450 different colleges and universities with a 97% first-year retention rate, an 87% 5-year retention rate, and a 78% 5-year graduation rate. More than 60% are majoring in STEM (STEM: science, technology, engineering, mathematics) fields. Their realistic self-appraisal score has a significant relationship with their first-year college grade point average (GPA) and their leadership score has a significant relationship with engaging in academic activities while in college (Sedlacek and Sheu, 2008).

Oregon State University (OSU) has developed a selection system based on the noncognitive variables shown in **Table 1**. The OSU application contains six short-answer questions which cover the eight noncognitive variables. Responses are limited to 100 words and are scored independently from other application materials. Raters from many parts of the campus are trained to score the six questions. Inter-judge agreement was estimated at .85. OSU uses its system in selection, academic advising, student services, on and off campus referrals, financial aid, and teaching. OSU noncognitive scores correlate with retention, and since employing noncognitive variables the OSU retention rate is higher, there is more diversity in the applicant pool and first-year class, campus offices are working better together, applicant GPA is up, referrals are better, and new courses and student services have begun based on the noncognitive information.

The noncognitive variables can be used along with any other variables, models, or techniques that are employed in whatever role or type of mentoring or advising is involved. Teachers, advisors, or counselors who use the system can expect to obtain better student outcomes in terms of grades, retention, and satisfaction, as well as greater satisfaction themselves in employing something systematic with demonstrated utility in an area that often produces confusion and anxiety. Sedlacek *et al.* (2007) provide examples and case studies of how noncognitive variables can be used in postmatriculation programs.

The Problem of Defining Peace Education

Peace education is notoriously difficult to define. There are arguably three levels of understanding peace education. The primary concern of peace education is to prevent the suffering and wastage associated with warfare. A secondary concern is the linkage with cognate social concerns, such as those reflected in development education, education for international understanding, human-rights education, futures education, inclusive education, education for social justice, and environmental education. A third level of peace education is what might be called the intrapersonal and interpersonal aspects of peace education, dealing with self-understanding, self-fulfillment, and how we interact with each other and our environment at a personal level.

One of the noteworthy after developments in peace education has been an increasing interest in the above interpersonal and intrapersonal aspects of peace education. In other words, we need not be merely concerned with the prevention of violence on a governmental and social level, but we need also to be concerned with local and domestic violence, and with the quality of our everyday relationships. Ultimately, the personal and social dimensions of peace education are only classifications, and each is uniquely linked. Indeed, one of the overall lessons of peace education is that the personal is uniquely important: we teach peace education substantially through who we are.

Maximalist Versus Minimalist Peace Education

Another way of understanding peace education is through the notion of maximalist versus minimalist peace education. The maximalist understanding of peace education involves educating individuals toward sensitivity and responsibility in a range of areas, including personal fulfillment, the creation of a just and cooperative society, inclusiveness, and care for the environment. Minimalist understandings of peace education involve educating individuals toward learning to reject war and aggression, and learning to reject militarism and arms races. Both understandings pose challenges. Clearly, it is insufficient to educate people to reject war without encouraging an awareness of social injustice and inequality. However, at the same time, one problem is that peace education can be

seen as encompassing all educational endeavor so that peace education merely becomes a synonym for education.

The definitional problem of peace education can be seen as an extension of the definitional problem of peace itself. The Norwegian peace researcher Johan Galtung is widely recognized for emphasizing the difference between negative peace, that is, the absence of armed conflict, and positive peace, that is, the presence of cooperative and harmonious relationships. Johan Galtung has also developed a threefold classification of direct, structural, and cultural peace: direct peace denoting the absence of armed conflict, structural peace denoting the presence of justice and just structures, and cultural peace denoting the presence of a vital culture of peace.

The above classifications can be useful for peace education. Peace education can be seen as promoting both negative and positive peace. Peace education can be seen as encouraging direct peace, that is, educating individuals to see the dangers of war; encouraging structural peace, that is, educating individuals to see the importance of social justice; and encouraging cultural peace, that is, educating individuals to see the importance of a culture of peace.

A Brief History of Peace Education

Peace education arguably has a long history. If we view the major world religions as striving to encourage cooperation and harmony, if only internally, then the propagation of these world religions serves as a form of peace education. Similarly, one of the interesting historical phenomena of European history has been recurring peace plans, aiming to prevent wars between European monarchs. These too can be seen as a form of peace education. The beginning of a self-conscious idea of education as a means of preventing war can be traced to the philosophy of education of John Dewey and Maria Montessori. Both were motivated very much by reflection upon modern warfare, either a world war just ended (for John Dewey) or a new world war on the horizon (for Maria Montessori).

In more recent times, the importance of peace education has become directly recognized in international law, namely, in United Nations documents and declarations. One of the interesting aspects of international declarations on peace education is that these have become more explicit in recent years. Peace education is now increasingly recognized as a professional field, with the Peace Education Commission recognized as one of the Commissions

of the International Peace Research Association. Peace education is widely represented in scholarly publication, with the publication of numerous monographs, and with articles on peace education common in many educational journals. There is also now a specialist international scholarly periodical, the *Journal of Peace Education*.

Peace Education and International Law

It is easy to decry peace education as being at best an idealistic nonessential aspect of educational endeavor and at worst political indoctrination in the guise of education. This is why the recognition of the importance of peace education within international law is so important. International law has no enforceable authority of its own. However, there is a powerful moral and symbolic force within international law, and the recognition of the importance and role of peace education is an indicator that peace education is not merely an invention of particular interest groups and is indeed an essential part of education.

The Charter of the United Nations remains one of the core documents of international law, and the Charter outlines the special purpose of the United Nations in preventing future war. Peace education is one crucial means by which this aim can be fulfilled. The Preamble to the Charter refers to reaffirming faith in the dignity of the human person and establishing conditions under which justice and respect for international obligations may be maintained. It is difficult to see the above task of reaffirming faith in the dignity of the individual or establishing respect for international obligations as being anything other than an educational task.

Another fundamental document of international law is the Universal Declaration of Human Rights. Article 26 indicates that education shall be directed to strengthening respect for human rights and fundamental freedoms, promoting understanding, tolerance, and friendship, and education shall further the activities of the United Nations for the maintenance of peace. The idea of maintaining peace suggests the more limited notion of negative peace, although the other elements of Article 26 clearly refer to a wider notion of encouraging what we might describe as education for positive peace. Within both of the above documents, there is an implicit endorsement of the importance of education for peace.

Peace Education and UNESCO

The agency within the United Nations with primary responsibility for educational policy is the United Nations Educational, Scientific and Cultural Organization (UNESCO). The Preamble of the UNESCO Constitution indicates that the organization was formed for the promotion of a culture of peace; that is, as war commences in the minds of

individuals, so too defenses against war must be similarly constructed in the minds of individuals. UNESCO has regularly issued documents confirming the importance of peace education, most recently as the lead agency in the United Nations commitment to encouraging a culture of peace, such as in the International Year for the Culture of Peace, and the International Decade for a Culture of Peace and Nonviolence for the Children of the World.

Within United Nations programs on education for tolerance, there are numerous commitments to peace education. The 1995 UNESCO Declaration of Principles on Tolerance and the 1996 United Nations General Assembly Follow-up to the United Nations Year for Tolerance make it clear that tolerance is an essential component of peace. Article 1 of the UNESCO document describes tolerance as the virtue which makes peace possible and which contributes to the replacement of a culture of violence by a culture of peace. Article 4 of the UNESCO document involves a commitment to improve teacher training, curricula, textbooks, lessons, and educational materials in order to create caring and responsible citizens who are open to other cultures, able to appreciate the value of freedom, respectful of human dignity and differences, and able to prevent conflicts or resolve such conflicts through nonviolent means.

Peace Education and Disarmament Education

Disarmament education can be considered a subfield within peace education. The 1978 United Nations Special Session on Disarmament I, the 1980 World Congress on Disarmament Education, and the 1982 United Nations Special Session on Disarmament II all urged governments and international organizations to develop programs in disarmament and peace education. The Special Session II initiated the World Disarmament Campaign, which in turn became a catalyst for many peace movement initiatives of the following decade. The World Disarmament Campaign was an example of how intergovernmental action can impact upon popular culture and of how it is possible to lead in promoting peace.

Since that time, the World Disarmament Campaign has been succeeded by a permanent agency, the United Nations Office of Disarmament Affairs (UNODA), the focus of which has been on diplomacy rather than education. However, in 2002, the United Nations General Assembly commissioned an expert report, The United Nations Study on Disarmament and Non-Proliferation Education. The report renews the United Nations commitment to peace education, specifically in Articles 6–10. Article 20 usefully describes peace and disarmament education as a base of theoretical and practical knowledge, allowing individuals to choose values which reject violence, resolve conflicts peacefully, and sustain a culture of peace.

Peace Education as a Right

If it is tempting to see peace education as merely an ideal, one counter to this is to view peace education as a right. The 1959 Declaration of the Rights of the Child emphasizes the rights children have to protection and education, and Principle 7 expressly states that a child has a right to an education that will develop a sense of moral and social responsibility. One could argue that a corollary of this is that a child has a right to peace education. The same thrust can be discerned in the 1989 Convention on the Rights of the Child, with Article 29.1(d) indicating that education should be directed toward the preparation of the child for responsible life in a spirit of understanding, peace, equality, and friendship among all peoples.

If we see peace education as a right, then it is not too difficult to see the connection between a right to peace and a right to peace education, and the connection between peace education and human rights education. The 1984 United Nations General Assembly Declaration on the Right of Peoples to Peace recognized peace as a right. Rights are meaningless if individuals do not know of these rights, and in particular if peace is a right, then it follows that individuals have a right to know about this particular right. If peace is a right, it follows that peace education ought also to be regarded as a right. It is thus not surprising that the 1993 World Convention on Human Rights in Vienna recognized peace education as being part of human rights education. One flows from the other.

Peace Education and the Culture of Peace

The expansion of the concept of peace education has been reflected more recently in the culture of peace programs of the United Nations. The rationale behind the culture of peace movement is that peace involves more than governmental action; it is a civil and cultural process, encompassing all sectors of society. Peace is not merely institutional but personal. Thus peace education must ultimately involve teaching to encourage a culture of peace, however complex and difficult this might be.

This integrated understanding of peace and peace education is reflected in the 1999 United Nations General Assembly Declaration and Programme of Action on a Culture of Peace. Article 4 of the Declaration indicates that education is one of the principal means of building a culture of peace. Article 9 of the program of action contains specific actions for fostering a culture of peace through education, including involving children in activities for instilling the values and goals of a culture of peace, revision of curricula and textbooks with regards to peace, encouraging and strengthening efforts in developing skills and values supporting a culture of peace, and expanding the culture of peace initiatives in institutions of higher education.

Delimiting Peace Education

Any discussion of peace education ought to include the relationship of peace education to peace advocacy, and the relationship of peace education to peace research. Peace advocacy is practiced by peace groups seeking to emphasize the importance of peace and the destructiveness of war. Peace education similarly seeks to emphasize the importance of peace and the destructiveness of war. However, the difference is methodology. An important aspect of the educational task is that the educator must always respect the autonomy of the learner; thus, there is a fundamental difference between preaching and teaching peace. What makes this distinction more complex is that the task of emphasizing peace is no doubt better accomplished through recognizing the importance of the autonomy of learning.

The relationship of peace education to peace research is similarly a complex one. If we define peace research as normative applied research with the aim of emphasizing the importance of a commitment to peace, then it becomes clear that this is not far removed from the aims of peace education itself. It is for this reason that peace research and education are often linked together. Peace research is ultimately an educative endeavor. Similarly, peace education aims to clarify the causes of war and social injustice, and how we might work to prevent these in the future. Thus peace education may also be seen as a research process.

The Philosophy of Peace Education

On a fundamental level, one of the problems facing peace education has been the dearth of developed educational rationale or philosophy of peace education. One of the reasons for this is that those who are involved in peace education are likely to see the need for peace education as obvious, and thus the temptation is to see the need to articulate a philosophy of peace education as unnecessary. However, one of the marks of any valid educational endeavor is the existence of a developed educational rationale. Without such a rationale, peace education can be dismissed as indoctrination or political correctness.

There have been recent attempts to develop a coherent philosophy of peace education. Maltese educationist Joachim James Calleja sees a possible basis for peace education in the notion of duty and specifically in the Kantian categorical imperative. The fact that Immanuel Kant was a peace proponent adds weight to this specific line of argument. Australian educationist James Page identifies five possible ethical foundations for peace education: virtue ethics, consequentialist ethics, conservative political ethics, esthetics ethics, and the ethics of care. It is argued that none of these is conclusive in themselves, but each is part of a whole and credible rationale for peace education.

The Methodology of Peace Education

Just as there are layers of levels to peace education, so too one can suggest there are layers to the methodology of peace education, involving curriculum, structures and process, and personal leadership. The curriculum level is perhaps most appropriate to secondary and tertiary education. For instance, it is important to have a curriculum that does not necessarily follow a narrow nationalistic agenda and that allows for a genuinely international perspective. It is important to have a curriculum which acknowledges dispossession and marginalization of peoples. The teaching of history and civics is where this comes into focus most clearly, although it is also important in a range of other subjects and fields.

Structures and processes are important in that without just structures and processes within educational institutions, then all the discourse about peace within any curriculum can remain mere rhetoric. Indeed, without just structures and processes, discourse about peace within a curriculum can be destructive in that it can engender cynicism and disengagement. Peace and justice go together. If one has an educational program with much discourse about peace, and the educational context of that program is an educational institution with a dearth of justice in structure and processes, then clearly students will tend to be cynical about the peace education program.

The final level of peace education – personal leadership – is the most challenging. We learn through example and role modeling. We learn peace through seeing peaceful people in action. If someone aspiring to teach peace has a domineering teaching style, then this clearly is counterproductive. Peace education is concerned with the empowerment of the other. The role of a peaceful and encouraging teacher is not a simple one, especially in demanding and often conflict-ridden educational settings. Yet, there are steps which can be taken to empower and support the teacher. The methodology of peace education, and indeed peace education itself, remains an emerging field. Overall, more research, both theoretical and practical, is needed within this field for the future.

Moving to South Africa in 1994 was both a political and personal victory, to live in a free South Africa, when the past 10 years were spent, like millions of activists, in the hope of a free South Africa, but on the education front, where do we find ourselves, ahead, with the pack, or otherwise?

The author's field of interest has always been in the area of people development; in the traditional corporate human resource (HR) profession; or in change management via people development interventions.

In 1995 the author found her first job in South Africa (SA) in the higher education sector, but in her HR field. This was the eye-opening experience that left the author with the why question. This experience was further enriched by exposure to her partner's job at the University of the Witwatersrand, Johannesburg, fondly known as Wits or Wits University.

The more than 5 years the author spent in the corporate world reaffirmed the thinking that education is the cornerstone for intellectual and economic stimulation and development. This reaffirmation was frighteningly confirmed during her consultancy stint via the audit of the HR interventions by the Tertiary Education Linkage Program (TELP) between 2000 and 2005 in SA higher education (HE) institutions.

In her current role as director of the Wits International Office (WIO) at the University of the Witwatersrand, Johannesburg and her recent immediate past president portfolio at the International Education Association of South Africa (IEASA), she came full circle to the place of departure of her thinking about the role of aid, if the aid is indeed done in the interest of the 'developing' country that is supposed to benefit from it; in the race to secure economic dominance via access and control of the world's pool of talent.

Recent statistics has indicated that Africa's contribution to the world's pool on scientific and technological research is less than 1%, in fact 0.97% of this contribution, South Africa contributes 90%. This then translates into the reality that, outside of South Africa, the rest of Africa does not really feature as developing the talent that they need, or more accurately, retaining talent.

Research in the return rate of African nationals taking up studies in Europe, North America, and Australia revealed that over 80% of this talent pool do not return to their home country, even when their education is

financially supported and often part of a national scheme to revitalize their home country's talent pool.

The new study says some 65 000 African-born physicians and 70 000 African-born professional nurses were working overseas in developed countries by the year 2000. It says this represents about one in five African-born physicians and about one-tenth of African-born professional nurses. According to the British government, more than 17 000 doctors and nurses from Africa were recruited in 2007 to work in Britain. (Tendai Maphosa London, VOA, 11 January 2008)

What this illustrates is that African universities are quite capable in producing quality talented individuals; however, the retention of such individuals is not factored in by any schemes either by government or donors. This leads to support, especially in areas of infrastructure, salaries, benefits, and good working conditions. While many western donors are putting together elaborate schemes to develop talent under many schemes, the majority of the schemes are for the participants to study abroad, where such talent is recruited by those institutions and such talent rarely returns to the home country. This is clearly a flawed solution and lends itself more to controlling what they want to develop for themselves.

While institutions like UCLA working in Africa focused schemes that support postgraduate programs that are on condition that the recipients of the scholarship must return to their home country on completion of the program, fellows are expected to return to their home countries (African Development Dissertation Workshop Program: Institute of International Studies; UC Berkeley Funding Opportunities for Africans and Foreign Nationals). This example is rare. However, it only goes so far; an improvement would be for such programs to financially assist the African university to pay for a lab or the professor's salary for the first year, to create a welcoming environment to assist the professor's re-entry.

The Southern African Norwegian Training, Education and Development (SANTED) initiative, fully funded by the Norwegian government, provided an open forum for Southern African countries in the HE sector to look for creative solutions for indigenous projects that addressed regional needs and solutions. This funding created capacity development for all participating institutions.

The collaboration that the University of the Witwatersrand, Johannesburg, fondly known as Wits, collaborated with three other institutions, primarily the University of Namibia, University of Eduardo Mondlane, and in one subject area, the University of Botswana. The collaboration was in economics and labor studies, biological sciences, and engineering. With additions of new projects to further build capacity in the region, fulfilling the goals of SANTED and working toward the realization of the SADC Protocol on Education.

The institutional cooperation is intended to develop high-level capacity through the production of quality graduates and postgraduates who engage in advanced research projects. Apart from meeting elements of the SADC Protocol for HE, the project has obvious benefits for the institutions themselves and for the region as a whole. The specific projects chosen have either become, or will be, at the end of the project, embedded in the institutions and will be sustainable beyond the project funding.

All three universities bring to the project skills, expertise, and capacities; human, capital, and infrastructural resources; and challenges and limitations that will be addressed in this report.

The participating institutions, universities of Namibia, Eduardo Mondlane, and the Witwatersrand have similar backgrounds in their national demands; education and training, as well as research and development programs have been designed to meet national and international, human resource requirements. This is done through quality teaching, research, consultancy, and community service. The university continues to concentrate on key objectives of enabling students to reach their optimum levels of academic performance and improvement with respect to independent thinking and practical learning, communications skills, knowledge, networking for problem solving and trans-disciplinary approaches, research capabilities, publications, and writing skills. The university's graduate employment record continues to be encouraging. However, without a deliberate plan to attract, develop, and retain talent, the country's ability to grow its intellectual pool to respond to its domestic and regional needs will continue to lose talent to the west. This is the case of every African HE institution, the country, and the continent.

Wits University was identified as the coordinating host institution for the SANTED 'NEW' II project, which was championed by Professor Thandwa Mthembu, DVC (Prof. Mthembu is now the vice chancellor of Central University of Technology); currently, the project falls under the portfolio of Prof. Yunus Ballim, who is the deputy vice-chancellor (academic) and vice principal. The coordinating project team from the Wits International Office included Ms. Fazela Haniff, Mr. Lebethe Malefo, and Ms. Cindy Fredericks and the Late Ms Deborah McCONNell, who was part of the first SANTED team.

A unique element of the program lies in the biological science collaboration, where team teaching at a remote research location was developed. This allowed for faculty development via team teaching and the students experiencing the teaching styles and technique from different institutions. One of the highlights of this section of the project was seen by the group presentations of the students, to name a few, in the areas of:

- The distribution of phytoplankton in the Benguela.
- Variation in densities of *Welwitschia* and occurrence of small mammals in the gravel plains of the Namib.
- Comparisons of the morphological adaptations of *Meriones* lizards in the Namib desert.
- Changes in species richness, composition, and cover of terrestrial vegetation from coastline inland in the Namib desert.
- Namibian rocky shores: the nature of zonation on the northern Namibian coast.

The university senate approved the program as recommended by the postgraduate committee. Plans are underway for the program to be taught in 2009. Lecturers will be sought from all participating universities to deliver the lectures.

The challenges of communication and proper reporting, particularly from UEM, remain the greatest obstacles and limitations. Capacity has been increased in the Wits International Office to galvanize more support to all the projects managed from that office.

Like any collaboration project, it is imperative that commitment and buy-in from all stakeholders is solicited concurrently in order to achieve the objectives of this project. This is an ongoing process. SANTED 'NEW' II offers the SADC region a tremendous opportunity in the development of skills and building of capacity for all stakeholders. Once this is internalized, the project model will offer the region and other African institutions another option to maximize the value of the talent already on the continent.

The program funding provided resources in the following subject areas and categories. In the biological sciences, engineering, and economics, the program included curriculum development, support for materials, computers, books, research field trips, relief teaching, translation of course packages, support for university structures to approve masters curriculum, faculty development at masters and PhD levels for all participating institutions, and postgraduate and administrative coordination.

The example at UCLA, the joint program of SANTED 'NEW' II with Wits, UNEM, and UEM funded by the Norwegian government are few of the good things that are happening for African HE. However, the latter example of SANTED II will be soon closing, and there is practically no funding program that allows only African universities to develop and deliver their model of development.

The new order is that funding is no longer directly given to institutions unless there is a 'home-based' benefit. For the funding home country, the African university must partner with the funder's home-country institution. However good the intention to share skills, knowledge, etc., this scenario still benefits the funding home country's knowledge base and ultimately remotely controls how Africa develops, at what pace, and even what is developed – usually mostly to the benefit of the home country.

Within efforts to participate in and initiate initiatives to resuscitate either country development plans, to strengthen HE institution's capacity in Africa the west's intervention has been calculating and quite deliberate to favor schemes that primarily focus on strengthening their diversity goals, their quest to access data, and research intellectual capital to maintain their dominance in this sector. The most common misinformation is that foreign-aid money is used to assist others. This is primarily the most successful international marketing scheme of selling a product that does not exist. This is primarily a product to employ nationals of rich countries to spread some crumbs under the guise of international development programs.

Whilst the above example illustrates the uniqueness of regional capacity building, to assist with indigenous relevance and capacity development; the shift now by the Nordic countries, including Norway, and the European and North American philanthropical organizations to pull away from these models shows a reluctance or deliberate attempt to remotely control the pace and the path of HE development in Africa. The USAID's recent focus on Africa to dish out a mere one million dollars for all of African intuitions to access these funds – only if they participate in partnerships with other US institutions and only if that institution's area of interest happens to fall within the needs of the funding institution or country – is based on such a joint program for funding. The same trends are also now being followed by the Scandinavian and European countries. If one is not working with a funding-country institution, funding is primarily not available.

In the philanthropy world, the trend is youth centered; however, the skills to help the youth, counseling, research, intellectual capital at masters or PhD level, and support to strengthen universities to attract and retain professors and researchers have virtually been depleted.

Martin Davidson, Chief Executive of the British Council, said: "Fundamentally, this report shows the shift of axis of our education system from one that operates predominantly domestically to one that operates on a truly international basis. However, our position is vulnerable. Unless we start taking education much more seriously as a global business, we will lose out to other countries who understand the value of education to their economy much better than we do."

From Davidson's remarks, international education is moving toward running universities as a business, one that values talent and develops talent for national interest.

In the UK scenario, the British government and business community responds to this need by financially supporting their HE institutions. The growing need to quench the thirst for knowledge by workers, many governments are shifting gears to streamline their outreach to developing countries to 'help' Africa, or to help themselves. Most schemes are developed to hand out scholarships for African nationals to attend their universities; however, going back to our initial position, all these initiatives are assisting these governments and their institutions to have access to talent and ultimately retain this talent, to foster their diversity, and take control of knowledge and the knowledge economy.

Bernard makes the point that the categories of prior residence and country of prior education limit the data to be conclusive about its correlation to mobility and the residency, after the degree. Is this because the data-collection bodies, normally funded by those funding sources do not want to show that these schemes take talent away from developing nations, in this case Africa, the same group that such schemes are supposed to develop their talent and enable them to return to the home country to rejuvenate their intuitions and ultimately their economies? (Higher Education on the Move: New Developments in Global Mobility: Bernd Wachter, p. 59)

Further, in the same publication, Jane Knight also makes the case that graduates from top universities and their employability are closely linked. With investment in talent, and such talent not returning home, this situation then takes away the 'development' from African economies – hence remotely controlling the HE sector and economic development in developing countries.

The South African Network of Skills Abroad (SANSA) is an example. Through its website, it invites professional South Africans to sign up. It reports that at least 22 000 graduates from five major South African universities resident abroad remain in touch with the universities. SANSA estimates that about 60 per cent of the country's expatriate graduates are located in six countries, with Australia, the UK and the US accounting for more than half of them. Looking at the nature of their skills, the group estimates that about 30 per cent of the University of Cape Town's contactable doctoral graduates are living overseas. They comprise significant proportions of the university's graduates in medicine, commerce, education and engineering, all areas in which South Africa has an acute shortage of skills. (Gumisai Mutume, 2003: 1)

This further illustrates that the goodwill of education either within or outside South Africa is not enough in the equation to attract and retain talent. While it has taken the aid community and the government has taken some time to find a solution; there are some pockets of Industrialised countries are in growing need of two types of immigrant labour—those willing to do poorly paid, dirty and dangerous

jobs that their own nationals scorn, and highly specialized professionals, such as software specialists, engineers, doctors and nurses. The US has 126 000 fewer nurses than it needs and government figures show that the country could face a shortage of 800 000 registered nurses by 2020. Because of such shortages, industrialized nations have embarked on massive international recruitment drives. South Africa recently had to appeal to the government of Canada to desist from recruiting its medical professionals. In the rural province of Saskatchewan, Canada, more than 50 per cent of doctors are foreign trained and at least 1 in 5 of the 1 530 doctors there earned in Northern countries is forecast to grow, as younger people are needed to maintain productivity. In poorer countries, millions will continue to seek opportunities in richer countries to find better paying jobs and raise their standards of living. And in a globalizing world, where the dominant economic paradigm promotes the free movement of capital, it will become increasingly difficult to restrict the free movement of skilled labour their first medical degree in South Africa. However, it may become even tougher to stem the outward flow of skilled professionals from developing countries in future. With falling birth rates and aging populations, demand for labour. (Gumisai Mutume, 2003: 4)

The trend now is for western countries to offer wonderfully packaged schemes for teams of African universities to pool their talent to willingly participate in different consortiums, research groups to offer their findings for the 'global' funding agency. Long gone are the opportunities for such agencies to support Africa to develop and retain its own talent. The October 2008 USAID meeting in Kigali to address their African development agenda only promised \$1M for projects with African universities that must include a US university partner institution. This scenario clearly gives the US partner university the upper hand in the relationship.

Even the great idea of several foundations joining hands to deliver bigger and better funding initiatives now runs the risk of being managed as a corporate, with participating foundations taking the role of corporate board members to 'be kept happy', risking the initial intent. The author truly hopes that it can stay true to its founding principles.

Relative Merits of Investing in Institutions Rather than Individuals

At a relatively recent Grant-makers Affinity Group retreat (Johannesburg, South Africa, February 2008), there was a brief discussion on grant-making of institutions or individuals and the relative merits of each. Rather than dichotomizing the issue into institution versus individual,

it was agreed that consideration should be given to what is the most effective means of accomplishing the goal. If one desires institutional capacity building, institutions are more important because funding to individuals may not necessarily lead to institutional capacity building. Moreover, attention to individuals alone will not address the structural issues affecting universities. However, there is need for an interlocking system. Funding individuals is significant because attitudes, behavior, cultures, and traditions shape institutions. When individuals receive scholarships or funding, it changes their perspectives and subsequently affects institutional culture. However, when individuals study abroad and return to their home institutions, too often they find these institutions to be dysfunctional or limited in their capacity to support them and eventually decide to leave. Finally, the decision whether to invest in institutions or individuals is dependent on the availability of funds as investments in institutions are more sizable than in individuals.

Even as the grant makers ponder the institutions versus individuals aspects, the question does arise as to why choose? After all this group cannot be concerned about money when they have put together billions to create this body, for the common good, to pool their resources to make an effective contribution. A decision was not forthcoming; was this because of lack of foresight among the people who really care for developing Africa or was it politics?

In every situation, African institutions do, in some way, be it small, benefit from the different international partnerships and African scholars get the opportunity to study overseas. What the author cannot understand is why the failure to support the grand program or, say, 10 000 post-graduate scholars annually? Why only support a few hundred? Surely this cannot make a difference in one country, much less the whole continent of Africa. Is this the real plan to move forward Africa's economy and for reduction in poverty? Is funding the universities to rejuvenate their faculty, infrastructure, and their capability to increase their capacity to deliver more graduates to support economic growth inconsistent with real capacity development? Do the corporate companies who need the talent to develop their businesses not see the value in making a more meaningful contribution? Surely they do not want their business ventures to fail. Is the author too naive? Does the donor community not see that giving support for more African intellectuals to be home grown will enhance all the other aid programs? Is it a treat, to the funders/developed world, to help Africa to become self-sufficient?

The question is whether the schemes to develop talent are enough? In the author's view, the answer is no; there is a matrix of concurrent activities that must take place. Developing talent without an environment to use such talent and such individuals playing their part in broader society are the missing links. If we develop scholars

and the home institution has no way of attracting and competing with its international counterpart, we do not need to do any fancy research to know the result. The funding agencies need to consider the role they play in supporting talent to leave Africa and should engage in strategies to assist in the retention of talent. Without this shift in the grant-making world, be it philanthropical organizations, the business communities, or the governments, Africa will continue to be controlled remotely by those who purport to be its friends.

While the author presents a window that may reveal grant makers as indifferent to the parallel constraint, she does so with the intention that they will prove her wrong in her observations.

Introduction

Movies such as *Varsity Blues*, *Friday Night Lights*, and *Coach Carter* portray the American socialization of high-school student-athletes who have aspirations of attending college with the common ultimate goal of playing professional sport. Many of the characters in these three feature films prioritize athletics over academics and have an unrealistic understanding of their chances of making it to the pros. These representations of sport and student-athlete focus in American society enable youth, teachers, coaches, and fans to examine the values that sport and society teach through athletics and other cultural organizations (Coakley, 2004).

In American higher education, a greater emphasis is frequently placed on the athletic abilities of student-athletes and the success of athletic teams, as compared to the classroom achievements of student-athletes. The primary purpose of higher education is too often overlooked, and the academic success of student-athletes is too often overshadowed. As high-school and college athletics become increasingly commercialized, secondary and post-secondary institutions are now facing the challenge of addressing an increasing lack of academic productivity among some student populations. Specifically, the student-athlete culture in higher education possesses certain sub-cultures that tend to underachieve educationally (Bowen and Levin, 2003). This issue, compounded by the National Collegiate Athletic Association (NCAA) Academic Reform Movement, requires the creation of new cultural paradigms and educational programs that have the ability to challenge student-athletes to apply a competitive spirit not only on the playing field but also in the classroom and in the development of life skills (Brand, 2003).

A lack of commercial and institutional emphasis on education still remains. This lack of focus on branding and marketing student-athlete academic success permeates into all sectors of high-school and collegiate sport and influences how student-athletes are presented in the media and perceive themselves. To solve some of the problematic issues relating to student-athlete academic performance and motivation, a group of colleagues, all of whom are former student-athletes, created a nonprofit

organization called Scholar-Baller®, which was established in 1995 as a working theory and concept. Scholar-Baller has developed and implemented culturally relevant incentive-based educational programs at the high-school and college levels to help bridge the gap between education, sport, and popular culture, to help reposition the current model of sport in American society and to help create a new mindset among student-athletes in terms of their perceptions about education, sport, and career aspirations.

The curriculum intervention programs and related initiatives developed by Scholar-Baller serve as an excellent example of a marketing platform to reposition student-athletes and to tell true and meaningful stories about their successes on and off the playing field. Scholar-Baller, which is endorsed by the NCAA, recognizes the academic achievements of student-athletes who attain a high *grade point average* (GPA) or who demonstrate significant academic improvement. For some academic institutions who have partnered with Scholar-Baller, marketing and positioning of the student-athletes takes place in part via the display of a uniform patch or a helmet sticker called ThinkMan™ or ThinkWoman™ (see **Figures 1** and **2**), which helps to draw attention to the academic performances of the student-athletes while still allowing the players to demonstrate their athletic skills – truly epitomizing a student-athlete. In addition, Scholar-Baller, in conjunction with the National Consortium for Academics and Sports, sponsors the Academic Momentum Award, which recognizes 16 student-athletes each year for their academic accomplishments. Many institutional partners of Scholar-Baller have begun to market the academic successes of their student-athletes. Images and stories relating to the academic performance of student-athletes can be found in school media guides and on websites of college athletic programs. What follows is an overview of what constitutes a Scholar-Baller as well as further discussion of the Scholar-Baller program.

Scholar-Baller

Dr. C. Keith Harrison, director of the Paul Robeson Research Center for Academic and Athletic Prowess,

Figure 1 ThinkMan™.

Figure 2 ThinkWoman™.

first introduced the term Scholar-Baller in his continued discussion and academic research on Paul Robeson's incredible commitment to education and sport (Harrison, 1995, 1996).

Scholar is a term used to describe an individual who possesses academic prowess or a commitment to education and learning. For example, Paul Robeson, a 1919 graduate

of Rutgers University, possessed the intellectual capacity and political awareness to earn the status of Phi Beta Kappa scholar, valedictorian of his class, and legendary political icon. Robeson represented a scholar on many levels, as he earned his law degree from Columbia University and gave numerous speeches throughout the world.

Baller is an urban term that resonates with individuals of all origins and has taken on global meaning in recent years. In popular culture, baller has been mainstreamed on ESPN, Music Television (MTV), in major newspapers such as USA Today, and in speeches by President Obama. The term baller can be used as a noun, adjective, or verb to signify aspects of achievement or success. For example, an individual who is considered a high achiever in any task or vocation can be labeled as a baller. Many of today's student-athletes view a baller as someone who has gone to the top, won the biggest prize, and who has simply just made it. Ask a room full of high-school or college football players, "Which one of you is a baller?" and nearly all the hands in the room reach sky high. It is a concept student-athletes understand and embrace. Paul Robeson was a baller, as he played professional football and was a renowned actor.

Scholar-Baller essentially means an educated individual who also participates in sport, art, music, or any other extracurricular activity. The Scholar-Baller concept promotes the willingness of students to accept the challenge of harmonizing academics and athletics. At a pragmatic level, Scholar-Baller is about cultivating education, sport, and entertainment consumption into one lifestyle. Any misunderstanding about the term or any uneasiness has come from coaches and administrators who do not identify with young people and what they are into. Dr. Harrison has published numerous articles and book chapters relating to how popular culture (e.g., sports and entertainment imagery) impacts the educational aspirations and perceptions of youth in society.

Scholar-Baller Paradigm: Promoting Critical Literacy Through Engaging Popular Culture with Urban Youth

The Center for the Study of Sport in Society (1997) reported that 66% of African-American male youth between the ages of 13 and 18 stated they perceived that their first career would be as a professional athlete. Another related study found that 48% of African-American inner-city youth responded that hip-hop/rap music is their favorite musical genre. Just over one out of three (34%) of the respondents in that study reported watching 4 h or more of television per day, and 62% of the respondents reported going to the movies two or more times a month. According to the study's findings, urban youth disproportionately

spent their disposable income on the following items: shoes, music, and jewelry (MEE Report, 1993).

Teachers, coaches, and administrators need to be able to interact with today's student-athletes in a culturally diverse and impactful manner that allows the students to be prepared for the next level and for life after sports. Teachers, coaches, and administrators must engage student-athletes and must re-emphasize the importance of education. The message that school is cool must get out to all student-athletes. As those at Scholar-Baller often say, it is imperative that we help "make the cool students smart and the smart students cool."

People in academic circles must know what they teach and why the material is relevant to today's student-athletes. For this to happen, it is essential for educators to identify desired results (i.e., what do we want students to know?), determine acceptable evidence (i.e., what counts as proficiency?), and plan learning and instruction (i.e., what do we do and how do we teach it?). There are a few things that allow learning to be maximized when trying to create a lifelong learner. Course content must be relevant and meaningful. Teachers must also find ways to be engaging and should utilize a variety of teaching styles that incorporate concepts from the sport and entertainment industries.

As utilized by scholars such as Taylor (1999), this concept suggests that sport and athletic principles (i.e., character, determination, perseverance, and commitment) should be applied to academics, which should improve the motivation of student-athletes in the classroom. This motivation for academic excellence is enhanced through utilizing aspects of popular culture entertainment (i.e., music, film, athletics, and the arts) to challenge and motivate student-athletes. Scholar-Baller uses popular culture as a framework to engage and motivate student-athletes. Numerous colleges and universities have implemented the Scholar-Baller curriculum intervention program, which uses DVDs, CDs, social media platforms and other relevant mass media materials that student-athletes already consume and understand.

Implications for Practice: A Collegiate-Level Case Study

Pilot implementation of the Scholar-Baller program began in August 2001 at a major NCAA Division I institution with their football program. Student-athletes on the football team were first introduced to the concept of Scholar-Baller during fall training before the 2001 season. The team was asked how many of the student-athletes considered themselves to be ballers; approximately 85 out of 105 raised their hands. When asked how many of them saw themselves as Scholar-Ballers, only a few raised their hands. The students' responses illustrate the fact that

many college student-athletes who participate in a revenue sport such as football or basketball tend to focus narrowly on their athletic prowess while trivializing their academic and social development.

However, with the introduction of the Scholar-Baller program, it was immediately evident that the concepts, messages, and approach resonated with the student-athletes, in this case those who participated in the revenue sport of football. During the weeks following the initial introduction of the Scholar-Baller program, multiple student-athlete football players approached both the head football coach and the football academic counselor and communicated sincere interest in attaining Scholar-Baller status and recognition. The football student-athletes at this institution were challenged to employ their competitive spirit in the arenas of academics and social development.

A series of strategies were utilized to establish a consistent message that subpar (or even an average performance) in academics was simply unacceptable. Some of these strategies included helping student-athletes examine their social- and self-identities to reinforce that they were complete human beings with a multiplicity of abilities beyond athletics. Student-athletes were exposed to Scholar-Baller icons (i.e., Paul Robeson, Ralph Bunche, Vince Carter, and others) via innovative lesson plans. Academic goals for the football program were displayed in the locker room alongside football goals. In addition, team members engaged in an academic team competition in which groups of football student-athletes competed against each other throughout the school year.

Additionally, the head football coach and assistant coaches embraced the Scholar-Baller concept and soon incorporated it into some of their pedagogical vernacular, including utilizing the term in memorandums and letters to the team during the off-season, encouraging academic excellence during team meetings, and including the term in the school's players manual. More importantly, an incentive and disincentive system was established that rewarded the student-athletes for high performance in the classroom. This same system parallels internally what the NCAA Academic Reform Movement is attempting to do externally with its incentive/disincentive system to increase academic achievement and graduation rates.

At this particular institution, a Scholar-Baller was defined as a person in a given academic year who earned a fall, spring, or cumulative GPA of 3.0 or above. First-year Scholar-Ballers earned a T-shirt. After completion of the academic team competition during the second year of the program, the top three academic teams earned sweat suits that lauded them as "Scholar-Ballers competing in the classroom." Needless to say, the entire Scholar-Baller program was very well received and reinforced that it really was a benefit to compete and perform well in school. Scholar-Ballers were acknowledged by the head football coach at the beginning of each semester, and at the end of

a particular academic term the Scholar-Ballers were rewarded with a steak dinner, hosted by the athletic director. In fall 2004, football student-athletes who achieved Scholar-Baller status were recognized with the ThinkMan logo jersey patch, the first known time in the history of NCAA Division I football that academic prowess had been acknowledged on the jersey of student-athletes.

In the first 3 years that the Scholar-Baller program was implemented (2001–04), there were significant increases in team-cumulative GPA, fall-team GPA, freshman-cohort GPA, and retention rates of student-athletes. For example, retention rates skyrocketed to 80% for the three classes that entered during the first 3 years of the program. The number of football student-athletes earning a GPA of 3.0 rose from figures in the teens in 2000 to 38 in 2004. Another shift occurred with decreases in the number of football student-athletes on probation, which went from five after spring semester in 2000 to zero in 2004. Finally, 33 student-athletes earned B or better averages during the academic semester that coincided with the 2004 football season (see Steinbach, 2004).

Student-athletes in this football program understood from day 1 that they had entered a culture in which it was not acceptable to do the minimum work required to pass classes and remain eligible. Academic excellence became the verbal and written goal of most of the student-athletes. The following are some quotes and narratives from 2004 Scholar-Baller participants (28 football student-athletes) who were interviewed about becoming the first NCAA Division I school to acknowledge academic success on the front of a football jersey:

- It feels good because of the stereotypes that have been set that football players can't be smart but society always changes. Happy to represent [support the program's image and concept] by wearing the patch.
- It feels good to be recognized for something positive. Many people think of football players as dumb jocks so this was a way to prove that they were wrong.
- It gave me something to push for. I feel it is a great honor to wear this patch. The patch is not about separating yourself from others, yet its purpose is to glorify those who work hard in all phases of life. This is a motivation for those who do not have one.

Implications for Practice at the High-School Level

As implied by Scholar-Baller, it is assumed that this paradigm will serve as a resource for academic and athletic success for all student-athletes at any educational institution across the nation. Because this model is currently most widely utilized at the intercollegiate level and has

been proven to be successful, it can be assumed that it would be effective if implemented on a wide-scale level at some of the nation's high schools that are most in need of Scholar-Baller's program and message. However, the model would have to be flexible enough to fit the needs of any interscholastic program in which implementation would take place.

There are many things to consider related to the implementation of the Scholar-Baller program at the high-school level, many of which have already been discussed above. Other aspects to be considered in the implementation process of Scholar-Baller would include the socioeconomic status, ethnic background, demographic region, and overall morale of the students at the particular high school in which implementation of the Scholar-Baller would take place.

The Scholar-Baller implementation process begins with high-school coaches, administrators, counselors, and teachers involved in a life-skills curriculum designed to challenge student-athletes to create powerful visions for their future. The typical curriculum covers content standards such as: (1) self-identity, (2) the competitive spirit, (3) the Scholar-Baller paradigm, (4) purpose/vision/mission and goals, (5) decision-making system, and (6) living the Scholar-Baller way. The goal of Scholar-Baller is to create an environment on high-school campuses that will allow student-athletes as well as other students to view education and athletics as means to success. The Scholar-Baller program empowers student-athletes to be better prepared for the rigors of college and the many challenges that college provides; GPAs will likely continue to increase, and parents will be empowered to support their children not only athletically but also academically. Finally, Scholar-Baller should also help students develop critical life skills and should equip student-athletes with the ability to make positive future decisions relating to career and other aspects of life.

The Scholar-Baller Patch and Related Incentives: The New Badge of Coolness

As mentioned above, the Motivational Entertainment Educational (MEE) Report (1992/93) found that 387 urban youth, ages 13 to 18, spent most of their disposable income on clothes, food, music, shoes, and jewelry. This finding has significant implications. First, urban youth set the trends for popular culture, and hip-hop culture is currently one of the most consumed products and commodities in American society (Boyd, 2004). Specifically, marketing, fashion, language, and urban styles permeate the most mainstream cultural spaces (Simmons, 2002). In addition, athletic identity is a valued status symbol in secondary and post-secondary education. Thus, the desire to be cool often involves the attainment of some of the

material items found in the MEE Report. Through the previously mentioned cultural facts about urban styles and athletics in secondary and post-secondary education, we hope that the Scholar-Baller, ThinkMan, and ThinkWoman logos (see **Figures 1 and 2**) will become a tipping point and trend (Gladwell, 2000) in American culture. This is possible if Scholar-Baller continues to become aligned, associated with, and embedded in social activities and academic programs that today's student-athletes value, understand, and embrace.

The essence of the primary Scholar-Baller logos, such as the ThinkMan and ThinkWoman images, are of a student-athlete sitting at a desk studying – representations that are powerful in their simplicity, with or without additional wording.

These logos, when applied to a piece of apparel, are meant to be a badge of honor that can be proudly worn, a statement of the acceptance of the Scholar-Baller ideals and the related accomplishments made by each individual. The Scholar-Baller logos and their related marks and graphics will continue to evolve with recognition, acceptance, specific individual or team needs, and style trends.

To date, ThinkMan and ThinkWoman have adorned team jerseys, football helmets, polo shirts, sweatshirts, sweat suits, shorts, hats, shoes, coffee cups, duffel bags, dress shirts, visors, and more. For instance, Arizona State University became the first NCAA Division I football team to recognize academic achievement during athletic competition on 2 September 2004. Hampton University and Morgan State University also sported the patch during the New York Urban League classic, becoming the first of the historically black colleges and universities to participate in the Scholar-Baller uniform-patch recognition program. Coincidentally, during the 2004 Vitalis Sun Bowl, Arizona State University and Purdue University became the first bowl teams to recognize academic achievements on student-athlete jerseys based on the Scholar-Baller concept. Finally, one of the historical moments of the NCAA and higher education occurred on 10 November 2006 when Southeast Missouri State University and Tennessee State University became the first two institutions with the same symbol/patch to honor student-athletes for their academic success immediately before an athletic contest; what made this recognition ceremony unique is that both teams interacted with the administration, staff, and the Ohio Valley Conference Commissioner at mid-field.

Much more is planned for the Scholar-Baller logo set, including continued evolution of the base trademarked logos, creation of complementary logos such as the emerging It's Cool to be Smart, AthletesThink, and ThinkKids logos, and development of additional recognition and motivational items. Not only do we want the Scholar-Baller ideals and related curriculum to be

embraced by many, but we also want those that are deemed to be Scholar-Ballers to be able to proudly express this recognition in a variety of ways.

Conclusion and Implications

For over a century, improving the academic success of student-athletes has been a complex challenge for high-school and college educators and administrators. There are major cultural disconnects between the educational, athletic, and entertainment communities in America. This gap and lack of synergy between the three areas impacts the lifelong learning and consumption patterns of student-athletes. Two obvious questions are (1) when did this disconnect begin? and (2) how do we connect education, sport, and entertainment in a constructive way so that student-athletes become intellectually engaged and dedicated to lifelong learning? The disconnect and gap between academics, athletics, and popular culture are poignantly articulated by Coleman (1960) in three powerful narratives. First, speaking of adolescence, Coleman said,

What our society has done is set apart, in an institution of their own, adolescents for whom home is little more than a dormitory and whose world is made up of activities peculiar to their fellows. They have been given as well many of the instruments which can make them a functioning community: cars, freedom in dating, continual contact with the opposite sex, money, and entertainment, like popular music and movies, designed especially for them. The international spread of rock-and-roll and of so-called American patterns of adolescent behavior is a consequence, I would suggest, of these economic challenges which have set adolescents off in a world of their own. (p. 338)

This world of their own often consumes American youth in nearly all cultural forms, except in educational engagement and intellectual development. Student-athletes are especially influenced by and susceptible to the bombardment of messages about material gain based on the athletic and entertainment identity of professional athletes, actors, and musical artists (Gerdy, 1997). What are the effects of a cultural system that reinforces athleticism and not intellectualism? The second narrative by Coleman is key to understanding and responding to this question.

Coleman (1960) continues to frame the incentive and reward system of American education and society by having a vision that

the fundamental change which must occur is to shift the focus: to mold social communities as communities, so that the norms of the communities themselves reinforce educational goals rather than inhibit them, as is at the present case. (p. 338)

Presently, the social communities have learned to consume athletics, material objects, and immediate gratification at such an influential rate that education is overlooked and neglected as a viable option for success (Harrison, 2002). In a Coleman culture the movies, music, video games, and athletic contests would compliment the pedagogy of school systems with competency in reading, writing, and arithmetic (commonly known as the three Rs). This method could easily enhance educational goals instead of inhibiting them – hence, a method that inspires youth to desire learning and intellectual development throughout their lifetime. This leads to the third and final narrative by Coleman.

In the final analysis, Coleman (1960) exposes the bias in American sport and entertainment by indicating the cultural fact that “the outstanding student has little or no way to bring glory to his school” (p. 347) (in comparison to athletics). This is where the Scholar-Baller paradigm may theoretically and practically influence the culture of American sport by ending the silence about the importance of student-athlete academic success. This is an approach we hope will become the new roadmap for success in American higher education. We must continue to inspire youth to excel in education and life by making the most of their cultural interests in sport and entertainment. Having visual evidence such as the ThinkMan logo visible on the uniform and discussions of Scholar-Ballers in print stories, on the Internet, and on television are essential in repositioning high-school and college athletes as student-athletes and ultimately establishing that image as the norm rather than the exception. More middle schools, high schools, and colleges need to implement culturally relevant programs that incentivize and motivate student-athletes to balance playbooks with textbooks.

Postscript: Coach Carter Film Screening

On 13 January 2005, the triangle of success (education, sport, and entertainment) celebrated a collaborative moment of combining influential cultural worlds. Scholar-Baller® and its team of educators, Rush Philanthropic led by Russell Simmons, the *Women's National Basketball Association*

(WNBA) represented by Diana Taurasi, and the NCAA represented by Senior Vice President, Bernard Franklin, all partnered together for a film screening of *Coach Carter* for over 300 urban and inner-city youth in New York City. Educational and critical dialog followed, with a panel and group discussion about the influence of sport and entertainment on the educational aspirations of America's youth.

Glossary

Campus Compact – A national coalition of more than 1100 college and university presidents, who are committed to fulfilling the civic purposes of higher education. Campus Compact provides leadership, resources, and advocacy to support civic education, community building, and campus engagement.

Modern racism scale – The concept of modern racism has also been termed symbolic racism. Symbolic racism is the expression in terms of abstract ideological symbols and symbolic behaviors of feeling that blacks (and other racial/ethnic minority groups) are violating cherished values and making illegitimate demands for changes in the racial *status quo*. The label was changed from symbolic racism to modern racism in order to emphasize the contemporary, post civil rights movement nature of the beliefs and issues.

Pluralistic orientation – The ability to see multiple perspectives; ability to work cooperatively with diverse people; ability to discuss and negotiate controversial issues; openness to having one's views challenged; and tolerance of others with different beliefs.

Project pericles – A not-for-profit organization that encourages and facilitates commitments by colleges and universities to include education for social responsibility and participatory citizenship as an essential part of their educational programs, in the classroom, on the campus, and in the community.

Background and Introduction

There is a common concern among scholars, public officials, and the general public that young adults today are apathetic, uninvolved, and dispassionate. Public perception that college students are increasingly becoming more 'me oriented', has coincided with a general discontent with how colleges and universities are addressing (or failing to address) this concern. Educating, training, and preparing future leaders for many segments of society continue to be the responsibilities of colleges and universities. Hurtado

et al. (2002) report that at college entry students are not exhibiting certain characteristics and understandings, fundamental to life in a diverse democracy (e.g., views about the importance of engaging in social action activities). Thus, the college experience may be a critical juncture in the development of young people into actively engaged citizens, leaving higher education institutions with a gravely important responsibility. In recent years, higher education has been faced with great scrutiny, as institutions have been challenged to be more socially responsible and to produce more socially responsible graduates. Indeed, as the economic and social importance of higher education becomes greater, the public is more critical of what universities are doing and how they are doing it.

Since the 1990s, there has been an increased interest in college students' community and civic involvement and their attitudes toward members of other races and ethnicities. In educating a more diverse student body, colleges have undertaken numerous initiatives to increase student engagement with social diversity in order to achieve desired outcomes. What is known is that meaningful opportunities for diversity exposure and a variety of civic engagement activities/experiences produce individuals who are better able to function in a diverse and global society. Salient approaches to equipping students with the faculty to transform society include civic and community engagement, civic goals and value development, and social issues awareness or democratic sensibilities. The two main areas that researchers focus on to better develop these democratic competencies are diversity related, ranging from diversity coursework to increasing structural representation of diverse groups on college campuses to structured programs on campus created to develop more socially responsible citizens. Examples of these structured programs include the provision of service learning and other community-based experiential learning opportunities. Specifically, the aim is to review the relationship between service learning, multicultural competencies, and subsequent civic engagement and is framed by a larger interest in the role of educational institutions in preparing students to assume the responsibilities of citizenship in a democratic society. Civic engagement is essential to foster in students because it allows them to use their knowledge and values to solve societal problems. Thus, utilizing current research in the sociology of education, this article provides a synthesis of the existing literature on US colleges and universities' roles in producing a civically engaged citizenry who can function

in a diverse, pluralistic society highlighting research that focuses on systematic attention to educating students for such a society.

Diversity Exposure and Preparation for a Diverse Democracy

Racial and ethnic diversity research has received increased attention in the last 20 years. Research on racial and ethnic diversity has been concerned with how diversity experiences affect the quality of the undergraduate experience and, in particular, the extent to which exposure to diversity alters students' appreciation and understanding of different races, ethnicities, and cultures. There is ample evidence of the educational benefits of campus diversity for students and society. In a report filed on behalf of the University of Michigan, Gurin (1999) provided a comprehensive explanation of how diversity enables educational institutions to fulfill their mission by improving student learning, instilling civic virtues, and promoting democratic ideals (Jayakumar, 2007).

Although the 2003 US Supreme Court's ruling in *Gratz v. Bollinger* struck down the method the University of Michigan had used to achieve a diverse undergraduate student body, it did support the educative value of diversity. The court not only affirmed the importance of diversity in higher education, but also reminded us that higher education institutions have a responsibility to train their students to become leaders across a diverse, pluralistic society and that these future leaders should also be diverse.

Thus far, diversity research has been divided into three major strands. These strands are often presented as distinct categories, yet they are best understood in relation to one another. Jayakumar (2007) succinctly organizes and reports these as:

Structural diversity or numerical representation of students of Color as the starting point from which benefits emerge. However, increasing the enrollment of students of Color will not, in and of itself, lead to positive outcomes. A second dimension of diversity is the extent and quality of one's engagement with people of different racial/ethnic backgrounds, called both *interactional diversity* (Gurin *et al.*, 2002) and *cross-racial interaction* (Chang, 1999) in the extant literature. The third component encompasses formal exposure to diverse peoples through curricular and cocurricular offerings, or *classroom diversity*, also referred to as *curricular diversity* (Gurin *et al.*, 2002; Jayakumar, 2007: 22)

This section thus summarizes the literature on the benefits of diversity experiences across the three aforementioned dimensions on students' democratic skills including civic responsibility.

Researchers have found that the structural diversity of a campus is positively related to whether students will socialize with someone of a different race and develop greater tolerance and awareness of different racial/ethnic groups. Although institutional-type variables (e.g., mission, size, selectivity, etc.) show little relation to changes in racial/ethnic attitudes, peer, faculty, and administrator support of diversity issues on campus do lead to students' reports of lower racial tension on campus. Another manner in which the higher education institution can enable change in student attitudes is through attention to the peer and faculty context of the institution. The more the student and the faculty body deem service important and exhibit service commitments and action, the positive net benefits that accrue to the individual student as well. The evidence is rather conclusive, with a few exceptions, that typical characteristics that differentiate higher education institutions (e.g., mission, size, type, selectivity, etc.) do not predict stronger civic competencies reminding the reader that all higher education institutions can and do aid in the development of socially responsible citizens.

Providing opportunities for cross-racial interaction (i.e., dining, classroom, friendships, and studying) also results in enhanced leadership skills, cultural awareness, and civic interest. Several forms of classroom diversity have been evaluated including classroom racial composition, classroom interactions and dialog, and content of the curriculum. The effects of classroom diversity have also been investigated across multiple institutions, particular classrooms within an institution, and single institutional-wide programmatic efforts. Regardless of the approach or the context, all of these studies unanimously support the value of classroom diversity on students' multicultural competencies. In most cases, classroom diversity alone does not appear to maximize the benefits of campus diversity with regard to civic and democracy-related skills unless attention is also paid to the quality of the intergroup relations as that has a deeper impact on democratic outcomes than classroom diversity. Further, in her meta-review of the literature on classroom diversity, Jayakumar (2007) concluded that structural diversity in the classroom, much like at the institutional level, is most beneficial when accompanied by efforts to make the curriculum relevant for all students.

Other campus-facilitated activities to bring awareness and action to social issues and diversity include diversity-oriented workshops. Benefits accrue not only for students of color but also for white students. Additional programmatic factors on campus that impact multicultural competence include curriculum offerings. Analyzing the relationship between freshman to senior-year changes in a student's social activism orientation, Astin (1993) found that enrollment in ethnic and women's studies courses, discussions of racial/ethnic issues with other students, and participation in campus-based racial or cultural awareness

workshops increased students' orientation to social activism and concluded that this was not due to social change or maturation. Who teaches the course may also impact the intended outcomes. In other words, how the instruction is delivered and by whom may be just as important as what the curriculum is. Researchers have concluded that instruction of diversity-related issues by female instructors and instructors of color produce more meaningful changes in students' attitudes.

Civic Engagement and the Development of Democratic Competencies

In addition to the positive benefits of diversity opportunities on civic competencies, the next broad area attended to includes specific engaged learning opportunities that facilitate the development of civic competencies. The emphasis of this section is on how various forms of service experiences lead to the preparation and development of global citizens. The section begins by operationalizing what falls under the term civic engagement and then follows with existing research in the area. Typically, the research in the area of civic engagement practices examines everything from moral development, to cognitive development to understanding of difference. Because this article's aim is to examine higher education's role in developing socially responsible citizens by way of cross-cultural understanding, the research on civic engagement will necessarily be limited to work that examines students' experiences, attitudes, and goals toward pluralistic orientation and democratic ideals and work related to diverse groups and perspectives.

Specifically, experiences that campuses utilize to engender social responsibility and social awareness in students are reviewed here. The previous section presented diversity-related experiences, broadly speaking, while this section presents civic engagement practices such as service learning and volunteerism and campuses' roles in facilitating these opportunities for undergraduates to prepare them to live and work in a diverse society. The primary interest is on civic engagement as an outcome with service or volunteering as the actual process. These are different practices but often used interchangeably in the literature, thus leading to confusion. In the higher education literature, the term civic engagement encompasses a wide range of activities, motivations, and commitments. Traditionally, civic engagement referenced political engagement (such as voting in an election or running for political office); however, today this term has been expanded to include other types of social engagement such as protests, community advocacy, and service learning. Below is a rubric adapted from Astin *et al.* (2006) who identify multiple categories of engagement. This work is not meant to defend what constitutes civic engagement but rather it includes a synthesis

of work that also employs these varied definitions. Again, the ultimate aim is concerned with how college service and volunteer experiences affect students' civic engagement and simultaneously undergraduates' readiness for participation in a diverse society. This could range from out-of-class activities to volunteering to internships.

Astin *et al.* (2006) conceptualize engagement into three broad categories:

1. *Political Engagement.* This includes voting behavior, commitment to political action, and political activism and expression. This article does not focus on the traditional political science view of civic engagement, but it is rather expanded to include other types of service activities that lead to developing competencies for successful participation in a democracy. What we do know about young adults is that they are less likely to vote in elections and possess less political knowledge than older citizens. In fact, when compared to older adults, young adults are less attentive to news, less likely to volunteer for political organizations, and are less likely to contribute money to various causes.
2. *Civic and community engagement.* This includes forms of service learning and community involvement including volunteerism as well as giving of time and money to political and social causes. Service learning is viewed as one form of engaged learning that can enhance the skills and motivation necessary for civic engagement.
3. *Civic goals and values.* This includes pluralistic orientation, self-efficacy, and developing racial understanding.

This section narrows its focus to include how service practices contribute to undergraduates' preparation for and readiness for a diverse and global society.

Young Adults and Civic Participation

Generally, what do we know about civic engagement and what do today's US college students look like? Citizens in general are becoming less involved in community efforts, less likely to take on leadership positions and less likely to participate in traditional political activities. Previous research finds that the period of young adulthood is one of less engagement in civic and voluntary endeavors, compared to other stages in one's life. However, evidence suggests that young adults tend to participate in nonpolitical volunteer work at rates close to those of older adults. In fact, today's college students are increasingly participating in alternative and new forms of engagement, such as buy-cotting (intentionally purchasing a product because of the values of the company), or utilizing media, such as Facebook, to engender social or political consciousness and awareness. Historically, educational institutions have played a fundamental role in cultivating an educated citizenry in a democratic society. In general, the research is unanimous that with increased educational levels so do the

rates of civic participation and many educators and policy-makers believe that civic participation, in particular, is best fostered and increased through student engagement in service learning. Service learning includes a structured service component tied to classroom content. Included in this section is also attention to generic service and volunteering activities as research also demonstrates the positive benefits that accrue even if a formalized classroom component is not attached.

Relationship to Student Attitudes, Values, and Behaviors (During College Years)

This section offers a brief overview of what we have learned about service participation generally, and then it follows with specific attention to service participation's contribution to diverse perspectives and sensibilities. The research evidence is overwhelming regardless if the study was conducted using large, national, databases, single-institution-wide evidence, or small-scale surveys. Further, these results are consistent when researchers use established scales or rely on student self-reports. Finally, the effects of service participation are evidenced over a variety of time measures. That is, whether the outcome was measured during the course, after the semester, at the end of the year, or postcollege. Students who perform service learning show increases in their plans for future civic action, assessments of their own interpersonal, problem solving and leadership skills, and agreement with items emphasizing society factors that affect individual outcomes (i.e., social justice).

Based on a variety of civic participation scales, students score significantly higher on civic participation scales after engaging in a service-learning course and state that service provides them an opportunity for understanding the communities they serve more thoroughly. Over the course of the service-learning experience, students become advocates of community service, become personally and emotionally engaged, learn about their positions of privilege in society, recognize the assumptions that they bring to the class, and strengthen feelings of social responsibility. These findings are confirmed even after controlling for freshmen-year pretests, service propensity, academic major, race, ethnicity, gender, and structural characteristics of the institution. Overwhelmingly, outcomes are favorably influenced by service participation.

In terms of enhancing student learning, the effects of service learning and community service on college undergraduates' cognitive and affective development have also been explored, and it has been found that service participation shows significant positive effects on multiple outcome measures with service participation having its strongest effect on students' decisions to pursue service careers. Most students believe their service made a difference. However, students' degree of interest in the

subject matter was the most important factor associated with positive experiences. Further, both faculty and students develop a heightened sense of civic responsibility as a result of their service experience.

Civic Engagement and Multicultural Competence

We move forward with civic participation and attitudes toward diversity and creating democratic citizens. Students engaged in service work also show increases in their civic responsibility defined as commitment to the life goals of helping others and promoting racial understanding and increases in their life skills which include critical thinking, interpersonal skills, leadership skills, social self-confidence, knowledge of different races or cultures, and conflict resolution skills. Not surprisingly, the more time devoted to service the more positive the effect on students.

Service learning affected students in their awareness and involvement in the community and sensitivity to diversity. Other outcomes related to civic participation that contribute to diversity awareness include an awareness of personal philosophy regarding racial issues and concerns regarding specific multicultural or race-related incidents. Engaging in service also showed reductions in contemporary racism attitudes measured using the Modern Racism scale. Neither political orientation and gender nor race were predictors of change on the Modern Racism scale, suggesting that the learning component of service is more predictive than background attributes and characteristics. Thus, US colleges and universities can structure opportunities for the development of civic engagement regardless of gender or social-class backgrounds.

In addition to the positive benefits that accrue to the students who engage in service participation, positive benefits also accrue for the community agencies and the faculty involved in instructing these courses. Researchers stress the importance of understanding not only the influence of students but also of the agencies in which students serve out their roles. The impact on community agencies was evident in that they perceived an effect on their capacity to serve clients, received economic and social benefits, and were satisfied with student interactions. Finally, faculty members felt that community service experiences could be fertile ground for research and other scholarly work.

This section and much of the literature on civic engagement evaluate within and during college changes. Less is known about the long-term effects. Clearly, sustained skills are important as we expect undergraduates to continue their attention to serving communities. The next section highlights our knowledge of the long-term effects.

Impact on Student Attitudes, Academic Skills, and Behaviors (Long-Term Effects)

Astin *et al.* (1999) show that students who spent 6 or more hours a week in volunteering during their last year of college were almost twice as likely to perform volunteer work after college. Nine years after graduating, the frequency of volunteering still correlated with the amount of volunteering during high school. Volunteering was associated with the following 13 behavioral and value outcomes: attending graduate school, donating money to the undergraduate college, frequency of socializing with diverse people, helping others in difficulty, developing a meaningful life philosophy, promoting racial understanding, participating in community action programs, participating in environmental cleanup, a sense of efficacy, highest degree earned, hours spent volunteering, career preparation, and degree aspirations.

In a recent longitudinal study examining the effects of college service participation on young adults' service participation 4 years out of college, Astin *et al.* (2006) show that participating in service-learning courses and generic service during college appears to have positive effects on postcollege outcomes including working with communities, volunteering, and commitment to political/social change. Unique positive effects of service learning (over and above the effect of generic service) are associated with three postcollege outcomes: civic leadership, charitable giving, and overall political engagement.

Campus Initiatives to Increase Engagement: Why/How Can We Make Civic Engagement More Meaningful

We know service matters, but how do students come to understand diversity in the context of service learning. Findings suggest that it is the importance of relationships that are developed initially through finding common ground and then strengthened as efficacy is enhanced and empathy and compassion are nurtured. A key factor in whether or not service learning has any impact on students appears to be the quality of the experience. The design and quality of service-learning programs play a critical role in determining the effectiveness of these programs. There is overwhelming evidence that service learning and community service influence students' democratic and multiracial competencies. The next section provides research rationales for how and why service and other forms of diversity-related experiences matter. Several factors shape the extent of learning outcomes. The consensus reached is summarized below. First, is the quality of placement or the sense of what the student obtained from their experience as well as the challenge and variety of work performed. Second, the effects of both service learning and generic community service appear

to be mediated in part by the use of reflection. Reflection can take the form of journaling, writing essays, and engaging in formal and informal discussions with peers and faculty. Third, the number of hours spent in service. The more time devoted to service, the more positive the effect on students. Fourth, the degree to which course objectives and content aligned with actual service behavior. In problem-solving interviews, students had the chance to demonstrate their analysis of a social problem linked to their service. Over the course of a semester, students in service-learning classes in which service and academic study were continuously and closely linked showed significantly more change in the complexity of their problem analysis, their assessment of the locus of the problem and solution, and in their critical thinking ability than did students in programs with little linkage between the service option and the course of study or students with no service options. Students in the well-integrated service-learning courses were also more likely to apply subject-matter knowledge to their problem analysis and to have well-developed practical strategies for community action. In both the survey and the single interviews, students reported greater learning when they had higher quality experiences (Eyler and Giles, 1999). Fifth, having diverse perspectives resulted in greater learning for students. Finally, attention to the preparation students receive is important in enabling them to fulfill their service opportunities as the most beneficial learning outcomes occur when students are adequately trained for service.

A small body of evidence finds that mandatory volunteerism can reduce the impact of the positive effects. For this reason, campuses need to stress upfront the learning outcomes and what the expectations are for students to become engaged.

Recommendations for Campuses to Engage More Students

Since we know that students who are more engaged also report greater civic and pluralistic competencies, it is important to offer recommendations for how campuses can create or bolster environments to engage more students.

The content, skills, pedagogy, and structure that should guide the design of service-learning curricula for multicultural citizenship education are highlighted below. For service learning to teach youth about their responsibilities as citizens in a democratic society, content and strategies must model and support democratic principles. Battistoni (1997) and others offer some recommendations of ways to institutionalize and prioritize service and diversity on campus.

1. *Involve faculty.* Faculty members are important because they teach the courses that can prepare students for

- civic roles. Thus, it is important for faculty members to connect their work to community issues through the application of their research. Checkoway (2001) stresses the importance of faculty involvement and of diversity in renewing the institution's civic mission. Faculty should establish collaboration with students to allow the sharing of ideas that may lead to establishing new methods for solving problems. By working in groups, students develop the ability to work with a group to "analyze a problem, plan and implement a strategy, and work with others to evaluate results" (Schneider, 2001).
2. *Increase institutional capacity.* Capacity can be increased by creating collaborations with communities. Service-learning programs, if planned and executed correctly, benefit both the community and the institution. By creating learning partnerships both communities and universities benefit: communities are provided with consultation and students are given the ability to engage in the real world and learn from practice. Service learning serves to meet both the objectives of class courses and community needs. Campus-community partnerships are conceptualized as relationships that must maintain effective communication and a clear purpose. In order for campuses and communities to develop partnerships that benefit both students and communities, both must develop and maintain healthy relationships through a clear mission, compatibility, effective communication, and skilled staff.
 3. *Connect democracy and diversity.* Diversity must be recognized and implemented in education so that students can learn to respect and work with a diverse America. Students should interact with diverse groups, as diversity provides them with the ability to understand, communicate, and collaborate with multicultural groups. This can be accomplished by engaging students in research projects that address important issues.
 4. *Offer service-learning curricula.* Students should be involved in service-learning courses in which they serve the community and learn from experience. Institutions should also create academic courses/programs that discuss such issues. By adding new courses (i.e., cultural studies, gay and lesbian studies, and peace studies), institutions can engage students to think about issues that are prevalent in society. Hands-on programs that are combined with academic courses can establish connections between scholarly and applied knowledge. Who teaches the course may also impact the intended outcomes. In other words, how the instruction is delivered and by whom may be just as important as what the curriculum is.
 5. *Provide cocurricular service opportunities.* Students should be involved in cocurricular activities with a strong civic purpose. Integrating service into student clubs and organizations reinforces the importance of service to others.
 6. *Encourage residential living.* The available evidence also recommends residential living. The size of the impact varies but the evidence does suggest that exposure to 'others' influences understanding of others and openness to diversity. The most dramatic effects not surprisingly occur in students who live in residence halls designed specifically to address social issues and themes related to multicultural understanding.
 7. *Establish a permanent institute for education for democracy.* This is a forum for research dissemination and learning from other campuses and organizations.
- Another important component to civic engagement to consider is the relationship to policy making and understanding. The organization Campus Compact has a goal of involving students in various agencies so that they can understand "what it takes to be successful in influencing policy." Campus Compact integrates academics and hands-on experiences with the hope of creating civically engaged students. Campuses that do not collaborate with a national organization have helped students create strong relationships with one or two organizations in their local community. By emphasizing student volunteerism, campuses hope that students will help the social conditions of the communities while simultaneously gaining a better understanding of society. Caputo (2005) also argues that faculty and administrators must support the civic engagement efforts of their institutions. Project Pericles stresses civic engagement on the part of an institution's board of trustees and faculty. By engaging the institution as a whole, students can have easier access to activities and projects on campus and in their communities that lead them to develop their civic engagement. Regardless of the approach used, institutions should expect certain goals. These goals include: (1) increasing the number of individuals who are engaged in policymaking and debates; (2) ensuring that students have a clear understanding of the effects of their participation in policy making; (3) as students learn about and participate in their communities they should want to become civically engaged later in life; and (4) increasing civic engagement should lead to the development of stronger public policies which in turn should reinforce engagement and democracy. In order to achieve these goals Caputo (2005) lists the following recommendations: institutions should emphasize civic engagement from the first year through the last year, students should receive more applied experience (i.e., through an internship), and students should be allowed to participate in group projects so that he or she can acquire leadership skills.
- The development of successful partnerships is an effort of community leaders, students, and faculty. If the goal of the university is to institutionalize service learning, the following are additional areas to consider: creation of a service-learning committee; development of clear mission

and goals for on-campus service learning; educating faculty members regarding the benefits of service learning; generation of enthusiasm among student body; educating the community and community agencies about the potential benefits of service learning; and continued outreach to all areas of campus and community by distributing information regarding current service-learning projects (Merger and Brungardt, 2007).

Conclusion

This article can help to revitalize higher education's mission in preparing a diverse student body, merge research and practice in the effort of meeting the campus needs, and assist campuses in overcoming a student culture of disengagement to cultivate citizenship for the future. Institutional research can play a pivotal role in coordinating the curricular and cocurricular activities that enhance the campus-wide efforts to improve students' preparation for a diverse democracy. For example, institutional researchers can examine student enrollment, funding, and diversity of academic programs to determine the institution's readiness to prepare students for a pluralistic society. As our national community diversifies, institutional researchers must create partnerships with administrators and faculty to assure that students can emerge as active participants in a diverse democracy.

The research evidence reviewed reaffirms the role of service learning and diversity in fostering civic engagement because it encompasses learning and teaching, leads to additional forms of civic engagement, and involves students in meaningful activities that address common issues.

As Boyer (1997) remarked, scholarship of engagement has meaning at two levels: (1) connecting the university's rich resources to the most pressing social, civic, and ethical problems, making it the staging ground for action; and (2) creating a climate in which academic and civic cultures communicate more continuously and creatively, enlarging the universe of human discourse and enriching the quality of life for all.

Success and Failure in Education and Criminal Justice: Identifying Common Mechanisms

S Ramirez and A Harris, University of Washington, Seattle, WA, USA

© 2010 Elsevier Ltd. All rights reserved.

The aim of this article is to investigate links between academic failure in the United States educational system and incarceration in the United States criminal and juvenile justice systems. From a sociological perspective, we focus in particular on the disproportionate dropout and incarceration rates among young people of color in high school and prison, respectively. The purpose is to highlight current research that speaks to the obvious – yet little understood – link between the two institutions, and to shed light on related mechanisms that produce racial disparities and negative outcomes. One glaring piece of the pipeline linking these two institutions that has had little attention is the phenomena of alternative schools. These schools are public programs which provide individualized educational options for students, many of whom have been expelled from mainstream schools. Much of this article reviews research investigating these unconventional programs and discusses how alternative schools can both lead to educational failure and criminal justice embroilment.

Recently, the United States Department of Education highlighted the fact that the United States has had the highest high school graduation rate ever at 85%. In 2003, the total graduation rate for adults aged 25 and above was 85%, and among this same-age population, 27% had college degrees. However, we see varying completion rates by racial/ethnic groups. Among whites, the graduation rate was 89%, African-Americans it was 80%, and among Latinos the rate was 57% (US Department of Education, 2007).

It is important to note that if we do not include other types of credentials for high school graduates in these statistics (such as General Educational Development (GED) degrees), the graduation rates by racial/ethnic group are much more bleak. A recent analysis was conducted that estimates graduation rates for 1998 (Green, 2001). This investigation includes only those individuals who received high school diplomas and is based on the number of students enrolled in public schools in eighth grade, thus accounting for high school dropouts. The study estimates a 71% completion rate among United States high school graduates, compared to the National Center for Education Statistics that show an 86% graduation rate for the class of 1998 (Greene, 2001). Furthermore, the study finds that among white students the high school completion rate was 78%, while it was 56% for

African-American students, and 54% for Latino students. State-level differences among the racial/ethnic categories varied dramatically. For example, African-American students had the lowest graduation rate at 40% in Wisconsin, yet had a 71% graduation rate in West Virginia. The lowest graduation rate among Latinos was 32% in Georgia and peaked to 82% in Montana (Greene, 2001).

In contrast, the point is that traditional measures for generating high school education statistics ignore both the dropout rate, as well as obfuscates the number of students who are not receiving high school credentials through traditional schooling channels. Furthermore, the traditional measures do not indicate (nor include in their calculations) the relatively high dropout rate among students of color. For example, the 2003 dropout rate among whites was 6.3%, and was 10.9% for African-Americans, and 23.5% for Latinos (US Department of Education, 2007).

At the same time we see these racial/ethnic disparities in graduation and dropout rates, we see even more dramatic disparities in juvenile and criminal justice conviction and incarceration rates. As of 2001, it is estimated that there were 5.6 million US adults (2.7% of the adult population) who served time in state or federal prison (BJS, 2003). The prevalence of imprisonment was higher for African-American males (16.6%) and Latino males (7.7%) than for white males (2.6%). Of those in prison in 2001, 64% were people of color (nonwhite). The lifetime chances of a person going to prison are highest among African-Americans (18.6%) and Latinos (10%), than for whites (3.4%). An even more dramatic figure is that estimates show that one out of every three African-American men will be sentenced to state or federal prison in their lifetime (Travis, 2005).

Several questions are raised by these statistics. What is leading to the relatively high dropout rate among youth of color? What does the pathway look like for students who take a nontraditional route to receiving high school credentials (via alternative school programs and GED programs)? What are the mechanisms that lead to the bleak incarceration prospects for African-Americans? Are the mechanisms that lead to failure in the educational system similar to those that lead to selection into the criminal justice system?

We know that there is a direct relationship between education and incarceration. For example, among men born between 1965 and 1969, 3% of whites and 20% of

African-Americans served time in prison by their 1930s. Furthermore, among this population 30% of those without a college education and nearly 60% of high school dropouts went to prison (Pettit and Western, 2004). This trend appears to be consistent among more recently incarcerated populations as well: of those in state prison facilities in 2001, only 57% had a high school diploma or its equivalent (BJS, 2003). Furthermore, schooling has been found to significantly reduce the probability of incarceration and arrest (Lochner and Moretti, 2004).

Thus, individuals who fail at education – either by dropping out of school, or by not continuing on to higher education – have much higher likelihoods of having contact with the criminal justice system and of being incarcerated. However, what is less clear are the mechanisms that create this linkage. Research has shown dramatic negative consequences for individuals from decreased wages (Western and Pettit, 2005), unstable families (Uggen *et al.*, 2005), loss of citizenship rights (Manza and Uggen, 2006), and health-related problems (Travis, 2005). Thus, it is increasingly important that research turn toward identifying factors that connect the two institutions and produce the disparate outcomes.

The remainder of this article investigates research focusing on the mechanisms that may link the United States educational and criminal justice institutions. We begin with a discussion of the reciprocal relationship between the two systems – how failure in one leads to failure in the other, and vice versa. More specifically, we move to explore alternative or probationary schools – common options for youth who have had disciplinary or learning problems in mainstream schools. We conclude with a discussion about future research that should be explored to further our understandings of the linkages between education and incarceration.

The Link between Education and Incarceration

The juvenile justice system was originally intended to provide rehabilitation in the way of schooling, work experience, and vocational skills to wayward children who were engaging in delinquent behavior or were at risk for child abuse and neglect (Platt, 1967). Despite this noble intent to provide guidance and education to such children, evidence suggests that youth under the supervision of the juvenile justice system, upon reentering society actually have lower performances in school, experience high dropout rates, and thus have limited opportunities for employment in their transition to adulthood.

For example, as contact with the justice system increases, the performance in math and reading decreases (Hirschfield, 2004). Furthermore, first arrests have unclear effects on grade 7- and 8-level math and reading

scores, but the chances of having to repeat grade 8 sharply increases. First arrests which occur in grade 9 not only decrease school performance in reading and math, but also increase the likelihood of dropping out of school or of greater instances of truancy. For those children who experience detention or incarceration or who are arrested multiple times, drop in school performance, likelihood of truancy, and dropping out are experienced at even higher rates. Most likely spending time away from school during a stint of detention, or having to attend court hearings likely explains why it is easy for these children to fall behind. However, such evidence suggests that a justice system originally meant to deter future behavior actually decreases the chances of being able to succeed in school after a youth's first arrest.

Just as involvement in the justice system is an indicator for poor school performance, low school performance is also a significant predictor of future delinquency or more serious criminal behavior. It is well documented in criminological literature that school is an extremely important socializing institution for children in adolescence (Warren, 2000). Research indicates that irregular school attendance and school behavioral problems are a good predictor of delinquency as well as recidivism for youth (Sieverdes and Cunningham, 1977). Indicators such as school performance and involvement in school are even better predictors of delinquency than measures of self-control and deviant peer pressure (McGloin *et al.*, 2004); these measures of school performance are also important in predicting future criminality (LeBlanc, 1994).

In sum, prior research suggests that not only school performance is a significant predictor of delinquency and future criminal behavior, but also involvement in the justice system decreases the ability for adolescents to succeed in school.

School Dropouts

Similarly to research on school performance, research on youth who drop out of school reveals interesting implications for the relationship between the educational system and the criminal justice system. Early signs of delinquency in the form of drug use are associated with high school dropout rates as well as other adult life-course markers experienced at an early age, such as teenage pregnancy. In turn, dropping out of school increases the risk of drug and alcohol use, especially for males.

It is important to note that dropout rates tend to affect specific social groups, such as those living in poverty. For example, dropout rates for children living on public assistance have dramatically increased over the past 10 years (Orthner and Randolph, 1999). Transitions off welfare and consistent parental employment decrease the risk of dropping out of school. Such evidence suggests that there are implications for the relationship between poor

or incomplete schooling and the most impoverished segments of society.

Together, evidence from research on the role of school, dropping out of school, and low school performance suggests that not only is involvement in school an important factor for delinquency and future criminality, but also that initial delinquency and involvement in the juvenile justice system does not promote success in future educational achievement. Furthermore, consequences of this nexus between the justice system and education system seem to be exacerbated for people of color (namely African-Americans and Latinos).

Race-Specific Consequences

Sociologists have well documented the disproportionate trends in sentencing and other justice-outcome processes for people of color (Krisber, 2005). African-Americans are overrepresented in almost every area of the criminal justice system, including arrest, likelihood of being adjudicated delinquent, severity in sentence types, probation restrictions, and violations (Leiber, 2002). In addition, Bridges and Steen (1998) find that probation officers' construct attributions differently for black and white youth. In an analysis of probation narratives, they found that probation officers were more likely to rely upon external reasons to explain white youth's delinquency, such as parental involvement, influence of drugs, and peer pressure. In contrast, probation officers relied on internal characterizations to make judgments about African-American youth's offending, such as having low self-control or poor character. In turn, these attributions had substantially different justice consequences for the two groups of youth.

Along similar lines, recent work suggests that youth of color experience hyper-criminalization in the juvenile justice system. For example, Rios (2006) found that Latino and black youth experience sentences common for violent offenders even for nonviolent offences. Rios suggests that this stigma translates to other institutions such as the educational system. Thus, even in institutions built to nurture youth, youth of color experience a racialized socialization process.

Similarly to the justice system, within the educational system, indicators illustrate that youth of color experience poor performance disproportionately to white youth. Katsinas (1989) finds that in Illinois, higher education has an under-enrolment of Latino youth that results from extremely high dropout rates of 60%. Katsinas also suggests that the dropout rate is influenced by socioeconomic status and lack of Latino teachers. These results are even more exaggerated for Mexican immigrants who achieve only 50% of the educational levels of their native-born counterparts and non-Latino whites. In addition, Mexican immigrants are 300–400% more likely to drop out of school (Charvez, 1989).

Harris and Allen (2003) show that similar patterns exist for African-Americans. In an analysis of the link between the overrepresentation of black youth in the justice system and underrepresentation of black youth in education, Harris and Allen show that African-Americans represent only 8% of high school graduates in California; furthermore, only 27% of these graduates completed the required coursework for college eligibility. In addition, Maralani (2006) finds that those with a GED certification rather than a traditional completion of a high school diploma are less likely to go to college. While Maralani (2006) does not specifically talk about racial disparities, given what we know that youth of color are more likely to drop out of school or have less success in high school, and thus may have to rely on nontraditional ways of completing a high school equivalent education such as the GED certificate, this link between the justice system exposure and educational exposure may help explain the under-enrolment of youth of color in higher education. This is likely to have implications for future employment as youth make the transition out of school and into the workforce.

Overall, literature on educational failure points to some common elements that may explain why youth of color have a disadvantage for school success. Specifically, research suggests that youth of color do not receive as much support in school as their white counterparts due to the lack of opportunity to attend quality schools. Furthermore, schools with high percentages of youth of color tend not to have the necessary resources for a well-rounded education, nor do these schools have culturally appropriate curricula or ethnically diverse teachers (Hirschfield, 2004; Katsinas, 1989; Habteyes and Steinkamp, 1985).

Not only do school experiences in general seem to negatively impact youth of color, but also zero-tolerance policies for inappropriate conduct in school generally target youth of color (Johnson, 2003). Such policies, which automatically punish students for a host of school infractions, have also been found to disproportionately punish youth of color. Some argue that this is because youth of color are more likely to be disproportionately involved in bad school behavior. However, Johnson (2003) argues that socioeconomic status underpins this disproportionality. Regardless, zero-tolerance policies increase the rate of high school dropouts and thus the proportion of youth of color involved in the juvenile justice system.

Alternative/Probationary Schools

How schools deal with students identified as discipline problems has had limited attention in sociological literature. However, the presence of alternative schools is important in any discussion regarding the link between educational failure, involvement in the justice system, and how these institutions disproportionately disadvantage

youth of color. Alternative schools were first seen as an option for parents to have their children educated. These schools were looked to as alternatives for students to specialize early on in certain subject areas, work at their own learning levels, and explore learning in a more hands-on manner. However, today, alternative schools are often used as a holding area for children deemed difficult by traditional school staff. The following section outlines some of the literature about alternative school education and how they may be an important link between educational failure and involvement in the justice system, incarceration, and future criminal behavior.

Alternative or probationary schools have typically been framed as institutions which provide an avenue for parents and school systems to manage difficult students. These students are typically disruptive in a traditional school setting and/or are in transition from juvenile detention. These schools were thought to be useful in curbing juvenile crime (Gottfredson, 1987) given that these schools would provide disruptive children with a more supportive environment.

While there is no standard format for alternative school programs, common elements include low student-teacher ratios, individualized self-paced instruction, non-competitive performance assessment, and less-structured classrooms (Cox, 1999). These elements allow for a more individualized approach to student learning that was thought to improve school attendance, motivation for school instruction, and school performance. While these alternative programs are available to all students in public school systems in the United States, scholars have argued that these programs become a dumping ground for disruptive children that traditional schools find difficult to handle (Cox, 1999; Lehr Lanners and Lange, 2003).

Mixed Results about Effectiveness

Evidence for the success of alternative school programs in increasing school performance, motivation for school involvement, and decreasing involvement in delinquent activities has been mixed. Early evaluations of alternative school programs provide little evidence that these programs have any positive effect on delinquency or school performance for students. Raywind (1981) found that the lack of improper effects were a result of school officials using these alternative programs as punishment for students who were uncontrollable in traditional classrooms. More recent analysis suggests that improvement in school performance was short lived for students at an alternative school program. Cox (1999) finds that students in an alternative school showed marked improvement in school grades, school attendance, and self-esteem; however, at a 1-year follow-up, these effects did not remain. Cox also finds no evidence that the alternative program had any

observed effect on attitudes toward school or delinquent behavior.

Some research has suggested that alternative schools do well in their ability to discipline and train students for lower aspirations. Duke and Perry (1978) find that alternative school staff are less likely to rate behavior problems as a major school issue compared to traditional school counterparts. Further, they suggest that these schools markedly improve problem behavior and school performance in youth enrolled in alternative schools. Furthermore, a recent ethnographic study (Inderbitzen, 2007) found that school staff at one alternative program attempted to refocus students' conceptions of success and aspirations to something more achievable. Specifically, these students were taught to aim low for opportunities that were more consistent with what educators felt was more appropriate and realistic. While this case study may not be generalizable to other alternative programs, these findings indicate that important questions should be asked about the long-term trajectories for delinquency, criminal behavior, and future employment for youth involved in alternative school programs.

Research on alternative schools and their students is limited in sociological and criminological literature. As such, we know very little about the affect these alternative school programs have on delinquent youth or at-risk youth in educational outcomes, propensity for further delinquent behavior, or transition to adult roles in employment. However, consistent in both academic literature and high school evaluations is that alternative schools are perceived as a dumping ground for students who are labeled as uncontrollable in the traditional school system and those who are involved in delinquent activity. As such, alternative schooling might be perceived as punishment rather than an alternative opportunity to become an educated citizen.

For example, annual reports from one alternative school in an urban school district in Washington State suggest that in all academic performance indicators, students in the alternative schools performed well under the state standard for academic performance. For example, in 2004, 48.6% of students in traditional schools performed at the state standard for grade 10 reading ability, while only 28.6% of students in the alternative high schools met the state standard. Similar patterns can be observed for mathematics. These results are based on the Washington State Assessment for Student Learning (WASL) administered to eighth and tenth graders. The alternative schools also reported lower number of Scholastic Aptitude Test (SAT) test-takers and graduation rates than traditional schools in the same district (Seattle Public Schools Annual Reports, 2007). Demographic information on the alternative high schools suggests that a typical student is African-American, not living with both parents, enrolled in a reduced or free lunch program, and almost

Table 1 Performance indicators for WA alternative and traditional schools percent meeting state standards for WA State WASL

	Year	District (%)	Traditional (%)	Alternative (%)
Reading	2007	81	79	52
Writing	2007	84	83	54
Mathematics	2007	50	52	15
Science	2007	36	33	8
Dropout rate ^a				
	2005	29	18	62
	2006	28	15	54
	2007	28	17	57
Graduation rate ^b				
	2005	70	83	35
	2006	69	86	39
	2007	63	76	27
Students of color ^c	2007	58	59	71
Number of schools	2007	17	12	5

^aBased on all students who enrolled since 2002 who expected to graduate in 2005, 2006, and 2007.

^bDoes not include students transferred to other schools.

^cIf students do not meet standards in 12th grade they will not graduate (first class 2010).

50% of the enrolled students have been placed in special-education curriculum (Seattle Public Schools Annual Reports, 2007). **Table 1** compares the percent of students meeting state performance indicators at a tenth-grade level between traditional and alternative schools, and dropout and graduation rates. Among the alternative schools, rates are considerably lower for performance indicators, graduation rates, and dropout rates than for traditional schools.

To conclude, Rios (2006) suggests that the juvenile justice system is an intermediary between school and future criminal behavior and as such, schools play a vital role in the trajectory of youth toward criminal careers. Disproportionately, people of color have been ensnared in the juvenile and criminal justice systems, suggesting that when certain schools, such as alternative ones, become a holding area for youth of color with actual or perceived behavior problems and, possibly, current justice system monitoring, further justice system involvement and educational failure are likely to persist.

Common Mechanisms

Clearly, a link exists between youth's experiences in the educational system and experiences in the justice system. Juveniles who fail or have difficulties in school are more likely to experience some kind of supervision from the justice system such as probation or detention

(Hirschfield, 2004). In addition, failure in school is a well-known predictor of future delinquency and/or criminal behavior (Hirschfield, 2004; Krohn *et al.*, 1997). Conversely, those who have experienced justice system supervision are less likely to be able to succeed in school (Hirschfield, 2004; Rios, 2006). These youth may have to turn to alternative methods of receiving high school equivalent education such as GED certification, or may be forced to attend alternative schools rather than traditional high school programs.

At this time, there is not enough evidence to demonstrate a causal link between failure in one institution and failure in the other; however, with an examination of the common mechanisms within the two systems, we gain understanding on how these two institutions are related and also why youth of color are overrepresented in the justice institutions and underrepresented or are failing in educational institutions. This has important implications for future behavior, success, and other life-course stages of children and young adults.

At the very least, the above review shows that common to both failure in school and criminal/juvenile justice outcomes is the quality of schooling that programs such as alternative schools may be providing students. This is particularly important for students of color, and students who have been placed in alternative education due to delinquency or a lack of success in traditional school.

Furthermore, young adults' attachment to conventional institutions and norms may be mechanisms linking the two institutions. For example, dropout rates are significant for students from low socioeconomic families. Perhaps these students are encouraged to drop out from school in favor of taking up paid employment in order to support family income. In sociology, two differing perspectives on early work experienced dominate the literature. First, some argue that early work experiences (as a part-time job while still in school) are beneficial by building confidence and responsibility, thus aiding the transition from adolescence to adulthood (Staff, 2005). Conversely Paternoster *et al.* (2003) argue that teenage work experiences remove children from school and thus make them more vulnerable to delinquency by placing them in low-skilled jobs with little stability and security. Not only do these students become more vulnerable to delinquency but also vulnerable to other problem behavior and future criminal behavior (Paterneoster *et al.*, 2003). Assuming that high school dropouts leave school and find some kind of employment, legitimate or illegitimate, Paternoster's (2003) argument may illuminate an important link between delinquency, school participation, and the transition into adulthood, especially where perpetuating deviant behavior might be concerned.

Involvement in the juvenile justice system may be a risk factor in and of itself for school dropouts since justice system requirements take children out of school. Court

appearances and detention remove youth from school from both short and extended periods of time and therefore disrupt educational involvement. Control theorists might argue that high school dropouts have a weak commitment and attachment to school as a socializing institution and thus it is not surprising that these youth are at a higher risk for delinquent involvement (Hirschi, 1969).

No discussion about the link between education and the justice system can be complete without noting the trends in government funding to these institutions. Western *et al.* (2003) argue that while states spend more on education than corrections in general, the growth in spending rates have favored spending on corrections and legal systems rather than education. For example, from 1977 to 1999, funding for corrections has increased by 946% and funding for the legal system has increased by 1518%. In contrast, funding for education has increased only by 370%.

Discussion and Conclusion

Clearly, rates of low school performance, quality of available education, and high dropout rates affect students of color disproportionately. At the same time, the association of high rates of youth of color represented within the justice system cannot be ignored. Yet, sociologists and criminologists have not given the apparent reciprocal link between education and incarceration and justice system involvement much attention. Not only is it clear that educational failure is associated with involvement in the justice system, but detention and incarceration as well as arrest as criminal justice supervision are also associated with future educational failure. Ironically, the juvenile justice system was designed to rescue wayward children and reform them into valuable citizens for society; yet, mounting evidence suggests involvement in the justice system impedes adolescents' ability for future success.

Very little sociological or criminological research has been done on alternative school programs. If students in alternative schools perform academically lower than traditional schools, it is unlikely that these programs promote further educational achievement such as completing a high school diploma, or admission into higher education. Therefore, how much do alternative schools perpetuate the disproportionate rate of people of color in the criminal justice system? While education seems to play an important role for avoiding incarceration and gaining employment, might not the quality of education also play a role?

International Perspective

As sociologists, we must be careful in assuming that other nations have experienced the extent of discrimination

toward people of color that has become part of the socialization process in the United States. However, it is clear that there are lessons to be learned about how education systems and justice systems influence each other and may be able to work together in order to combat social inequality, discrimination, and widespread social problems.

Similar trends in low school performance have been found in the UK and Australia, suggesting that these indicators are also closely linked to delinquency, teenage pregnancy, drug use, and future criminal behavior (Dwyer and Wyn, 2001). In particular, Australian Aboriginals have experienced high dropout rates and high incarceration rates, especially in rural areas where aboriginal communities are concentrated (Palmer, 1999; Michalos and Orlando, 2006).

In order to amend discriminatory practices within the justice system for people of color, the UK, Australia, and New Zealand are using or currently experimenting with new ways to do justice (Consedine, 1999; Braithwaite and Mugford, 1994). In particular, restorative justice practices that involve more participation on behalf of the offender's family, victim, community members, and teachers are designed to provide a different experience of social control for groups in society that have experienced adverse outcomes and extreme consequences, such as suicide and other forms of mental illness, and failure in education and employment (Grabosky, 1998).

Restorative practices such as these may provide one way for closer collaboration between justice institutions and educational institutions, especially for youth of color. If teachers do provide motivation for success in school and quality of education as research suggests (Cox, 1999; Backstrom, 2004), having offenders and teachers involved in justice system outcomes may provide necessary motivation to continue to engage or reengage them in education and thus help contribute to less-frequent contacts with police and detention (Weidjers and Duff, 2004).

In another example, post-apartheid South Africa has made several changes to the availability of basic social institutions such as education to ethnic minorities. However, because of such widespread and deep-rooted discrimination practices of the past, cities and communities still remain quite segregated and thus quality of education and involvement in the justice system are still experienced disproportionately for South African blacks (Marx, 1998). As such, given the trends and research discussed here, sociologists might expect a similar relationship between educational failure, high dropout rates, and justice system involvement in South Africa that is disproportionately experienced by people of color. Consequently, future policy might explore the possibility of a closer working relationship between educational systems and branches of criminal justice.

The History of Education: Race and Education

J O Jewell, Loyola Marymount University, Los Angeles, CA, USA

Introduction

Historically, schools have been viewed as both the object and the means of struggle between groups, facilitating the social control of various populations while simultaneously embodying the potential to ameliorate various types of social inequality, such as class, gender, and race. In the case of those social systems structured by race, the distribution of educational opportunities has tended to be shaped by a durable but malleable racial structure. The current body of social science literature on education focuses on the role that schools played in reinforcing and legitimizing hierarchies of race through a variety of means including, but not limited to, curricular choices, patterns of organization, and policies governing school funding.

What Is Race?

Race is best understood as the complex set of social meanings ascribed to real or perceived phenotypical and/or cultural differences among human populations that generate the unequal distribution of valued resources. Among scholars who study race and its impact upon human societies, three general principles guide current research. First, within social systems structured by race, all social actors are familiar with and subjected to racialized schemes of classification, systems of belief, and cultural strategies that tend to construct and reproduce racial meanings over time. Second, the socially constructed nature of racial categories and its accompanying meanings, evinced by sociohistorical variations and shifts in the number and composition of racial categories, mean that actors and groups of actors have a vested interest in either maintaining or substantially rearticulating racial identities. Third, the pervasive and entrenched nature of racial hierarchies in social systems means that they interact systemically and frequently as structures with other hierarchical systems such as class, ethnicity, gender, and sexuality, with which they are deeply articulated and in ways that mutually construct and reproduce their existence over time.

Schools as Raced Spaces

Scholarship on race and education contends that racial hierarchies are frequently reflected in the distribution of

educational opportunities. However, a more recent body of scholarship posits that within racialized social systems, schools operate as raced spaces, in which students are actively assigned to racial categories which have significance for the content of school experiences and the broader social context in which those experiences take place. As such, schools are implicated in the construction and ongoing maintenance of racial hierarchies. In the late nineteenth and early twentieth centuries, the growth of the educational system in the United States occurred within a context of large-scale change to the nation's racial structure due to rapid industrialization, urbanization, foreign immigration, westward expansion, and emancipation. These changes generated extensive debate about how, to what extent, and in what social context children from various racial groups should be educated (Fass, 1989; Spring, 2004; Tyack, 1974).

African Americans, who were considered chattel property until the late nineteenth century, were almost totally excluded from educational access. In the postbellum South, educational access for blacks became a primary issue as its outcomes would affect not only the chances of African Americans for mobility within a new economic and political regime, but also the future of the South as a region. Conflicts among those who wished to maintain blacks' subordinate social position and those who desired educational opportunities commensurate with full and equal citizenship were common in this period. Ultimately, despite the efforts of blacks and their progressive white allies, those who advocated for limited access in racially separate institutions held sway for nearly more than a century. In the north, state-sanctioned practices of *de facto* segregation, in which blacks were concentrated in schools that received fewer economic and physical resources, had much the same result, effectively limiting black economic and occupational mobility.

Native peoples, long seen as both cultural and physical obstacles to nation building and modernization, were targeted by the mission agencies of religious bodies with an educational program designed to supplant native cultures with that of the Anglo-Protestant majority. Native-American education became a primary focus with westward expansion in the mid- to late nineteenth century. Americanization or civilization of native children continued through a system of boarding schools that functioned as total institutions – teaching vocational skills while eradicating native culture. These institutions grew in number in the late nineteenth century, numbering 25 federally

funded off-reservation schools in the continental United States and more on-reservation community schools which employed the Americanization curriculum until 1928. However, educational opportunities remained limited as late as the 1970s.

Asian Americans, who had come to the Western territories in large numbers since the 1840s, experienced similar treatment. Initially, no educational provision had been made for the children of Chinese, Japanese, Korean, and East Indian laborers, leaving them dependent upon voluntary or community efforts or the missionary agencies of various religious bodies. In 1885, the California Supreme Court's decision in *Tape vs. Hurley*, which gave Chinese Americans access to the public schools of California, was modified that same year by the State legislature with an emergency provision that established separate schools for children of Mongolian or Chinese descent. Twenty years later, the San Francisco School Board created separate schools for Chinese, Japanese, and Korean students that persisted until the 1960s.

Mexican Americans, who found themselves incorporated into the United States as a result of international warfare, also experienced various forms of exclusion owing to both ideologies of race and culture. Seen by the new Anglo-American English-speaking power structure as cultural outsiders of indeterminate racial status, patterns of segregation similar to that experienced by blacks and other minorities emerged. In 1855 and 1870, California and Texas, the two largest states with Spanish-speaking populations, passed laws requiring that English be the sole language of instruction in all public schools. This later enabled the state-sanctioned establishment of separate schools for all students of Mexican descent on the grounds that their cultural peculiarities might hinder the educational progress of native-born Anglo children. As with blacks and other groups, these Mexican schools were often deprived of material resource and employed limited curricula geared toward vocational training. This Americanization plan to erode cultural differences and place Spanish-speaking populations within the US racial hierarchy would subsequently include migrant laborers and refugees from Mexico and later Puerto Ricans with the annexation of the island after the Spanish–American War.

The successive waves of European immigrants, who came to the United States in the late nineteenth century, prompted various types of reactions from the Anglo-Protestant majority. Those coming from Western Europe, who shared some degree of familiarity with Anglo-Protestant culture were seen as culturally (though not always intellectually) compatible with the nation's educational institutions and encountered little separation that was not a voluntary attempt on their part to preserve language and culture in the face of structured Americanization (read assimilation). By contrast, those who came from countries in Southern and Eastern Europe, Catholics and Jews in

particular, were seen as threats to the cultural homogeneity of the United States and were often subjected to exclusionary practices in schooling with limited educational opportunities.

The state-sanctioned unequal distribution of political resources, such as the vote and citizenship rights along racial lines, undermined the ability of racial minorities to secure public education and influence educational policies, ultimately contributing to educational disparities between groups. However, these populations continued to find ways to influence educational policies and to improve access to educational resources. As the state gradually conceded to the demands of these populations for access to schooling that would at the very least Americanize the other, those who perceived the education of racial minorities as a threat to white social and political dominance relied upon the use of ideologies that constructed these populations as innately inferior and best suited for subordinate places in the economy, often performing low-wage or manual labor. As a result, blacks, Mexicans, Native Americans, Asians, and some European immigrants were cast as moral and intellectual inferiors, whose educational content and conditions required high levels of external control and spatial separation.

Race, the State, and the Distribution of Educational Opportunities

The distribution of educational opportunities and resources by the state, in the form of assigning students to particular schools and making material resources available to schools serving various populations, has historically been structured by class and race. Although the processes by which educational opportunities and resources are distributed may shift over time, and they may operate differently in varying social contexts, their end result has been maintenance of durable systems of inequality. What follows is an examination of these mechanisms as they relate to the construction and maintenance of racial inequality.

Racial Segregation

In those US states and territories with large concentrated populations of immigrant, domestic, and colonized minorities, it was common practice to assign children to schools on the basis of race. Despite residing in communities where they often represented significant parts of the population, racialized minorities could never assume that they had the ability to control their educational destinies – neither in choice of curricula and teachers nor the availability of school facilities, or the length of the school term. In the case of the United States, although segregationist practices existed in some form or fashion in various regions of the country directed against Asians, Native Americans,

Mexican residents of the conquered Western territories, and African Americans (Adams, 1997; Anderson, 1988; Iber and De León, 2006; Nakanishi and Nishida, 1995), they were given legal backing in the US Supreme Court's 1896 ruling in *Plessy v. Ferguson*, which under the separate-but-equal doctrine allowed states to effectively separate access to educational resources on the basis of race. Even in those states where it was not codified in law, *de facto* practices or social conventions sanctioned the practice, facilitating the unequal distribution of symbolic and material resources. Although the ruling stated that the resources provided to each racial group must be equal, few, if any, legal enforcements were typically made to ensure and maintain equality between schools.

Nevertheless, minority populations used these segregated institutions with varying degrees of success to challenge racial inequality, producing activist leadership who petitioned the state for change. This was especially true in the Southern United States, where for nearly a century the racially segregated private and publicly funded colleges and universities for blacks also fostered the growth of a black leadership class that figured largely in the struggle for racial equality (Jewell, 2007). For this reason, local and state authorities often maintained a close watch on the curricular and extracurricular activities of students within such institutions, withholding financial and other resources as a method of social control.

Intelligence Testing

In the late nineteenth and early twentieth centuries, multi-ethnic and multiracial states continued to justify the unequal distribution of educational resources along racial lines using new, scientifically imbued mechanisms of inequality. The growth of scientific racism and the popularity of the eugenics movement fueled the development of standardized examinations, which claimed to objectively measure cognitive ability and learning potential. As the twentieth century progressed and educational systems expanded due to industrialization, urbanization, immigration, and imperialism, these instruments were considered to be effective tools for organizing public schooling (Fass, 1989; Kliebard, 1995; Spring, 2007; Tyack, 1974; Tyack and Cuban, 1995). Despite their claims to universality, however, such tests typically reflected contemporary racial and cultural biases, having been developed by native-born white elites (see Young, 1922; Binet and Simon, 1916). Not surprisingly, these tests tended to label the children of racialized minority populations as intellectually and/or morally deficient, and in need of distinct types of instruction best carried out in separate educational facilities. As an alternative to separation between schools, minority children could be and often were placed in separate classes or curricular tracks in the same schools on the basis of their

perceived ability. Within these classes, they were prepared for positions in the economy as low-level or menial workers.

Race and Educational Reform

Desegregation

State-supported racial segregation in schools lasted for nearly 60 years, during which time minority populations lagged behind whites on most indicators of educational progress. In the mid-twentieth century, the United States Supreme Court, as a result of continued legal challenges to state and local practices of segregation and the findings of social scientists, decided unanimously in *Brown v. Board of Education of Topeka, Kansas* (1954) that the practice of segregated schooling was not only unconstitutional, but also inherently damaging to children with dire effects for society as a whole. The ruling in the *Brown* case forced widespread reassessments of the ways in which educational opportunities had been made available for racial minorities. Similar cases concerned with the detrimental nature of separate or hierarchical schooling on other minority groups both preceded and followed *Brown*, including *Mendez et al. v. Westminster School District of Orange County* (1946), *Delgado v. Bastrop Independent School District* (1948), and *Cisneros v. Corpus Christi ISD* (1971), which addressed Mexican Americans and other Latinos; *Lau v. Nichols* (1974), which dealt with the issue of bilingual instruction for Asian Americans; and the 1969 publication of *Indian Education: A National Tragedy – A National Challenge* by the US Senate Committee on Labor and Public Welfare, which examined the failings of education offered to Native Americans (US Senate Committee on Labor and Public Welfare, 1969). The ruling in the *Brown* case and the subsequent reexaminations of the American educational system it inspired called attention to the complex effects of race on academic access and achievement. The Elementary and Secondary Education Act of 1965, in which schools with a significant proportion of poor or disadvantaged students received additional federal monies, grew out of the concerns expressed in the *Brown* case.

Perhaps one of the most influential works of social science research in the immediate post-*Brown* era was *Equality of Educational Opportunity* by Coleman *et al.* (1966), sponsored by the US Department of Health, Education, and Welfare, to evaluate indicators of educational opportunity among white and minority students (blacks, Puerto Ricans, Mexican Americans, Asian Americans, and Native Americans) by assessing educational quality in terms of the availability of curricula, school facilities, academic practices, and the academic characteristics of teachers and student bodies in schools. Among Coleman's chief findings was that while persistent and unequal separation by race was found to be detrimental as per the Supreme Court's ruling in *Brown*, it was the combination of the socioeconomic

composition of the school, the familial and socioeconomic background of the students, and the nature of their peer groups together that accounted for the majority of the differences observed in academic achievement between white and minority schoolchildren. Racial integration alone, Coleman and his associates concluded, could not improve the academic performance of poor minority children. The effectiveness of these findings in dismantling racial segregation was, however, limited due to continued institutionalized resistance on the part of many state governments and local districts and the common focus on the *de jure* segregation common in certain parts of the country. As a result, the *de facto* segregation that had been practiced in the Northeastern and Midwestern states remained largely unaddressed.

The Post Civil Rights Era and Market-Based Reforms

Race and legacies of racial inequality continued to inform educational reforms long after the end of the Civil Rights Era. Influenced by the findings of the Coleman Report and other studies which took a dim view of compensatory education, neoconservative reformers sought to remedy race and class achievement gaps through what they described as a focus on standards and accountability, and an application of market forces to education. The publication of *A Nation at Risk*, which marked what some consider the end of liberal hegemony in American education, cited generally lower rates of performance among American schoolchildren and a persistent achievement gap by race and class as proof of the failure of liberal reforms which had tried to address inequalities stemming from race and class.

Many scholars contend that racial inequalities of a previous era continue to be perpetuated within and between schools. Patterns of residential segregation, in which whites leave racially mixed urban districts for homogeneous suburban ones, continue to influence the distribution of educational resources and opportunities. Within racially mixed schools, minority students often find themselves tracked into low-performance courses on the basis of perceived ability using newer versions of the standardized tests that have become *de rigeur* in assessing educational ability and outcomes. Rather than continuing to search for governmental solutions for failing urban schools, where the majority of African-American and Latino students are concentrated, the parents of poor and minority schoolchildren are encouraged to exercise their rights as consumers of public education and to improve their educational prospects by leaving failing schools and choosing those schools (whether public, private, or charter) with demonstrated levels of achievement. The 1994 Improving America's Schools Act (Public Law 89–10) also endorsed the establishment of charter schools

as means of improving teaching and student performance. This pattern of reform has greatly expanded under the 2002 No Child Left Behind Act (Public Law 107–110). NCLB has as its expressed goal to close the persistent race and class gap in educational achievement using legislative guidelines for the use of Title I funds rather than increasing the amount of federal support for public education.

Conclusion

The American educational system's foundations, as an unequal system rooted in hierarchies of race, have both inspired and limited attempts at reforms that seek to remedy the long-term effects of these inequalities. Over the course of the twentieth century, the expansion of the nation's educational system has been implicated in the ongoing construction and maintenance of a racialized social system through a variety of mechanisms, including physical separation, curricular differentiation, and unequal funding. The efforts of minority populations, both immigrant and domestic, to address these inequalities through self-help, petitioning the state, and activist traditions were central in effecting reform, but were often limited by the efforts of state and local bodies to preserve privilege within these hierarchical systems, demonstrating that schools are both the source and the means of effecting inequality in racially stratified systems.

PREFACE

A preface usually provides a brief introduction to a work, intended to set the stage, provide some background insight, and whet the appetite of the reader. In our case, however, this preface has to address a fundamental question, one that was in our minds at the time we were recruited as Editors-in-Chief for the International Encyclopedia of Education. The question was “Why do we need an Encyclopedia? Its subtext was inspired by the ever-growing, ever-popular Internet. We believe that *this* Encyclopedia is desperately needed and will become a valued resource in education and associated social sciences and arts. The reasons are intellectual and procedural. Anyone with a modicum of knowledge knows that finding and trusting information gleaned from the Internet are two separate actions. The reliance on browsers to help discover references and comments result in resources based on popularity not quality. Pithy titles catch the eye and references rise in the ranks of browser searchers. Related to this is the “editing” in the Internet realm of populist efforts at encyclopedia, references, and other compilations. Once again, after removing offensive material, the accuracy, completeness, lack of bias, and other provenance for entries simply do not exist. Experienced researchers in education can sort through and make intelligent choices. Novices and many journeyman, or practitioners, parents, and policy makers cannot. Contrast how this Encyclopedia was built. Key domains of educational research were identified, and a tentative list of sub-domains or useful applied areas was posited. Then the Editors-in-Chief (apologies for the awkwardness of the term) identified the leading researcher in a particular domain, and with surprisingly little effort, recruited them to participate. They in turn identified the two best researchers in a sub-domain, such as formative assessment or the training of pre-school teachers. The authors of the sections of the Encyclopedia do not represent a collective group of friends and acquaintances, although friendships have been made. Rather they embody a deep and broad scholarly community. The difference from compiled Internet resources is the built-expertise and intellectual engagement of the authors. The summary of the developments and futures in their personal areas of scholarship have been filtered through their years of experience, both as scholars and communicators. Quality, then, is endemic to each piece, developed through this top-down identification of expertise, and made indelible by the bottom-up application of high standards from people leading the sub-domains – the authors, and the domains themselves, the section editors.

On a procedural level, the publishers early committed to the notion that this Encyclopedia would also be an online resource, and access would be available through print, for those with strong bookcases and the persisting love of turning real pages. The Internet version will allow multiple prisms through which the reader may access articles and provide, as it were, an emulation of the Internet in our field, albeit bounded by expertise and high quality.

What must be underscored in the assessment of this effort are the Editors-in-Chief and the publishers’ commitment to find excellence worldwide. We tried very hard to persuade notable scholars from all parts of the world to make contributions. Less than to fulfill the title of “International,” we were on the hunt for perspectives that would enrich the scope and depth of the sections. Our section editors put in enormous time attempting to find the best in the field, wherever they resided. Yet, not everyone is in the volume. Some were overcommitted. Many were not fully confident of their English, and the automated translation software has not yet met standards for technical writing. We believe that such writing and editing tools will make the outreach to an even broader International group of scholars possible in future revisions, or online updates. Furthermore, the birth of the World Educational Research Association (in 2009) will provide a better set of interlocking networks to find and evaluate scholarship from any place on the globe.

Finally, the scope of the effort must be acknowledged: 28 section editors, 926 articles were commissioned, drafted, reviewed, redrafted, edited, and put together in the space of four years. The publishers underwent some internal changes, and alterations in management. We as Editors-in-Chief, changed roles, moved, and also had to keep our own research and development enterprises afloat. Deadlines wobbled; authors dropped from view and had to be replaced.

Yet, at times frustrating as all development is, we find the final product exhilarating. We are enthusiastic not simply because it came into being at all, but because the collective light of the minds that wrote have left a bright resource for the future, one that will impact the way our colleagues understand and experience the educational knowledge, improvement, and impact in the future.

HOW TO USE THE ENCYCLOPEDIA

The International Encyclopedia of Education is intended for use by students, research professionals, and interested others. Articles have been chosen to reflect major disciplines in the study of education and common topics of research by academics in this domain. Each article serves as a comprehensive overview of a given area, providing both breadth of coverage for students, and depth of coverage for research professionals. We have designed the encyclopedia with the following features for maximum accessibility for all readers.

The contents of the encyclopedia are arranged alphabetically by section, and within sections, alphabetically by article. The Subject Index is located in Volume 8. Some topics are covered in a multitude of articles from differing perspectives, while other topics may have only one entry. We encourage use of the index for access to a subject area, rather than use of the Contents list alone, so that a reader has a full notion of the coverage of that topic.

The articles include cross-references to other related encyclopedia articles, suggested further readings where applicable, and many contain relevant websites for additional information. We encourage readers to use the cross-references to locate other encyclopedia articles that will provide more detailed information about a subject.

The Further Reading sections include recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research articles that are considered of primary importance to the understanding of a given subject area are also listed. These suggested further readings are not intended to provide a full reference listing of all material covered in the context of a given article, but are provided as next steps for a reader looking for additional information.

VOLUME 1

A

Adult Education

Adult Education Overview	<i>K Rubenson</i>	1
--------------------------	-------------------	---

Adult Education – Adult Learning, Instruction and Program Planning

Adult Learning	<i>S B Merriam</i>	12
Adult Learning and Instruction: Transformative Learning Perspectives	<i>P Cranton</i>	18
Adult Learning in a Biographic Perspective	<i>L West</i>	25
Adult Learning, Instruction and Programme Planning: Insights from Freire	<i>P Mayo</i>	31
Characteristics of Adult Learning	<i>K Illeris</i>	36
Informal Learning: A Contested Concept	<i>P Hodgkinson</i>	42
Organizational Learning	<i>P-E Ellström</i>	47
Program Planning	<i>A L Wilson and R M Cervero</i>	53
Workplace Learning Frameworks	<i>S Billett</i>	58

Adult Education – as a Field of Study

Class Analysis in Adult Education	<i>T Nesbit</i>	64
Gender Analysis	<i>J Stalker</i>	70
Race and Ethnicity in the Field of Adult Education	<i>J Johnson-Bailey and D Drake-Clark</i>	77
Trends in Workplace Learning Research	<i>T Fenwick</i>	83

Adult Education – Concepts

Lifelong Learning	<i>J Field</i>	89
Rewriting the History of Adult Education: The Search for Narrative Structures	<i>B J Hake</i>	96

Adult Education – Domains and Provision

Adult Basic Education: A Challenge for Vocational Based Learning	<i>R Höghelm</i>	102
Adult Literacy Education	<i>L Tett and R St.Clair</i>	107
Citizenship and Immigrant Education	<i>D Schugurensky</i>	113
Community Based Adult Education	<i>B Connolly</i>	120
Continuing Professional Education: Multiple Stakeholders and Agendas	<i>R M Cervero and B J Daley</i>	127
Financing of Adult and Lifelong Learning	<i>Å Sohlman</i>	133
Labor Education	<i>K Forrester</i>	139
Learning Cities and Regions	<i>C Duke</i>	144
Museums as Sites of Adult Learning	<i>R S Grenier</i>	150
Overview of Lifelong Learning Policies and Systems	<i>D-B Kwon and C H O Daeyeon</i>	156
Popular Adult Education	<i>S Tøsse</i>	162
Provision of Prior Learning Assessment	<i>P Andersson</i>	169
The Age of Learning: Seniors Learning	<i>P Jarvis</i>	175
University Adult Continuing Education: The Extra-Mural Tradition Revisited	<i>M Slowey</i>	183

Adult Education – Economy and Society

Adult Education and Civil Society	<i>J Crowther and I Martin</i>	191
Adult Education and Nation-Building	<i>S Walters</i>	198
Economic Outcomes of Adult Education and Training	<i>A Ferrer and W C Riddell</i>	204
Health and Adult Learning	<i>P Bélanger and M Robitaille</i>	211
Modernization Processes and the Changing Function of Adult Learning	<i>H S Olesen</i>	217
The Political Economy of Adult Education	<i>G Rees</i>	223
Wider Benefits of Adult Education	<i>R Desjardins and T Schuller</i>	229

Adult Education – Participation

Barriers to Participation in Adult Education	<i>K Rubenson</i>	234
Participation in Adult Learning	<i>R Desjardins</i>	240

C**Comparative Education**

Comparative and International Education: English-Language Scholarly Publications	<i>D Post and M Fedri</i>	251
Comparative Education: Philosophical Issues and Concepts	<i>M Mason and C W Evers</i>	257
Comparative Education: Societies and Associations	<i>M Bray</i>	266

Curriculum Development

Curriculum and Religion	<i>C Kapitzke and P Graham</i>	272
Gender and Curriculum	<i>J Marsh</i>	277
Local Teacher-Based Curriculum Development	<i>M D Osborne and H B Barker</i>	283

Curriculum Development – Contexts

Curriculum and Human Rights	<i>C Lohrenscheit</i>	287
Curriculum and the Education of Cultural and Linguistic Minorities	<i>S May</i>	293
Curriculum in Postcolonial Contexts	<i>A Hickling-Hudson</i>	299
Curriculum, Economic and Cultural Development	<i>A Rampal</i>	307
Globalization and Curriculum	<i>R Dale</i>	312
Popular Culture	<i>K Schultz and R Throop</i>	318

Curriculum Development – Evaluation and Research

An Overview of Research in Curriculum Inquiry	<i>F M Connelly and S J Xu</i>	324
Curriculum Evaluation: Approaches and Methodologies	<i>V Klenowski</i>	335
Curriculum Studies, Discourse Analysis, and the Construction of Historical Time	<i>J Laspina</i>	342
Curriculum Use in the Classroom	<i>M Ben-Peretz and B Eilam</i>	348
The Roots and Routes of Teacher-Based Action Research and Curriculum Inquiry: An Historical Perspective	<i>L G Putney and J L Green</i>	355

Curriculum Development – Planning and Development

Curriculum and Syllabus Design	<i>A Woods, A Luke, and K Weir</i>	362
Curriculum and the Publishing Industry	<i>J Larson, A-R Allen, and D Osborn</i>	368
Curriculum and Teacher Change	<i>J G Ladwig</i>	374
Curriculum Governance and Planning	<i>B Levin</i>	379
Curriculum Planning and Systems Change	<i>Z Deng</i>	384
Curriculum, Digital Resources and Delivery	<i>Y Zhao, G Zhang, and C Lai</i>	390
Textbook Development and Selection	<i>P Shannon</i>	397

Curriculum Development – Subject Matter

Curriculum and Globalization: Higher Education	<i>K H Mok</i>	403
Curriculum Development as Subject Matter: Social Studies	<i>J Brophy and J Alleman</i>	411
Curriculum Development in the Area of Reading	<i>C L Madda and T E Raphael</i>	415
Curriculum in the Arts	<i>C M Thompson, L Bresler, and T E Costantino</i>	423
Curriculum: Foreign Language Learning	<i>Angel M Y Lin</i>	428
First Language Learning	<i>T Rogers and L Moffatt</i>	435
Learning a Second Language in First Language Environments	<i>E Bernhardt and D J Tedick</i>	441
Literature	<i>S Hynds</i>	447
Mathematics	<i>B Kaur and C P Vistro-Yu</i>	453
Physical Education and Sports	<i>D Kirk</i>	459
Primary and Elementary/Middle Grades Reading	<i>D E Alvermann and C A Mallozzi</i>	464
Science	<i>Y Kali and M Linn</i>	468

Curriculum Development – Theory

Bilingual Learning (Learning L1 and L2 in an L1 and L2 Environment)	<i>D Schwinge</i>	475
Curriculum and Complex Systems Theory	<i>W-M Roth and J Thom</i>	481

Curriculum and Constructivism	<i>B Davis and D Sumara</i>	488
Curriculum and Critical Theory	<i>L Yates</i>	494
Curriculum and Poststructuralist Theory	<i>J L Miller</i>	499
Curriculum and Structuralist Sociology: The Theory of Codes and Knowledge Structures	<i>J Muller and J Gamble</i>	505
Curriculum Reform	<i>R Gilbert</i>	510
Early Childhood Curriculum and Developmental Theory	<i>S M-Y Lim and C Genishi</i>	514

D

Demography and Social Change

An Evaluation Framework for E-Learning Effectiveness in the Arab World	<i>W AbuSneineh and M Zairi</i>	521
Globalization and Social Justice in Higher Education	<i>E Kimura-Walsh</i>	536
Racial Inequality and the Economic Payoffs of Higher Education	<i>S A Lachtman</i>	542
School Health Education	<i>J S Yang</i>	547

Demography and Social Change – Demography

A Paradigm of Contradictions: Racism and Science Education	<i>B A Brown and J W Mutegi</i>	554
Africana Studies: Past, Present And Future	<i>B R Hare, A Young, J B Stewart, and D P Aldridge</i>	565
Beyond Black Nationalism to Black Internationalism: The Compelling Case for Examining Black Educational Challenges Globally	<i>K Freeman</i>	573
Beyond Racial, Ethnic, and Gender Bias in Education Statistics	<i>J T Lott and C Bennett</i>	581
Caste and Education in India	<i>G G Wankhede</i>	589
Demography, Community, and the Education of Asian American and Pacific Islander Students	<i>R T Teranishi</i>	595
Educational Attainment and Mortality Differentials	<i>H D Horton, L Hixson, and S M Monnat</i>	602
Educational Opportunity and Latino/Chicano College Choice: New Findings, and Theoretical Perspectives	<i>M A Ceja and P A Pérez</i>	610
Ethnic Minority Identity and Educational Outcomes in a Rising China	<i>G A Postiglione</i>	616
Ethnic Studies and Women's Studies: From the Past to the Present, Providing a Space in the Academy for Scholarship Focused on the Histories and Experiences of Marginalized People	<i>C A Brown</i>	623
Gender Equity in Higher Education: Challenges and Celebrations	<i>L Morley</i>	629
Locating Space and Place in the College Access Debate: New Tools for Mapping and Understanding Educational Inequity and Stratification	<i>B Cantwell and J F Milem</i>	636
Public Policy and Inequality in Postsecondary Opportunity: Educational Statistics and the Failure of Education Reform	<i>E P St. John, K Williams, and K Moronski</i>	649
The Education of Indigenous Students	<i>J W Tippeconnic and S C Faircloth</i>	661
The Health Advantages of Educational Attainment	<i>G Y Dinwiddie</i>	667
To Go or Not to Go: Access and Barriers to Ethnic Minority Participation in Higher Education within the United Kingdom	<i>P Brug and T L Oliver</i>	673
Universal Secondary Education and the Two-Tiered School System in the English-Speaking Caribbean	<i>P Anderson and J Devonish</i>	679
Women of Color in Science, Technology, Engineering and Mathematics (STEM): Refining the Concepts, Reframing the Issues	<i>C B Leggon</i>	686

Demography and Social Change – Social Change

Educational Diversity in U.S. Law Schools	<i>C E Daye, A T Panter, W R Allen, M E Deo, and L F Wightman</i>	691
Educational Reform	<i>F Lopez-Segrera</i>	698
Emergence of For-profit Higher Education	<i>X Li</i>	705
Engaged Education: Experiential Learning, Intensive Field Experiences, and Social Change	<i>T R Rone</i>	711
Higher Education and Social Change in Mexico	<i>A Mungaray, G Estrella, P Moctezuma, and M Ramírez-Urquidy</i>	719
The Changing Role of the State in Higher Education	<i>K Gürüz</i>	728
The Role of the State in School Reform: Responding to Increasing Ethnic Diversity in Britain	<i>P Ratcliffe</i>	737
Transforming Mindsets Through Education for Sustainable Development	<i>V M Segovia</i>	746

Demography and Social Change – Sociology

Achievement Motivation in Ethnic Minority Youth	<i>S Graham and E Bryant</i>	753
Affirmative Action and Higher Education in Brazil	<i>J T dos Santos and D M Queiroz</i>	760
Black in White: Black Students at White and Black Colleges	<i>L Evans and J R Feagin</i>	767
Bologna Process: On the way to a Common European Higher Education Area	<i>A V Rezaev</i>	772
Critical Race Theory in Education Research	<i>R Vue and C B Newman</i>	779
Cultural Diversification and Japanese Education: Social Constructions of the New Diversity	<i>R Tsuneyoshi</i>	787
Education in War Countries: A Disempowerment of Society	<i>J L Nkata</i>	793
Educational Attainments of U.S. Black Males and Females: 1971 to 2003	<i>F B Bonner, M-C Jipguep-Akhtar, and R J Harrison</i>	799
Educational Preparation: Fostering the Self-Efficacy and Resilience of Urban Adolescent Youth	<i>M B Spencer and B Tinsley</i>	806
HIV Education for Low-Literate People: Transforming Students and Communities through Paulo Freire's Praxis and the Pedagogy of Action	<i>N Z Haniff</i>	814
How Are Discussions of Interdisciplinary Studies Linked to Diversity Discourse?	<i>C N Spence</i>	823
Identifying Patterns of Doctoral Attrition Across Academic Fields	<i>A James, K J Fosnacht, E B Stolzenberg, and D Thirumalai</i>	827
Male Underachievement in Education Across the Globe: A Shift in Paradigm for Gender Disparities Regarding Academic Achievement	<i>J F L Jackson, J L Moore III, and R A Leon</i>	838
Noncognitive Measures for Higher Education Admissions	<i>W E Sedlacek</i>	845
Peace Education	<i>J Page</i>	850
Remote Control: Africa's Development and Outflow to Developed Nations of Technical Talent	<i>F Haniff</i>	855
Scholar-Baller®: Student Athlete Socialization, Motivation and Academic Performance in American Society	<i>C K Harrison, S Bukstein, J Mottley, E Comeaux, J Boyd, C Parks, and D Heikkinen</i>	860
Service-Learning and Diversity as Mediums to Foster Civic and Community Engagement in Undergraduates	<i>L Oseguera</i>	866
Success and Failure in Education and Criminal Justice: Identifying Common Mechanisms	<i>S Ramirez and A Harris</i>	874
The History of Education: Race and Education	<i>J O Jewell</i>	881

VOLUME 3

Education of Professionals

An Overview of Accreditation, Certification, and Licensure Processes <i>J J Norcini and M van Zanten</i>	1
Educating America's Military Officers <i>M H Adamshick</i>	7
Education for Architecture in the United States and Canada <i>S Schreiber</i>	13
Education for Medicine <i>M B Anderson</i>	19
Education for the Legal Profession <i>J W Wegner</i>	25
Education of Clergy <i>D O Aleshire</i>	31
Framing Professions Education <i>P S O'Sullivan</i>	37
Issues in Accounting/Business Education <i>W H Gijsselaers and R G Milter</i>	39
Professions – Engineering <i>J Heywood</i>	45
Professions – Health-Related <i>G M Jensen and C B Royeen</i>	51
Professions – Pharmacy <i>D E Beck</i>	58
Teaching for the Complex Practice of Nursing <i>P Benner and M Sutphen</i>	65
Veterinary Education <i>K M Edmondson</i>	71

Education Research Methodology: Quantitative Methods and Research

Abductive Research Methods <i>B D Haig</i>	77
Field Experimentation in Education <i>M A Constan</i>	83
Internal Validity <i>M H Clark and S C Middleton</i>	90
Methods for Approximating Random Assignment <i>B Schneider and S-K McDonald</i>	97
Methods for Approximating Random Assignment: Regression Discontinuity and Propensity Scores <i>L M Scheier</i>	104

Multitrait–Multimethod Designs	<i>M Bong and S Hong</i>	111
Multivariate Longitudinal Data Analysis	<i>H Liu and L Chang</i>	120
Quasi-Experimentation: Two Group Design	<i>E Hong</i>	128
Regression Discontinuity Designs	<i>A Kelava, S Rohrmann, and V Hodapp</i>	134
Sampling	<i>R S Brown</i>	142
Statistical Conclusion Validity	<i>P L Busk</i>	147
Survey Research Methods	<i>A Fink</i>	152

Educational Assessment

An Overview of Educational Assessment	<i>M James</i>	161
Assessment and the Evaluation of Institutional Effectiveness	<i>S M Thomas</i>	172
Assessment in Schools – Dispositions	<i>R D Crick</i>	181
Assessment in Schools Related To Literacy: Reading	<i>K J Topping</i>	189
Impact of Assessment on Students' Learning Strategies and Implications for Judging Assessment Quality	<i>M Segers, F Dochy, and D Gijbels</i>	196

Educational Assessment – Assessment Activities

Alternative Assessment	<i>G Stobart and C Gipps</i>	202
Classroom Assessment Tasks and Tests	<i>J Phelan and J Phelan</i>	209
Dynamic Assessment	<i>J G Elliott, E L Grigorenko, and W C M Resing</i>	220
Instructional System Provided Feedback	<i>H F O'Neil, S Chuang, and T Huang</i>	226
Peer and Self-assessment	<i>C Harrison</i>	231
Portfolio Assessment	<i>V Klenowski</i>	236
Records of Achievement: Beyond Traditional Tests	<i>P Broadfoot</i>	243

Educational Assessment – Assessment in Domains

Assessment in Higher Education	<i>D R Sadler</i>	249
Assessment in Schools – Affective Domain	<i>M Ventura, R D Roberts, and M Zeidner</i>	256
Assessment in Schools – Creative Subjects	<i>T E Costantino and L Bresler</i>	262
Assessment in Schools – Learning to Learn	<i>A Hautamäki, J Hautamäki, and S Kupiainen</i>	268
Assessment in Schools – Literacy Writing (Extended)	<i>J M Parr and L Earl</i>	273
Assessment in Schools – Mathematics	<i>M Brown and J Hodgen</i>	279
Assessment in Schools – Oracy	<i>A L Bailey</i>	285
Assessment in Schools – Primary Science	<i>W Harlen</i>	293
Assessment in Schools – Secondary Science	<i>J Shemwell, A Fu, M Figueroa, R Davis, and R Shavelson</i>	300
Assessment in Schools – Technology Education and ICT	<i>A Jones, B Cowie, and J Moreland</i>	311
Assessment in the Early Years	<i>M J Drummond</i>	316
Assessment in the History, Civics and Social Studies Domains	<i>P G Avery</i>	323
Assessment in the Workplace of Performance, Developing Expertise and Competence	<i>A J Brown</i>	330
Assessment in Vocational Education	<i>K Ecclestone</i>	337

Educational Assessment – Concepts and Issues

Assessing Group Work	<i>M Galton</i>	342
Assessment and the Regulation of Learning	<i>L Allal</i>	348
Challenges of Developing and Implementing Formative Assessment Practices in Schools	<i>R Sutton</i>	353
Formative Assessment	<i>P Black</i>	359
Formative Assessment and Instructional Planning	<i>B Marshall</i>	365
Progression and Assessment: Developmental Assessment	<i>M Forster and G Masters</i>	369
Students' Rights in Assessment and Evaluation	<i>J Gardner and B Holmes</i>	378
Summative Assessment by Teachers	<i>R Daugherty</i>	384
The Multiple Purposes of Assessment	<i>P E Newton</i>	392
The Relationship between Assessment and the Organization and Practice of Teaching	<i>L B Resnick, D William, R Apodaca, and E S Rangel</i>	397

Educational Assessment – Enhancing Quality and Use

Assessment Conversations: Reading and Writing Conferences with Students and with Parents	<i>M Barrs</i>	403
Assessment: Pre-service and In-service Teacher Education	<i>A Davies</i>	410
Classroom Assessment in Policy Context (Australia)	<i>J J Cumming</i>	417
Classroom Assessment in Policy Context (England and France)	<i>M Osborn and M Raveaud</i>	425
Classroom Assessment in Policy Context (French Sources)	<i>D Laveault</i>	432
Classroom Assessment in Policy Context (Hong Kong)	<i>D Carless</i>	438
Classroom Assessment in Policy Context (New Zealand)	<i>T J Crooks</i>	443
Classroom Assessment in Policy Context (Sub-Saharan Africa)	<i>S J Howie, L Zimmerman, and K Draper</i>	449
Moderation of Student Work by Teachers	<i>G S Maxwell</i>	457
School Policies and Practices to Support Effective Classroom Assessment for Learning	<i>D Pedder</i>	464
Student Assessment: Policy and Practice in Eastern Europe	<i>G Bethell</i>	472

Educational Assessment – Key Relationships

Assessment Practice in Policy Context: Latin American Countries	<i>F M Rizo</i>	479
Impact of Assessment on Learner Groups (Boys/Girls)	<i>J Elwood</i>	486
Impact of Assessment on Learner Groups (Disabilities)	<i>M Rouse</i>	492
Impact of Assessment on Students' Test Anxiety	<i>P Buchwald and C Schwarzer</i>	498
Impact of Assessments on Classroom Practice	<i>J L Herman</i>	506
Social Practices in School Assessment and their Impact on Learner Identities	<i>A Pollard and A Filer</i>	512

Educational Evaluation – Concepts, Practice, and Future Directions

Educational Evaluation: Concepts, Practice, and Future Directions	<i>Y J Ni</i>	518
---	---------------	-----

Educational Evaluation – Contemporary Themes in Evaluation

Evaluating E-Learning	<i>D D Williams and C R Graham</i>	530
Evaluating Schools as Learning Communities	<i>S M Thomas</i>	539
Evaluation of Adult Education and Training Programs	<i>G McNamara, P Joyce, and J O'Hara</i>	548
Evaluation of Integrated Health Programs in School	<i>T M Franke</i>	555

Formative Assessment in Teacher Education and Teacher Professional Development	<i>H Tillema</i>	563
Informal Education and Evaluation	<i>T Jeffs</i>	572
Methods to Evaluate Technology	<i>W L Bewley</i>	578

Educational Evaluation – Contexts of Educational Evaluation

Cost Analysis in Evaluation Studies	<i>J D Fletcher</i>	585
Cultural Issues that Can Affect the Validity of Educational Evaluations	<i>R P Durán</i>	592
Evaluation and Accountability	<i>E Sato and S N Rabinowitz</i>	600
Evaluation Governance and Planning	<i>R Picciotto</i>	607
Evaluation Use	<i>V G Thomas</i>	614
Moral and Ethical Issues in Evaluation	<i>M Morris</i>	622
The Role of Stakeholders in Educational Evaluation	<i>S Taut and M C Alkin</i>	629

Educational Evaluation – Evaluation Domains

Curriculum Evaluation	<i>T Levin</i>	636
Evaluating Education in Three Policy Eras	<i>M A Peters, R Britez, and S M Weber</i>	645
Evaluation of Mathematics Education Programs	<i>J Cai</i>	653
Evaluation of Science Education Programs	<i>G Berberoğlu</i>	660
Evaluation of Social Studies and Civic Education Programs	<i>S G Grant</i>	667
Evaluation of Teacher Quality and Practice	<i>W Robinson and J Campbell</i>	674
International Evaluations	<i>A Schleicher</i>	681
National Assessment Programs: The Example of the U.S. National Assessment of Educational Progress	<i>M Schneider</i>	690
Principal Evaluation: Concepts, Needs and Realities	<i>N S Glasman and L D Glasman</i>	698
Program Evaluation	<i>C A Christie and L A Fierro</i>	706
School Based Evaluation: Purposes, Protocols and Processes	<i>J MacBeath</i>	713
School Inspection/External School Evaluation	<i>C Chapman and P Earley</i>	719
The International System for Teacher Observation and Feedback: A Theoretical Framework for Developing International Instruments	<i>L Kyriakides, B P M Creemers, C Teddlie, and D Muijs</i>	726

Educational Evaluation – Evaluation Methods

Evaluation Methodology	<i>M Chatterji</i>	735
Evaluation Reporting and Communicating	<i>R T Torres</i>	746
Longitudinal Evaluation Designs	<i>X Ma</i>	757
Meta-evaluation: Purpose, Prescription, and Practice	<i>L A Wingate</i>	765

Educational Evaluation – Purposes and Models of Educational Evaluation

Defining Quality in Evaluation	<i>P Dahler-Larsen</i>	775
Internal and External Evaluation	<i>D Nevo</i>	781
Needs Assessment in Education	<i>J W Altschuld and T L Lepicki</i>	786
The Purpose of Educational Evaluation	<i>S Mathison</i>	792
Understanding Approaches to Evaluation	<i>A J Love</i>	798

VOLUME 4**Educational Measurement**

Ability Testing	<i>P B Tymms</i>	1
Admissions Testing	<i>R Zwick</i>	7
Appropriateness Measurement: Person Fit	<i>R R Meijer and A M Weekers</i>	15
Automated Essay Scoring: Writing Assessment and Instruction	<i>M D Shermis, J Burstein, D Higgins, and K Zechner</i>	20
Classical Test Theory Reliability	<i>M D Miller</i>	27
Criterion-Referenced Measurement	<i>S A Shrock and W C Coscarelli</i>	31
Differential Item Functioning	<i>M D Hidalgo and J Gómez-Benito</i>	36
Educational Measurement: Overview	<i>R L Linn</i>	45
Equating and Scaling	<i>A A von Davier</i>	50
Fairness	<i>C Gipps and G Stobart</i>	56
Generalizability Theory	<i>R L Brennan</i>	61
Impact of Assessment on Classroom Practice	<i>J L Herman</i>	69
Intelligent Systems	<i>V J Shute and D Zapata-Rivera</i>	75
Item Response Theory	<i>W J van der Linden</i>	81
National Assessments	<i>T J Crooks</i>	89
Norm-Referenced Measurement	<i>H D Hoover</i>	95
Progress Monitoring	<i>L S Fuchs and D Fuchs</i>	102
Rasch Models	<i>D Andrich</i>	111
Scoring Rubrics	<i>J A Arter</i>	123
Second Language Assessment	<i>L F Bachman</i>	140
Self Adaptive Testing	<i>J Revuelta</i>	148
Student Test Results in School Accountability	<i>L S Hamilton</i>	153
Test Development	<i>S M Downing</i>	159
Test Translation and Adaptation	<i>A Allalouf and P Hanani</i>	166
Testing Creativity	<i>M A Runco</i>	170
Testing in History	<i>S Wineburg and B Fogo</i>	175
Validity	<i>R L Linn</i>	181
Validity of Achievement Gains on High-Stakes Tests	<i>D Koretz</i>	186
Validity of Educational Indicators	<i>B P M Creemers and L Kyriakides</i>	193

G**Globalization of Universities and Institutions**

Globalization, Universities and Medium of Instruction	<i>J Lo Bianco</i>	201
The Washington Accord on Engineering Curriculum	<i>E Ko</i>	209

H

Higher Education

Higher Education: An Overview	<i>P Scott</i>	217
-------------------------------	----------------	-----

Higher Education – Management, Leadership and Governance

Academic Managers – Heads of Departments/Schools	<i>S Marshall</i>	229
Leading and Managing the University – Presidents and their Senior Management Team	<i>R Middlehurst, T Kennie, and S Woodfield</i>	238
Management of and in Higher Education Institutions	<i>B Sporn</i>	245
Managerialism and Collegialism in Higher Education Institutions	<i>M Shattock</i>	251
Strategic Planning in Higher Education	<i>L Zechlin</i>	256
The Changing Role of University Presidents, Vice-Chancellors and Rectors	<i>M F Green and P D Eckel</i>	264
The Changing Roles of University Governing Boards and Councils	<i>J Fielden</i>	273

Higher Education – Research and Scholarship

Funding of University Research	<i>G Harman</i>	279
Mobility of PhD Students and Scientists	<i>S Avveduto</i>	286
National Science Policy and Universities	<i>M Henkel and U Kogan</i>	294
Research Commercialization	<i>S Slaughter</i>	300
Research Quality Assessment	<i>I McNay</i>	307
The Management of University Research	<i>J Kirkland</i>	316
The Training of New Scientists	<i>R Neumann</i>	322

Higher Education – Society

Academic Freedom	<i>S F Macintyre</i>	328
Access and Equity in Higher Education	<i>G Baldwin and R James</i>	334
Boundaries of Institutional Autonomy and their Impact on Higher Education	<i>V L Meek</i>	341
Diversity of Higher Education	<i>U Teichler</i>	347
Employability of University Graduates and Graduate Outcomes	<i>J Brennan</i>	354
Higher Education and the Knowledge Society	<i>J Välimaa</i>	360
Higher Education and the Labor Market	<i>J Enders</i>	365
Higher Education and the Transformation of Society	<i>P Scott</i>	370
Quality Assurance in Higher Education – Practices and Issues	<i>D Dill</i>	377
The Role of Accreditation of Higher Education Institutions	<i>J S Eaton</i>	384
Universities and Regional Development	<i>J Goddard and J Puukka</i>	390
Universities' Engagement with Society	<i>D Watson</i>	398

Higher Education – Teaching and Learning in Higher Education

Distance Education and Open Universities	<i>A Kanwar and J Daniel</i>	404
Education Development in Higher Education	<i>Y Ryan and K Fraser</i>	411
Effective Use of Technology in Teaching and Learning in HE	<i>D Laurillard</i>	419

Facilitating Students' Success – Student Support and Learning Resources in Universities	<i>E Woodberry and C Barnes</i>	427
Faculty Values and Expectations and Their Implications for Teaching, Learning and the Organization of Higher Education Institutions	<i>K Harman</i>	433
Flexible Learning in Higher Education	<i>S Alexander</i>	441
Innovation in Teaching and Curriculum Design	<i>J M Dearn</i>	448
Productivity of University Faculty Staff	<i>S Kyvik</i>	455
Promoting Effective Student Learning in Higher Education	<i>K Trigwell</i>	461
Student Attrition from Higher Education Institutions	<i>M Hayden</i>	467
University Students' Experiences of Higher Education	<i>C McInnis</i>	473
What Do University Students Learn?	<i>G D Kuh and B K Bridges</i>	479

Higher Education – Tertiary Education in a Globalized World

Associations of Universities	<i>G F Moodie</i>	485
Collective Bargaining in Higher Education	<i>C Allport, K McAlpine, and S Roberts</i>	491
Financing of Higher Education	<i>B Chapman and P Tulip</i>	499
Higher Education Crossing Borders	<i>J Knight</i>	507
Higher Education in Post-Conflict Societies	<i>M Daxner</i>	514
Higher Education in the New Economies	<i>J Fielden</i>	520
Human Resource Issues in Higher Education	<i>E El-Khawas</i>	527
International Accreditation in Higher Education	<i>A Stella and D Woodhouse</i>	533
Internationalization of Higher Education	<i>M van der Wende</i>	540
National and International Rankings of Higher Education	<i>S Marginson</i>	546
Steering of Higher Education Systems – The Role of the State	<i>K Yokoyama and V L Meek</i>	554
Student and Faculty Transnational Mobility in Higher Education	<i>U Lanzendorf and B M Kehm</i>	559
The Bologna Process in European Higher Education	<i>D Rich</i>	566
The Economics and Finance of Higher Education	<i>A Wolf</i>	573
The Role of the OECD in the Development of Higher Education in a Globalized World	<i>R Yelland</i>	584
Transforming Higher Education in Developing Countries: The Role of the World Bank	<i>J Salmi and R M Bassett</i>	590
UNESCO's Role in the Development of Higher Education in a Globalized World	<i>S Uvalić-Trumbić</i>	597

Higher Education – The Organization and Financing of Higher Education

Higher Education in Federal Systems	<i>M A M Cortés and U Teichler</i>	603
Pathways and Articulation into Higher Education	<i>G F Moodie</i>	609
Unitary, Binary and other National Systems of Higher Education	<i>L Goedegebuure</i>	616
Viewing Private Higher Education: How Much, Where, Why, and What?	<i>D C Levy</i>	622

I

Immigration

Children of Migrant Populations	<i>M M Suárez-Orozco and C Suárez-Orozco</i>	629
Third Culture Kids	<i>R E Van Reken</i>	636

International Comparisons

IEA Studies in ICT	<i>N Law</i>	644
IEA Studies in Mathematics and Science	<i>F K S Leung</i>	650
IEA Study in Civic Education	<i>J Torney-Purta, J-A Amadeo, and J Schwillie</i>	656
IEA: Globalization and Assessment	<i>H Wagemaker</i>	663

International Organizations in Education

Education and the European Union	<i>S Hegarty</i>	669
National University on Educational Planning and Administration, New Delhi	<i>J B G Tilak</i>	676
On School Management – International Council on School Effectiveness and Improvement, Commonwealth Council on Educational Administration and Management	<i>A Walker and T Townsend</i>	681
UNESCO's International Institute for Educational Planning	<i>S J Hite and M Bray</i>	688

L**Leadership and Management**

Leadership and Management Overview	<i>B Mulford</i>	695
------------------------------------	------------------	-----

Leadership and Management – as a Field of Study

Contexts for Leadership at the Beginning of the 21st Century	<i>M Bottery</i>	704
Educational Leadership: Philosophical Issues	<i>C W Evers</i>	710
Ethical/Moral Issues in Educational Leadership	<i>R J Starratt, L Langlois, and P Duignan</i>	717
History of Educational Leadership/Management	<i>R Bates</i>	724
Educational Leadership as a Field of Study: Professional Journals 1994–2006	<i>A R Thomas</i>	731
Research on Educational Leadership – Approaches/Promising Directions	<i>W A Firestone and V M J Robinson</i>	740

Leadership and Management – Leader Preparation

Leaders for Productive Schools	<i>J Murphy, S N Elliott, E B Goldring, and A C Porter</i>	746
New Approaches in Preparing School Leaders	<i>S G Huber</i>	752
Research for Leaders: The National College for School Leadership	<i>G Southworth</i>	762
School Leadership Standards	<i>L Ingvarson</i>	768

Leadership and Management – Leadership Issues

Effective Leadership in Challenging Schools	<i>A Harris</i>	777
Esthetics, Educational Leadership and Management	<i>R Bates</i>	783
Leader Mistreatment of Teachers	<i>J Blase and J Blase</i>	790
Leadership and Gender	<i>J Blackmore</i>	797
Leadership and Student Voice	<i>C Lanskey and J Rudduck</i>	803
Leadership and Urban Education	<i>K A Riley</i>	809
Leadership for Learning	<i>J MacBeath</i>	817
Leadership in Diverse Cultures	<i>A Walker and P K Yu-kwong</i>	824

Leading Diverse Schools	<i>J Ryan</i>	832
Supervision and Personnel Administration	<i>P D Tucker and D G Pounder</i>	839
The Big Challenge: Leadership for Inclusion	<i>M Ainscow and A Sandill</i>	846
The Educational Leader's New Work	<i>P Gronn</i>	852

VOLUME 5

Leadership and Management – Leadership Types

A Distributed Perspective on School Leadership and Management	<i>J P Spillane</i>	1
Leadership: Authentic	<i>P T Begley</i>	7
Leadership: Democratic	<i>J Møller</i>	12
Leadership: Instructional	<i>P Hallinger, K Leithwood, and R H Heck</i>	18
Leadership: Transformative	<i>C M Shields</i>	26
Strategic Leadership	<i>B Davies and B J Davies</i>	34
Teacher Leadership and Organizational Development	<i>A Harris</i>	40
Understanding How Leadership Influences Student Learning	<i>K Leithwood and B Levin</i>	45

Leadership and Management – Politics and Governance

Equity and Educational Effectiveness	<i>P Sammons</i>	51
Leading/Managing Schools in Communities Made Poor	<i>P Thomson</i>	58
Principals Role in Restructuring Schools	<i>G M Crow and K D Peterson</i>	66
School Reform and Restructuring: Self Managing School	<i>B J Caldwell</i>	72
System Leadership	<i>D Hopkins and R Higham</i>	78

Leadership and Management – School and Community

Educational Leadership and Social Capital	<i>J West-Burnham</i>	85
Networked Learning Communities School-to-School Collaboration as an Essential Component of a System Reform Strategy	<i>D Jackson</i>	92
Networks and Communities of Knowledge	<i>T Schuller and H Theisens</i>	100
School Community Relations	<i>R L Crowson and E B Goldring</i>	106
Social Capital, Educational Institutions and Leadership	<i>S Kilpatrick, S Johns, and B Mulford</i>	113

Leadership and Management – School Effectiveness and Improvement

Leadership and Technology	<i>C F Webber</i>	120
Leadership in the Implementation of Innovations	<i>I E Bogotch, T Townsend, and M Acker-Hocevar</i>	128
Leadership: School Improvement	<i>R H Heck and P Hallinger</i>	135
Organizational Learning in Schools	<i>B Mulford and H Silins</i>	143
Professional Learning Community	<i>L Stoll</i>	151
Transformational School Leadership	<i>K Leithwood</i>	158

Learning and Cognition – Issues and Concepts

Attention in Cognition and Early Learning	<i>M Heimann, T Tjus, and K Strid</i>	165
Concept Learning	<i>S J Unsworth and D L Medin</i>	172
Cooperative Learning	<i>R E Slavin</i>	177
Intelligence	<i>R J Sternberg</i>	184
Learning from Multiple Information Sources	<i>H I Strømsø and I Bråten</i>	191
Memory	<i>S Magnussen and T Brennen</i>	197
Metacognition	<i>L Baker</i>	204
Personal Epistemology in Education: Concepts, Issues, and Implications	<i>I Bråten</i>	211
Piaget: Recent Work	<i>L Smith</i>	218
The Adult Development of Cognition and Learning	<i>E A L Stine-Morrow and J M Parisi</i>	225
Vygotsky and Recent Developments	<i>J V Wertsch</i>	231

Learning and Cognition – Issues and Concepts – Focus on Cognition

Cognition and Emotion	<i>F Pons, M de Rosnay, and F Cuisinier</i>	237
Cognition: Overview and Recent Trends	<i>J Wiley and B D Jee</i>	245
Development of Creativity	<i>M A Runco</i>	251
Knowledge Domains and Domain Learning	<i>L Maggioni and P A Alexander</i>	255
Problem Solving and Human Expertise	<i>T J Nokes, C D Schunn, and M T H Chi</i>	265
Problem Solving and Reasoning	<i>R E Mayer</i>	273
Reasoning, Moral and Social	<i>N S Jampol, C B Richardson, and M Killen</i>	279
Remembering as Social Activity	<i>D Middleton</i>	285

Learning and Cognition – Issues, Concepts, Types

Computer-Supported Collaborative Learning: Basic Concepts, Multiple Perspectives, and Emerging Trends	<i>S R Ludvigsen and A I Mørch</i>	290
Learning as Inquiry	<i>S R Goldman, J Radinsky, S Tozer, and D Wink</i>	297
Learning Through Narrative Socialization	<i>A Fasulo</i>	303
Neuroscience Bases of Learning	<i>M H Immordino-Yang and K W Fischer</i>	310
The Neuroscience of Reading	<i>U Goswami</i>	317

Learning and Cognition – Issues, Concepts, Types – Focus on Learning

Learning Strategies	<i>C E Weinstein, J Jung, and T W Acee</i>	323
Learning Through Play	<i>K Aronsson</i>	330
Situated View of Learning	<i>A Collins and J G Greeno</i>	335
The Neuroscience of Aging and Cognition	<i>W J Hoyer and B Bessette-Symons</i>	340

Learning and Cognition – Language, Literacy and Subject-Related

An Overview of Language and Literacy in Educational Settings	<i>V G Aukrust</i>	345
Bilingualism and Learning	<i>L S Verplaetse and E Schmitt</i>	355
Classroom Discourse and Student Learning	<i>L Hemphill</i>	361
Early Writing	<i>B E Hagtvet</i>	367

First Language Acquisition	<i>N B Ratner</i>	375
Foreign Language Learning	<i>C Kinginger</i>	382
Learning Science	<i>J Leach and P Scott</i>	387
Learning to Read	<i>M S Burns and J K Kidd</i>	394
Mathematics Learning	<i>L Verschaffel, B Greer, and E De Corte</i>	401
Music Learning	<i>S Hallam</i>	407
Reading Comprehension: Reading for Learning	<i>C E Snow</i>	413
Second Language Learning	<i>J S Arnfast, J N Jørgensen, and A Holmen</i>	419
Writing: Advanced	<i>R Andrews</i>	426

Learning and Cognition – Other Issues

Gender and Learning	<i>L Yates and J McLeod</i>	432
Parent–Child Relationships in Early Learning	<i>C P Edwards, S M Sheridan, and L L Knoche</i>	438
Peer Interaction and Learning	<i>S Blum-Kulka and S Dvir-Gvirsman</i>	444

Learning and Cognition – Places of Learning

Learning in a Cross-Cultural Perspective	<i>L-F Zhang and R J Sternberg</i>	450
Learning Outside of School	<i>T Nunes</i>	457
Reasoning and Explanatory Talk: Learning in Everyday Settings	<i>D E Beals</i>	464

Learning and Cognition – Theoretical Perspectives – Learning

Apprenticeship Approach to Learning	<i>K Nielsen</i>	469
Connectionism and Learning	<i>T R Shultz</i>	476
Constructivism and Learning	<i>S Sjøberg</i>	485
Cultural–Historical Activity Theory	<i>A Havnes</i>	491
Learning in a Sociocultural Perspective	<i>R Säljö</i>	498
Self-Regulated Learning and Socio-Cognitive Theory	<i>P H Winne and A F Hadwin</i>	503

N

National Systems of Education

Australia	<i>C N Power</i>	510
Austria	<i>M J Gaertner</i>	517

VOLUME 6**P****Philosophy of Education**

Philosophy of Education: Overview	<i>P Enslin</i>	1
-----------------------------------	-----------------	---

Philosophy of Education – Contemporary Issues

Neoliberalism, the Market and Performativity	<i>M A Peters</i>	11
Parents and Children's Rights	<i>M Clayton</i>	17
Peace Education	<i>I Gur-Ze'ev</i>	22
Philosophy and Educational Research	<i>D Bridges</i>	29
Race, Critical Race Theory and Whiteness	<i>B Applebaum</i>	36
School Choice and the Common School	<i>G Haydon</i>	44

Philosophy of Education – Philosophical Perspective

African Philosophy of Education	<i>K Horsthemke</i>	50
Feminism	<i>L Stone</i>	56
Hermeneutics	<i>C Bingham</i>	63
Islamic Education	<i>Y Waghid</i>	69
Liberalism and Education	<i>W Feinberg</i>	74
Phenomenology and Existentialism	<i>B Levering</i>	80
Pragmatism	<i>B Thayer-Bacon</i>	86
Psychoanalysis and Education	<i>P Smeyers</i>	92
Social and Cultural Capital in Education	<i>M Print</i>	97
The Aims of Education	<i>R Marples</i>	103
The Analytical Tradition	<i>D Carr</i>	108

Philosophy of Education – Philosophical Themes

Adult Learning: Philosophical Issues	<i>D Beckett</i>	114
Autonomy	<i>C A Wringe</i>	121
Bildung	<i>J Masschelein and N Ricken</i>	127
Critical Theory and Pedagogy	<i>M Mason</i>	133
Critical Thinking	<i>H Siegel</i>	141
Environmental Education	<i>M Bonnett</i>	146
Identity	<i>M S Merry</i>	152
Inclusion	<i>R Cigman</i>	158
Justice and Care	<i>M Tjiattas</i>	164
Lifelong Learning	<i>J Halliday</i>	170
Post-Structuralism and Education	<i>M Mason and M Clarke</i>	175
Reason and Rationality	<i>P Hogan</i>	183

Religious and Spiritual Education	<i>J C Conroy and S J McKinney</i>	189
The Capabilities Approach	<i>L Terzi</i>	194

Primary and Secondary Education – Learning and Teaching in School Age Education

Class Size – Arguments and Evidence	<i>P Blatchford and K C Lai</i>	200
Continuing Professional Development of Teachers	<i>P Earley</i>	207
Homeschooling	<i>P Farenga</i>	214
Innovations and Early Intervention in the Teaching of Literacy	<i>R E Slavin</i>	221
Personalized Learning in School Age Education	<i>D Hopkins</i>	227
Perspectives on Schooling in the Middle Years	<i>V J Russell</i>	233
Reform of the School Workforce	<i>H M Gunter and G Forrester</i>	242
Secondary Education in Developing Countries	<i>P Hughes and A Walker</i>	249

Primary and Secondary Education – Social Justice Issues in School Age Education

Community Focused Schools	<i>A Dyson</i>	255
---------------------------	----------------	-----

Primary and Secondary Education – The Effectiveness of School Systems

Reforming the American School System	<i>M Barber</i>	261
School Effectiveness in Developed Societies	<i>D Reynolds</i>	269
School to School Collaboration: Innovation and Improvement	<i>R Higham</i>	274
Studies of School Improvement in Developing Countries	<i>S E Anderson</i>	281
Sustainable Educational Reform	<i>A Hargreaves</i>	289
The Role of the District in Tri Level Reform	<i>M Fullan</i>	295
Whole School Designs for Enhancing Student Achievement	<i>S Stringfield and J Nunnery</i>	303

Q

Qualitative Research

Action Research in Education	<i>E Stringer</i>	311
Classroom Ethnography	<i>F Erickson</i>	320
Computer Assisted Qualitative Data Analysis	<i>C Silver and A Lewins</i>	326
Conversational Analysis	<i>H G Levine</i>	335
Critical Ethnography	<i>D Foley</i>	337
Critical Race Theory	<i>D Gillborn and G Ladson-Billings</i>	341
Critical Theory	<i>J J Ryoo and P McLaren</i>	348
Cultural Studies	<i>R Gaztambide-Fernández and K Cairns</i>	354
Cultural–Historical Activity Theory	<i>Laboratory for Comparative Human Cognition</i>	360
Design Experiments	<i>A Collins</i>	367
Discourse Analysis	<i>P Nikander and S Vehviläinen</i>	373
Document Analysis	<i>T Rapley and K N Jenkins</i>	380
Ethnography	<i>M Hammersley</i>	386

Ethnomethodology in Education Research	<i>D Macbeth</i>	392
Focus Groups	<i>D L Morgan and K Hoffman</i>	401
Grounded Theory	<i>K Charmaz and A Bryant</i>	406
Hermeneutics	<i>J Dyer</i>	413
Interpretive Research	<i>E Rauscher and M E Graue</i>	419
Interviews and Interviewing	<i>A Marvasti</i>	424
Life History	<i>J A Hatch and S K Newsom</i>	430
Narrative Inquiry	<i>D J Clandinin and J Huber</i>	436
Participant Observation	<i>J Schostak</i>	442
Phenomenology	<i>M van Manen and C A Adams</i>	449
Qualitative Case Studies	<i>S B Merriam</i>	456
Qualitative Data Management	<i>C Grbich</i>	463
Semiotics	<i>M Danesi</i>	475
Symbolic Interactionism, Naturalistic Inquiry, and Education	<i>J A Forte</i>	481
The Quality of Evidence in Qualitative Research	<i>S K Biklen</i>	488
Visual Data in Education Research	<i>J Wagner</i>	498

Qualitative Research – Standards of Proof

Validity: Mapping Diverse Perspectives	<i>G B Rossman, S F Rallis, and A M Kuntz</i>	505
--	---	-----

Quantitative and Qualitative Approaches to Research – Integration

Mixed Methods	<i>A Tashakkori and I Newman</i>	514
---------------	----------------------------------	-----

Quantitative Methods and Research Design

External Validity	<i>G E Matt, A Brewer, and M Sklar</i>	521
-------------------	--	-----

R

Role of NGOs in Globalization

NGOs and Globalization of Education	<i>M Ahmed</i>	529
-------------------------------------	----------------	-----

S

Social and Emotional Aspects of Learning

Achievement Goal Theory: Definitions, Correlates, and Unresolved Questions	<i>T Urdan</i>	537
Affect, Mood and Emotions	<i>S Schnall</i>	544
Anxiety	<i>M Zeidner</i>	549
Attribution Theory	<i>B Weiner</i>	558
Children's Friendship	<i>S R Asher and K L McDonald</i>	564
Coping with Stressful Situations: An Important Aspect of Self-Regulation	<i>M Boekaerts</i>	570
Culture in Motivation Research: A Challenging and Enriching Contribution	<i>K Kimmel and S Volet</i>	576
Early Social Development and Schooling	<i>G M van der Aalsvoort</i>	585

Emotion in Educational Contexts	<i>P A Schutz, P D Quijada, S de Vries, and M Lynde</i>	591
Empathy	<i>R Arnold</i>	597
Flow in Education	<i>J A Schmidt</i>	605
Interest	<i>M Ainley</i>	612
Intrinsic and Extrinsic Motivation	<i>C Levesque, K J Copeland, M D Pattie, and E L Deci</i>	618
Motivating Students in Classrooms	<i>J Brophy</i>	624
Motivation Regulation	<i>C A Wolters and S A Mueller</i>	631
Peer Learning in the Classroom	<i>N M Webb</i>	636
Poverty, Effects of on Social and Emotional Development	<i>N Philipsen Hetzner, A D Johnson, and J Brooks-Gunn</i>	643
Seeking Help as an Adaptive Response to Learning Difficulties: Person, Situation, and Developmental Influences	<i>S A Karabenick and R S Newman</i>	653
Self-Concept in Learning: Reciprocal effects model between academic self-concept and academic achievement	<i>H W Marsh and L F Scalas</i>	660
Self-Efficacy Beliefs	<i>D H Schunk and F Pajares</i>	668
Social and Emotional Outcomes of Learning	<i>J Vorhaus</i>	673
Social Aspects of Collaborative Learning	<i>M Arvaja and P Häkkinen</i>	685
Social Development and Schooling	<i>G W Ladd</i>	691
Social Interaction and Learning	<i>K Littleton</i>	698
Social Networks and the Education of Children and Youth	<i>B Schneider, T G Ford, and L Perez-Felkner</i>	705
Sociocultural Issues in Motivation	<i>R A Walker</i>	712
Socioemotional Aspects of Technology-Supported Learning	<i>S Järvelä</i>	718
Volitional Control of Learning	<i>J Husman and L Corno</i>	724
Wellbeing	<i>T Hascher</i>	732

VOLUME 7

Statistics

An Overview of Statistics in Education	<i>S Sinharay</i>	2
Analysis and Interpretation of Multivariate Data	<i>D J Bartholomew</i>	12
Analysis of Covariance	<i>N T Longford</i>	18
Analysis of Extreme Values in Education	<i>J Beirlant, G Dierckx, K Luwel, and P Onghena</i>	25
Analysis of Variance	<i>B M King</i>	32
Bayesian Statistical Analysis	<i>G Kokolakis</i>	37
Bootstrap Method	<i>K Singh and M Xie</i>	46
Canonical Correlation	<i>A Basu and A Mandal</i>	52
Categorical Data Analysis	<i>S E Fienberg and B W Junker</i>	58
Causal Inference	<i>D B Rubin</i>	66
Cluster Analysis: Overview	<i>S Landau and I Chis Ster</i>	72

Cognitive Psychology and Educational Statistics	<i>H S Kim and S Embretson</i>	84
Computational Statistics	<i>J E Gentle</i>	93
Continuous Probability Distributions	<i>S Sinharay</i>	98
Correspondence Analysis	<i>M Greenacre</i>	103
Data Mining	<i>R S J d Baker</i>	112
Decision Theory	<i>M Mendoza and E Gutiérrez-Peña</i>	119
Design of Experiments	<i>C A Albers and T R Kratochwill</i>	125
Discrete Probability Distributions	<i>S Sinharay</i>	132
Discrimination and Classification	<i>R C Neath and M S Johnson</i>	135
Empirical Bayes Methods	<i>E Ip and G Molenberghs</i>	142
Evaluation Research	<i>T Kellaghan</i>	150
Exploratory Data Analysis	<i>A Unwin</i>	156
Factor Analysis: An Overview and Some Contemporary Advances	<i>F A N Alhija</i>	162
Generalized Linear Mixed Models	<i>S Rabe-Hesketh and A Skrondal</i>	171
Generalized Linear Models	<i>J J Faraway</i>	178
Generating Random Numbers	<i>P J Pashley and A Amodeo</i>	184
Goodness-of-Fit Testing	<i>A Maydeu-Olivares and C García-Forero</i>	190
Graphical Models	<i>R G Almond</i>	197
Growth Modeling	<i>I Plewis</i>	203
Hierarchical Linear Models	<i>D Rindskopf</i>	210
Hypothesis Testing and Confidence Intervals	<i>T R Konold and X Fan</i>	216
Instrumental Variables	<i>E P Bettinger</i>	223
Jackknife Methods	<i>S Sinharay</i>	229
Large-sample Statistical Methods	<i>J M Singer and D F Andrade</i>	232
Latent Class Models	<i>J K Vermunt</i>	238
Markov Chain Monte Carlo	<i>A M Johansen</i>	245
Matrix Algebra	<i>H Yanai and H Ishii</i>	253
Measure of Association	<i>G-H Huang</i>	260
Measures of Central Tendency	<i>D Clark-Carter</i>	264
Measures of Dispersion, Skewness and Kurtosis	<i>D Rindskopf and M Shiyko</i>	267
Meta Analysis	<i>J Sánchez-Meca and F Marín-Martínez</i>	274
Missing Data	<i>C A W Glas</i>	283
Model Selection	<i>S J Haberman</i>	289
Monte Carlo Methods	<i>A M Johansen</i>	296
Multidimensional Scaling	<i>Z Zhang and Y Takane</i>	304
Multiple Comparisons	<i>C Lewis</i>	312
Multivariate Analysis of Variance	<i>N T Longford</i>	319
Multivariate Linear Regression	<i>S Ganesh</i>	324
Multivariate Normal Distribution	<i>J Tacq</i>	332

Nonlinear Regression Analysis	<i>H-H Huang, C K Hsiao, and S-Y Huang</i>	339
Nonparametric Statistical Methods	<i>K Sijtsma and W H M Emons</i>	347
Observational Studies	<i>P R Rosenbaum</i>	354
Order Statistics	<i>I Bairamov</i>	360
Point Estimation Methods with Applications to Item Response Theory Models	<i>F Bartolucci and L Scrucca</i>	366
Principal Components Analysis	<i>D J Bartholomew</i>	374
Probability Theory	<i>T Rudas</i>	378
Recursive Partitioning	<i>S Landau and S Barthel</i>	383
Sampling	<i>J Qian</i>	390
Sequential Probability Ratio Test	<i>T J H M Eggen</i>	396
Sequential Testing	<i>H J Vos</i>	401
Signal Detection Theory	<i>H Abdi</i>	407
Small Area Estimation	<i>A Noble</i>	411
Statistical Analysis of Functional Data	<i>F Ferraty, P Sarda, and P Vieu</i>	417
Statistical Inequalities	<i>H M Mahmoud and J L Gastwirth</i>	426
Statistical Paradoxes	<i>Y-K Tu</i>	429
Statistical Power Analysis	<i>L V Hedges and C Rhoads</i>	436
Statistical Significance Versus Effect Size	<i>X Fan and T R Konold</i>	444
Stochastic Processes	<i>F Baudoin</i>	451
Structural Equation Models	<i>S-Y Lee and X-Y Song</i>	453
Survival Data Analysis	<i>A F De Champlain</i>	459
The Normal Distribution and its Applications	<i>J Tacq</i>	467
Time Series Analysis	<i>P J Brockwell</i>	474
Univariate Linear Regression	<i>M L Hazelton</i>	482
Value-Added Models	<i>D F McCaffrey</i>	489

T

Teacher Education – Evaluation in the Teacher Education Program

Accreditation and Standards in Teacher Education	<i>R J Yinger and K L Daniel</i>	495
Determining Long Term Effects of Teacher Education	<i>C N Brouwer</i>	503

Teacher Education – Evaluation of the Prospective Teacher

The Evaluation of Prospective Teachers in Teacher Education	<i>D E H Tigelaar and J van Tartwijk</i>	511
---	--	-----

Teacher Education – Macro Factors

Diversity in Teacher Education	<i>T Wubbels</i>	518
Social and Cultural Influences on Teacher Education	<i>M Ben-Peretz and R Lotan</i>	525
The Role of Governance in Teacher Education	<i>G E Karlsen</i>	532

Teacher Education – Post-Initial Professional Development

Action Research as a Tool for Teachers' Professional Development	<i>P Ponte</i>	540
Contemporary Approaches to Teacher Professional Development	<i>H Borko, J Jacobs, and K Koellner</i>	548
School Development for Teacher Learning and Change	<i>P Sleegers and K Leithwood</i>	557
Teacher Induction	<i>D Beijaard, J Buitink, and C Kessels</i>	563
Teacher Learning as Workplace Learning	<i>J Imants and K van Veen</i>	569
Teacher Learning with Lesson Study	<i>A Murata</i>	575
Teachers Career Stages and Professional Development	<i>R Fessler and E Rice</i>	582

Teacher Education – Preservice Teacher Education

A Pedagogy of Teacher Education	<i>J Loughran</i>	587
Case Methods in Teacher Education	<i>M Sato and C Rogers</i>	592
Conceptions of Teacher Education	<i>J A Whitcomb</i>	598
Inquiry-Oriented Teacher Education	<i>R Schulz</i>	604
Narratives and Biography in Teacher Education	<i>G Kelchtermans</i>	610
Supervision in Teacher Education	<i>J McCarthy and L F Quinn</i>	615
Taking Prospective Teachers' Beliefs into Account in Teacher Education	<i>M Valcke, G Sang, I Rots, and R Hermans</i>	622
Teacher Education and Models of Teacher Reflection	<i>V K LaBoskey</i>	629
Teacher Education as Teaching for Understanding with New Technologies	<i>M S Wiske and D E Spicer</i>	635

Teacher Education – Preservice: The Knowledge Base

Experienced Teachers' Craft Knowledge	<i>P C Meijer</i>	642
Moral Values in Teacher Education	<i>W Veugelers</i>	650
Pedagogical Content Knowledge	<i>J H Van Driel and A Berry</i>	656
Teacher Education and the Educational Foundations Knowledge Base	<i>F B Murray</i>	662
The Relationship Between Theory and Practice in Teacher Education	<i>F A J Korthagen</i>	669

Teacher Education – Teacher Educators

Characteristics, Scholarship and Research of Teacher Educators	<i>M Lunenberg</i>	676
Professional Development of Teacher Educators	<i>P K Smith</i>	681
Self-Study by Teacher Educators	<i>T Russell</i>	689

Teacher Education – Teaching Specific Domains

Arts Teacher Education	<i>L Beudert</i>	695
Mathematics Teacher Education	<i>K Krainer and S Llinares</i>	702
Music Teacher Education	<i>M W-y Wong</i>	706
Science Teacher Education	<i>J H Van Driel and S K Abell</i>	712
Social Studies Teacher Education	<i>A-L Halvorsen and S M Wilson</i>	719
Teacher Education for Elementary Education	<i>K D Brown and G N Carnes</i>	725

Teacher Education for Teaching the Gifted	<i>A Y Baldwin</i>	732
Teacher Preparation in Mother Tongue Education	<i>M Kooy and H Hulshof</i>	738
Vocational Teacher Education	<i>S Johansson</i>	744

Teacher Education – The Cooperating School

Mentoring in Teacher Education	<i>P D Tomlinson, A J Hobson, and A Malderez</i>	749
Partnerships Between Schools and Higher Education	<i>C Day and L Smethem</i>	757

VOLUME 8

Technology and Learning

An Overview of Technology and Learning	<i>B Means and J Roschelle</i>	1
Educational Data Modeling	<i>S Iksal</i>	11
Student Data Systems and Their Use for Educational Improvement	<i>J C Wayman, V Cho, and M P Richards</i>	14
Technology and Learning: Access in Schools Around the World	<i>R Anderson and J Ainley</i>	21

Technology and Learning – as a Subject of Instruction

Conceptions of Technology Literacy and Fluency	<i>O Erstad</i>	34
--	-----------------	----

Technology and Learning – Assessment

Technology and Formative Assessment	<i>J W Pellegrino</i>	42
Technology for Large-Scale Assessment	<i>R E Bennett</i>	48
Technology Supports for Assessment Design	<i>R J Mislevy, F I Winters, I I Bejar, R E Bennett, and G D Haertel</i>	56

Technology and Learning – Education Reform and Economic Development

National Strategies to Build a Technology Workforce	<i>H-M Cheah</i>	66
Public–Private Partnerships for Educational Reform	<i>V Quah, C P Lim, and C Brook</i>	73
Relating Technology, Education Reform and Economic Development	<i>R B Kozma</i>	81

Technology and Learning – Evaluating Technology

Examining the Effects of Educational Technology Programs: Challenges and Strategies	<i>M Russell</i>	88
---	------------------	----

Technology and Learning – Global Trends

Equity in Technology Access and Opportunities	<i>T Matuchniak and M Warschauer</i>	95
Internet-Based Education	<i>M Bakia</i>	102

Technology and Learning – Issues

Media Use and School Achievement	<i>K Roe</i>	109
Technology and Physical and Social Health	<i>K Subrahmanyam</i>	112

Technology and Learning – Meeting Special Students’ Needs

Universal Design for Learning *D H Rose and J W Gravel* 119

Technology and Learning – School Leadership for Technology Integration

Technology as a Support for School–Community Connections *K M Culp* 125

Technology and Learning – Supports for Managing Instruction

Classroom Uses of Technology to Manage Instruction *W R Penuel* 133

Technology and Learning – Supports for Skill Learning

New Media, Learning from *W Schnotz and H Horz* 140

Reading and Technology *N DeFrance, D Khasnabis, and A S Palincsar* 150

Technological Supports for Acquiring Twenty-First-Century Skills *C Dede* 158

Technology Supports for Acquiring Inquiry Skills *T de Jong* 167

Technology Supports for Acquiring Mathematics *M J Nathan* 172

Technology Supports for Lifelong Learning *A Collins and R Halverson* 184

Technology and Learning – Supports for Student Collaboration

Knowledge Communities in the Classroom *J D Slotta and H Najafi* 189

Technology and Learning – Supports for Subject Matter Learning

Technology Supports for Science Learning *C Delgado and J Krajcik* 197

Technology Supports for Second Language Learning *D Nunan* 204

Technology and Learning – Teacher Learning

Teacher Skills and Knowledge for Technology Integration *N Law* 211

Technology in Preservice Teacher Education *N Davis* 217

Technology Resources for Teacher Learning *J E Hinojosa, C Labbé, and L López* 222

V

Vocational Education and Training

An Overview of Vocational Education and Training *T Karmel* 229

Informal and Non-Formal Learning in Vocational Education and Training *F Beddie and S Halliday-Wynes* 240

School-Based Vocational Education and Training *B Knight and R Sweet* 247

The Economics of Vocational Education and Training *P Carneiro, L Dearden, and A Vignoles* 255

Vocational Education and Training – Individuals and Students

Age Equality in Education and Training *P Taylor* 262

Career Guidance in Vocational Education and Training and in the Workplace *P Plant* 269

Displaced Workers, Unemployed and Vocational Education and Training *B Kriechel* 275

Immigrant Investment in Host Country Vocational Education and Training *I Kogan* 280

Indigenous People and Vocational Education and Training	<i>R G Schwab</i>	289
Persons with a Disability and Vocational Education and Training	<i>F Ferrier and C S Smith</i>	294
Prisoner Education and Training	<i>S Dawe, S H Wynes, and J Misko</i>	300
Vocational Education and Training and the School-to-Work Transition	<i>G Hayward</i>	306

Vocational Education and Training – Industry and Employers

Apprenticeships	<i>E Smith</i>	312
Skills Shortages: Concepts, Measurement and Policy Responses	<i>C Shah and G Burke</i>	320
Training and Learning in the Workplace	<i>R L Jacobs</i>	328
Training in Small Businesses	<i>H Matlay</i>	337

Vocational Education and Training – Research on VET

Language of Vocational Education and Training	<i>J Misko, J MacKenzie, and R-A Polvere</i>	343
Research on Vocational Education and Training	<i>J Robson and B Bailey</i>	352
Vocational Education and Training Information Resources	<i>L-A Harris, R Naidu, and M Saunders</i>	358

Vocational Education and Training – Teaching and Learning

Employability Skills	<i>E Smith</i>	368
Learning Styles in Vocational Education and Training	<i>J Vorhaus</i>	376
Modularization in Vocational Education and Training	<i>H Ertl and G Hayward</i>	383
Personalized Learning and Vocational Education and Training	<i>I Duckett</i>	391
Recognition of Prior Learning and Vocational Education and Training	<i>J Keating</i>	397
The Competency Model	<i>A Gonczi and P Hager</i>	403

Vocational Education and Training – VET in Context

Globalization and Vocational Education and Training	<i>P Loveder</i>	411
Learning to Work for the Future	<i>J Fien, R Maclean, and D N Wilson</i>	416
The Relationship between Technical and Vocational Education and Training and Innovation	<i>K Ruth and L Deitmer</i>	423
The Status of Vocational Education and Training	<i>J Lasonen</i>	429
Vocational Education and Training in Post-Conflict Countries	<i>E Lyby</i>	441

Vocational Education and Training – VET System

Dual System	<i>T Deissinger</i>	448
Industry Involvement in the Vocational Education and Training System	<i>M Hughes and C Hughes</i>	455
Non-Completion in Vocational Education and Training: Issues, Patterns and Possibilities	<i>S Lamb and A Walstab</i>	463
Planning and Policy Development for Technical Vocational Education and Training Systems	<i>R Maclean and M Pavlova</i>	469
Qualifications Frameworks and their Role in the Reform of Education and Training	<i>M Young</i>	476
Quality Assurance in Vocational Education and Training	<i>D Gunning</i>	482

Training Finance	<i>A Ziderman</i>	489
Training Markets	<i>P Ryan</i>	496
Vocational Education and Training Teacher Training	<i>S Nielsen</i>	503
Vocational Education and Training Workforce	<i>D L Wallin</i>	513

Introduction and Overview

Historically, the development of education systems has spurred ongoing tensions with regard to the appropriate roles of the family, the market, and the state in the provision, funding, or regulation of services. These debates have been even more heated when it comes to the early years of children's lives. Unlike schooling – which has been recognized as a public good for children from about 6 years of age – most countries have a long tradition of informal and private services for children of preschool age. The role of the family continues to be strong, and government is, often, ambivalent about its responsibility. In recent years, many countries have developed strong publicly funded early-childhood systems as part of their welfare states or social protection systems, whereas others have left this responsibility to family and to the market.

Early-childhood education and care (ECEC) straddles many policy domains. As revealed in the Organization for Economic Cooperation and Development (OECD) thematic review of 20 advanced industrialized countries carried out between 1998 and 2006 (*Starting Strong I & II*, 2001 & 2006) and the United Nations Educational, Scientific and Cultural Organization (UNESCO) reviews of developing countries, the funding and delivery of ECEC involves parents and families, civil society and the market, and government (employment policies, income transfers and the prevention of social exclusion, health, education, care and leave policies, etc.). In some developing

countries, conditional cash transfers (CCTs) can also be viewed as a component of education policy, as income supplements for poor families are provided as long as they follow certain behaviors such as enrolling their children in school (or bringing them to regular healthcare check-ups).

This article focuses on the roles of the family, the market, and the state in the provision of ECEC for children younger than the compulsory school age – involving elements both of physical care and education (socialization as well as cognitive stimulation). Throughout the world, ECEC services may be publicly funded and delivered, publicly funded and privately delivered (by for profit or nonprofit organizations), or privately funded and delivered; and they tend to be heavily subsidized by government in most OECD countries. ECEC programs include a wide range of part-day and full-day programs under education, health, and social welfare auspices. The major cross-national differences have to do with such variables as the locus of policymaking authority (national or local), administrative auspices (education, health, social welfare, or a combination), scale of coverage, age-group served (infants and toddlers, preschoolers, primary school aged, etc.), other eligibility criteria (poor, with working parents, etc.), funding strategies (government, employer, parents fees, combination, etc.), delivery strategies (supply or demand), locus of care, primary caregiver (professional, paraprofessional, parent, etc.), and program philosophy, as relevant (**Figure 1**).

The US has adopted a different model from most OECD countries, which assumes that parents will carry personal responsibility for the provision of an adequate standard of living, and that they will achieve this through the workings of the market, primarily. US policies toward ECEC follow a similar pattern. The US provides free primary and secondary public school education for children aged 6–16, and kindergarten, for almost all 5-years-olds; but it does not provide the equivalent for younger children. Several states (Georgia, Oklahoma, and New York) provide universal prekindergarten, part-day programs for 4-year-olds, often in a range of settings, including schools and community-based programs.

Nor does the US ensure universal, equitable access to ECEC. In 2005, 72% of children under age 5 had a primary nonparental care arrangement in the US primarily care by a relative. About half of the 19 million children in the US under age 5 were cared by a relative, usually a grandparent or a parent. Among the 11.3 million children younger than 5 whose mothers were employed, 30% were cared for on a regular basis by a grandparent during their mother's working hours. A slightly higher percentage was cared for in an organized facility such as a center or preschool (US Census Bureau News, February 28 2008). One-third of infants under age 1 are in relative care and those in nonrelative care are often in family day care (child mindres). Furthermore, working parents often choose to work different shifts in order to ensure parental care for their young children. When they do purchase child care, US poor and near-poor parents pay a disproportionate share of their income for ECEC services (in 2008, 29% and 15% respectively) in contrast to 6% for upper income families. (US Census, 2008). In the US, families continue to bear a far larger part of the operating costs of ECEC services than parents in other industrialized countries.

Figure 1 ECEC in the United States: A market approach.

Around the world, the family continues to carry the major responsibility for childcare, early-childhood education, child rearing, and socialization. However, increasingly – both in developed and developing countries – with the rise of women's participation in the labor force, the family's role is supplemented by other institutions. The trend toward the greater involvement of nonfamily resources is characteristic of the industrialized countries, in particular, but there is great variation with regard to which institutions, employing which roles, how they are paid for, and by whom.

This article, next, reviews the distribution of responsibility for the education, care, support, and socialization of young children in the OECD countries among the family, the market, and the government. Fundamental questions remain with regard to the appropriate role of each in the early years of young children's lives. In particular, two cross-national issues are: how should responsibility be allocated among these institutions with regard to policy strategies such as funding, production, and regulation of service quality? Also, what are the implications for quality, access, and equity?

The Role of the Family

The family continues to have the primary responsibility for children and their support internationally – as it has historically, but not exclusively. Several different strategies have been employed to support the family in its role. Most importantly, women (married as well as single) have entered the labor market to compensate for the inadequacy of the traditional family model of two parents

and one wage-earner – because one average wage is not adequate to support a family with children. In addition, there has also been a rise in female-headed, single-parent households.

In addition to the financial support provided by mothers entering the labor force, major policy strategies providing financial support for family care include those that the government gives to the family to offset the costs of childcare, early education, and child rearing. What the European countries, for example, have done to support family care – where they believe it is especially important – is to enact policies that subsidize the family in carrying out caring tasks.

Child Allowances and Tax Benefits

One form of financial support for the provision of family care is a child or family allowance – a cash benefit provided to families with children, based on the presence, number, age of children, and, sometimes, the ordinal position of the child and the employment status and income of the parents. These cash benefits are frequently employed for supplementing earned income for families with children (SSWTP, 2007; Kamerman and Gatenio, 2002; Kamerman *et al.*, 2003; Kamerman, 2005).

A second form is a tax benefit, credit, or allowance – another device for supplementing earnings or off-setting some of the costs of child rearing or childcare. In some countries, family allowances (and tax exemptions for dependent family members) have been replaced or supplemented by tax credits. For example, the United States provides a tax benefit for modest-income working

families with children, and another tax benefit for families with incomes above the tax threshold where children are present. However, the United States has not provided a universal cash benefit as in other countries, nor does it have any other fully universal child benefit. The provision of the Earned Income Tax Credit (EITC) and the Child Tax Credit offer some evidence that the United States acknowledges some level of responsibility for assuring families with children adequate income, but it is only partial, at a limited level, and only for some families with children. The US family-benefit package provided through the tax system is nowhere near as generous as the comparable tax and cash-benefit packages provided by many other countries (Kamerman and Gatenio, 2002).

Third, cash benefits are provided as a guaranteed, minimum child-support benefit advanced by government if the noncustodial parent does not pay maintenance or pays it irregularly or at an inadequate level – and then collected to the extent possible from the noncustodial parent.

Leave Policies

A fourth form of financial support is the enactment of paid and job-protected leaves from employment for working parents – supporting them in their parenting and infant-care roles, providing financial support, and parental care, etc. In OECD countries, the under 3s are especially likely to be cared for by family members, or if not, by family day-care providers. In recent decades, many European countries have enacted a different approach to supporting the family's role in providing infant and toddler care. This comprises a policy of paid and job-protected maternity parental, child rearing, or childcare leaves following childbirth or adoption – lasting 1–3 years, sometimes limited to working parents and, other times, for all parents – fully or partially replacing wages foregone while on leave (Kamerman, 2000a, 2000b; Waldfogel, 2001). The European Commission (EC) enacted a maternity leave-policy directive in 1986, providing for a 14-week paid and job-protected leave for working women at the time of childbirth, followed, in 1992, with a directive providing for a 3-month unpaid albeit job-protected parental leave for each parent.

Sweden is known for its generous leave policies. It provides an 18-month job-protected parental leave following childbirth or adoption. For 1 year on leave, a working parent receives a cash benefit replacing 80% of prior wages. For the next 3 months, a parent on leave receives a flat-rate cash benefit and the final 3 months are unpaid. In addition, fathers can obtain an additional 2 months of paid leave, but this is only available to fathers; if not claimed by the father, it is lost. The objective is to make it possible for parents to take care of their infants at home instead of placing them in out-of-home care, without being subject to a substantial economic penalty.

In October, 2008, the at present 27-country European Union (EU) unveiled a package of proposals in the social policy area. The proposed family-policy package amends the existing maternity and parental leave policies by extending the existing maternity leave from 14 to 18 weeks, with a benefit replacing full wage, and with more flexibility with regard to when the leave can be taken (before or after childbirth). The Commission announced that it would also launch negotiations on other forms of family-related leaves with the social partners (employers and employees organizations) such as paternity leave (a brief period of leave for fathers at the time of birth or adoption of a child), adoption leave (similar to maternity leave following childbirth), filial leave, (a leave to care for dependent family members), and parental leaves. The aim is to conclude negotiations and reach consensus within 9 months. With regard to such policies as well, the United States follows a different path, stressing family responsibility without societal support.

Across Europe, care leaves allow parents to take job-protected leave (often paid at a low, flat rate) and to extend maternity leaves for up to 3 years. These policies provide an alternative to subsidizing expensive infant care. Hungary initiated such a policy – first, in 1967 – while Finland also enacted a 3-year job-protected, modestly paid leave, in 1990, contingent on nonuse of publicly funded childcare or, as an alternative, with the right to a place in public childcare from the age of 1 year. Yet another policy package is that provided by Iceland – where a job-protected, fully paid 9-month leave is provided. Three months are assigned to the mother, another three months to the father, and the final three months are a family leave, with the parents able to decide who should take primary responsibility. Increasingly, attention is being paid to fathers – with the goal of achieving gender equity. The objective is for fathers to participate equally in providing childcare as well as economic support. Parental leaves of long duration have also been used to help fight unemployment by providing incentives for mothers to stay out of the workforce (Morgan, 2006a).

Across countries, most of the care provided by family members is unpaid, but this does not mean it comes without costs. Parents pay for the care they provide themselves by forgoing current earnings from the labor market and by reducing their likely future earnings; they, often, pay for the care provided by other family members by trading goods or services. These costs can be substantial and need to be taken into account when thinking about the resources expended in this sector (Young and Nelson, 1973). Most of the financial, time, and emotional burdens of rearing children (and the pleasures) are borne by parents, sometimes aided by other relatives as well. However, an increasing share is provided outside the family, either purchased in the market or provided by or funded by government, or provided by the family but with the help

of government – as has already been discussed in the previous sections. Next, the role of the market is discussed (Table 1).

The Role of the Market – The Private Sector

(This section draws on Kamerman and Waldfogel in Nelson (2005) and Kamerman and Kahn (1989).)

The terms public and private childcare are commonly used to distinguish among the main auspices of ownership of regulated childcare. These are, generally, viewed as including three main types:

- Public – owned and operated by a level of government (national, state, or local).

- Private nonprofit sector (or voluntary sector) – owned and operated by a nongovernmental educational or social service organization (nongovernment organization (NGO)).
- Private for-profit sector – owned and operated by an individual, a partnership, or a small or large company. A for-profit childcare company may be a publicly traded company (corporate childcare) traded on a stock exchange or a private company.

According to the *UNESCO Statistical Yearbook*, a formal – albeit slightly different – distinction was first made between public and private ECEC programs in 1961. Public preschools were those operated by a government agency, irrespective of whether or not funded by the government; and private preschools were those operating

under private auspices, whether or not receiving private funds. Private providers continue to be of two types: (1) those established by NGOs, women's groups, and religious institutions; and (2) those established by private individuals for profit. Private establishments tend to be regulated when subsidized by government or included in the public system.

Private Provision of ECEC Services

How large is the private sector for ECEC today? In most of the OECD countries, ECEC programs are publicly funded and delivered. The portion of children enrolled in private programs – largely under religious auspices or other types of nonprofit sponsors – range widely across countries from being a major component of the delivery system in Australia, the United States, the United Kingdom, New Zealand, Germany, and the Netherlands to playing an insignificant role in the Nordic countries. In Australia, for example, the private, for-profit sector provides about 70% of full-day child-care centers (~70%), and at least 25–30% of these are held by the ABC Learning Corporation that recently went bankrupt (see below).

In Europe, the privatization of early care and education, since the 1980s, has occurred in partnership – rather than in competition – with the state. A range of alternative forms of provision has emerged, albeit unevenly, to accommodate diverse families and diverse communities. In France, nonprofit and voluntary organizations involved in child care proliferated during the 1980s and 1990s (Ullman, 1998). Since the late 1970s, nonprofits have grown from a little over 10% to more than 40% of all childcare providers. These organizations tend to be small – and in contrast to the past – most are not religiously affiliated. Much of the growth in the nonprofit sector is linked to the development of parent cooperatives (Eme and Fraisse, 2005). French local policymakers increasingly recognize the potential of private programs to provide flexible services for parents who work nonstandard hours or live in rural areas where there are not many family supports. In 2003, for the first time, private, for-profit *crèches* could receive public subsidies to address the supply shortages, but the issue remains ideologically charged (Neuman, 2007).

In Sweden, the proportion of children in preschool who attend nonmunicipal provision grew from 5%, in 1990, to 17%, in 2002. Parent cooperatives still account for nearly half the places in nonmunicipal preschools. Pysslingen – the largest for-profit early-care and education provider in Sweden (established in 1984) – expanded from six preschools in 1991 to more than 60 in 2007. Two-thirds of private preschools are cooperatives and one-third are for profit. Even if the private sector constitutes less than 20% of the total provision, it remains an influential part of the welfare state contributing to the

expansion and diversification of early-care and education services (Vamstad, 2005). It is important to emphasize that the growth of the private sector, in most of Europe, has occurred within the infrastructure of a carefully publicly regulated and funded system, so that even the differences between France and Sweden, for example, will be small relative to those nations that have adopted a more free-market approach to ECEC.

The standard arguments in favor of a private sector role in ECEC include: (1) The likelihood of the private market producing a larger supply; (2) freedom of choice for consumers; (3) the greater efficiency among for-profit providers; (4) support for individual choices versus societal choices; and (5) the greater responsiveness of the private market to consumer preferences. The major arguments against a role for the private sector, or limiting its role, include: (1) the inadequate supply of ECEC services produced by the private market; (2) inequitable access to ECEC services; (3) the reluctance of market providers to invest in poor neighborhoods exacerbating the problem of inequity in access, especially with regard to low-income families; and (4) the inadequate quality of ECEC services produced by the private market. This section focuses on the impact of privatization on quality and access issues.

Impact of the market on quality

There has been a long-standing debate in the childcare literature as to whether for-profit providers operate differently and – in particular, whether they offer lower-quality care, on average – than nonprofit providers. Most of the research has focused on countries with large for-profit sectors (Australia, Canada, New Zealand, United States, etc.). Although generalizations are hard to draw – given that there is a range of quality in both settings – the weight of the evidence suggests that these providers do operate differently and that on average for-profit providers do offer lower quality care than nonprofit providers (see, e.g., Gormley, 1995; Smolensky and Gootman, 2003; Cleveland and Krashinsky, 2003). In the landmark Cost, Quality, and Outcomes Study in the United States, for example, states with low licensing standards had lower quality for-profit centers than nonprofit centers (Morris and Helburn, 2000).

To make a profit, centers may cut costs by hiring poorly trained staff at low wages – leading to higher staff turnover, which jeopardizes quality. A recent research review of privately owned and community-owned early-childhood education provision in New Zealand found statistically significant differences in the employment of staff holding a teaching qualification, and of staff holding no early-childhood qualification between community- and privately owned education and care centers (Mitchell, 2002). Private centers tend to employ fewer staff with ECEC qualifications and they also tend to pay their staff less than community centers. These findings are consistent

with research in Canada and the United States. An analysis of four Canadian datasets with information about quality of childcare services and for-profit/nonprofit status of centers found significant quality differences between nonprofits and for-profits across Canada. In larger or thick markets, they are able to attract better staff, directors, and leadership because of their mission and ability to produce better-quality care for children at an affordable price. Even with financial resources held constant, nonprofits are better at producing quality services, with an advantage ranging from 7.5% to a 22% across the datasets. Only in thin markets, with less competition between public and private centers – and with inadequate parental ability to pay for higher quality care – did the researchers find no average quality difference between for-profits and nonprofits (Cleveland and Krashinsky, 2005).

It should be noted that most countries require private and public providers to follow the same quality standards if they are to receive public subsidies and, in many cases, if they are to operate at all (e.g., Belgium and Denmark). Regulating private early-childhood services, in France and Sweden, appears to help reduce quality disparities across different forms of provision. In both France and Sweden, the nonprofit sector was viewed as a model for parental involvement and innovative pedagogy – although these programs also have difficulty meeting the same quality standards as public services. By increasing innovation and responsiveness to local needs of families (e.g., parental involvement and different pedagogies), privatization improves some aspects of quality. The regulation of staff training and ratios are critical as these two variables are among the strongest predictors of quality (Neuman, 2007).

Impact of the market on access

An earlier analysis (Kamerman and Kahn, 1989) found that childcare services constitute the prototypical illustration of privatization and a stress on the private market as an explicit social service policy. The childcare industry has always been a mixed economy in the United States as in Australia, Canada, New Zealand, and the United Kingdom. Privately funded and operated programs have always coexisted with totally public programs. Publicly funded, but privately delivered, child-care services came to dominate the childcare market in the United States as the supply of services increased during the 1970s and 1980s, in response to federal regulations which permitted public funds to be used to purchase services from private nonprofit providers, and the Child and Dependent Care Tax Credit permitted working parents to purchase services from for-profit providers and still benefit from the tax credit. Subsidizing demand created an incentive for parents/consumers to purchase care in the open market and encouraged private sector providers to produce and deliver services. It is also worth emphasizing that the private sector in the United States consists of more for-profit

providers, and fewer nonprofit providers, than is the case in many other countries.

Another difficulty is when one corporation becomes a relative monopoly by purchasing other smaller providers that fail to make a profit. In Australia, the world's largest childcare company went bankrupt in November 2008 – when it could not repay the \$1.54 billion debt that it acquired during an expansion into the United States and the United Kingdom. ABC had expanded rapidly, since the late 1990s, when the conservative government ended subsidies to nonprofit providers in favor of a market-based approach that gave parents tax rebates for purchasing care. The downfall of a company which covers 25% of the childcare population will have potential consequences for the tens of thousands of working parents stranded without childcare services – and, of course, to the 120 000 children enrolled in ABC Centers. (In contrast, the largest child care providers in the United States and Britain control only about 2% or 3% of child-care places.) Children's advocacy groups have called on the government to rethink its market-based approach to childcare which they argue has led to higher costs, fewer options, and lower quality (Foley, 2008).

If ECEC is viewed as an important and increasingly essential service, the challenge is how to ensure equitable access. Leaving ECEC to the market will not redress that problem, since – without governmental intervention – only the more affluent families will be able to afford high-quality care. A further concern is that the private sector or the voluntary agencies may siphon off the more affluent consumers or the more able children while compromising access and quality for the poor by leaving the more difficult cases in the hands of an underfunded voluntary sector or an understaffed public sector. In countries such as France, Germany, Sweden, and the Netherlands, the private sector (nonprofit and, to a lesser extent, for-profit) expanded supply, as well as diversifying the types of programs available (e.g., part-time and parent cooperative). There are equity concerns – as low-income families tend to be underrepresented in private early-care and education programs, including parent cooperatives. In sum, greater market involvement can expand options and choices for parents, it may also foster inequities of access, quality, and cohesion between public and private services (OECD, 2001). Although there has been some increase in private provision recently, the public role remains overwhelmingly dominant. Governments expand their supply by funding and operating more programs or by increasing subsidies offered to providers.

The Role of Government

The role of the government in ECEC has increased as a means to support working parents – especially mothers – with young children, as well as to promote young

children's early development and learning and their success in formal schooling. As a result, several OECD countries now guarantee children a place in ECEC when they reach a certain age (age 1 in Denmark and Sweden; age 2.5 in France and Belgium; age 3 in Germany and Italy). More than 60% of 3-year-olds in the EU were enrolled in day-care or preschool programs, in 2004, and 21% of the under 3s (OECD Family Data Base).

Governance or administrative auspice is another key dimension affecting ECEC policies and programs. The major difference is whether the auspice is education, health, social welfare, or some combination, and, if a combination, whether responsibility is carried out sequentially (as children get older the auspice shifts) or simultaneously. The dominant European pattern (and increasingly in developing countries) is one in which the programs serving the 3–6-year-olds, until compulsory school begins, are cared for under education auspices while the younger children are cared for under health or social welfare auspices. There is an emerging trend in Europe to include care of the under 3s also under education – as can be seen in England, Norway, Scotland, Slovenia, Spain, and Sweden – in addition to such non-European countries as Brazil, Kazakhstan, and New Zealand.

As provision of care and education of young children increasingly shifts from families to nonfamily institutions, one question is what role belongs to the government? In reviewing the role of government in ECEC internationally, government clearly plays a major role – in the funding, production/delivery, and regulation of ECEC. In terms of funding, in most of Europe, the costs of enrolling a child in ECEC is heavily subsidized, and fees are often determined on a sliding-scale basis according to parental income. Sweden enacted a policy whereby a maximum fee for ECEC programs for all children is set at no more than 2–3% of family income to shift some of the cost burden from families to the state. (In the 1990s, during difficult economic times, the parent share of the total cost of preschool had increased from 10% to about 18% (Blomqvist, 2004).) Preschool in Belgium, France, and most of Italy, covering all children in the age range of 3–6, is universal and free as a part of the educational system. Universal, free preschool for 4–5-year-olds was introduced in England and Sweden in more recent years.

What is the government's role in directly providing these services? All the advanced industrialized countries have moved toward government having the dominant role with regard to primary school and some countries have gone further by beginning primary school at the age of 5 or 4 (e.g., United Kingdom and Netherlands). Even in the United States, there is a good deal of movement toward universal preschool at age 4 – a position adopted by governors of 43 states. Government's role is especially strong in those countries that have adopted an educational framework or model for their ECEC programs, especially

for those serving children from 3 to compulsory school age, whether by delivering ECEC services directly or publicly funding NGOs to deliver these services. ECEC preschool programs serving children of this age are operated, largely, under education ministries or departments and viewed as part of the education system.

In contrast, ECEC services for the under 3s are more diversified, involving governmental support but also voluntary agencies and the market as well. Moreover, in some countries, nonfamily care of the under 3s is largely family day care or child minding, with funding and delivery, largely, private but, sometimes, with governmental regulation and monitoring – another role assigned to government. Although there is little debate with regard to a significant role for government in preschool programs, the measures used for distributing the funds remains a matter for debate, especially among programs serving the under 3s.

A second question is whether government should provide financial support for care delivered by the private sector (nonprofit or for-profit). If government does not provide the services directly, what is its responsibility for funding these services? In addition, if it does provide financial support for these services, a third question is – what measures should government use for distributing the funds, especially among programs serving the under 3s? Should it use demand-side or supply-side measures to allocate its investment in ECEC – should it subsidize the parent/consumer of ECEC services or the provider? The main issues are choice, quality, and access and whether these dimensions are enhanced or diminished in the private sector or through demand-side subsidies?

The Netherlands has opted for a unique demand-side approach with a tripartite financing of government, employers, and parents. There has been spectacular growth in the number of childcare places – from 22 000 places in 1989 to 206 714 in 2004. In 2004, each place was occupied by about 1.6 children. The 2005 Childcare Act seeks to further stimulate supply by creating more choice for parents and a greater scope for market forces. Employers are required to cover one-sixth of childcare costs per parent; the government steps in only if the employer fails to contribute. The Act includes only limited quality requirements. Services compete in terms of price and quality, and the impact for children needs to be monitored (SZW, 2005). Hasan (2007) cautions that demand-side subsidies (tax benefits or vouchers) assume that parents have adequate information to choose from among the alternative programs. However, parents may not have adequate knowledge to select the best-quality program and poor-quality providers may drive quality providers out of the market. In contrast, supply-side measures may end up involving higher costs.

The OECD reviews (OECD, 2001, 2006) pointed to the need for substantial public investment in ECEC

services and the infrastructure to support a sustainable system of quality, accessible services. Without governmental investment, regulation, and supervision, children's services will be disorganized, and of low quality. Government alone may not guarantee quality, but without government funding or regulation, quality is likely to be poor, programs weakly monitored, and access constrained (Bennett, 2007).

A final issue is with regard to government's role in relation to parental leave policies, involving labor-market policies with regard to job-protected and paid parental leaves from employment. Clearly, if there is no statutory provision, leaves are likely to be inadequate, access limited, and coverage sparse – as can be seen in the United States and Australia, for example.

Conclusions

Although the family continues to have primary responsibility for the care and rearing of its young children, it is no longer the institution with exclusive responsibility and the role of nonfamily institutions continues to increase. Given the increased time that children spend in care, education, and socialization carried out by nonfamily institutions, adequate and equitable access to decent-quality care is essential. The role of the family in ECEC is obviously important; however, the family can no longer do the job by itself – meaning that government or the market must step in – because if decent-quality ECEC services are not available for preschool-age children, the children, the schools, and the society will suffer.

History shows us that when families cannot meet the education and socialization needs of their children, the government has stepped in – as it did when establishing public primary schools. Experience has shown that when families cannot meet the care and education needs of their preschool-age children on their own, the private sector alone will not do an adequate job. Government must play a role – whether as a provider of services directly or as a funder and regulator of services provided by the private sectors.

The trend toward the greater involvement of nonfamily resources in ECEC has been observed in all industrialized countries. Where countries have diverged is in who has picked up this responsibility. In the United States, policy in this area has tended to look first to the family and private sector and to look to government only in the event that the market fails or if there are compelling reasons of public interest for the government to get involved. In European countries, in contrast, policy has tended to look first to the government, and the role of the private sector in the ECEC sector has been minimal. Where the private sector exists, it has developed within the framework of a publicly regulated and funded system which minimizes disparities in access and quality.

If society values quality ECEC services, either government will provide the services, or it will provide the resources and ensure adequate quality, or the private sector will provide the services, and the government will subsidize access and regulate them. Thus, key policy issues are to ensure the adequacy of the resources provided (largely requiring public funds); expanding equitable access irrespective of income; recognizing differential quality and good management and accountability to ensure quality; and acknowledging the importance of government supporting families in their parenting roles.

Access (the ease of obtaining a place in an ECEC program) and coverage (the percentage of an age-cohort enrolled in these programs) are clearly important indicators of a country's commitment. The most extensive access and most complete coverage are in those countries with a strong governmental role both in funding and delivery of ECEC. The highest rates are for children enrolled in programs under public education auspices. Between 95% and 99% of this age group are enrolled in the public, voluntary, free, and universal programs in Belgium, France, Italy, and Spain – covering the normal school day, often with supplementary after-school services as well. The EU Barcelona targets of at least 90% coverage of 3–6-year-olds in ECEC by 2010 have largely been reached, with strong governmental support, although not all coverage is for a full workday. The target for the under 3s, at 33%, is close to being reached if coverage by parental leave policies are included. Looking ahead, the missing link in the Barcelona targets are guidelines for adequate resources and appropriately trained and qualified staff – critical components of quality.

Gender Issues in Early Childhood Education and Care

B Pocock, University of South Australia, Adelaide, SA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Carer-citizens – The notion that citizenship can be built around care activities, as well as around other activities like paid work. Contests the notion that citizenship should require participation in paid work.

Dependency ratios – The ratio of those of nonactive age (i.e., not in paid work) to those of active age in a given population.

Gender contracts – The unwritten cultural, social, and economic ‘contracts’ between the sexes which distribute paid and unpaid work and care, and other social and economic resources unevenly between women and men, disadvantaging women.

Gender regime – The prevailing set of social, cultural, and economic policies within which male and female citizens live and work, and which differentially shape outcomes for men and women, often disadvantaging women.

Male-breadwinner households – Households where men are the breadwinners and women the unpaid carers and domestic workers.

Work-care chains – These are the chains of care that are created internationally by changing work patterns as immigrant workers are drawn into caring for the children of those in higher income households and countries, leaving behind care deficits in their countries and households of origin.

‘Work first’ policies – Social and labor market policies that require participation in paid work in exchange for state support, or which give priority to entering paid work.

Working-carer citizens – Workers with caring responsibilities who need access to full citizenship that recognizes these joint responsibilities.

The care and education of young children has, for long, fallen unevenly between the sexes, making the gendered nature of care – and its consequences for women and men – an important aspect of the discussion and practice of the care of children. As mothers, women have been the major carers of children from time immemorial. As the majority of paid workers in childcare and early-education systems around the world since the industrial revolution, women are also differentially affected from men as care-providers, educators, and workers. The value placed on care and care work and its terms and conditions – in both the world of the

private household and the world of the public workplace and nation – significantly shape gender inequality. Care regimes – that is the complex cultural, social, and institutional practices of care – help constitute gender regimes (and vice versa). Beyond the nation-state, cross-country work-care chains also construct international chains that link-up workers who emigrate to provide care in richer, industrialized countries to those who provide and receive care in poorer, less industrialized countries. These work-care chains are also gendered. Thus, early-childhood education and care (ECEC) of children is highly gendered – and the nature of care and work arrangements around children have shaped the spoken and unspoken gender contracts between men and women in many countries – both individually and at the wider national level.

In this article, perspectives on care and women’s equality, the nature of the gender contract, the search for new ECEC policy principles to underpin greater equality for women, some comparative ECEC international experiences and their impacts upon women, and the notion of international work/care trades and gender equity are considered.

Care and Women’s Liberation

Education and care arrangements for children have been central concerns of women’s movements in both their first-wave (in the eighteenth and early nineteenth century) and second-wave configurations (since the 1960s).

A prominent first-wave feminist Mary Wollstonecraft – writing in 1792 – argued for the education of women, including girls, partly on the grounds that better-educated women would make better-educated mothers and carers. More equality for women was justified on the grounds that it would improve women’s mothering and care. Feminist writers, such as Carole Pateman, have coined the term Wollstonecraft’s dilemma to describe the difference between arguments – such as those advanced by Wollstonecraft – for women’s equality based on their biological and social responsibility for social reproduction and care, versus arguments rooted in women’s right to be treated as equal citizens, irrespective of their biology or maternity. Should action fostering women’s equality rest on responses that deal with their differences from men, or should such action aim at equal treatment with men, treating them the same as men without discrimination? The answer to Wollstonecraft’s dilemma is obvious when it comes to consideration of care issues: to ignore their differential effects

on women and men, as if men and women are the same, cloaks one of the main drivers of gender inequality – the differential impact of care – under a mistaken discourse of equal treatment.

From the early 1970s and the first days of second-wave women's liberation, the gendered nature of the care of children has been a concern of women and their political organizations – attracting attention as a practical policy issue as well as a theoretical concern at the heart of understanding gender relations.

For example, among the earliest writings of the women's liberation movement in 1969–72 in Britain, concern with regard to the care of children figured prominently. Alongside equal education and opportunity, equal pay, and free contraception and abortion, 24-h nurseries were among The Four Demands made by the first national women's conference at Ruskin College Oxford in February–March 1970.

For gender theorists, the care of children is a critical issue that sits at the interface where the public and private worlds meet. The male-breadwinner family form – dominant in many industrialized countries in the postwar years – included a female carer, naturalized as the normal child-carer. As Germaine Greer put it in *The Female Eunuch*, in 1970, “Mother duck, father duck and all the little baby ducks. The family, ruled over and provided for by father, suckled and nurtured by mother seems to us inherent in the natural order” (p. 219). The unwinding of the male-breadwinner household in many countries, since the 1970s, has made the issue of caring for children of vital importance to discussion of gender equality in both theory and practice.

The Gender Contract: The Slow Decline of the Male Breadwinner

The contract at the core of the male-breadwinner/female-carer model states that men will work for pay while women will provide care at home and undertake all the tasks of social reproduction – of children, the male worker, the female carer herself, and much of the community in which they are located. In this model, the state may also play some role, for example, helping to provide some public childcare or assistance with paid maternity leave. However, the nature of this private/state sharing varies from nation to nation.

To work, the male-breadwinner model relies on several factors: household/relationship stability; women's willingness to accept economic dependence on a male breadwinner; citizenship for women conferred primarily through household life, care, and maternity; and male earnings high enough to sustain a household with two adults and children (what is, often, referred to in the United States as a family wage). Many threads of this model have unraveled in Western countries in the past 30 years with changing female aspirations, women's active pursuit of independence, rising divorce

rates, declining real individual wages that cannot sustain a family, and a labor market hungry for women's contribution to paid work.

While countries such as Australia embedded the male breadwinner at the core of their wage-fixing system for most of the twentieth century, the proportion of male-breadwinner households has fallen sharply so that they are now in a minority. In most Organization of Economic Cooperation and Development (OECD) countries, the proportion of dual-earner households has increased rapidly, since the 1970s, along with the proportion of single-parent households.

In the context of rapid change in household shape and labor-force participation rates, arrangements for ECEC have been under increasing pressure in many places.

Complex, Competing Drivers for Increased ECEC

Childcare has become a major policy concern in OECD countries, reflecting several drivers. These include increasing female participation in paid work and a push to increase female labor supply; an interest in increasing (or at least moderating the rate of decline in) fertility rates; public policy interest in increasing children's welfare and well-being and protecting the rights of the child; recognition of the importance of quality care early in life to children's optimal development; and a desire to narrow inequality between young children through the provision of quality early-childhood services.

Improvements in ECEC systems have also been motivated by a desire to reduce inequality between women and men, and reshape the gendered nature of economic and social citizenship. However, the relative strength of this motivation varies greatly between countries and economic contexts.

These multiple policy goals do not always sit easily alongside each other: for example, it is possible to rapidly increase childcare provision in ways that compromise quality and, thus, the well-being of children and it is possible to provide care of infants by paying mothers to stay at home and out of paid work, but the implications for gender equity are not always positive.

Who Should Care? Mothers, the State, and the Market?

The balance of ECEC provision by the private household (mostly through the work of mothers), the state, and the market has been shifting in many countries in the face of women's rising labor-market participation. This balance is affected by a complex set of factors including the nature of the gender regime that prevails (e.g., whether supportive

of maternal care or public ECEC provision), the nature of work arrangements and supports (including the availability of paid maternity and parental leave, and flexible work arrangements), and the extent and availability of public childcare, as well as prevailing tax and welfare systems. These arrangements vary widely from country to country. Consider the examples of Denmark, Iceland, Germany, and Australia.

Denmark

In Denmark, in dual-earner households both partners are likely to work full-time prior to and following their children. Parents, generally, have a year off with the birth of each child, earning around 80–90% of their usual earnings in that year. However, as in most countries (even where paternity leaves are relatively generous), men take only a small portion of this leave. There is, in effect, little earnings or career penalty for either parent when they take time out to look after children, and the tax system encourages dual earners. Core working hours, in Denmark, are 37 and long hours (such as those affecting significant numbers of men in the United Kingdom, Japan, South Korea, and Australia) are less common than in many countries. What is more, quality, well-regulated childcare options are available in Denmark. Following the first year of an infant's life, publicly available childcare is, generally, available and its use is socially accepted. Indeed, public childcare is seen by some as preferable to parental care because of the high-quality childcare standards, removing social sanctions against the use of nonmaternal care. One consequence of all of this is that women who take breaks from paid work around their children suffer relatively slight negative effect upon their life-time earnings in Denmark.

Alongside this, couples in Denmark tend to share housework and unpaid care more than in most other developed countries, although still far from equally. While women in Denmark, often, shoulder a full-time job as well as the main load of domestic work – making them tired and pressed for time – they have a high level of social support from the state, a narrow gender pay-gap (women earn around 89% of men's earnings), and the prospect of a retirement without poverty. Interestingly, Denmark enjoys both high female-participation rates (71.7%) and high fertility (total fertility rate (TFR) of 1.8).

Iceland

Even better than Denmark is the example of Iceland, which has the highest birth rate in Europe, high labor-market participation among women, and tops the world on measures of overall human development (such as expectancy, education, and standard of living) and happiness – at least prior to the Global Financial Crisis of 2008/09. With the highest divorce rate in Europe, the country also has a

culture that is relatively accepting of change in family shape, and supports transitions, rather than penalizing them. Mothers and fathers enjoy 9 months shared paid parental leave at close to replacement earnings and some attribute the high levels of well-being in the country to the relative equality that women enjoy.

Germany

Compare this with Germany – ranked much lower on human development measures – where the lack of childcare, marginal part-time work for mothers, a family-based rather than individually based tax system, and – until very recently – limited maternity leave are associated with both low fertility (TFR of 1.3) and low female participation in paid work. Gender pay-inequity is wide, with women earning around 74% of men's earnings.

Australia

Australia scores well on general human development and happiness scales but mothers have been increasing their attachment to paid work and retaining responsibility for domestic work and care at the cost of their personal time – with the majority of mothers, often, feeling rushed and pressed for time (Pocock *et al.*, 2009). Public childcare has increased in availability in Australia in recent years. However, much of it is provided not by the state but by large monopolistic corporate for-profit providers. The proportion of Australian women – who are working before their child is 1 year old – doubled between the mid-1970s and 2001, to reach 36% and many parents look to grandparents for help with childcare because of problems of cost, quality, and accessibility associated with formal care. The gender pay-gap is narrow by international standards but Australia's occupationally based superannuation system implies that only a minority of Australian women can look forward with confidence to a comfortable retirement – given that women work, on average, around half as many effective years as men (20–38). Lively debates with regard to the morality of nonmaternal care for children in Australia have been overtaken by women's behavior with increasing use of ECEC services and most Australians, at present, experiencing some type of formal childcare prior to their entering school.

Women's 'Choice' in Different Contexts

As in most countries, women in Denmark are more time pressured than men, but they do not have to choose between maternity and labor-market attachment, unlike many women in Germany, with long-term consequences for their earnings, pensions, and the welfare and income available to them and their children – especially if they

divorce. These brief examples illustrate how the terms for combining work and family are much more positive for women in some countries than others – with important consequences for gender equity. In this context, cultural norms and institutional arrangements (including parental leave from paid work, the availability of ECEC services, and tax-and-benefit systems) matter a great deal in terms of their implications for gender equity.

The Role of Men in Domestic Work and Care

In most countries – irrespective of patterns of participation in paid work – women do much more domestic work and care than men. According to the OECD, women do 80% of domestic work and childrearing in the European Union (EU), and men's behavior has barely evolved since good surveys of behavior and time-based activities began – except in the United States and the Nordic countries.

In 2006, Australian women, on average, did twice as much unpaid work and care as men and this hardly changed between 1992 and 2006. It appears that women's increasing entry to paid work has hardly shifted the distribution of unpaid work, leaving most of it with women. The hardy persistence of these gendered norms – and men's resistance to its redistribution – remains one of the great puzzles of masculinity and a significant barrier to gender equality, especially in relation to housework and the care of children.

One of its consequences is the low value – rhetoric aside – placed on mothering and all care work. This valuation casts a long shadow in the labor market, with many forms of feminized work – such as care and early-childhood education work – paid much less than other forms of work that require less skill, training, and effort and involve less responsibility. In Australia, for example, childcare workers are among the country's lowest paid workers, despite the demands of their work.

Conceptualizing Gender Equity in a More Individualized World of Work

The decline of the male breadwinner/female carer model throughout OECD countries has given rise to discussion of an adult worker model – where it is assumed that individualized men and women both work and both care. The key issue in considering gender outcomes in this adult-worker state is the actual distribution of work and care and the terms on which they occur. Variable conditions of work and care lie beneath summary measures of participation in either work or care. For example, many women who manage to enter paid work do so through insecure part-time – or by undertaking complex juggles of work/care – arrangements which leave them pressed for

time and, sometimes, making use of poor quality or unsafe childcare. In this context, the quality of paid work, its rewards, and the ease of its combination with care become very important, as does the capacity of the state (or the market) to help meet the care gap when more adults work.

While some suggest that decisions around care and paid work are simply a matter of choice, the country differences described above show that such choices are socially embedded and constructed by cultural contexts (especially dominant beliefs with regard to the role of women, mothers, and fathers), institutional arrangements, and social policies. Real choice – especially for women – depends upon considerably more than personal decisions. In addition, gender equality depends on much more than equal participation in paid work. For many women, this means the right to add paid working hours to an unchanging and disproportionately large care and housework load.

Work, Care, Gender, and Citizenship

Many OECD countries are introducing work and social policies that – embedded in a discourse of rights and responsibilities – require work of those who can do it including mothers in exchange for social supports (for example, work-first policies). However, the attachment of the rights of full citizenship to the working citizen should not exclude from full citizenship those who withdraw from work to care, or those who combine work with various forms of care over the life cycle – as carer-citizens and working-carer citizens, respectively. In addition, it cannot be assumed that all care can or should be commodified – given that parental care of children is much more than mere work: it is relational and emotional.

In this light, some writers have suggested that all workers should have both the capability (i.e., the real choice underpinned by necessary supports) to work and to care. Achieving this relies on a menu of commodified care options, some of which are within the family (such as paid leave and/or payments to parents allowing them to withdraw from paid work to provide care) and some of which are defamilialized through the establishment of ECEC systems and/or subsidies to parents to organize nonparental care. The outcomes of these various policy options have different gender effects: for example, the provision of paid maternity leave will assist women but may embed mothers as carers unless accompanied by paid paternity leave, with some incentive to fathers to take it. Cash payments to parents to stay at home to look after children, in place of using a state-provided childcare place, increase pressure on mothers to withdraw from paid work – to provide care, with long-term effects on life-time earnings and employment possibilities. In other words, different policy settings and options have contrasting effects on gender equity.

The EU has set a female participation-rate goal of 60%, by 2010, to meet economic objectives. However, achieving this without widening gender inequality or facilitating the movement of children into poor-quality care relies on an expansion of the supply of quality non-familial care as well as quality jobs. At present, European approaches to these challenges are diverse, with countries in Eastern Europe moving to reduce state-based supports for services such as long, paid parental leaves and child-care, while western European countries have approaches that vary from the traditional family-care model of Southern Europe to the caring-state models of the Nordic countries. It appears, however, that there are some signs of convergence in Western Europe and the United Kingdom, New Zealand, and Australia, with greater public responsibility for childcare and increasing care-related social rights (including improved rights to paid leave).

Policy Directions for Gender Equity When Mothers Work

Societies that are to enjoy high levels of gender equity – while increasingly relying on the paid work of mothers – have to provide a number of practical policy supports. These include quality, affordable, accessible ECEC; long parental leaves; quality part-time jobs and flexibility at work; and work practices that permit workers – especially women – to reconcile paid work with care. Real choices for mothers – with regard to their work and care options – rest on an active state that meets the differences in the situations of women and men and mothers and fathers, with support. While not all households will evenly share unpaid housework and care – and this gendered inequality has important effects on women’s labor-market standing – without significant provisions such as publicly provided ECEC systems, there are few prospects of genuine equality for women. What is more, the effects of poor ECEC systems do not fall evenly in terms of social class – with poor women most likely to have to make use of inferior-quality care, to take poor-quality work, or return to work more quickly than they would prefer following the birth of a baby, in pursuit of an adequate income.

International Care Trades to Underpin Work

Beyond the national level, international gendered circuits of care and work are very visible. A gendered global care economy exists, underpinning labor markets. Rising dependency ratios in every OECD country (defined as the ratio of those of nonactive age to those of active age in a given population) are predicted to increase significantly over

coming decades, especially following 2010 and particularly in the EU and Japan. This reflects the declining birth rate and increasing life expectancy. Thinned care capacities do not speak well for the future of care in some OECD countries. As a result, many are entering new international care trades with poorer countries – with particular implications for women.

Rapid population growth in poorer countries – accompanied by high levels of national poverty – is accelerating immigration to countries facing a shortage of carers. This has important implications for global care and work-flows. Rachel Salazar Parrenas, in her 2001 book, *Servants of Globalisation*, describes how 6.5 million Filipino immigrants, mostly women, are at present residing in over 130 countries as domestic workers, cleaning and caring for children in wealthy countries and households.

These international circuits of care are not only gendered: they are also racialized. Rich white nations (such as the United States, Canada, the EU, and Australia) draw on, mostly, women of color from Asia and Africa to do their care and dirty work – usually at very low pay. This creates an international, gendered distributional care injustice, as care is drawn upward and away from the country of origin, where a local care-deficit results.

This has important personal implications in the family networks and dependents in families, where poor workers of color provide care to the white rich at the cost of caring for their own families who may miss out on adequate care as a result – resulting in a tiered transfer of reproductive labor and care. The quality of care – and certainly its rewards – often, deteriorates as care is passed down an international chain of care and the poorer Third World takes on a share of the care and reproductive work essential to labor participation in richer First World countries.

In Arlie Hochschild’s words, a ‘care drain’ thus enjoins a ‘brain drain,’ as private acts of immigration are undertaken to meet the public problem of a First World care-deficit – at great emotional cost arising from what she calls ‘global heart transplants.’ At the bottom of the international hierarchy of reproductive care are the children of the end-carers in the Third World. Rich nations can mitigate the care deficit, created by women’s entry into paid work, by drawing on imported female carers, but only by creating a care deficit down the global care chain – one that poorer communities are least equipped to meet. A labor of grief is created both for the mothers who leave their children behind and the children who plead for their mothers to come home. Some argue for a global ethic of care to meet this problem which creates obligations for those who draw on the care of poor female immigrants and drain the quality of care in the country and family network of origin. The international character of care chains creates a strong argument for international cooperation around the creation of good national systems of ECEC and improving gender equality by providing decent employment standards for carers, the

fair remuneration of care work, and good national public systems of care to underpin the growing labor-market participation of women – society's traditional carers.

Introduction

Early childhood is an important social, developmental, and educational stage in a child's life. Young children from preschool to early elementary school age (generally categorized from age 3 to 8 years) are most vulnerable to conditions of risk, abuse, and neglect, and are the age group most often referred to social services agencies because of concerns for their well-being. Conditions that put a child at risk of abuse or neglect also influence a child's ability to reach important life milestones.

For these reasons, organizations involved in providing services to children – from social service agencies to schools – share an interest in responding to concerns about need, risk, and abuse. However, the ways in which different organizations respond to concerns depend on the context in which services are provided – from the organization itself, to the community, society, and national contexts in which these are situated. Furthermore, the purposes of service provision depend on underlying assumptions behind definitions of risk, prevention, and abuse in these contexts.

Although there are thousands of peer-reviewed articles on the broad subject of child abuse, there has been relatively less conceptualizing about the challenges of reaching a shared understanding of the concepts of risk, protection, and abuse in childhood. Classifying and distinguishing between concepts in child welfare and child protection are hindered by the lack of agreement on definitions. It is not, however, simply a difference in opinions on definitions between disciplines such as education, psychology, and social work. Arrival at shared definitions is also hindered by the complexity of the political, social, and historical contexts in which definitions are created.

Given the amount of contact between children and educators, this is as much an educational concern and it is important, therefore, to understand approaches to

understanding key concepts connected with children at risk. This article offers a means to approach the complexity of early-childhood risk, protection, and abuse prevention by highlighting some of the key areas wherein concepts of need, risk, protection, and abuse can be elucidated.

Forms of Child Maltreatment

Child maltreatment is a social phenomenon embedded within the particular historical, political, and legal contexts in which it is identified. It appears in the milieu of class, gender, age, and race and is influenced by the key processes of modernization and individualization. The ways in which the problems of child abuse and neglect are defined by service providers and the wider society lead to particular ways of constructing responses to the problem and determining the grounds for state intervention in the protection of a child's well-being.

Although child maltreatment is a social construction, there is an increasing acceptance of the definition of child abuse or maltreatment as any act or failure to act – by a parent or other person in the context of a relationship of responsibility, trust, or power – which results in serious physical and/or emotional harm, sexual abuse, neglect or negligent treatment, or commercial exploitation resulting in actual or potential harm to the child's health, survival, development, or dignity.

Physical Abuse

Physical abuse is normally defined as a nonaccidental and substantial physical injury to a child, for example, striking, kicking, burning, or biting the child, or any action that results in a physical impairment of the child. It may also include acts or circumstances that threaten the child with harm or create a substantial risk of harm to the child's physical health or welfare.

Sexual Abuse/Exploitation

Some jurisdictions refer – in general terms – to sexual abuse, while others specify various acts, from invitation to sexual touching to incest, as sexual abuse. Sexual exploitation is an element of the definition of sexual abuse in most jurisdictions. Sexual exploitation includes allowing the child to engage in prostitution or in the production of child pornography.

Emotional Abuse

Emotional abuse has, more recently, entered into the scope of definitions of child abuse and neglect. Typically, it is defined as an injury to the psychological capacity or emotional stability of the child as evidenced by an observable or substantial change in behavior, emotional response, or cognition, or as evidenced by anxiety, depression, withdrawal, or aggressive behavior.

Neglect

Neglect is frequently defined in terms of deprivation of adequate food, clothing, shelter, medical care, or supervision. Some jurisdictions also include failure to educate the child as required by law in their definition of neglect.

Parental Substance Abuse

Parental substance abuse is an element of the definition of child abuse or neglect in some states. Parental behavior that exposes a child to harm is considered neglect, whereas it is considered abusive to intentionally or carelessly distribute alcohol or other illicit substances to a child.

As knowledge of child development and children's needs has increased, so too has our recognition of other kinds of abuses they may experience. These include: medical neglect, child prostitution and pornography, honor and race-related violence, bullying, Internet sexual exploitation, and institutional abuse.

Risk Factors in Early Childhood

Certain factors in a child's life are associated with the likelihood or risk of child maltreatment. These factors are often termed risk indicators. Researchers have noted that it is easier to identify indicators for physical abuse than sexual abuse and emotional abuse or neglect because several of the risk indicators for physical abuse are demographic variables. Risk factors apply to any variables (whether child, parental, or social) associated with an increased risk for child maltreatment. Because much of our information concerning these risk factors is based on retrospective accounts, these should be referred to as correlates rather than causal factors. Furthermore, these factors which place

Table 1 Risk factors

<i>Early-childhood risk factors</i>	
<i>Child</i>	<ul style="list-style-type: none"> • Excessive health or medical problems • Developmental delays • Diagnosed handicapping condition • Temperament
<i>Parent</i>	<ul style="list-style-type: none"> • Parents experienced poor parenting during their early childhood • Parent has attachment issues stemming from childhood • Perceptions of child • Inappropriate child expectations around development • Lower educational level, low school achievement • Authoritarian • Substance abuse • Chronic illness (physical, mental, or emotional), particularly depression • Single parenthood, Teen parenthood • Unemployment/low family income • Aggressive behavior • Incarceration
<i>Family</i>	<ul style="list-style-type: none"> • Coercive child-rearing practices • Family density (number of members) • Few positive interactions • Family lacks leadership, closeness, and negotiating skills • Language deficiency: family from immigrant background
<i>Environment</i>	<ul style="list-style-type: none"> • Lack of caring individual in child's life • Neighborhood lacks both formal and informal social supports • Living in a violent community • Lack of connection with community
<i>Macro system</i>	<ul style="list-style-type: none"> • Attitudes toward how mothers should behave as parents • Cultural values that support violence • Culturally promoted attitudes and behaviors about parental rights to physically punish

children at risk of maltreatment are also connected with children becoming educationally disadvantaged and, therefore, in need of special assistance. **Table 1** presents an ecological perspective of risk factors related to the child, parents, family, community, and wider social contexts.

Approaches to Assessing Risk and Need

When an allegation or suspicion of child abuse or neglect is reported to statutory authorities, social workers or other professionals gather information during this initial contact to determine if an investigation is warranted and, if so, whether the child needs further protection during the process. Authorities use a number of screening procedures that establish thresholds for the level and immediacy of the response – ranging from an immediate investigation to follow-up or a referral to community supports. Some of

these screening approaches are integrated with standardized and structured risk-assessment instruments.

Structured risk assessment

In the face of growing demands for services, jurisdictions around the world are increasingly turning to structured risk assessment to assist child-protection authorities in rationing their services. This movement toward structured risk assessment is representative of trends toward evidence-based practice (emphasizing methods built on a solid foundation of scientific research) and demands improved practice procedures.

Risk-assessment models can be divided into two kinds: actuarial and consensus-based, with some models combining elements of both. Actuarial models are based on the empirical study of child-protection cases and their future maltreatment outcomes. The object of actuarial research is to identify factors known to be statistically predictive of future maltreatment and to use this information in the construction of an instrument that can be scored in a mechanical fashion. In consensus-based risk assessment, workers rate selected characteristics originally identified by consensus among experts and, subsequently, these factors are processed using professional judgment instead of a standard algorithm. Whether actuarial or consensus-based, an often-cited benefit of structured risk assessment is that it leads to greater consistency of evaluation and reliability of response among child-protection workers.

Consensus approaches dominate in child-protection systems. The instruments in these approaches require assessors to determine if there are grounds for service and whether the child is in immediate danger, as well as assess a wide range of risk indicators – first to determine which indicators are present and then to determine the level or severity of potential risk.

Critics have argued that – despite their increasing use – risk-assessment approaches are based on instruments that have questionable reliability, have never been validated, and for which no empirical evidence exists. For example, a risk-assessment instrument cannot determine whether to remove a child from a parent's care or how much intervention to provide. Yet, sometimes, professionals use risk assessments to guide their judgments about such decisions (Figure 1).

Ecological approaches to needs assessment

Standardized risk assessment is not always the best way to safeguard the well-being of children. Recognizing this, many countries and jurisdictions – from England, Canada, and Australia to Denmark and Sweden – have begun to use holistic approaches rooted in the ecology of child development, resilience, and attachment theories. These approaches and child-welfare research inform us that significant life events, as well as quality of parenting, affect individual development most critically in childhood. Moreover, these approaches are child-centered, concerned with equality, and equip social workers with tools to more systematically document and evaluate children's circumstances. They are further promoted as quality-assurance approaches wherein child-welfare investigation, planning, and follow-up can be improved while concomitantly strengthening children's rights.

Ecological approaches contain records for use by social workers wherein gathered information is from the first contact to closure and recorded in a structured manner. The overall ecological approach is illustrated in an assessment-framework triangle (Figure 2) where the three different domains represent: (1) the child's developmental needs, (2) the parent's capacity to meet the child's needs, and (3) factors in the family and the environment which may

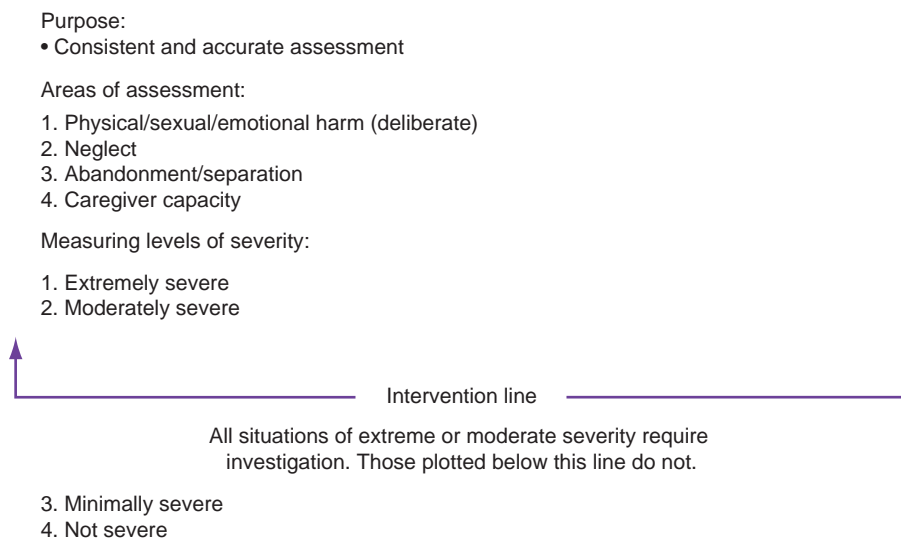

Figure 1 Risk-assessment approaches.

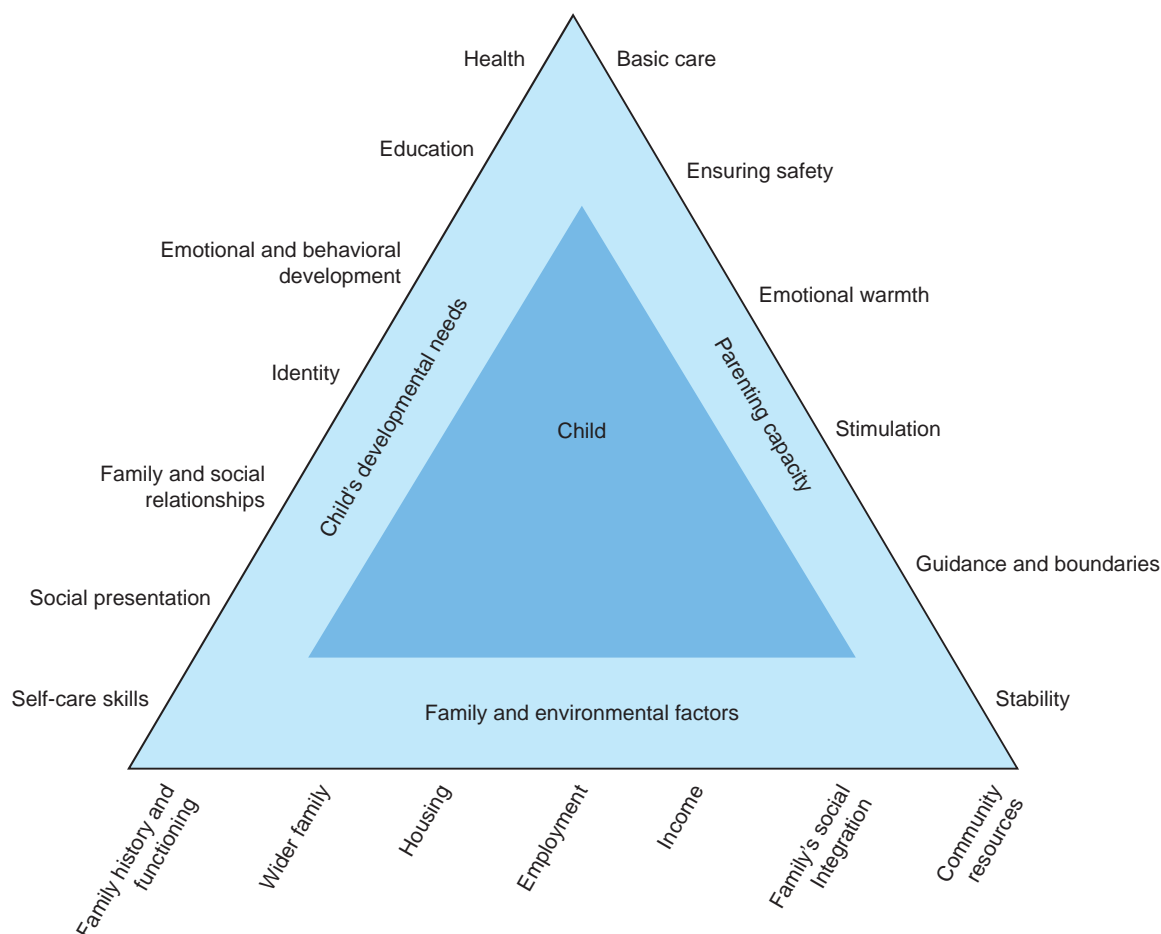

Figure 2 Needs-assessment triangle.

influence parenting capacity and hence also the overall situation of the child. These approaches also contain special procedures and protocols to facilitate work with other professionals – in particular, with teachers.

Effects of Child Abuse and Neglect

Accumulated research evidence indicates that children who are maltreated, often experience disrupted growth and development. Adverse effects have been identified in maltreated children's physical, cognitive, emotional, and social development, and these adverse effects accumulate over time.

The psychological, emotional, or physical damage that a child suffers as a result of maltreatment depends on aspects of the abuse itself and on the child's stage of development. In addition, individual children respond differently to the same kinds of abuse. Some children do not appear to show significant effects from maltreatment. These resilient children may have personality characteristics (high cognitive ability, optimism, high self-esteem, hopefulness, etc.) that buffer against harm. Damaging

effects may be mitigated if the abuse occurs only once, or if a supportive adult is available who lets the child feel he or she is believed and will be protected.

In other cases, the consequences can be longlasting. For example, physically abused children tend to have greater difficulty in relationships with peers, show less ability to empathize, and are more aggressive toward peers and adults. Studies of neglected toddlers show that they, often, have an impaired ability to trust others which may, in turn, lead to feelings of being unloved and unwanted. They may be less able to develop the social skills required to form healthy relationships with other children and adults. When a child cannot master developmental tasks (such as learning to trust) at the appropriate age, it becomes more difficult to accomplish later developmental tasks throughout the life span.

As they get older, abused and neglected children are more likely to perform poorly in school. The younger the child is at the onset of maltreatment, the more important it is to accurately assess and ameliorate the effects of the experience so that the child can recover and go on to master other life tasks successfully.

There are two main limits to these general research findings. First, most research on maltreated children comes through clinical studies of young children who have been referred for treatment and who exhibit the most serious behavioral problems. Additionally, most research is of children involved with public child welfare agencies and who belong to families of lower socioeconomic status and minority populations. Therefore, these findings do not represent the entire – and often hidden – population of abused and neglected children.

Responses to Child Maltreatment

Child Welfare and Child Protection

Child protection is a term used to describe philosophies, policies, standards, guidelines, and procedures to protect children both from intentional and unintentional harm. The definition reflects the duty of organizations – and the people in them – toward children in their care.

Child protection emphasizes the legal grounds upon which social workers and police can intervene to identify children who have been harmed or are likely to be harmed, and to then intervene to protect children from future harm. Child protection is often used to delimit specific services for children in need of protection from abuse and neglect. It is a term more often used in Anglo-Saxon welfare states. Child protection can be characterized as social work practice – guided by large amounts of official written material and lengthy procedural guidance used locally – but tightly coordinated and controlled by the central authority. Child-protection systems are criticized for their lack of social solidarity in comparison to child-welfare systems.

Child welfare is a term most often used in a general sense to encompass the broad scope of involvement by the state and its authorized professionals in assisting children and their families – both in cases of abuse and neglect and when families and children are found to be in need. In this sense, child welfare is concerned with protecting children through general prevention services including health, education, recreation, family support, and treatment services.

Depending on the context, safeguarding children and child and family services have replaced the terms child welfare and child protection or are used interchangeably with them. A child in need of protection may also be a child with welfare needs that could be successfully addressed through the provision of preventive services.

Early-childhood centers and schools

Child protection in early-childhood educational settings involves both responding to concerns about abuse and neglect and also proactively helping children to develop

personal skills and values with which to avoid or resist dangerous situations and abuse.

Responsibility for Child Welfare and Child Protection

The state

Legislative responsibility for child and family services rests with the different levels of government from provinces/states in federal systems to national government. Each may have its own specific legislation that provides protection to abused and neglected children. Policy describes the roles and responsibilities of statutory authorities, and establishes the framework for the organizational structures, tools, and resources used by authorities in carrying out their responsibilities.

When considering prevention and screening measures, effective governance may reduce the number of children at risk. Governance also provides policies and guidelines that facilitate the deployment of people and resources to effectively respond to the needs of children at risk. Good governance can also help to ensure the safety of children by enforcing best practices in the organization and enactment of child-welfare and child-protection policy, legislation, and service delivery.

Although the goals and philosophies of child welfare and child-protection services vary, they reflect the principle that families have the primary responsibility for the care of children. These approaches also share the general position that children should have certain rights to be protected from abuse and neglect and that governments have a role in protecting children from harm.

Different jurisdictions, generally, share some basic belief that the best interests of the child should be a primary consideration and that the least intrusive form of intervention is best. When intervention does take place, the range of services available can vary enormously but can be broadly categorized as voluntary or compulsory services. Services begin with the investigation of concerns about need or allegations/suspicions of abuse or neglect using a variety of approaches established according to the legislation, policy, and protocols of the jurisdictions in which they are found. Where appropriate and necessary, the state or its delegates provide services ranging from counseling and support to removal of a child from parental care on temporary or permanent bases. Further, there is, generally, oversight of child welfare and child-protective services, ensuring that standards and requirements of treatment and care services are met.

Interagency cooperation

Many jurisdictions have begun to formalize committees responsible for collaborating with the care and protective needs of vulnerable children. These committees are often

comprised of social workers, healthcare providers, and educators.

Increased interagency cooperation has led to the development of protocols or agreements between collaborators which define and give direction on concerns about children. Protocols may address the reporting of concerns about a child (ranging to concerns about children in need to more serious concerns about harm caused to a child). Protocols may operate internally within multidisciplinary or multifunctional agencies, locally to coordinate the activities of different community actors, or on a wider scale, involving different authorities or government departments. The purpose of protocols is to clearly define the responsibilities of each collaborator, to minimize harm to children, coordinate responses, and also to inform the public of different mandates. Protocols help organize the activities of professionals in various capacities including day care centers, schools, hospitals, policy, and child-welfare agencies.

Mandatory reporting

Mandatory reporting refers to a legal obligation to report certain kinds of concern to child-welfare authorities. The intent of mandatory reporting is to encourage the good faith (without malice and with reasonable cause) reporting of concerns for the safety and needs of children. Sometimes, reporting standards apply to professionals and, at other times, to both professionals and the public at large. In some places, only social workers, healthcare providers, and the police are legally required to report that a child is in need of care and protection. In other places, local guidelines and professional codes of conduct (e.g., teachers) indicate the duty to report. However, individuals are not bound to report as a matter of law.

Recognizing and reporting suspicions of abuse then becomes an ethical obligation that requires early-childhood educators and teachers to have the appropriate training, to be familiar with symptoms of abuse/neglect, and to be able to follow legal requirements and community procedures to protect children.

Educators are the group of professionals that report most cases of concern to child-protection authorities, although research shows that they only report about 25% of suspected concerns. Reasons for not reporting may include a lack of knowledge about how to do so, fear of making an inaccurate report, or a belief that child-protective services do not help families and children. Mandatory reporting systems have faced criticism for being overburdened and ineffective in responding to the concerns of teachers and other professionals.

Abuse Prevention

Abuse prevention can be considered on a continuum from primary prevention to tertiary intervention. Primary

prevention is targeted at the stress factors shown to have the capacity to lead to abuse. Poverty, unemployment, single-parenthood, lack of social networks, and lack of access to healthcare can all contribute to the conditions in which abuse can develop. Therefore, social policy, healthcare policy, and family policies that address these strategies can be viewed as forms of primary prevention. In education, primary prevention may include general public education campaigns, educational information to new parents, and education programs for children (e.g., Safe Touch programs to prevent sexual abuse). Early education, open/free preschools, and community-based services can enhance family stability and reduce the stresses and strains in the family circle.

Secondary prevention is targeted at high-risk families or the risk factors that have a cumulative risk characteristic. In this instance, we can think of programs for teenage mothers, access to birth control, home visitors, parent relief, day care, or preschool as secondary prevention measures. These measures enhance the chances for positive development in children and are not associated with the stigmatizing and labeling features often associated with child-welfare services.

Tertiary prevention is action taken to help families after abuse happens. Child-welfare agencies provide case management, family support, and child-in-care services while court services handle legal issues. Tertiary prevention may also include therapeutic intervention – sexual abuse-treatment groups, nonoffender treatment groups, groups for violent men, family therapy, and intensive family-preservation interventions.

Primary and secondary prevention have shown the most promise, according to research, of having an impact on child maltreatment. Tertiary prevention has not had a positive impact on re-abuse rates and there is little evidence to suggest that tertiary prevention is effective in child neglect. An ongoing problem is that few studies have systematically evaluated these interventions in a methodologically rigorous way. There is a lack of experimental designs, small sample sizes, high attrition rates, and inadequate outcome indicators.

Educational Responses

Early-childhood professionals are particularly important in risk, protection, and abuse prevention because many abuse victims have, at some point, attended early-childhood-education centers and almost all, eventually, are in schools. Most often, children are victimized by family members, although child maltreatment occurs much less frequently in the contexts of schools, childcare, and organized after-school activities.

Outside of the family, educational professionals have the most contact with young children. Young children are the most vulnerable to all forms of abuse – given that

they are easily manipulated and powerless, being wholly dependent on adults for their care and safety. In their positions and with their knowledge of child development, early-childhood professionals are in a position to be able to observe children, detect behavioral changes, and respond to their needs. Thus, early-childhood educators and teachers play important roles in the prevention, identification, and reporting of abuse, as well as in providing support to child victims of abuse and neglect.

Primary preventive programs include ensuring safe and high environmental standards within schools and childcare settings, developing appropriate standards to reduce the potential of abuse within these settings, and establishing policies of inclusion of parents in developing programs. Educators can also help protect children from abuse and neglect by advocating for children and their families for access to well-designed, sufficiently funded, and effectively implemented programs, supports, and regulations.

Secondary preventive approaches can support and build family strengths and understandings of child development. When concerned about the potential of risk to a child, communication with parents and families becomes critical. Therefore, the aim of educators is to be supportive to families while providing information, referrals, and follow-up. Collaborating with other professionals, including child-welfare professionals, promotes a shared understanding of child development and supports and empowers families.

Educators can also play an important role in abuse prevention by introducing an explicit and developmentally appropriate child-protection program. Young children can be taught personal safety skills and will practice them if activity methods are used with reinforcement. They will also be more confident, know their rights, and understand what constitutes abusive behavior. Children with the best safety knowledge and skills are those who have undertaken a comprehensive child-protection program with parental reinforcement. Parents who are told what abuse prevention is and why it is being taught are less likely to undermine the program by promoting secrecy, not listening to children, or defending those who touch children inappropriately.

Evaluating Early Childhood Education and Care Programs

M Janus, McMaster University, Hamilton, ON, Canada

Early childhood education and care has been gaining recognition as a very important factor in influencing lifelong human development and outcomes. Sheer numbers of preschools, child-care centers, playschools, and early childhood programs have been steadily growing, both in the public and for-profit sectors. Many claim that their curriculum or principles are based on the available evidence of what works best for young children. Nevertheless, formal evaluations of new or existing programs are completed less frequently than would be expected in an area that deals with such a crucial and vulnerable period in child development.

There are many factors that have led to the current proliferation of early childhood services. Since the inception of Head Start in the United Kingdom and Early Head Start in the United States similar programs have become popular, and the model and ideas have been adopted in socially conscious programs and policies. Increased workforce participation by women and the degeneration of traditional family networks, contributed to the demand for such early childhood services. Parents are seeking preschool environments for their children more frequently now than they did 30 years ago, whether for child care, or as a supplement to their children's activities. Much of this growth has been closely followed by the increase in evidence on the importance of high-quality early childhood education and care (ECEC).

In the first section of this article we briefly describe the types of evaluation and their relevance to the ECEC; in the second, we present current challenges and concerns in evaluating ECEC; and in the third, we describe the international perspectives on ECEC.

Types of Evaluation and Their Relevance to ECEC

Any educational structure or service can be evaluated based on general principles. The ECEC systems, however, are unique for at least three reasons. First, unlike school-based education, they are rarely governed by uniform legislative bodies, even though they are often centrally licensed or accredited. Second, there is no discernible consensus among professionals as to the most optimal assessment. Third, the types of early education and care vary dramatically among providers. These reasons make it

especially challenging to summarize the current state of knowledge on this topic.

The categories of evaluation are broadly based on: What are the goals of assessment (e.g., monitoring of the outcomes or implementation)? Who is doing the evaluation (e.g., government, external consultants, etc.)? Who is providing the data (parents, providers, managers)? Also, what are its intended uses (summative, formative, for accountability reasons)? These categories are not mutually exclusive. Alternatively, evaluation studies could be categorized based on methodologies used.

Target of the Evaluation

Impact evaluation

The majority of evidence regarding the evaluation of ECEC comes from outcome-oriented approaches. In this category, the evaluation is being undertaken to assess whether the particular program or system improves outcomes for the participants. Outcomes need to be defined as a type of skill or developmental area so that the appropriate methodology can be applied. This type of evaluation is known as an impact evaluation, and thus whether the program is fulfilling the intended goals is the target of evaluation. The methodology used is most often quantitative.

Quality evaluation

The goal of quality-oriented approaches is to monitor how the programs are delivered, thus, they are focused on how the outcomes may be achieved rather than on what they actually are. This type of evaluation tends to consider the quality of classroom environments, staff training, parent satisfaction, and uses either only qualitative, or a combination of both qualitative and quantitative methodology. Recently, there have been an increasing number of voices advocating for the inclusion of children's perspectives on aspects of the programs they attend, not in the more established format of test results, but in terms of their narrative impressions.

Process evaluation

A process evaluation aims to evaluate the implementation aspects of a program, and thus essentially it is also quality oriented. It is claimed, however, that this particular type is best suited to a program in its initial stages, and in fact,

that its goal is to establish whether the program is ready for the impact evaluation.

Confirmatory program evaluation

A variation on impact evaluation is a confirmatory program evaluation. According to its proponents, this is a systematic, theory-driven investigation on how program participation leads to the outcomes. Since its clear goal is to confirm that the program works in the way its philosophy predicts, the hypotheses are narrower than in the pure impact evaluation, and they do not include the evaluation of implementation. Nevertheless, the more complex methodology suggested for this more strictly causal evaluation approach (regression, path modeling) allows to create clear criteria for interpreting findings.

Evaluators

Evaluations are often legislated into state-funded ECEC programs. Such evaluations may be contracted to independent consultants, or sometimes, government systems establish their own evaluation units or departments whose entire mandate is to carry out and report on the evaluations of the funded services. In a number of jurisdictions in the United States, Canada, Australia, and the United Kingdom, the consultants tend to be affiliated with education departments at local universities, thus providing a solid research base and some continuity of effort.

The identity of the evaluating body can also be dependent on the goals. Short-term evaluations may be run by government agencies for accountability reasons, while a programmatic, long-term evaluation may be carried out by an independent agency.

Data Sources

Clearly, the data sources for any evaluation are determined by its type and goal. Nevertheless, either one or many types of informants can be engaged in the process of providing the data: children themselves (through tests, direct assessments, observations, or interviews); teachers/providers (through their standardized assessments of children, observational assessment such as the Early Development Instrument (EDI), program delivery, environments, and own experiences); parents (through their assessment of children, teachers, environments, and satisfaction); or managers (through their assessment of the program). A good system evaluation would include at least two or more informants, in order to ensure reliability of the collected data. Of particular importance is the fact that the ultimate target population – the young children who participate in the ECEC programs – are on a steep developmental curve, and outcomes of any assessment can rapidly change with age.

Intended Uses of the Evaluation

Three intended uses are most frequent in evaluating ECEC programs: formative, summative, and programmatic evaluation.

Formative evaluation

Formative evaluation is usually undertaken early in the development of the program to inform the providers and stakeholders about the trends in results, whether the goals of the program are likely to be fulfilled, and to identify the barriers and facilitators of implementation. Results of the formative evaluation are then incorporated into the program with the necessary adjustments made to improve program implementation. These evaluations are usually less formal, and more likely to be internal, than the summative evaluations, and while they are often mentioned in descriptions of new programs, the evidence is rarely published.

Summative evaluation

Summative evaluations are intended to provide a package of results used to assess whether a program works or not. These types of evaluations are dominating the field when it comes to evaluating ECEC programs. While the timing of a summative evaluation has to allow the program to have a reasonable chance to achieve its goals, it is often carried out for the evaluation of short-term goals. In general, summative evaluations provide quantitative data and are focused on outcomes. However, alongside the developmental, behavioral, or cognitive outcomes for children these evaluations often also include program statistics, for example, attendance, staff characteristics, funding, and cost-effectiveness data. Summative evaluation can form part of an impact evaluation, or be carried out in conjunction with a qualitative or process evaluation to provide complementary evidence.

Programmatic evaluation

Programmatic evaluation is meant to provide a broad, inclusive, yet detailed and definitive assessment of a program in relation to both whether and how it fulfills its goals. These evaluations tend to involve long-term aspects of programs, and by the very nature of their purpose are fairly costly. By definition, they should also consider how well the program's implementation is following the program's philosophy as set out in the design of the program. Programmatic evaluation is most useful in evaluating ECEC programs that have considerable longevity (and thus sustainable funding sources) as well as long-term goals. Perhaps due to these reasons, government-funded initiatives are most likely to be the subject of such evaluations.

Methodologies

The goals of an evaluation mandate the basic methodology. Generally, impact evaluation requires quantitative data collection, while a quality or process evaluation cannot be undertaken without qualitative strategies. The interpretability of the evaluation outcomes is inherently linked to the qualitative data and research designs utilized.

Quantitative Methodologies

The basic evaluative tool for assessment of outcomes is a test of children's abilities. Such a tool could be administered directly, through observations, or based on teacher report. What makes a test score a component of evaluation is its comparison with another test score. The change in outcome for a child who attended the program could be compared with the change in outcome of a child who did not attend this program (comparison group). The children's scores are taken prior to attendance and then compared over time. They can also be compared to a standardized score for a child meeting specific characteristic (usually age and gender).

Comparison group

By far the most scientifically grounded methodology is to include a well-selected comparison group. Randomized control trials (RCTs) prescribe a longitudinal involvement with the sample, and a random assignment to the experimental (program) or control (no program) group. While excellent for statistical reasons, this method rarely works with ECEC due to logistics, but most importantly, ethics – some parents would have to be denied the opportunity to participate in the program. Evaluators of ECEC often seek to modify an RCT approach to make it acceptable, feasible, and yet scientifically sound. One approach taken is to include families on the waiting list. The positive aspect of this selection is that these are families who are motivated to participate in the program and they are easily accessible, so their potential participation in other programs while waiting could be monitored (as this might influence the results). An approach that is gaining an increasing popularity is the regression discontinuity (RD) design for evaluating causal effects of interventions. The RD design is an experimental pre-test/post-test comparison group strategy. In RD designs, participants are assigned to program or comparison groups based on a score taken before the program participation. Thus, program can be targeted toward those who most need it and avoid the ethical RCT issues. Another approach is to select families with similar characteristics (e.g., same neighborhood and similar risk factors), whose children do not attend the program. While also acceptable, this choice is less optimal due to the possible levels of parental

motivation, lower interest in the program, as well as decreased access. An added difficulty is the need to specify whether the group of nonattendees is composed of children who do not attend any program, or just do not attend the program being evaluated. Selecting the best control or reference group is challenging, and there are documented cases where over the course of evaluation the composition of such groups changed so much as to render the evaluation outcomes uninterpretable. The programs with the most longitudinal high-quality evaluation follow-up evidence – Perry Preschool, Carolina Abecedarian, Infant Health and Development Program, and Chicago Child-Parent Centers – all have employed the control group design with well-matched ethnic and socioeconomic characteristics.

Pre-test/post-test methodology

For best results, the pre-test/post-test methodology also requires an appropriate comparison group. Considering the age of children, the maturational changes are very likely to contribute to the increase in children's test scores from pre- to post-test. Such change can be statistically controlled for, if the test is standardized and well documented, however, the evaluators would need to have sound evidence that the groups on which the test was standardized were similar to those tested (and thus the maturational growth over time comparable between them). Inclusion of a comparison group has to be guided by all the same considerations as in the previous paragraph. A well-chosen comparison group can make the outcomes of a pre-/post-test methodology a solid base for program improvement and policy recommendations.

Comparison to standards

Some early childhood evaluations follow the practices used in higher-level educational systems by using established norms (standards) as a comparison. While it appears to be an acceptable compromise, the cautions are numerous. Apart from those already mentioned above, such as the suitability of the test or maturational influences, the possibility of bias has to be taken into account: first, in terms of the group tested, and second, in terms of opening the possibility of teachers developing the teaching to the test habits.

Group randomization

Recently, the “randomize groups not individuals” was proposed as an overall program strategy in assessing ECEC (St. Pierre and Rossi, 2006). Its authors claim that it provides the most effective methodology to answer the question “what works better?” rather than the more common “whether” a program works. They reject the feasibility of a no treatment group with respect to ECEC as unrealistic. In this context, the group randomization offers

a much more effective alternative, even if more costly. Since groups (schools, neighborhoods) would be randomized to participate in different programs, there are no ethical issues; the necessary larger sample, though more costly, offers less attrition and larger variation than randomization of individual children and families. The current availability of sophisticated statistical methodologies like multilevel modeling, makes it possible to account for the impact of within-group, and between-groups factors. The major attraction of this methodology, its breadth, is also its drawback, as it requires extensive and long-term funding investment. The proponents of this strategy suggest that the US Head Start has infrastructure, resources, and the will to engage in such an evaluative effort.

Qualitative Components

Many evaluations use qualitative methodology as a component complementary to the quantitative data. The results of parent satisfaction surveys, open-ended interviews with parents and service providers, are often found in evaluation reports, however, not reported as frequently and as fully as the results of quantitative impact evaluations. This could ultimately lead to the low level of sharing knowledge on the nonquantifiable aspects of the ECEC, and potentially impede progress. In fact, there is some evidence that early childhood practitioners are concerned that quantitatively oriented evaluations are incomplete and inadequate to inform practice. The current recommendations in the literature require the qualitative input from child, family, service providers, and the community to an integrated component of any evaluation.

Challenges

Evaluating ECEC programs is not without its challenges. A paper by a group of early childhood educators and professionals from diverse international backgrounds (Jalongo *et al.*, 2004) suggests seven dimensions for a global vision of ECEC. The seventh dimension is rigorous evaluation, which should be comprehensive, ongoing, longitudinal, and broad-minded enough to consider the value-added characteristics. The value-added component contributes program-wide and individual family perspectives for both expected and unexpected outcomes. A program-wide perspective would include impact on children's health even if that was not the focus of the program, or the fact that by providing high-quality, affordable child care, the mothers were encouraged to seek more education. Individual family perspectives need to be added through interviews and case stories, and can be used for advocacy and recommendations.

Contextual Information

The necessity to include contextual information is perhaps most strongly emphasized within the international context (see section titled 'International perspective' below), however, it could be also crucial for comparisons of programs within a country or state, or over a number of years. For example, changes in the parental leave policies can have major impact on the demand for early childhood services; fluctuation in economy can affect the numbers of families qualifying for state assistance in child-care funding; social awareness about the impact of early childhood could influence the quality of child care; levels of immigration could be crucial in determining the language needs of families. Even within scientifically sound evaluation designs, context is often considered solely at the individual level (such as child characteristics) and in some circumstances the family level. The ability to control individual- and family-level contexts are basic requirements in rendering the outcomes of any evaluation usable. Nevertheless, the population and community context is often just as crucial.

Policy Ramifications

A theme reoccurring in many recent publications in the field is that very few countries have an established policy framework with stated goals and philosophy, which would provide the basis for evaluation. Without such a framework, it is more difficult to ensure that results of any evaluation are being translated into improvements in early childhood education.

While the majority of state-funded programs have formal evaluations mandated in legislation, in reality, few of those are well-conducted or well-documented impact or quality evaluations. Evaluation as a process is often misunderstood by legislators and providers, and interpreted as the need to carry out financial reviews, informal surveys of parent satisfaction, or assessment of participation rates. In the United States, of the 33 states identified to have had a state-funded preschool program, 22 reported having completed a formal evaluation, of which only 13 had data usable for a meta-analysis (39%). According to another statistic from the United States, less than 1% of total expenditures for social programs are spent on research and evaluation.

Applied Research Perspective

The goals of an evaluation can vary, and therefore the process of evaluating can vary according to those goals. Nevertheless, evaluation can be considered an exercise in applied research, and has to lead to answers to fairly routine questions. These could be "what works?", "what works better?" (impact), or "how well do we make it work?" (quality), but the evaluation process and underlying research

should result in answers that can be used for program improvement. These can range from “it does work in this area” to “we do not know whether it works, because . . .” but the answers have to be pragmatic enough to allow a follow-up: with recommendations for program improvement, or with recommendations for another, better evaluation. There is a concern that evaluation practices in the early childhood education field are underdeveloped in comparison to evaluation in other educational areas. Inaccuracies in understanding the process of evaluation while designing the ECEC programs can have long-reaching detrimental consequences not only in terms of impact on child development but also in misuse or misallocation of funds available for early childhood. The lack of solid evidence that evaluation results are routinely incorporated into action plans seems to highlight this issue.

Accountability Controversy

Increased emphasis on accountability in education as a whole, which also appears to include the education of younger children, raises the concern in some professionals that it not only impacts the quality of the education, but also shortchanges the evaluation process. Too strict and prescribed achievement standards, especially for the younger children, can easily lead to teaching to those standards, with the sole purpose being, to enable children to pass the test. This concern has a lot of validity in early childhood education for a number of reasons: the development of young children can be variable, and the domains of development are interconnected; thus, assigning a value-laden consequence to results of any one test (or achieving any one or two cognitive skills) is misguided. Moreover, the role of the teacher is especially important in the early years, and there are fears that the focus on accountability leads to a pressure to teach more and sooner, within a narrowing, standardized range, thus de-professionalizing the teachers making their profession akin to those of technicians monitoring discrete bits of knowledge or behavior rather than enabling them to use their thinking, judgment, and insight to tailor programs to each child's learning needs. For the children themselves, this approach seems to value performance over learning. It appears that in the early childhood education field more than in the education of older children, there is a strong need to develop a consensus in understanding the differences between accountability and evaluation. This should be communicated clearly through the governance of early education and care.

Perspectives on Program Quality

While there is an improvement in the level of understanding that test scores do not equal program quality, definitions

of quality still raise concerns as to the appropriateness of evaluative efforts. Literature suggests that there are three basic concepts of program quality evaluation: (1) outcome-based, where the quality of the program is judged on the basis of the outcomes usually obtained through children's results on tests scores; (2) standards-based, where the quality of the program is judged based on how it complies with externally developed standards (which routinely include tools like the Early Childhood Environment Rating Scale (ECERS) to rate the quality of the classroom, sometimes tools to assess caregiver behavior, or program implementation or state/national standards); and finally, (3) quality based on the program's utilization of developmental appropriateness practices (DAPs), usually in relation to distinctions outlined in the US National Association for the Education of Young Children guidelines. Ironically, while the DAP guidelines are commendable in principle (and in many ways represent the full pendulum swing from skill-oriented practices), if they are used as a sole evaluation criterion, they share the major problem with evaluating the ECEC programs solely on test-based outcomes: children's development in the early years is fluid, uneven, and idiosyncratic, and at any given point in time their needs and performance may dramatically differ from a day before or after. They have been criticized for relying too heavily on the dominant, Western, ideals. Nevertheless, the inclusion of broadly based, inclusive DAP among the criteria for evaluating program quality, is very likely the avenue for future evaluations.

International Perspective

The dimensions of high quality in early childhood education are universal. The knowledge as to the extent to which they are implemented and evaluated at the national level is very poor. Most evidence is available for English-speaking countries, simply because most accessible results are published in English. This constitutes a very significant bias in assessing international perspectives, as lack of accessible evidence does not mean that there is no evidence at all.

What can be learned from the limited international evidence is that there are both cultural and societal differences in the quality and effectiveness of ECEC and also differences in the infrastructure on which the ECEC programs and their evaluations are built. Research for the Organization for Economic Cooperation and Development (OECD, 2006) Report, *Starting Strong II: Early Childhood Education and Care*, indicates that a critical mass of academics in the field of early childhood education is imperative for high-quality research and evaluation of ECEC. The report suggests that a number of developed countries have established comprehensive, early-childhood-oriented research agendas through which universities actively participate in

partnership with government agencies. United States is clearly in the lead with the longitudinal agenda of following children, thus creating the opportunity to provide evaluative evidence on the impact of ECEC on later development, but countries like Canada, Australia, the UK, and Korea have longitudinal study cohorts that have been (or currently are) followed through childhood. In the Canadian National Longitudinal Study of Children and Youth, the oldest children are now young adults; in the Ontario Child Health Study (a provincial study in Canada), recently published research examined the impact of early childhood living conditions (neighborhood and family) on the study participants' life as adults. The Longitudinal Study of Australian Children is in its fourth year. While these studies offer opportunities to examine the impact of children's participation in a broad range of ECEC services, they cannot evaluate any one type of program, as they were never originally designed for such purpose. Longitudinal studies more closely linked with specific early childhood education goals, like the UK's Effective Provision of Pre-School Education Project, conducted on children's development between 3 and 7 years of age is an example of a much more focused evaluative research activity. While not evaluation in the strict meaning of the term, practitioner-based research allowing for self-evaluation and reflection on their own practice is utilized in countries like Norway, Belgium, and Italy, and has been incorporated into professional development in Belgium, Norway, Sweden, Finland, and the United Kingdom. If supported by established and rigorous methodology, this research can often contribute to a fuller picture of ECEC.

In their vision for a globally blended high-quality ECEC systems, Jalongo *et al.* recommended that each country should establish its own framework guiding the provision of culturally responsive and sensitive programs, which at the same time would have demonstrated effectiveness and responsiveness to the needs of all types of families. A greater level of international communication and sharing of experiences could only be beneficial in approaching the evaluation of ECEC programs from the sociocultural perspective. The dominant models of early childhood education are often criticized for their rigidity in some aspects. The process of evaluation has to evolve with the changing composition and needs of a society and its children. Some basic truths remain the same – children have an unshakeable right to develop optimally and be provided with the best environment in which to do so. However, some of the context has changed: the understanding of the importance of the early years has grown among the general public, children with special needs are no longer isolated from the mainstream education, and the diversity of societies in which children grow has increased, to name just a few of the important factors. Evaluating the ECEC programs that serve the youngest members of society has to be flexible enough to incorporate the contextual

information, rigorous enough to produce interpretable results, and articulate enough to be incorporated into action.

The dramatic social and demographic changes that have occurred in developed nations over the past several decades have led to significant changes in the circumstances in which families are raising young children, and in the conditions that young children experience as they grow up. In parallel with these social and demographic changes, there is evidence of worsening health and developmental outcomes for many children and young people (Perrin *et al.*, 2007). These have associated social and economic costs that undermine the general productivity and well-being of countries, and the fact that they have occurred in those very countries that have benefited most from economic and technological advances has been termed modernity's paradox (Keating and Hertzman, 1999).

There has been extensive research into those biological and environmental factors that increase the risk of poor outcomes, in children and throughout the life course; similarly, much is known about the protective factors that foster resilience in children who are otherwise at risk. While the pathways that lead to health, developmental, and social problems have been well described, the research about effective interventions is less than robust, both at an individual and, especially, at a population level.

Factors That Influence Child Health and Development

There are many factors, both biological and environmental, that impact on child health and development – genetic, familial, environmental, community, and societal. It is rare that any one of these factors determines child

health outcomes, or that they act in a simple causal fashion. While there are some genetic causes that act in a direct, linear causal fashion to threaten health and well-being, multiple factors usually interact with each other in a more complex fashion to influence outcomes. This representation of interactions among multiple influences that affect children's health has been called a kaleidoscope model (National Research Council and Institute of Medicine, 2004). These interactions between factors may occur within single domains, such as behavior or social environment, or they may extend beyond domains, for example, the child's social environment, behavior, and local or national policies. Changes in any one factor may influence others, thereby giving rise to a complex interaction of factors that may all play a role in determining the child's current and future health. Each influence, in turn, interacts with other influences to form a pattern, which in turn sets up the substrate for future patterns. In this way, children's health and well-being are determined by the prior state of the child's health, and by the presence or absence of risk and protective factors, and their interaction.

Genetic Factors

Genes have their effect either in correlation with or in interaction with the environment. Individual differences in human development may to a large extent be explained by gene–environment interactions that result in differential susceptibility. Common childhood conditions, such as obesity, asthma, and attention-deficit hyperactivity disorder (ADHD), have all been described as having a strong genetic foundation. Nonetheless, changes in the gene pool

cannot explain the recent dramatic growth of these conditions, suggesting that the strongest etiological pathways are environmental (Perrin *et al.*, 2007).

Familial Factors

Poverty

One of the most consistent associations in developmental science is the relationship between economic hardship and compromised outcomes in children's health, well-being, and development. Furthermore, it is suggested that "the malleability of young children's development and the overwhelming importance of the family . . . context suggest that economic conditions in early childhood may be far more important for shaping children's ability, behavior and achievement than conditions later in childhood" (Shonkoff and Phillips, 2000).

Maternal employment

There is some accumulating evidence that maternal employment in the child's first year of life, especially if the mother works long hours, can be a negative factor for infant development. However, beyond the first year, there is evidence that children may actually benefit from maternal employment, especially those from disadvantaged families, and particularly with regard to cognitive outcomes. In this context, the out-of-home care that these children experience can be regarded as a form of early intervention. Overall, parental employment can be seen as being either a positive or a negative factor for young children's development; this depends on the nature and structure of the job, the income it generates, and especially on the environments and relationships that children experience when they are not in the care of their parents.

Parental education

There is a strong consistent correlation between parental education level and their children's achievement and behavior. Parental education levels are strongly associated with the home literacy environment, parental teaching styles, and investment in a variety of resources that promote learning. Children of parents with limited education, especially maternal, are at an increased risk of behavior problems, poor literacy and school performance, and developmental delay.

Family structure

There is little evidence that family structure, in and of itself, is a significant factor in determining child outcomes. While growing up in a single-parent family may increase the risk of school difficulties and behavior problems, these are related to the socioeconomic realities of single parenthood – lower income and less parental time from both mothers and fathers – rather than from any direct effect of living with only one parent. There is no

evidence that children growing up in nontraditional family forms are at any increased risk of poor outcomes.

Parenting

An increasing body of research has documented the relationship between parenting and the development of a wide range of health, developmental, and behavior problems both in childhood and through to adulthood (Richter, 2004). For example, the quality of relationships that parents have with their children predict healthy eating, and the only programs that are successful (albeit modestly so) in treating childhood obesity are those that focus on parenting skills as well as lifestyle advice. Adverse parenting is also a risk factor for the adoption of smoking and alcohol use, teenage pregnancy, and poor mental health in children and adolescents. These relationships appear to be independent of socioeconomic status. It has been suggested that poor parent-child relationships have an adverse impact on the areas of the brain that deal with emotional and social functioning and with the physiological response to stress. Healthy and unhealthy patterns of relationships in the early years seem to be hard-wired into the brain early in life, dictating subsequent resilience of vulnerability to stress, and proving difficult, if not impossible, to moderate later in the life cycle.

Community Factors

Evidence on the impacts of community and neighborhood environments on child development and health is complex. Evidence suggests that dramatic changes – for example, moving from high-poverty to low-poverty neighborhoods – can enhance the physical and psychological health of children. Whether smaller, more easily achieved changes in neighborhood conditions produce improvements in children's health, well-being, and development is less clear.

Social support

Numerous studies of children and families have shown that social support has a direct influence on the well-being of children and families. Social support has been found to be linked to a number of child and family outcomes, including low birth weight, child abuse, child neglect, maternal adjustment, mental health, and physical health (Cooper *et al.*, 1999). Those families who are most in need of social support and who would benefit from it are often those that are the most isolated.

Societal Effects

Health is affected by environmental and social processes as well as by sociological factors, and the society and community in which a child lives are major determinants of health. Therefore, it has been argued that, because the primary determinants of disease in the twenty-first

century are mainly economic and social, the remedies must also include economic and social interventions (Rose, 1992). At a population level, the contribution of traditional medical care is modest, and health-care needs to focus more on prevention. “This involves community approaches as well as individual health care, and must take into account the physical and mental health of the adults who interact with children and young people” (Hall and Elliman, 2003).

Adverse health outcomes have been shown to be associated with environments that threaten personal safety, that limit the ability to develop strong social ties, or that are characterized by conflictual, violent or abusive interpersonal relationships. These effects occur across the lifespan. Positive health outcomes are associated with environments that provide safety, opportunities for social integration, and the ability to predict and/or control aspects of that environment.

Social capital

Social capital, defined as the networks of social relations that are characterized by norms of trust and reciprocity, has been shown to be related to health outcomes. In communities that are high in social capital, there are strong connections between members of the community based on mutual trust and reciprocal exchanges. Like social support, social capital has been linked to a number of factors, including improved health, greater well-being, better care for children, and lower crime rate (Kroll, 2008).

Social gradients

There is clear evidence of the relationship between social gradients and health outcomes: where we stand in the social hierarchy is intimately related to our chances of getting ill and to how long we live. The Commission on Social Determinants of Health (2008) took a holistic view of the social determinants of health:

The poor health of the poor, the social gradient in health within countries, and the marked health inequities between countries are caused by the unequal distribution of power, income, goods, and services, globally and nationally, the consequent unfairness in the immediate, visible circumstances of people’s lives – their access to health care, schools, and education, their conditions of work and leisure, their homes, communities, towns, or cities – and their chances of leading a flourishing life. This unequal distribution of health-damaging experiences is not in any sense a ‘natural’ phenomenon but is the result of a toxic combination of poor social policies and programs, unfair economic arrangements, and bad politics. Together, the structural determinants and conditions of daily life constitute the social determinants of health and are responsible for a major part of health inequities between and within countries.

How do social gradients affect health? Wilkinson (2005) argues that inequality is socially corrosive and affects health because the quality of social relations is crucial to well-being. In wealthy countries, health is not simply a matter of how material circumstances determine quality of life and access to healthcare; it is how social standing makes a person feel. Low social status – being devalued and looked down on – is stressful and can have devastating effects on people’s lives and communities. More unequal societies have poorer communal environments, which in turn is related to a range of social issues from higher levels of violence to more widespread depression.

Environmental Factors

Child health and development may be affected directly or indirectly by a number of environmental factors.

Climate change

Climate change poses direct and indirect risks to health, impacting on exposure to sun and extremes of climate, food safety, water supplies, and a higher risk of natural disasters such as fires and floods. There is almost no component of health and well-being that will be untouched by climate change. However, it is suggested that the risk is distributed unequally across society, as vulnerability to the effects of climate change depends on the degree of exposure, sensitivity, and adaptive capacity.

Environmental toxins

It is suggested that, over the past few decades, environmental exposures are contributing to children’s declining health status. Environmental agents that we know to cause health and developmental problems in humans include alcohol, nicotine, lead, mercury, arsenic, solvents, pesticides, and many others. Many of these are organic and inescapable; they enter the food chain from sources such as pesticides, chemical manufacturing, and incinerated waste, and accumulate in animals higher up the chain. However, there are many more chemicals in common use whose effects on children, either singly or in combination, are unknown because they have never been tested (Collaborative on Health and the Environment Learning and Developmental Disabilities Initiative, 2007).

Children are often more susceptible than adults to the effects of exposure to environmental agents. This is a particular issue during pregnancy, where the fetus is exposed to larger doses relative to bodyweight (International Scientific Committee of the International Conference on Foetal Programming & Development Toxicity, 2007). Exposure during fetal development can adversely affect health and well-being and can lead to lifelong functional deficits and increased disease risks.

Exposure to environmental pollution, although a major source of health risk throughout the world, is particularly problematic in developing countries where unsafe water, poor sanitation, and poor hygiene, along with indoor air pollution, are major sources of exposure.

Associations between environmental pollution and health outcomes are complex; individual pollutants may be implicated in a wide range of health effects, whereas few diseases are directly attributable to single pollutants. However, most of our exposures to these chemicals are not from sources traditionally regulated, such as remote waste sites and factories. Rather, the primary sources are close to us: within our indoor environments, and the personal activities, products, and materials inside those environments. The sources of these pollutants are largely unregulated – meaning that our environmental regulations, designed to protect and promote human health, are missing major sources of health risks.

Changes in urban environments

There is growing recognition that the built environment – the man-made physical structures and infrastructure of communities – has an impact on health. A good example of this is the opportunities children have for physical activity. Increased urban density, and reduced access to parks and safe places for children to play, accompanied by parental concern about children's safety, is said to have contributed to the increase in obesity (Perrin *et al.*, 2007). Physical environments and community recreation facilities have an impact on how children use their time, and particularly their likelihood of physical activity.

Changes in home living environments

Many allergies and immune system diseases have increased significantly in prevalence in the past few decades; asthma, hay fever, and food allergies the most notable among them significantly (Gibson, 2009). While the exact cause is debatable, it has been suggested that all of them may have a common explanation rooted in aspects of modern living. One theory, termed the hygiene hypothesis, suggests that these increases are due to children growing up in an increasingly sterile environment; other causes postulated include changes in diet, air pollution, and increasingly sedentary lifestyles. Evidence for the hygiene hypothesis comes from studies demonstrating lower rates of allergies in children who live on farms and whose mothers lived on a farm during pregnancy.

Changes in food consumption

There have been considerable changes in children's eating habits, including increases in high-energy foods, meals and snacks eaten outside the home, and increased

portion size. The so-called fast foods tend to have low-quality carbohydrates and fats, little fiber, few essential nutrients, and high-energy density. Fast-food outlets are more highly concentrated in lower socioeconomic areas, contributing to the higher rates of obesity in disadvantaged communities. Changes in food production and food consumption have seen increases in the use of food additives, reduction in fruit and vegetable intake, and an increase in the consumption of sugar-sweetened beverages.

Evidence of Long-Term Impacts of Early Experiences

Developmental pathways originate in the complex interplay between biology and experience; there is accumulating evidence of the child's immediate environment in the early years as having a major impact (Hertzman, 2004). The evidence suggests that early behavior and functioning are predictive of later behavior and functioning to the extent that children's social and physical environments remain unchanged. In other words, it is difficult for children and families to extricate themselves from adverse circumstances, especially when there are multiple risks or adverse factors in their lives.

However, there is also evidence of developmental plasticity over the life span. Plasticity is the potential for change in intrinsic characteristics in response to environmental stimuli. Children's development continues to be shaped by experiences throughout the course of childhood. Moreover, there is emerging evidence that suggests that the brain can change itself or can be changed by experience to a much greater degree than was previously recognized. For instance, stress neurobiology is highly responsive to changes in the environment: although very sensitive to early social contexts, it is not a fixed or inflexible system, but reflects both the organism's epigenetic history and its new circumstances. Improved living conditions, enriched environments, and corrective emotional experiences can reverse the adverse consequences of early adversity.

Hertzman and Power (2003) describe three mechanisms through which exposure to both beneficial and adverse circumstances over the life course impact on health and development.

Latency or Sleeper Effects

This hypothesizes that there is a relationship between exposure at one point in the life course and its impact on health many years later. In recent years, there has been an emerging body of research suggesting that the roots of adult disease lie in fetal and neonatal development (Barker, 1992).

It is suggested that the mechanism for this to occur is that nutrition or exposure to environmental toxins *in utero* in the neonatal period may affect the programming of tissue function that occurs during development. This concept is called the developmental basis of health and disease, and the process by which this occurs has been termed biological embedding (Keating and Hertzman, 1999).

It has been shown that low birth weight (small for gestational age) strongly predicts the subsequence of hypertension, hyperlipidemia, insulin resistance, type 2 diabetes, and ischemic heart disease (Heindel, 2007). Low birth weight is taken to be an indicator of poor nutrition during pregnancy, and it is hypothesized that the fetus permanently changes its structure and metabolism as an adaptation to a limited supply of nutrients. The metabolic demands of the growing brain and heart are favored at the expense of other tissues.

Cumulative Effects

In this model, there are either multiple exposures to a single recurrent factor (such as poverty) or a series of exposures to different factors; these exposures to risk factors (and protective factors) may accumulate over the life course. While in some cases exposure occurs in a dose-response manner – for example, the health effects of exposure to a toxic substance usually increase with the duration and intensity of exposure – the biological mechanisms by which disadvantages and inequities carried over a life course of differential exposures leading to health disparities are not well understood. One mechanism might be the body's biological response to stress, involving the autonomic nervous system, the hypothalamic-pituitary-adrenal (HPA) axis, and the cardiovascular, metabolic, and immune systems.

Many studies have shown the cumulative impact of risk and protective factors on young children's development. These studies show that the risk of core developmental outcomes in children and adolescents increases in a linear fashion as the number of environmental risks increases. The corollary is that the incidence of positive developmental outcomes increases as the number of protective factors in children's lives increases. There are well-established correlations between a range of adverse childhood experiences, including abuse, neglect, and household dysfunction, and later health problems such as ischemic heart disease. This effect is cumulative – the more the number of adverse childhood experiences, the more the likelihood of the child developing ischemic heart disease later in life. These adverse early experiences are more strongly predictive than traditional risk factors such as smoking, obesity, diabetes, and hypertension. Adverse events in childhood have also been shown to be

directly correlated with other problems in adulthood, including alcoholism, illicit drug use, and mental health problems such as depression.

Pathway Effects

In this model, exposure to risk factors at one stage of the life course influences the probability of other exposures later in the life course. Early events may influence the life-course trajectory, and once a child is established on that trajectory he or she is more likely to experience other exposures that strengthen the likelihood of poor outcomes. For example, children from disadvantaged backgrounds have a greater risk of poor school readiness, as measured by cognitive and social-emotional competencies at school entry. Due to this they are more likely to experience problems at school, with a subsequent increased risk of unemployment, poor self-esteem, and mental health problems. It is hypothesized therefore that early adverse experiences disrupt neurological development, resulting in social, emotional, and cognitive impairments, which in turn lead to increased risk to health behaviors that result in disease, disability, and social problems. Mechanisms for this are uncertain, although one suggestion is that a cascade of risks is created early in life that exacerbates certain genetically based vulnerabilities. This may lead to deficits in children's control of and expression of emotions and social competence, and also to the disturbance of physiological and neuroendocrine system regulation that can have cumulative, long-term adverse effects.

The three models described are not mutually exclusive, but are present simultaneously in any individual's life course. Environmental lead exposure can be used to illustrate this. This can have a cumulative impact because lead is retained in the body, and there is a dose-response curve so that the more it is retained, the greater the health risk. At the same time, lead exposure *in utero* may also have a latent effect on subsequent health and well-being through inhibiting the production of brain cells. Finally, there may also be a pathway effect since the socioeconomic position will affect the probability of exposure to lead *in utero* and in childhood, which may impact negatively on a range of outcomes throughout the life course.

Each of the three sets of influences on health described by Hertzman and Power (2003) – latency, cumulative, and pathway – carries with it a strategic message for policies and interventions to improve population health. The message of latency is, the earlier the better; the message of the cumulative model, is intervene wherever there is an effective intervention; and the message of the pathways model is, intervene at strategic points in time. All three of these forms of intervention will be needed if broad-ranging improvements in health and developmental outcomes for children are to be achieved.

Summary and Conclusions

Humans are unique in the degree to which they can adapt to their environments. Young children's neurology and biology are particularly adaptable, designed as they are to learn from their prenatal and early postnatal environments. They are highly sensitive to both positive and negative experiences, which lay down biological, neurological, and behavioral patterns that become increasingly difficult to change, and which can have lifelong consequences for health and well-being.

Given the evidence of the links between early experience and later health outcomes, there is a strong argument for greater investment in the early years to reduce the long-term burden of poor health in adulthood. Given the evidence that the primary determinants of poor health outcomes in the twenty-first century are mainly social and economic, these investments should focus not so much on traditional forms of medical care, but on addressing the social and economic conditions under which families are raising young children.

Cost-effective Early Childhood Programs from Preschool to Third Grade

A J Reynolds, J A Temple, and B White, University of Minnesota, Minneapolis, MN, USA

© 2010 Elsevier Ltd. All rights reserved.

The positive effects of early-childhood development (ECD) programs on child well-being have been documented in hundreds of studies and reviews since the 1960s (Karoly *et al.*, 2005; Reynolds *et al.*, 2003; Zigler *et al.*, 2006). Advances in scientific knowledge have contributed not only to the establishment of early-childhood programs but have helped spur recent expansion of programs and services in states and localities (Barnett *et al.*, 2007; Reynolds and Temple, 2008; Zigler *et al.*, 2006). Increased attention to the early years of life also has sparked greater interest in the transition to school and the experiences in the early grades that can reinforce preschool gains and strengthen school achievement (Bogard and Takanishi, 2005; Reynolds *et al.*, 2003). The creation of early-childhood systems and practices that enhance the continuity of development over the first decade of life is increasingly viewed as fundamental to shaping children's well-being.

Scope of Review

In this article, evidence is presented on the effectiveness and cost effectiveness of ECD programs for the outcomes of school readiness, school achievement, and performance, and long-term life-course development. The primary focus is on preschool or pre-kindergarten programs for 3- and 4-year-olds and early school-age programs including preschool to third-grade programs (PK-3) and practices. Two major questions are addressed:

1. What are the effects and economic benefits of ECD programs from preschool to the early elementary grades?
2. Which elements and principles of effectiveness are key to long-term effects?

In this article, ECD is defined broadly to include most of the first decade of children's life. Findings from prenatal and infant programs are beyond the scope of the article, although we summarize evidence comparing the effects of birth-to-3 program to preschool and early school-age programs. A much longer discussion of some of these programs can be found in Reynolds and Temple (2008).

Although findings on achievement and other short-term outcomes are reported, we emphasize the results of cost-benefit analyses (CBAs) of the effects of programs. There are three reasons for the focus on CBAs.

First, economic benefits relative to costs are the most relevant indicator for policy development. The value of

public investments can be judged, at least in part, on efficiency (Heckman, 2000). This is especially true in a time of scarce resources for educational and social programs. Second, in the economic-benefit approach, program effects on multiple outcomes can be converted into the metric of dollars and cents (Levin and McEwan, 2001). Other metrics such as standard deviation units or percent change cannot be used to combine or compare outcomes.

Finally, cost-benefit analyses emphasize longer-term effects of programs and practices. A focus on immediate and shorter-term effects, while an important first step, is not the ultimate program goal. Longer-term effects are a major focus of early-childhood programs. A major question for social policy is whether short-term effects translate into long-term effects of adaptive life skills and behavior.

How ECD Programs Influence Outcomes

Considerable research has documented that ECD programs impact later well-being through at least one of five processes or pathways (Reynolds, 2000; Reynolds *et al.*, 2004). In short, these can be viewed as the active ingredients contributing to impacts on child development. They have been conceptualized from the beginning of the early childhood as the primary mechanisms of intervention effects. As shown in **Figure 1**, the cognitive-advantage pathway indicates that the longer-term effects of ECD programs are primarily due to the enhancement of cognitive skills, including literacy, school readiness, language, and numeracy.

The family-support pathway indicates that impacts on child outcomes derive from greater parental investments in children's development, such as greater parent involvement in education, increased parenting skills, and greater resource supports for parents.

The school-support pathway suggests that longer-term effects would occur to the degree that post-program school experiences reinforce learning gains. Enrolment in higher-quality schools and schools with positive learning environments would strengthen or maintain learning gains while enrolment in schools lower in quality would neutralize earlier learning gains.

The social adjustment and motivational-advantage hypotheses indicate that noncognitive skills can be the

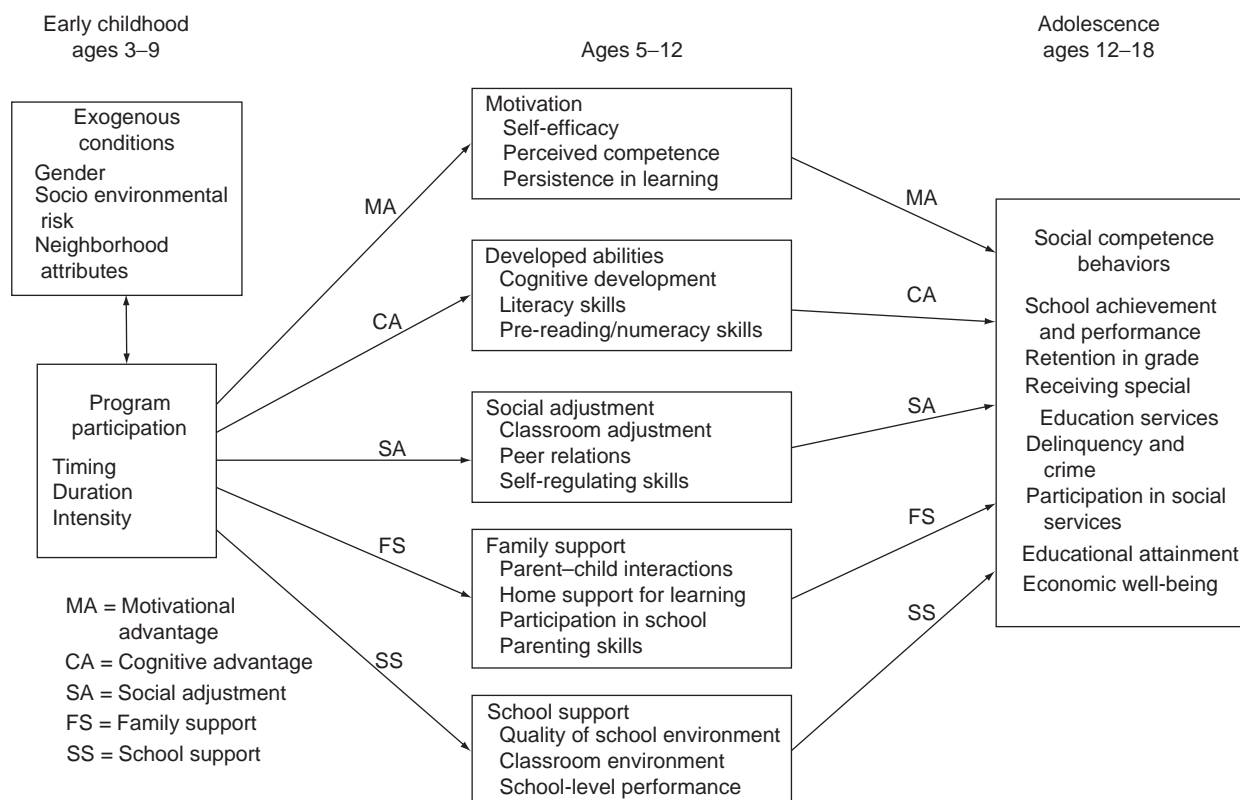

Figure 1 Pathways from early-childhood programs to long-term outcomes.

mechanism of effects of ECD programs, such as increased classroom and peer social skills, positive teacher-child relationships, achievement motivation, and school commitment. The greater the magnitude of effect of program experiences on a particular pathway or multiple pathways, the more likely that enduring effects would occur.

Notably, programs that provide comprehensive services would be expected to impact several of the pathways simultaneously. This is one explanation for why (or simply why) comprehensive programs are found to be more likely to have longer-term effects.

Cumulative Evidence of Effects

Given the size of the knowledge base, the effects of preschool ECD programs are summarized through findings from 19 reviews of preschool impacts published in the past decade (1995–2006; Reynolds and Temple, 2008). These reviews were selected as among the most thorough in assessing short- and longer-term effects of both model and large-scale programs (contact the author for additional information). **Table 1** shows the most frequently cited programs demonstrating beneficial effects along with the last age of follow-up.

Two major conclusions are evident from the reviews. First, many programs have assessed long-term effects into adulthood. Three-quarters of the reviews reported effects at

5 or more years after the end of participation. This is rare for social programs and indicates that impacts on life-course development and economic benefits can be accurately assessed. Second, the accumulated evidence includes both model programs, developed for research demonstration, and large-scale programs, developed for routine implementation by schools and other institutions. Consequently, the generalizability of the evidence for policy recommendations is much stronger today than a decade ago.

What are the main findings of the reviews? Of the hundreds of studies synthesized, there is substantial evidence that preschool programs for mostly children at risk, positively impact cognitive skills, school achievement, social and emotional development, as well as educational attainment, employment, and later social behavior. The average effect size on cognitive skills at or near school entry was 0.42 standard deviations (sd), which is roughly equivalent to one-half of a year of growth associated with preschool participation. Average effects were also statistically and practically significant for social and emotional development (0.24 sd), school achievement (0.35 sd), delinquency and crime (–0.22 sd), grade retention (–0.21 sd), special education (–0.46 sd), school completion (0.27 sd), and employment and earnings (0.37 sd). As a number of these significant outcomes can be translated to dollar terms, the method of benefit-cost analysis is well suited for analyzing the net benefits to society of these preschool programs.

Effects and Economic Benefits of Three Preschool Programs

Based on their prevention focus and strong evidence of enduring effects, three early-childhood programs listed in **Table 1** have been the subjects of extensive cost-benefit analyses: Carolina Abecedarian Project (ABC), High/Scope Perry Preschool (PPP), and the Child–Parent Center Program (CPC). Although there were important differences, all three programs provided high-quality educational enrichment to children at risk in group settings characterized by small class sizes, a focus on language and cognitive skills, and well-qualified and compensated teachers. ABC was the most intensive and lengthy, providing full-day, year-round care for 5 years (Campbell and Ramey, 1995). PPP provided the most established and organized curriculum, which followed the Piagetian cognitive principle of child-initiated learning (Schweinhart *et al.*, 1993). CPC provides the most comprehensive services by implementing an intensive parent-involvement component, outreach services, and attention to health and nutrition (Reynolds, 2000; Reynolds *et al.*, 2002). It also is the only program that became established in public schools and is still in existence. The major long-term findings of the studies generating economic benefits are shown in **Table 2** (see also Reynolds and Temple, 2008). Not shown are the substantial effect sizes for program participation on cognitive skills at kindergarten entry, and on school achievement through the elementary grades. CPC participation also was associated with higher levels of parent involvement in school.

CBA in ECD Programs

CBA is an economic approach for estimating the value of alternative programs and policies relative to costs. Levin and McEwan (2001) define CBA as the “evaluation of alternatives according to their costs and benefits when each is measured in monetary terms” (p. 11). Using CBA, program and intervention investments can be ranked according to their effectiveness per dollar of expenditure. The most frequently used outcome measures in CBAs of ECD programs and their data sources are shown in **Table 3**.

CBA is a major departure from traditional measures of effect size, such as the *d* statistic and percentage-change metrics, which take into account only program effects while ignoring their costs. The use of CBA in the field of ECD has increased dramatically. To illustrate estimation, relative to the control group, participants in the Child–Parent Center preschool program spent an average of 0.7 fewer years in special education from kindergarten to high school. The effect size is 0.29 standard deviations. This translates to an average savings in special education of US\$5317 per program participant, which was calculated by multiplying the program effect of 0.7 years by the average annual cost per child for special education services above and beyond regular instruction estimated in 2007 dollars for the Chicago school district in which they were enrolled and discounting the cost, occurring at an average age of 10, to age 3 by an annual rate of 3% (Reynolds *et al.*, 2002).

The major advantage of CBA is that benefits for multiple outcomes can be summarized in dollar terms, either

Table 2 Adjusted means or percentages for program and comparison groups on key outcomes for cost-benefit analysis (CBA)

<i>Outcome</i>	<i>Perry Preschool^a</i>	<i>Abecedarian</i>	<i>Child-Parent Centers</i>
Original sample sizes (program, comparison)	58, 65	57, 54	989, 550
Sample recovery for high school completion (%)	94	95	87
Special-education services by age 15/18 (%)	15 vs. 34	25 vs. 48	14 vs. 25
Grade retention by age 15 (%)	ns	31 vs. 55	23 vs. 38
Child maltreatment by age 17 (%)	n/a	n/a	7 vs. 14
Arrested by age 19 (%)	31 vs. 51	ns	17 vs. 25
Highest grade completed by age 21/27 (mean)	11.9 vs. 11.0	12.2 vs. 11.6	11.3 vs. 10.9
High school completion by age 21/27 (%)	71 vs. 54	70 vs. 67 (graduation)	66 vs. 54
Attended college by age 21/27 (%)	33 vs. 28	36 vs. 14 (4-year college)	24 vs. 18
Employed at age 21–27 (%)	71 vs. 59	70 vs. 58	ns
Monthly earnings at age 27 (mean)	US\$1219 vs. US\$766	n/a	n/a

^aFor the Perry Preschool Study, special education is for equated monthly instalment (EMI) placements by age 15. Ages for educational attainment and employment are 27 for Perry, 21 for Abecedarian, and 22 for Chicago. Employment for the Chicago study is full-time employment.

ns – not significant; n/a – not available.

Table 3 Examples of monetized benefits in cost-effectiveness analyses of early-childhood programs

<i>Benefit category</i>	<i>Treatment effect</i>	<i>Estimate</i>
Grade retention	Reduced rates of grade retention	Expenditure for 1 year of school
Special education	Fewer years of special education	Weighted average annual cost for special-education services
Childcare expenditures	Average duration of program participation	Annual opportunity cost of parents time
Child maltreatment	Fewer indicated reports of abuse/neglect	Weighted average annual cost for in-home services and out-of-home services, including administrative and investigation costs
Public assistance	Fewer months of public-assistance participation	Average monthly payment for AFDC, food stamps, and Medicaid, including administrative costs
Adult health	Lower rates of smoking	Monetary value of an additional year of life
Lifetime earnings	Higher rates of high school completion	Projected increase in lifetime earnings associated with high school graduation
Juvenile crime	Fewer petitions to juvenile court	Estimated juvenile justice system expenditures per court petition

AFDC – Aid to families with dependent children.

the net return (benefits minus costs) or return per dollar invested (benefits divided by costs). However, the ability to conduct a CBA depends on whether or not it is possible to reflect program benefits in dollar terms. Researchers have a long tradition of estimating the benefits of increased graduation rates and reductions in crime. Often program budgets contribute information used to create estimates of the benefits of reductions in services such as special education or child welfare. It is more difficult to monetize the benefits of higher test scores or problem behaviors because relatively few studies link test scores or behavior to the more monetizable outcomes of higher future incomes or fewer crimes committed. When program outcomes cannot be easily converted to monetary terms, cost-effectiveness analysis is the recommended approach (see Levin and McEwan, 2001).

Cost-effectiveness analysis typically assumes that there is one main outcome of interest such as test scores.

Summary of Results of Three Cost-Benefit Analyses

At a minimum, the economic return should equal the amount invested in the program – a return of at least one dollar per dollar invested. CBAs can illustrate the distribution of the benefits across different segments of society. Benefits to participants are returned to the child and parent attending the program but do not directly benefit others in society. These benefits include increased earnings capacity in adulthood projected from educational attainment as well as the benefit to parents from

the provision of part-day care for children. Benefits to the general public include averted expenditures for remedial education and social welfare spending by governments, reduced tangible expenditures to crime victims as a result of lower rates of crime, and increased tax revenues to state and federal governments as a result of higher earnings capacity. Benefits to society at large include the sum of benefits to program participants and to the general public. While societal benefits frequently are emphasized because they represent the total economic benefit to society, the existence of benefits to the general public (not including the program participants) often is used to justify government involvement.

As shown in **Table 4**, all three programs showed substantial economic returns of preschool into adulthood through government savings in education, justice system, and health expenditures and in increased economic well-being.

Although the costs of the programs are significantly different from each other, the economic returns of each program far exceeded the initial investment. As a ratio of benefits to costs, all three programs showed a large return on investment based on data collected into adulthood, ranging from a total societal benefit of US\$2.49 per dollar invested to US\$16.14 per dollar invested. These are equivalent to a 249% to 1614% return on the dollar. The CPC program showed a relatively high benefit-cost ratio at US\$10.15, in part reflecting its relatively lower costs. The lower costs are primarily a result of a higher child to staff ratio in the classroom (8.5 to 1 vs. less than 6 to 1 for PPP and ABC). That a routinely implemented school-based program demonstrates positive returns indicates that wide-scale programs can be cost effective. The other school-based program, PPP, demonstrated an economic return of US\$16.14 per dollar invested as assessed at age 40. At US\$2.49 per dollar invested, ABC had the lowest benefit-cost ratio. This is not surprising given its high cost. In terms of public benefits alone (i.e., government and

crime victim savings), benefit-cost ratios ranged from US\$0.50 to US\$12.90 per dollar invested.

The consistent findings of the economic analyses of the PPP, CPC, and ABC programs, despite their major differences in social context and instructional approach are encouraging evidence in favor of expanding preschool access. Nevertheless, the participants of the three programs were almost exclusively low-income, African American children. While there is no comparable evidence from studies of middle-income families or from more diverse samples, research on the short-term effects of state-funded preschool programs, which include more diverse samples by socioeconomic status and race/ethnicity, find positive impacts. For example, effects sizes on school readiness (average of reading and math scores) of state pre-kindergarten programs for 4-year-olds implemented from 2002 to 2006 in New Mexico, Arkansas, New Jersey, and Oklahoma ranged from 0.26 to 0.58. These are statistically and educationally meaningful (for details, see Reynolds and Temple, 2008).

CBA from Policy Simulations

To estimate the economic benefits of high-quality but routinely implemented preschool programs, several researchers have conducted cost-benefit simulations that either (1) modify assumptions of existing CBAs from longitudinal analyses of model programs such as the Perry Preschool Project or the Chicago Child-Parent Centers or (2) make projections of benefits from predicted changes in educational attainment, income, or criminal behavior using information from other studies that have shown correlations between these adult outcomes and the observed short-term outcomes such as achievement scores. Three such analyses are summarized below. All indicate that more widely implemented preschool programs for 3- and 4-year-olds would be likely to yield benefits than significantly exceed costs (also see Reynolds and Temple, 2008).

Table 4 Summary of costs and benefits per participant in 2007 dollars for three early interventions

<i>Program cost (US\$)^a</i>	<i>High/Scope Perry Preschool</i>	<i>Chicago Child-Parent Centers</i>	<i>Abecedarian Project</i>
Average per participant	18 261	8 512	73 159
For 1 year of participation	10 283	5 434	16 020
Program benefits (\$)			
Total benefits	294 772	86 400	182 422
Net benefits (benefits – cost)	276 511	77 899	109 263
Public benefits	235 544	58 476	36 429
Net public benefits	217 283	49 964	(36 730)
Total benefit per dollar invested	16.14	10.15	2.49
Public benefit per dollar invested	12.90	6.87	0.50

^aCosts are program expenditures and do not include estimated costs for comparison-group experiences. Ages of study participants for economic analysis of the Perry Preschool Program, Chicago CPC Program, and the Abecedarian Project were 40, 21, and 22 respectively. The public benefit of the Abecedarian Project is estimated by assuming that 25% of the earnings benefit to participants, parents, and future generations are tax revenues. In addition, the public is assumed to be responsible for two-thirds of the cost associated with increased college attendance /adult education.

Using short- and long-term data from 58 evaluation studies published from 1967 to 2003, Aos *et al.* (2004) estimated an economic return of US\$2.36 return per dollar invested for preschool programs for low-income 3- and 4-year-olds.

Karoly and Bigelow (2005) estimated the economic benefits of universal access to 1 year of preschool education at age 4 in California. Based in part on cost-benefit findings from the CPC program and assuming a 70%-participation rate, the estimated return to California society at large was US\$2.62 per dollar invested. The most conservative estimates were about US\$2 return per dollar invested and the most liberal were about a US\$4 return per dollar invested.

A broader national analysis by Lynch (2007) used modified estimates from the CBA of the CPC program (Reynolds *et al.*, 2002) to generalize across states and in the country at large. It was estimated that by the year 2050, a high-quality targeted preschool program for 3- and 4-year-olds would cost US\$6479 (2007 dollars) per child and provide a return per tax dollar invested of US\$3.10 in government budget savings alone. For a universal access program, the return per tax dollar invested was estimated at US\$2.00 for government budget savings. Considering all societal benefits, the long-range annual benefit per tax dollar invested was estimated at US\$12.10 for a targeted program and US\$8.20 for a universal-access program.

The Effects of Full-Day Kindergarten

The effects of full-day kindergarten (FDK) compared to half-day kindergarten, are well documented. Many studies have examined achievement gains at the end of kindergarten and in the early-school grades. Aos *et al.* (2007) synthesized the results of 23 well-designed comparison-group studies on the effects of FDK on academic achievement. The studies were published since 1970 and excluded those in which FDK was part of other interventions or the selection into groups was undocumented or uncontrolled. The average effect size of FDK on achievement at the end of kindergarten was 0.18 standard deviations for all children and 0.17 for economically disadvantaged children. This is equivalent to a 2-month achievement gain.

This relatively small advantage largely disappeared by first grade and did not reemerge later. The average effect size was 0.01 at the end of first grade, 0.048 at second to third grade, and 0.00 at fourth and fifth grade. Although no formal cost-effectiveness studies have been done, the lack of long-term achievement gains would be expected to yield a benefit-cost ratio close to zero.

Class-Size Reductions

In the most extensive study of class-size reduction, Project Student Teacher Achievement Ratio (STAR) in Tennessee

experimentally investigated the impact of enrolment in class sizes limited to 13–17 students from kindergarten to third grade relative to enrolment in class sizes of 22–26 students with and without teacher aides. A total of over 6300 kindergarten students in 79 schools were included. Although 1 or more years in small classes was associated with higher achievement in the short-term, longer-term effects by eighth grade were found only for students with 3 or 4 years of reduced class sizes (Finn *et al.*, 2001). The 3-year group had median effect sizes of 0.17 standard deviations in grades 4 to 8. The four-year group had median effects sizes of 0.25. Relative to control groups, only low-income students with 3 or 4 years of small classes had higher rates of high school graduation (Finn *et al.*, 2005).

Based on Krueger (2003), Project STAR was found to have an economic return of US\$2.83 per dollar invested in the program. The source of this benefit is an increase of 0.2 standard deviations in test scores, which is associated with a 1.6% increase in adult earnings.

In a recent synthesis of 38 studies of class-size reductions, Aos *et al.* (2007) reported that reducing class sizes in kindergarten through second grade was more cost effective than reducing class sizes in third through sixth grades, middle school, or in high school. A reduction from 25 to 15 students in kindergarten, for example, was found to increase achievement by 0.19 standard deviations. Based on higher test scores, Aos *et al.* estimated that the economic return of small classes in kindergarten through second grade was US\$2.79 per dollar invested and US\$1.38 for small classes in third through sixth grades.

Additional evidence on small class sizes comes from the school-age program of the Child-Parent Centers, of which the main program element was a reduction in class sizes from 35–1 to 25–2 (teacher and aide) during grades 1–3. The school-age program also included instructional resources to promote reading and math achievement and family-support activities under the direction of a program coordinator. The economic return for 2 years of school-age intervention was US\$2.13 per dollar invested (Reynolds *et al.*, 2002). While this return per dollar invested is much lower than that of the CPC preschool program, it is within the range of that found for Tennessee STAR.

Other School-Age Programs and Practices

Given their implications for cost effectiveness, two additional ECD programs are covered. The Skills, Opportunities and Recognition (SOAR) Program, formerly the Seattle Social Development Project, is designed to promote social and emotional skills (Hawkins *et al.*, 1999). Starting in grade 1 and continuing to grade 6, the supplemental classroom-based program includes cooperative, developmentally appropriate teaching practices and optional

parent-education classes. Six years after the end of the program, participants had greater attachment to school, higher-achievement test scores, and lower rates of delinquency, and lower rates of alcohol misuse. The economic return was US\$3.14 per dollar invested.

Reading Recovery, an instructional tutoring program for first-grade students who are having difficulty learning to read, provides 30 min of one-on-one daily instruction with a teacher outside of the regular school class. Students in the bottom 20% in reading performance are enrolled in the program. In more than 30 studies that have been conducted of Reading Recovery (D'Agostino and Murphy, 2004), findings are generally consistent showing that the program increases participants' reading performance and helps close the gap with more typically performing students but the benefit is reduced substantially by fourth grade. Although formal CBAs have not been reported, Shanahan and Barr (1995) estimated that the program would, at best, be expected to return about 30% (or US\$0.30 per dollar invested) of its costs through reductions in special-education placement as a consequence of the short-term achievement effects.

PK-3 Programs

A key rationale for transition programs and practices in the early school-age years is that elementary schools play an important role in sustaining the benefits of early-childhood programs, and a continuation of programs into the primary grades will promote successful transitions. PK-3 programs are the most comprehensive approaches for enhancing transitions and promoting positive child development. Four extended early-childhood programs have shown evidence of positive effects on school achievement and child well-being above and beyond that of preschool participation. These are the Head Start/Follow through Program, National Head Start/Public School Transition Demonstration Project, Abecedarian Project, and the Child-Parent Center extended intervention program.

Only the CPC extended intervention program has been the subject of CBA. Compared to participation in less-extensive CPC services (0–3 years of intervention), the CPC extended program returned US\$9.13 per dollar invested through reduced remedial education and child maltreatment, lower juvenile arrest for violence, and higher levels of educational attainment. The US\$6.11 return associated with the extended program is the public benefit cost ratio – not the return exclusive of intangible crime victim savings. This is the public benefit cost ratio reported in the age 21 CBA. This is the public return per dollar invested exclusive of intangible crime victim savings.

The school-age program alone demonstrated a return of US\$2.13 per dollar invested primarily through participants requiring fewer remedial-education services (Reynolds *et al.*, 2002). The US\$1.66 return associated with the school-age program is the public benefit cost ratio – not

the return exclusive of intangible crime victim savings. This is the public benefit cost ratio reported in the age 21 CBA. This is the public return per dollar invested exclusive of intangible crime victim savings. The main components of the school-age services were reduced class sizes, family services, and instructional support to classrooms.

Summary of Cost Effectiveness

Table 5 summarizes the economic returns of ECD programs from preschool to third grade. Preschool for 4-year-olds has demonstrated the highest returns across many programs in different contexts, decades, service systems, and curricular philosophy. New evidence from state prekindergarten programs shows positive effects on school readiness.

Small classes in the early grades show positive returns from test-score gains (Krueger, 2003) but long-term effects were limited to low-income children with 3 or 4 years of enrolment (Finn *et al.*, 2005). Substantial reductions in class sizes (i.e., 25–15) are needed to meaningfully improve achievement (Aos *et al.*, 2007).

The CPC PK-3 intervention shows substantial benefits above and beyond earlier intervention. The SOAR social-skills program also has demonstrated positive long-term effects leading to cost-effectiveness. Neither Reading Recovery or full-day kindergarten have findings suggestive of cost effectiveness. Across many studies, the average effect of full-day kindergarten is not detectable at the end of kindergarten.

For completeness, CBA estimates are available for select prenatal and home-visitation programs in the first 3 years of life. The special supplemental nutrition program for Women, Infants, and Children (WIC) provides nutrition education, referrals to social services, and a variety of food supplements to low-income families. A meta-analysis of 15 studies in different states by Avruch and Cackley (1995) found that WIC participation was associated with a 25% reduction in the rate of low birth-weight births, which significantly reduced hospital costs paid by insurers in the first year of life. The economic return in savings was estimated to be US\$3.07 per dollar invested.

The Nurse-Family Partnership (Olds *et al.*, 1993) is an intensive nurse home-visitation program for young mothers having their first child. For the high-risk sample. (unmarried and low-income mothers having their first child), Karoly *et al.* (1998) it was found that participation from prenatal development to age 2 was associated with lower rates of criminal behavior for both mothers and target children, lower rates of substantiated child maltreatment, higher-earnings capacity for the mothers, and increased tax revenues projected into adulthood. The estimated economic return was US\$5.06 for every dollar invested. For the lower-risk sample, the economic return

^aAll original estimates are converted to 2007 dollars using the Consumer Price Index for All Urban Consumers (CPI-U).

^bEstimates are based on a meta-analysis of studies investigating the effects of WIC.

^cThe cost for the Abecedarian Program represents the total costs of the intervention. Apply the marginal cost for the Abecedarian Program results in a return of \$3.64 for every dollar invested in the program.

^dEstimates for Lynch's (2007) synthesis of target and universal preschool represent per pupil program costs and associated annual government budget benefits. Total accrued benefits to government, the general public, and program participants and their parents relative to costs are \$12.10:1 and \$8.20:1 for the targeted and universal programs, respectively.

^eEstimates are not based on formal cost-benefit analyses.

^fThe cost of full-day kindergarten is relative to the cost of half-day kindergarten in Washington State.

^gEstimates from syntheses of reduced class sizes assume a reduction from 25 to 15 pupils per class.

was US\$1.10 per dollar invested. A more recent analysis of the Nurse-Family Partnership by Glazner *et al.* (2004) showed an overall return of US\$3.93 for every dollar invested in the Elmira, NY program.

In summary, findings show that a variety of ECD investments are associated with positive economic returns. Preschool programs for 3- and 4-year-olds have had the most research, and generally show the highest returns. This is illustrated in Figure 2 as the economic return per dollar invested for the accumulated research as a function of the age of entry into intervention. Age 0 corresponds with prenatal development (WIC and NFP). Early school-age programs show positive returns of close to US

\$3 dollars per dollar invested (Tennessee STAR). Combinations of programs such as PK-3 are not represented in Figure 2. These are other synergies that warrant further investigation. Nevertheless, cost effectiveness is one of many criteria for prioritizing investments. Social importance, feasibility, and capacity for sustainability also are important to consider in policymaking.

Key Principles of Effectiveness of ECD Programs

Findings summarized in this review indicate that greater investments in high-quality preschool and school-transition

Figure 2 Return per dollar invested by age of entry into intervention. The median return per dollar invested in presented in the figure is US\$2.81. The average return is US\$4.61 per dollar invested.

programs are warranted. Since relatively large percentages of children do not enrol in center-based preschool programs (Barnett *et al.*, 2007), and the quality of services that many receive is not high, the ECD programs summarized in the article provide effective models to be used in the design of coordinated early childhood systems. As shown in **Figure 1**, attention to the causal mechanisms of change can also strengthen program effectiveness. Research on three programs reviewed (ABC, PPP, and CPC) and many others suggest five major principles that can enhance the effectiveness of ECD programs and to increase long-term economic benefits.

The first principle is that a coordinated system of early education is in place beginning at age 3 and continuing to the early-school grades. Program implementation within a single administrative system in partnerships with communities can promote stability in children's learning environment which can provide smooth transitions from preschool to kindergarten and from kindergarten to the early grades. The three major programs we reviewed were either housed in elementary schools or provided continuity of services between preschool and formal schooling. This is a first-decade strategy of promoting child development. Today, most preschool programs are not integrated within public schools and children usually change schools more than once by the early grades. The CPC program, for example, is an established program in the third-largest school system in the nation. Findings from the CBA of a complete cohort

of CPC participants give a good indication of the size of effects that could be possible in public schools.

A second major principle of effective ECD programs is that the teaching staff should be trained and compensated well, preferably with earned bachelor's degrees, certification in early childhood, and competitive salaries. It is no coincidence that the three major programs reviewed in the article followed this principle. Being located in public schools, the Perry and CPC programs were implemented by teachers with at least bachelor's degrees and appropriate certification in early childhood. They were paid on the public-school salary scale, and Perry teachers received a 10% bonus for working in the program. In the Abecedarian program, teachers were compensated at level that was highly competitive with public schools. Turnover was low in all three programs. In most other early education programs, from child care to Head Start, staff did not have this level of education, training, and compensation, and turnover was significantly higher.

Third, educational content should be responsive to all of children's learning needs but special emphasis should be given to cognitive and school-readiness skills through a structured but diverse set of learning activities. All of the cost-effective programs reviewed had a strong emphasis on the development of cognitive and language skills necessary to do well in school within a responsive learning environment. Child to staff ratios of less than 9 to 1 in preschool helped as well. The curriculum appeared to be

less important since the programs spanned from Perry's child-initiated approach to Chicago's blended, teacher-directed approach. Extrapolating these findings, preschool and other social programs are more likely to have enduring effects if they provide services that are intensive and are dedicated to the enhancement of educational and social skills.

A fourth principle of effectiveness is that comprehensive family services should be provided to meet the different needs of children. As child development programs, preschool, kindergarten, and school-age programs must be tailored to family circumstances and thus provide opportunities for positive learning experiences in school and at home. Those with special needs or who are most at risk benefit from intensive and comprehensive services. Each of the cost-effective preschool programs discussed in the article provided family services. Abecedarian provided medical and nutritional services. The Perry preschool had weekly home visits by teachers. In the CPC program, parent involvement is more intensive as each center has a parent-resource room run by a certified teacher and provides school-community outreach. Parents' own educational and personal development are important program goals.

Finally, greater commitment to ongoing evaluations of effectiveness and cost effectiveness is needed. Even today, CBAs are rarely conducted. This state of affairs limits full consideration of the effects of alternative programs. Paramount in conducting CBAs is the availability of longitudinal studies of programs for children and youth. These studies are more likely to accurately assess the total impact of program participation. In addition, more studies are needed that address the differential effects of participation across a range of child, family, and program attributes.

Into my heart an air that kills
From you fair country blows:
What are those blue remembered hills,
What spires, what farms are those?

That is the land of lost content,
I see it shining plain,
The happy highways where I went
And cannot come again.

A E Housman

The Overriding Influences

Stark Contrasts

If one takes an ecological view of childhood and, having placed the child at the center of a diagrammatic map or target, looks first at the outer pressures on our central concern, children, there are clearly two overriding contextual features that dominate everything throughout the world; and though they do not sharply divide, but merge into one another, these broad health, and socioeconomic extremes may be represented fairly starkly. All the intermediate and close immediate pressures on children are shaped, result from, or are affected by them.

About 9–10% of children are born each year into somewhere in the relatively rich 30 Organization for Economic Cooperation and Development (OECD) countries, and despite the diseases of affluence (diabetes and heart disease, caused largely by underexercise and overeating fatty foods), they will live for about 80 or more years and will normally have opportunities for education up to and beyond university level. (In the OECD, there are 30 rich countries as members.) The contrast is with that of the remaining 90%, who are born into extreme poverty, sometimes poor sanitation and certainly inadequate diets and into cultures replete with diseases such as acquired immune deficiency syndrome (AIDS), malaria, polio, and tuberculosis. War, genocide, and famine will often also be their lot. Such children will have, in extreme cases (such as Rwanda in Africa), a life expectancy of half that of their rich cousins, that is, not much more than 40 years, and their education will be sporadic, tenuous, serendipitous, or nonexistent.

Of course, there are many variations and many within-group differences. Cuba, a relatively impoverished and embargoed country, provides tolerably well for the care

and education of its children, possibly more consistently than does a generally extremely affluent Australia. The latter has tended to rely on both state and central government provision mixed with a substantial commitment to private enterprise. Approximately 70% of all Australian child care was (in 2008) private, corporate, or requiring some form of substantial financial input from parents. Consequently, some of the poor children (and there are approximately 15% such in Australia, as there are in Canada and the UK; OECD, 2001; UNICEF, 2005) fall through the net and do not receive the support they deserve. This is especially true of Australian aboriginal children, whose conditions are more often similar to those of a Third-World country (Australian Institute of Health and Welfare, 2008). A major initiative of the Australian federal government (in cooperation with the states and territories, 2008/2009) is to improve early childhood provision, to assay its quality, and to regulate and guide it better.

Cuba, despite many financial difficulties, has within its overarching, official approach, a system of child-care/preschool institutions called Children's Circles and these are available from the age of about 12 months. For those who cannot benefit, or who are in rural areas where it is difficult to service completely, the education authorities have a system of trained coaches working within the community, who not only support and stimulate the family's approaches to the child's development and learning but also provide the equivalent of toy libraries and materials as well as advice and health support. There are no figures available for proportions of Cuba's gross domestic product (GDP) spent on such a system and it clearly has its gaps, but it is a basic right of the people and does not depend upon income (UNESCO, 2007). Moreover, as in many countries nowadays, Cuba has a ministry of education that embraces child care and sees it as an integral part of education, much as do the Tasmanian, South Australian, and Victorian states in 2009.

Thus, the broad outer circle of any contextual/ecological diagram, which places children at the center, would have to be one which takes clear account of affluence, or poverty, and how these are dealt with politically. A rich country can still display a relative disregard for its youngest and most vulnerable, and may especially, disregard the impact of seeming choice on the minority poor in a thriving market economy, whereas a poor country may have ingenious ways of supporting its young and their families and see systems of support as a major political imperative, such that no

child is left uncared for within the limits of its finance and power. Choice is a favored term in conservative political systems, which tend to regard education and child care as simple commodities, which can be bought and sold in the market place. According to such a view, one has the choice, to buy or not to buy. The politics of it all are themselves embedded in ideology and often of themselves provide the onlooker with a key to style and type of commitment, with (mainly) rich socialist countries viewing early childhood education and care (ECEC: the OECD term) as a definite part of tax-based public provision and rich conservative countries tending to emphasize the importance of family responsibility and free-market approaches. Even in Norway and Sweden, which have a high reputation for social and educational care there are mixed-market (though well-regulated) approaches to ECEC.

Intermediate Influences: The Meso-System

Demography, Families, and Change

The context of childhood is changing. In the affluent world, children are clearly a decreasing commodity. For instance, in the 30 rich countries of OECD, the total fertility rate (TFR) is, for the most part, well below replacement level (replacement being approximately 2.2 children per female child-bearing life). Indeed, in Australia and England the TFR hovers around 1.7 and in Europe as a whole is currently (2006 figures) about 1.46. Moreover, the TFR is hard to raise and, partly as a consequence of much later first parturition (now at about age 29.9 years per Western female), over one-third of the child-rearing age is statistically largely barren. This means that, in effect, many families have only one child especially in a family where both parents work. It also means that many children are in effect only, lonely children and it makes imperative the provision of good systems of community support, so that the child can have what might be appropriately termed pseudo-siblings; put simply, the chance to develop, share, and play with companions (Gammage, 2008).

Such a change is partly the impact of contraception and the efficiency and availability of the pill since the early 1960s, which in some ways has given women more power over their own bodies and changed the nature of planned parenthood. It is also partly the impact of economic change and the globalization of the economies and of the drive toward house purchase and technological advance generally. There are many interrelated causes. However, whatever these are (and the birth-rate is also low in Catholic countries: e.g., Italy 1.55 and Portugal 1.46), they have helped change the nature of childhood itself, since childhood as described within each culture is largely a cultural artifact. With both parents at work, it means that many children have to be involved in systems of care, be it Family

Day Care, or being looked after by a friend or relation, or placed in a formal child-care institution with qualified carers and teachers. Moreover, in a world of globalized expectation (via commonly accessed media), mobility of families and high mortgages, this means that many women feel the financial imperative to return to work as soon as possible after the birth of their child to help secure the family's finances. Under such circumstances, child care becomes a necessity, which is no longer a luxury afforded only by the upper classes; it becomes an integral part of state provision. Its vitality and coverage is as important as the provision of elementary or primary education, with which it now merges practically and philosophically.

Within this contextual, middle category of influence come divorce and the changing nature of families themselves. Divorce rates currently run at about 40% plus in much of Europe and appear in Australia, as well. (Eurostat, 2008) Thus, nowadays, many families are remade or restructured at certain times and the art (diplomacy and psychology) of step-parenting becomes crucial to the happiness and welfare of the child.

Day care, family centers, child-care institutions, kindergartens, *crèches* and nurseries, and many other terms are used for the various provisions subsumed under the term ECEC (the OECD and the United National Educational, Scientific and Cultural Organization (UNESCO) term for care and education from birth to about 8 years) and such institutions help in supporting revised family structures, working parents, patterns of shift work, economic needs, and remade families. They have, in the last decades of the twentieth century and the first of the twenty first, quickly become an essential part of a normal modern society.

There are other demographic effects, too. These are that in current affluent societies there are greater cadres of the elderly. These older people have to be looked after by the declining financial (tax) and resource (time) base of those (apparently now getting fewer) in work. Partly this may be compensated for by raising the age at which people retire – a relatively recent, but common, ploy in political systems in Europe and Australia. Such an approach may not be bad, since it recognizes greater longevity (and fitness for purpose) among the elderly and restores some status and dignity to the values and purposes of that group.

Therefore, families have altered and what matters is less the structure of the family and more its function; and how children may be best loved and socialized in a secure environment becomes a fundamental political issue. There will be families of all sorts and the child-care institutions need to be attuned to support and community involvement in a way that takes this into account, without stigma or prejudice perhaps, without excessive expense on the part of the individual. The whole society is responsible for the shift in mores, needs, and institutions. It seems that divorce and separation are inevitable, a part of adult choice

and of our mobile, longer-living, modern, postnatural societies (Giddens, 1999); and family change has to be viewed constructively, for the sake of both the children and the mental health of the adults involved. Surely, therefore (or so runs the argument), we need to find collective societal solutions.

The Close Inner Pressures

Technology and the Media

Children are increasingly socialized by the media. While this clearly provides for greater democratization of knowledge and the accessibility of sophisticated comment (at best), it can also result in the domination of information and attitudes by forces that are sometimes inimical to sound psychological and social health. Violence is a particular issue on our television (TV) screens and with many video games, as is the assumed consensus of beliefs and the dumbing down of complexity and difference. Coarseness of language and populism can provide a poor basis for a young child's early development. However, popular culture is big business and music and iconic performances by chosen stars are manipulated regularly for the benefit of marketization, almost regardless of merit. The technology of the home and the classroom is increasing, with interactive white boards in kindergartens and the attempts (in USA) to encourage lap-ware (the use of laptop software for soothing and educating babies). TV represents an especially potent force, in that the hours spent in front of the screen are probably now well in excess of the hours spent in child care, or with mother or father. (The *New Media* publication suggested, almost a decade ago, that about 20-plus hours viewing per week appeared to be the average for a South Australian 3-year-old.)

Mobile phones, game machines, computers, and personal players are common to many 5-year-olds and the interface with technology has a commanding hold on the developing brain, even if one is legitimately worried about the quality and amount of genuine interaction thus encouraged.

The Center

Early Brain Development

In an earlier publication, the author has discussed something akin to the following, and subsequent, more recent research has tended to support such a position, so the author reiterates it. It is especially important that we do not take too deterministic a view of early child development, although it is vital. Remediation and change are possible at almost any stage of human life. The disciplines of psychology and psychiatry are to some extent built on such assumptions.

There are somewhat contradictory views taken about the importance of what McCain and Mustard (1999) referred to as critical periods in the development of the brain. Research with small children is extremely difficult in this domain; and although there is some evidence of critical periods of development for some animals other than humankind, there is little that is specific to our children: for example, those for critical periods are McCain and Mustard (1999) and Wynder, among others. Wynder said, "It is the consensus of the participants that a 'critical period' exists during which the synapses of the dendrites are most ready for appropriate stimulation, be it through words, music, love, touch, or caring. If these synapses are not so stimulated early, they may never fully develop" (Wynder, 1998: 166). There are those less enthusiastic, however. "I suggest that the importance of timing lies not within a set of age parameters but rather in the match between experiences provided, the child's developmental status, and the child's need or readiness to learn a particular skill or concept" (Bailey, 2002: 2–3) (vide Gammage, 2003: 340).

What we clearly do know and where there is much consensus is that the child's brain is immensely plastic. During the first 3 years or so of life, some trillions of connections are gradually established, forming the maps of response, coordination, and information processing. Constant change is occurring as the networks grow in parallel and in sophistication through the infant's daily observation and curiosity. Processes of selective amplification occur in direct relationship to the frequency, intensity, and salience of the stimuli. Some networks are pruned and adapted. All these are embedded in the quality of attachment and consistency. Indeed the trinity of care might well be described as one of attachment (love), consistency (prediction and reliability), and boundaries (knowing what counts). These are the difficult areas that all parents have to chart and recognize in the upbringing of any small child. They are affected by culture and by personal disposition; and sensitivity to and awareness of them are not necessarily simple correlates of pregnancy. Parents often need support and knowledge to make the most of their own inclinations and attributes. Some parents might be considered almost lethal in their styles of child rearing, as many psychologists could point out. Such comment, if made publicly, is commonly frowned upon in a democracy and regarded as unsupportively critical and politically incorrect. However, human sciences casework would testify to its accuracy. There is such a thing as bad, ignorant, or inadequate parenting and we do a disservice to future generations if we fail to recognize that and plan accordingly. Some of recent policy changes in England and Australia can be laid directly at the door of political anxiety about what to do if a parent really wants to harm his/her child. It is doubtful whether any system is so good that it could assure that no child would ever be harmed. Scapegoats in the public services are common, but the problem lies very often in

the cyclic nature of psychological dysfunction within families themselves.

Boys and girls tend to excel at somewhat different tasks and though the density of their brains differs in some respects, no one has adequately explained the difference between the sexes. Recently, however, work on epilepsy has shown markedly different synapse density in actual synapse connection and clusters in different areas of the brains of men and women. It may be that such differences give some explanation as to why men and women show different levels of skill at different tasks (New Scientist, 2008). A critical feature seems, however, to be the overlay of cultural expectation as well.

Research on the development of the brain, while not offering what some people may claim in terms of explicit programs and curricula for the very young, or for different genders, does suggest that money is spent at the wrong end of the developmental curve. Put crudely, we tend to spend downstream, rather than upstream. Upstream spending would be a better investment and of great benefit to society. There is no doubt that what goes on in early child development is highly predictive of later adult behavior and there is considerable evidence from cohort studies to support this view. Such a perspective also tends to confirm what many teachers and carers have averred for many years, that high-quality social interaction and play are the absolute best basis for secure learning. Elkind (2008) sees play as the way in which dysfunctionality is countered and useful schema interpreted and established. He suggests that play leads to healthier, happier adults. Dysfunctionality would seem to be internalized young and has major implications for society both then and later, as many a psychiatrist and criminologist would testify and as many cohort studies clearly demonstrate. Perhaps how the 3-year-old behaves in the long-day care center tells one a great deal about how (later) the 23-year-old will behave in an adult environment (Silva and Stanton, 1996)! Yet, we have to be careful. It is all too easy to fit the Western developmental expectation coat upon every child, regardless of his/her experiences, perceptions, and his/her needs (Yelland and Kilderry, 2005). Prediction has its dangers.

The Child, Happiness, and Early Pursuits

The message that the early years are vital has now caught the attention of most politicians and policymakers. After all, few could ignore the two-stage study by the OECD, *Starting Strong* (OECD, 2001, 2006), or the constant ECEC papers provided by UNESCO on different country values and approaches. However, one suspects that some policymakers have entertained only certain parts of the message. They now know that learning is crucial from birth and they therefore see the child as an appropriate

investment for the future. They tend, however, to see the provision of early formal curricula as the best approach to achieving this. Regardless of the demonstrably poor match between such studies as the Programme for International Student Assessment (PISA) and the formal ECEC curriculum (the Finns do very well in PISA without formal ECEC curricula), they avidly pursue a diet of watered-down school approaches; and fail to recognize the here and now of a small child's life, the vital place of joy in motivation, or the need for well-trained staff (quality comes from quality staff – an almost universal research finding). Such policymakers adore measurement, even though the measures may not tell us much, or even when the measures drive and delimit the curriculum such that children are bored and joyless (Willis, 2007). Workers with children know that often what is difficult to measure is that which really counts in the child's progress to a healthy adulthood. Well-being, persistence, humor, empathy, engagement, and locus of control are all difficult to measure, yet form the vital core of children's drama, play, listening, sharing, and social activities and may be equally as powerful as success in literacy or numeracy. Even in early literacy, we now know from detailed studies that the emotional bonds are often key to the success of the child.

It cannot be emphasized enough that children need variation, individual attention, systematic, yet noncompetitive atmospheres, and ample opportunity to choose and to persist. Success lies in the fostering of dispositions and attitudes which lead to autonomy, yet sensitivity, creativity, yet responsibility. The true curriculum for small children is, in its core, that of relationships and democracy. These, as the Swedish policy documents aver, are the basis of a just and humane society (vide Bennett, 2007).

Politics and Policies: Freedom, Risk, Accountability, and Control

Childhood and being a child are in some respects under siege in many modern societies, since children are viewed (often at best) as little investments waiting to happen; at least, that is the rationale commonly offered by politicians. Much lip service is paid to children's rights, but few children are asked what they would really like to experience. They are done unto with all the zeal of religious reformers. The child must surely have the opportunity to be as well as become (Moss and Petrie, 2002; Morrill, 2003; Willis, 2007). Two compulsory institutions commonly exist in modern societies: school (which is starting ever-earlier in the child's life) and prison. Both are implicated in the withdrawal (necessarily, or otherwise) of human rights.

Although we know much more about early childhood and the developing brain, one sometimes wonders whether we should be more concerned over whether the brains of adults are actually equal to the task. As Erasmus said, "a

person is not born human, but becomes one.” What are we doing to make sure that the impact of the environment and opportunities we provide are equal to the task (OECD/CERI, 2007)?

There are quite contrasting perspectives among policymakers. While we should be clear that politics shape policies, this is not an easily discerned, nor necessarily rational, tidy, contiguous process. Moreover, ideology is frequently employed as theory, even at the very highest level. People know how they think children best learn, or are best brought up. They know it vehemently, with fervor and conviction. Research is usually not allowed to get in the way of such expressed convictions. In most situations, governments try to establish the facts, so that they have knowledge and the best up-to-date information before they act and before legislation. In the ensuing melee, however, they usually act according to pressures, lobby groups, personal beliefs, and values. In reality, while these seem to be very different perspectives . . . (cool information gathering, as opposed to strong conviction), most policy decisions have to try to accommodate all of them.

In all this, the media have increasing power, such that their moguls are increasingly courted and heeded by those elected to power. There is, in the public service, in the media and among politicians, a prevalent use of weasel words. These are words that summon up much spirit, but often mean relatively little, or are especially difficult to define. They can be insinuated into the discussion and work their magic helpfully, it seems. Thus, some politicians talk of curriculum delivery, spreading perhaps the image of simplicity, of Postman Pat going about his cheerful rounds with a great, easily described, and attractively shaped parcel of knowledge. Reality is not like that and each child requires curricula that match and mesh with the child’s needs and his/her stage of thinking. The parcel, however, fits the folklore view of teaching as filling up children with vital knowledge and, as an image, has much power and salience with the press. Many such words abound, partly, perhaps, because of the current preoccupation with management and leadership theory, or of the sound-bite approach to successful marketing. The current political vogue for target setting, spawns many such, from performance managing to children’s well-being, from curriculum framework (so as not to frighten those who are child-centered in approach?) to essential learnings. A lifetime in the field would yield some interesting words and fashions that last relatively short periods of time, yet have power and collective strength in the way they are used to persuade children and teachers that this or that is best for them. They are usually constructed to mesh well with populist views of education and care.

Closely following the media expositions of childhood (especially those of damaged or aberrant childhood) and its context comes the legal profession. They are above politics in any sane democracy, but there are

many interstices in which they can act for, defend, and indeed sometimes profit from, the concerns of the public. This has given rise, in some countries (there are marked differences), to what might be described as the culture of blame; accountability, risk management, and the overreliance on child outcomes (school achievement) being directly contiguous with teacher skill and effort. Accountability is commonly defined as being responsible for and able to explain one’s actions. In major parts of the Western world (broadly the English-speaking ones), principals, headteachers, and others in responsible positions have to be extremely aware of the ways that litigation can be employed destructively against a college, school, or center. This is not helped by the attitude of many politicians and policymakers who seem to think that there is clear connective tissue between the actions of a teacher and the intellectual outcomes for the child. While it is important that any professional should be accountable for his/her actions and certainly able to explain them rationally, the subtlety, the timing, and the myriad intervening variables are so often not clearly perceived in such simple equations. Moreover, the responsibility of the family and of others can so easily be lost in any ensuing discussion, as can the responsibility of those who talk of local management in education and yet support rigid central control, or inappropriate systems of assessment. Professionals make judgments, using the best knowledge available at the time – sometimes those judgments are wrong. The role of a surgeon, general practitioner, teacher, psychiatrist, and many others is not necessarily helped by the specter of litigation. In the beginning, somewhat punitive, approaches taken by the Office for Standards in Education, Children’s Services and Skills (Ofsted; the inspectorate system) in England in the early 1990s, contrived to make being accountable take on a meaning that may have directly led to the illness of leaders and even in some cases, suicide.

Risk is in fact a biological necessity for the human organism to progress and develop. Challenge is important. Small triumphs and occasional failures are the weft and warp of the growing child’s life. The question is, how much risk; and is it calculated sensibly and sensitively? Schools and children’s centers provide, in effect, substitute homes and pseudo-siblings for their charges. They also provide role models and control, education and care, and many other opportunities to develop and learn. In all that, there must be at times measures of calculated risk. The Outward Bound movement of the late Kurt Hahn would have some difficulty with the curtailing of enterprise and calculated risk, as would the international colleges like those in Singapore, Canada, and UK. Different countries clearly have different approaches to risk management. Some systems, typically those of the Nordic countries and Italy and Portugal, use it in what might be termed light-touch approaches, whereby children are still allowed to climb trees, light candles, play in the snow, and

do things which require care, self-control, and some deployment of good sense. Countries such as the UK, USA, and Australia are nowadays much more cautious. Even traditional playground apparatus, such as seesaws, being frowned upon, or well insulated from occasional bruising or harm by the judicious application of cork or wood chips around them. In all these, one is left with the question: How does one provide challenge, independence of action, responsibility, and safety, all in one institution? How does one make the context of childhood optimal? How does one cater to adventure and risk, for stimulation and excitement? Accountability and risk management, if too zealously applied, may make for exactly the opposite of what we want for our children – and what they need; good care and imaginative, motivating, and creative education.

Education is, rightly, always at the cross-roads (Maritain, 1943), but it is a crossroads as much, as Maritain pointed out, about ethics, as pragmatics and deserves constant vigilance and cautious attention by politicians and policymakers, as by teachers, pupils, and families themselves. ECEC is becoming a major part of Western culture, can be seen as supporting, or usurping, changed family functions, and structures. The joy of childhood must not be allowed to disappear in the midst of many well-meaning reforms which (sometimes) further restrict our children and their childhood. The joy of childhood, its partial freedom from responsibility, its soaring imagination, and creativity are part of our very humanity. Whatever is done to and for children must surely take their essential welfare and freedoms into account. According to Morris (1972)

The development of confidence in one's own genuine powers – however limited these may be – is the first essential of personal growth, and such confidence is rooted in an attitude to the world which finds it a good place and the people in it worthy of trust and love. In the beginning, belief in ourselves depends on someone else having believed in us, having cared for us, having loved us. This is the first responsibility of parents and teachers. . . (p. 261)

ECEC is now at the crossroads; its careful, but inevitable provision is as big a social revolution as the establishment of universal elementary education in the nineteenth century. "What is important is not the technology of it all, but the seeing. . ." (Maritain, 1943: 39).

It is up to us to make the spread of ECEC loving, joyful, and essentially worthwhile, so that our children

recognize their future gladly and see their essential humanity both now and into the future.

Investing in Early Childhood Education and Care: Some Policy Implications

J Bennett, OECD, Paris, France

The Childcare Transition: A Profound Social Change

In the past three decades, a profound change has taken place in how parents rear their children in the economically advanced countries. Following centuries of being a predominantly family affair, more than 80% of the rich world's 3–6-year-olds are now in early education and care by the time they enter school. Of children under the age of 3, the proportion using childcare is approximately 25%, the proportion using childcare is approximately 25%, for OECD countries as a whole, and in individual countries, such as Denmark and Sweden, more than 50% of 1–3-year olds can be enrolled. Across the industrialized nations, parents are increasingly placing their young children in out-of-home childcare at ever earlier ages and, often, in full-day care (UNICEF, 2008).

Powerful forces are driving this change – among which is the influx of women into the labor market. At present, women in the rich economies are more highly educated than men and desire a more active role in society. Their personal independence, social identity, and participation are based on finding salaried work that is viewed positively and remunerated. The new service economies – in which traditional divisions of labor between men and women have become redundant – provide this opportunity. In addition, women's work is, often, a necessity. The high cost of living in the industrialized world increases the need for dual-earner families. Women are conscious that their work contributes significantly to family budgets and, in many instances – in particular, when women become the sole providers for children – allows families to stay above the poverty line (OECD, 2006).

Childcare Outside the Home Brings Benefits to Economies, Women, and Young Children

In general, governments, business, and finance ministries strongly support the entry of women into the labor market as the larger workforce delivers important economic objectives. Greater participation by women boosts production, increases tax receipts, and reduces the number of families on welfare. Governments, therefore, encourage women to join the labor market, even if they have very young

children. Business, too, welcomes the entry of women into the labor market as the higher educational achievement of women and their relatively lower pay levels make them attractive employees. In parallel, as recent studies from California show, the growth of children's services can significantly expand economies and create many jobs and business opportunities at the local level (Centre for Community Economic Development, 2008).

Figure 1 the proportion of women, in employment, in selected OECD countries. The ratio ranges from a high of 81.2% of women working in Iceland to a low of 23.7% in Turkey.

In addition to serving the economy, investment in early-childhood services allows governments to strengthen other major policy fields – notably, social policy and education, for example, gender-equality goals (**Table 1**). (For a summary of research showing benefits from ECEC services, see OECD (2006), Annex D. This Annex summarizes research showing social, economic, labor market and educational returns from investment.) When governments ensure a sufficient supply of affordable childcare and early-education services, women are enabled to reconcile work outside the home with child-rearing responsibilities. This is good for women's autonomy, family budgets, and the national population–employment ratio. According to the research, the women who have most difficulty in accessing services and finding work are lone mothers and immigrant women – which leads, in general, to family and child poverty among these groups (European Commission, 2008). In addition, although access to work has emancipated many women, studies and data show that a level playing field does not exist for women where recruitment, promotions, and salaries are concerned (EUROSTAT, 2008; World Economic Forum, 2008). The difficulties of reconciling motherhood with a career also impacts on the economy, as many women engage in part-time work well below their potential or in the care sector where wages tend to remain low (Glass and Estes, 1997). **Figure 1** published by the World Economic Forum, in 2008, shows which countries have been successful in ensuring a certain equality for women across four important indicators: women's health and survival; economic participation and opportunity; educational attainment; and political empowerment (World Economic Forum, 2008).

Societies and governments also acknowledge the contribution that early education can make to education. The intense competition among trading nations has convinced

governments of the importance of human capital development. Increasingly, they see education as vital to future economic success, and look to the early years as the foundation stage of lifelong learning. Some countries, notably the continental European countries (Belgium, France, Italy, Spain, etc.) enrol 100% of children in early-childhood education services from the age of 3 years (Table 2).

Government Investment in Childcare Remains Weak

A clear disparity exists between investment in childcare services and in early education, particularly in the liberal economies. (The Nordic countries invest most in the care and education of young children. They have integrated childcare and early education both at administrative and centre level, and in general, provide financing directly to services.) In the liberal economics, childcare is often seen as a labour market tool to allow women to work, rather than as

Table 2 Enrolment rates of young children in early-childhood services

Country	0–36 months	36–60 months
Australia	29	71.5
Belgium	33.6	99.6

United States	35.5	62

Data taken from the OECD Family database, www.oecd.org/els/social/family/database.

a developmental and educational opportunity for young children. State investment in these services is relatively weak, with parents expected to purchase care in the childcare market – which is often weakly regulated. As a result, childcare services tend to be less developed in terms of coverage, and in some instances, have become a patchwork of small-scale providers and individual family day carers. Various reasons have been put forward to explain this reluctance to invest, for example, the notion that childcare is in the private sphere and not a question for government; the

reluctance of some governments to invest in social programs and equity; the desire to engage the private sector and to keep government small, etc. Whatever the reason, childcare services in many countries tend to be of poor quality: underfinanced and overcrowded, with poorly educated staff who are not able to provide high-quality pedagogical programming. Yet, countless pieces of research show the importance of the years from birth to age 3 in the human life cycle. Given a positive environment, infants and toddlers can make tremendous strides in this foundational period when the senses, language, and the higher cognitive functions are developing at an unprecedented rate (**Figure 2**).

Countries Prefer to Invest in Early-Education Services

The attitude of liberal governments toward early-education services is marked by greater engagement and investment. As children approach school age, targeted educational services – for example, Head Start in the United States of America or Sure Start in the United Kingdom – may be funded for children from low-income and/or dysfunctional families. In recent decades, all countries have become concerned by educational outcomes for low-income children. They are aware that low educational achievement among children does not serve the economy and may lead, later, to delinquency and dependence on social welfare. In response, they adopt a targeted approach to early-childhood services, creating, for example, special services for ‘at-risk’ children. Over the years, these services have become increasingly comprehensive – that is, they go beyond learning activities for young children to also focus on wider aspects of development, such as the general

health and the well-being of children, family support, and community environments. Typically, comprehensive services work in co-operation with other community services and pay particular attention to parents. Both Head Start and Sure Start are examples of comprehensive early-childhood services focused on the development and education of young children, but which can also provide parents with courses and advice on parenting, employment, job training, and leisure-time activities.

Despite this, critics note some fundamental weaknesses in targeted programs. First, services for the poor tend to become poor services, that is, they may not receive, over time, the funding, staff, and environments that disadvantaged children and families need (OECD, 2001). Educational expectations may remain low because of the exclusion of middle-class parents and children from these services. Second, there is the danger that governments, in their enthusiasm for interventions, may be treating only symptoms and not the underlying causes of child poverty – namely, social inequality and its attendant ills. Obviously, children at-risk of educational failure need high-quality programs (**Table 3**), but societies that tolerate extreme inequality and large-scale poverty are, at the same time, placing unacceptable numbers of children in a situation of disadvantage where educational achievement and life chances are greatly endangered.

To What Extent Do Governments Fund Early Education and Childcare?

To answer the question, it is useful to draw a distinction between early-education services, for children 3–6 years,

Figure 2 Human brain development in childhood.

Table 3 Investment estimates per child in high-quality early-childhood programs in 2005

<i>Source of estimate and year</i>	<i>Half-day, school year program</i>	<i>Full-day, school year program</i>	<i>Full-day, year round, with integrated child care</i>	<i>Reference</i>
Denmark, 2004			\$19 500 (this figure includes a parental contribution of c. 30%). The net public investment is \$13 650	BUPL, 2005
Finland, 2004			Over EUR 10 248 (not including parental contribution)	STAKES, 2005
Norway, 2005			EUR 12 520 (not including parental contribution)	BFD, 2005
France, 2008		EUR 4000.00 +	EUR 15 000 (including parental contribution)	Le Monde, 09/2008

and childcare. Broadly speaking, governments in all countries take charge of the major costs of public early education from the age of 3, 4, or 5 years. In European countries, governments generally provide free early education for 4, 6, or 8 h daily for children from the age of 3 or 4 (Ireland, Netherlands, etc.) years. In Australia, Canada, Korea, and the United States, free education comes about 2 years later: governments provide free preschool educational services for children, from about the age of 5 years – although, in some instances, efforts are made to provide free half-day services for 4-year-olds either under state/provincial auspices or through targeted central (federal) government programming. The Nordic countries provide paying services from the end of parental leave (generally, 1 year or more) up to the age of 6 years, but charges are modest (parents fund between 9% and 15% of service costs). Certain parts of the day (early-education periods) may be free of charge, and costs are waived for poorer parents.

With the exception of the Nordic countries, the picture in childcare is different. The main costs of childcare are taken charge of by parents, with subsidization – to a greater or lesser extent – by government, depending on the country and on the income level of parents. For example, middle-class parents in Ireland, the United Kingdom, and the United States pay most of the costs of childcare; whereas, in the continental European countries, public subsidies take charge of well over half the costs. In the Nordic countries,

state and local government subsidies take charge of over 85% of costs (excepting Denmark). In addition, in Finland and Sweden, a *de facto* right to highly subsidized childcare services from the end of parental leave exists, with parents paying much less than 15% of costs (9% in Sweden).

What Is the Actual Investment as a Share of Gross Domestic Product?

According to the OECD Family Data Base (2007) chart below, the following ranges are found within the industrialized world:

- *% of GDP devoted to childcare 0–3 from public funds:* The percentage ranges from just less than 1.2% in Iceland to 0.2% in Ireland and Korea;
- *% of GDP devoted to early education (3–6 years) from public funds:* The percentage ranges from 0.8% of GDP in Hungary to 0.1% in Korea.

What Share Should Countries be Investing if Quality is to be Achieved?

In 1996, the European Commission Network on Childcare (EC Network on Childcare, 1996) recommended, to European countries, an investment level of at least

1% of gross domestic product (GDP) in early-childhood services. As can be seen from the chart above, only five countries out of the 20 reviewed have clearly reached this investment level: Denmark, Finland, France (the 1% investment attributed includes local authority investments; *école maternelle* for children from age 2; and child-care services), Norway, and Sweden. The case can be easily made that 1% of GDP is a minimum figure if adequate quality is to be achieved. France's investment of about 1% provides a well-organized and free access system but does not ensure adequate child:staff ratios. The French system employs only graduate-level teachers (high salary costs), depends almost entirely on public financing (with no clawback from parental fees) and enrolls almost 100% of children from 3 to 6 years, but in classes of 20–30 children per teacher. In contrast, Finland spends over 1.3% of GDP on far fewer children attending early-childhood services (see **Table 2**), charges parental fees, but is able to maintain child:staff ratios at a much lower rate.

Another way of looking at early-childhood education and care (ECEC) investment is to ask: What is the average investment per child in a good-quality program or in a public ECEC system known to have good services. This may be a more concrete benchmark for early-childhood managers. From the evidence at our disposal – for example, average child costs in Denmark, Finland, Norway, and Sweden; American Abecedarian and Head Start average costs; estimates made by the Committee for Economic Development (CED, 2002, 2006), or as proposed by Kagan and Rigby (2003), the annual cost works out at over US \$8000 per child per year in early education (3–6 years) for a full-day, school-year program (36–39 weeks) in which reasonable child:staff ratios are practiced, and a majority of certified educators are employed. The CED (CED, 2006) proposes \$5000 as a rough starting point for a child attending a part-day, part-year program. (Abecedarian costs run to \$63 476 per child over 5 years. See also Gormley and Phillips 2004 on Oklahoma Pre-K costs, and the analysis of

Barnett *et al.* 2005 of pre-K costs across five states (Gormley and Phillips 2004; Barnett *et al.*, 2005)).

More detailed costs have been estimated by a number of authoritative sources (Kagan and Rigby, 2003; Masse and Barnett, 2003 (Abecedarian); Barnett and Hustedt, 2005; Barnett and Robin, 2006; CED, 2006). They indicate that costs per child in a high-quality early-education service – with child:staff ratios equal to or less than 10 children per trained adult – range from US \$8000 to \$14000 annually per child 1–3 years, and between \$6000 and \$10 000 per child 3–6 years. As can be seen from **Figure 3**, recent figures from France place annual early-childhood costs at a far higher level: €4000 for a place at the *école maternelle* (child:staff ratio of between 20 and 30 children per teacher); €10 000 for a place at an accredited family day care; and €15 000 per year (11 months) in a licensed crèche (Le Monde, 2008).

These figures suggest that current financing of early childhood services is insufficient if high quality is to be maintained. Our observation is corroborated by the financing costs provided by Head Start, the Nordic countries and several municipalities interviewed during the *Starting Strong* OECD reviews. In sum, costs per child in ECEC services will become a real challenge in the years to come. To move from an average OECD investment per child of \$4741 in early education (EAG, 2007) to double that amount (the current Head Start investment if one includes the 20% local contribution) will demand a significant financial effort on the part of governments.

What Funding Methods Do Governments Use?

Funding in Early-Education Services for Children over 3 Years

The funding of public education services for children over 3 years (or older in the liberal economies) is similar across most countries. Supply-side funding directly to services is

Figure 3 Public expenditure on childcare and early education as a percentage of GDP, 2003.

the major mechanism used. Services are often provided directly by government or local authorities, or by government dependents – that is, voluntary or private nonprofit organizations that receive more than 50% of their funding from government and who have agreed to run services in accordance with government regulations or to specific contractual obligations. The variety of accredited voluntary or private organizations used by governments to deliver services, in this way is varied. Possibly, the largest accredited government dependents in the early-education field for children 3–6 years – as in compulsory education – are faith-based organizations. In the Benelux countries, Germany, and Italy where church groups take charge of a third or more of all early-education services.

In such situations, it is customary for governments (central, state, or local) to provide funding directly to providers, linked to the number of children being served. Funding, generally, takes the form of operational subsidies, staff wages (or wage-enhancement grants), grants for capital equipment and supplies, supplementary grants made to services serving children with additional or special educational needs, and grants for the enhancement of quality or other public objectives. In general, the organizations that receive such subsidies come under strict regulation – although, in many of these services in Europe (excepting the Nordic countries), child-staff ratios can be high, and shortages of provision occur, particularly in growth urban areas. In most countries, governmental departments prepare legislation or regulatory frameworks, license programs, and set group sizes and staff qualifications. Depending on the country, government services may also be helped by provider management groups in monitoring quality and program standards, providing for educator support and professional development, and encouraging parental participation.

Funding for Children under 3 Years

For children younger than 3 years, both supply-side (funding to services) and demand-side funding (subsidies to parents) or a mixture of both models are used. In general, a division can be seen between the liberal economies and other countries. Countries in the former group (Australia, Canada, Ireland, Korea, the Netherlands, the UK, the US, etc.) tend to use, as their main financing mode, childcare subsidies to parents – such as cash benefits, vouchers, tax reductions, and so on. In contrast, the European continental countries use supply-side subsidies paid directly to services as their main mode of financing, although some countries – for example, Belgium and France – may also use tax credits to help parents meet childcare costs. In the social democratic countries, supply-side funding – and tax credits – are predominantly used. Direct municipal provision of day care services (including family day care) is also the rule in these

countries – except in Norway where, in 2004, private kindergartens already provided for the majority (57%) of children (Moser, 2005). However, family day carers in Denmark and the contracted private providers in Finland and Norway are not the independent (and often unregulated) operators found in the liberal economies, but are licensed and regulated by the local municipality.

Controlling Costs

As in other human services, the ratio of qualified staff employed generally sets the level of ECEC costs. This has led some governments either to cut back on qualified staff or to increase the number of children per qualified teacher. Thus, in the childcare sector, costs are often contained through the employment of poorly qualified and poorly paid staff – a feature found often in privatized childcare in the liberal economies. In early education, costs are, often, curtailed in public early-education services through allowing child:staff ratios to rise – for example, in France, Ireland, Korea, and Mexico where child:staff ratios in excess of 25:1 are to be found. Neither approach is adequate if the aim is to have services that provide high-quality education and care for young children.

A more positive approach to keeping costs at a reasonable level is to collect a financial contribution from parents and to build up team teaching. In some of the Nordic countries, university-trained, kindergarten educators form approximately a third (Finland) or half (Sweden) of staff in ECEC centers. They work in teams with trained children's nurses or child assistants. In this way, these countries can provide both appropriate child:staff ratios and graduate-led services. Staff knowledge and morale are maintained – especially for the lesser qualified staff – by acceptable work conditions and ongoing professional development tied to professional advancement. In the United States of America, Hartman (2008) proposes that savings could also be made through raising parental fees and through control of teacher benefits and pension rights, which are often far more favorable than for the general population.

Which Is More Effective: A Direct Funding-of-Services Model or a Parent Subsidy Model?

The experience of the OECD country reviews (OECD, 2001, 2006) suggests that, for the moment at least, a public supply-side investment model brings more uniform quality and superior coverage of childhood populations (1–6 years) than parent-subsidy models. The stratagem of directly funding parents, while politically attractive,

weakens both equity and governmental steering of the early-childhood field. Direct public funding of services (not to be confused with direct public provision of services) brings – in the majority of countries reviewed – more effective control, advantages of scale, better national quality, more effective training for educators, and a higher degree of equity in access and participation than consumer-subsidy models. In addition, advantages of scale can be considerable: public systems make it easier to enforce regulations, support educators, monitor quality and communicate good practice within the system. The comparison is striking when one compares the financing and organization of public early education with that of childcare in countries where these sectors are split. A similar difference in coverage and quality is also apparent, when marketized childcare models are compared with the predominantly public service model of the Nordic countries. The experience of Norway and Sweden also suggests that a public service model can accommodate private providers when they are properly contracted, regulated, and supported by public funding. However, a public service aiming at high quality is costly, as it implies employing well-qualified teachers, reasonable child:staff ratios, and adequate buildings and resources. Outside the nordic countries, these criteria are not always met in public services.

A possible solution to keeping down government costs is the contractual outsourcing approach, whereby private providers are brought into the provision network through public–private partnerships. This is the predominant approach, for example, in New Zealand and Norway. The approach can bring down the costs of services (particularly capital costs) and enlarge the choice of provision offered to parents. It can be acceptable also to ECEC workers, when the state supports a policy of higher qualifications and maintains a guaranteed wage structure for all qualified personnel, whatever their place of work. A similar situation pertains in the formal education system, where government dependents are contracted to deliver primary and secondary education. In many countries, these providers receive full government funding, but are not allowed to charge fees or (in the case of Sweden) fees greater than those charged by the public services. This is to avoid a growing disparity between services for low- and modest-income families and services for richer parents who can afford supplementary fees.

A more radical means of lowering costs is for governments to encourage an open, deregulated market in childcare services – with assistance given to poorer parents through parent subsidies. Up to the moment, results from such policies have not been encouraging (Prentice, 2005; Mitchell, 2002; Cleveland and Krashinsky, 2003, 2005). One reason is that the entry of private providers often leads to state disengagement from the field and a loosening of regulations. The situation, generally, leads to a

fragmentation of provision, a decline in quality, and clear inequalities in access and outcomes. The crux of the matter is that when public funding of the childcare system takes the form of subsidies paid directly to parents, the subsidies are, generally, too low to employ high-quality staff or to finance system infrastructure – for example, data collection, monitoring, inspection, in-service training, etc. In addition, the steering capacity of governments *vis-à-vis* services becomes considerably weaker than in funding-to-services systems. The conclusion reached in the PricewaterhouseCoopers (2004) report, on financing a universal ECEC system for England by the year 2020 is instructive:

Supply-side funding tends to be the dominant form of finance in countries with the best developed systems of early years education and care, such as Sweden, Denmark, France and New Zealand, whereas means-tested, demand-side funding is more typical of countries with less well-developed systems, such as the UK and the US. (Daycare Trust, 2004)

Investing in Early Childhood Education and Care: The Economic Case

G Cleveland and M Krashinsky, University of Toronto Scarborough, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

This article provides a guide to the economic case for public investment in early childhood education and care (ECEC) services. Public investment in ECEC can take many forms:

- Child-related leaves and associated benefits – including maternity, parental, paternity, and child-rearing leaves, with or without paid benefits, with or without full job protection.
- Publicly provided ECEC services – including preprimary education and ECEC services provided by public-sector bodies or nonprofit agencies (even with user fees so long as these fees are small for all users).
- Supply subsidies to ECEC services – operating grants, quality-enhancement grants, wage-enhancement grants, capital-equipment grants, tax benefits, and tax reductions given to ECEC services otherwise normally subject to taxation.
- Demand-side subsidies for the use of ECEC – subsidies to low-income families for the use of ECEC services, tax deductions of ECEC expenses or tax credits based on ECEC expenditure, vouchers for the purchase of approved types of ECEC services.

There are two broad sets of reasons why governments may invest in ECEC services. The first is to transfer resources to families with young children, as a matter of equity. Raising children is expensive and families with young children are typically themselves young; the incomes and assets of these families are low relative to what they may be later in life, and relative to the high cost of raising young children. The second is to protect and promote the public interest in the raising of children and the functioning of families; this can enhance economic efficiency by correcting market failure. While governments seek to preserve a wide scope of freedom for parents to decide what is in the best interests of children and family members, ECEC policies generally provide incentives, financial support, and regulation of services that are intended to help parents make decisions that are most positive for the interests of children, families, and society in the long run. This may go so far as to include the provision by governments of accessible, good-quality ECEC services with or without parent fees.

Why Private Markets May Fail in the Provision of ECEC Services

Thinking like an economist, the default position is to assume that all goods and services will be privately produced and sold in private markets, with private interests determining whether and under what conditions these goods and services will be bought and sold. In this manner of thinking, the arguments for public investment, regulation, and policy of ECEC services must proceed by explaining why and in what ways ECEC services should be an exception to this free-market pattern. This form of argument is particularly well suited to Anglo-Saxon countries with strong market orientations, which typically favor moderate amounts of demand-side (i.e., financial assistance directly to consumers) government intervention in ECEC markets. This form of argument may seem odd to those in countries who have always assumed that (publicly provided) ECEC is a public responsibility.

In a market economy, some goods and services can be bought and sold in competitive markets and, without substantial government involvement, buyers and sellers interact in ways that produce desirable results. In effect, buyers of these commodities weigh up the benefits and compare them to the costs when they make a decision to purchase. The sellers behave in ways that ensure that the prices faced by buyers reflect the true cost to society of producing this good or service. The private competitive market, without government action, allocates an appropriate amount of society's economic resources to the production of these goods. In these cases, competition keeps prices low and encourages producers to invest in new technologies and to seek new ways of satisfying customer demands. Furthermore, the multiplicity of potential sellers gives consumers maximum freedom of choice to find the combination of characteristics that suits them best.

However, certain goods or services do not have some or all of the economic characteristics required for competitive markets to deliver desirable results. For instance, a good or service may generate substantial positive external benefits which are not taken into account in private market transactions. Or a good or service may have characteristics that are difficult for potential consumers to judge

accurately and purchasing mistakes may be made with negative consequences. In these and similar cases, there is market failure, and these market failures can potentially be corrected by government action. Government action will be appropriate if the benefits gained by government policy are greater than its costs. Education, for example, is a service that, because of its characteristics, is typically provided through the public sector because private markets fail to deliver the appropriate amount of it to those who need it most; the benefits of publicly financed (and, typically, publicly provided) education are judged to exceed its costs.

Two broad areas of potential market failure exist in relation to ECEC: market failure in relation to the care and education of young children, and market failure in relation to the employment of parents (especially mothers) when children are young.

There is a public interest in children and in the care and education they receive when they are young. There would be no market failure related to children if this public interest completely mirrored the interest of parents and their ability to purchase good-quality ECEC services. However, an educated workforce is essential both for economic growth and for the maintenance of a healthy democracy, and these benefits spill over beyond the individual family to society as a whole. Further, society has an interest in assuring that children get an equal start in life; if ECEC decisions are financed entirely by the stretched incomes of young parents, this equal start is imperiled.

There is, in equal measure, a public interest in the employment attachment of young parents. Since mothers are likely to be primary caregivers for their young children, they are likely to have their employment relationships interrupted in children's early years. Mothers' employment, earnings, and related child-care decisions may be distorted by various forms of market failure. One distortion is the absence of perfect capital markets; in theory, since purchasing good-quality ECEC services for children should mean that those children prosper in the future, and because continued labor-force attachment for mothers should mean increased prosperity for these parents in the future, it should be possible to borrow the cost of ECEC services from a bank today, using the future prosperity as security for the loan. Of course, this is not possible. Public provision of ECEC services today, financed by future taxation on more prosperous parents and children, is an alternative, given the absence of perfect capital markets to bridge the present and the future.

Another important market distortion in countries in which ECEC is sold on the private market is the taxation of earnings which are used to purchase ECEC services; since the costs of ECEC are necessary costs of employment (rather than an expenditure of discretionary income), the failure to make these expenditures fully deductible from income before taxes are assessed produces an economically inefficient barrier to mothers' employment.

Another distortion, particularly important for lone-parent families, is provided by the tax-back rate, or benefit-reduction rate associated with social-assistance (or welfare) payments. These punitive benefit-reduction rates make employment unattractive for the majority of families on social assistance, leading to increased dependence over time. If, in addition to this, ECEC services are costly, this inefficient barrier to employment is still higher.

Finally, subsidization of ECEC may be desirable as a second-best response to gender discrimination in labor markets or within the family. If gender discrimination compels women to be the sole or main caregiver for young children, this discrimination may cause women and girls to make welfare-reducing decisions about labor-market participation, job promotion, occupational choice, and human-capital investment. Subsidization of ECEC services may provide a basis for greater gender equity in both work and home settings.

ECEC policies in many countries are directed toward reducing or eliminating one or another of these sources of market failure in relation to children and families. In general, ECEC policies that are directed toward both providing developmental/educational benefits for children and reducing employment barriers for parents will have a greater ratio of benefits to costs. Beyond these economic-efficiency concerns, ECEC policies are typically directed toward equalizing the economic and social opportunities of children from different backgrounds.

The Research on Benefits to Children

There are a very large number of factors that can affect a child's development and behavior. Isolating the separate effects of good-quality child care on children while holding all the rest of these factors constant is a difficult research task; many of the disagreements in this research area are methodological. The key research problem is that ECEC services are not normally randomly assigned to children. Most data come to researchers from a situation in which individual parents have chosen the type and quality level of ECEC that their child will use. As a result, it is difficult to separate the effects of family from the effects of ECEC. The research that is most trustworthy in evaluating the effects of ECEC on children is research that deals well with this issue (known as selection bias).

There have been several waves of research about the effects of child care on children. Many of the early studies were random assignment studies of children from lower-income families to good-quality child care centers. Overwhelmingly, these studies (e.g., the Perry Preschool Study, the Abecedarian Study, and the Chicago Parent-Child Center Program) found that good child care can have very positive effects on children and that these

advantages can be long-lasting. In particular, good child care can compensate, at least partially, for a disadvantaged home life.

A benefit–cost analysis of the Abecedarian Early Childhood Intervention has revealed how broad and long-lasting the effects of a well-designed ECEC program can be on disadvantaged children. The experiment involved 112 children, mostly African-American, whose family situations were believed to put them at risk of slowed development. On average, maternal education in experimental families was 10 years, maternal IQ was 85, and 55% of households were collecting social assistance. The benefits to participants (and the community) included:

- improved measures of intelligence and achievement over the long term, leading to higher earnings and fringe benefits now and in the future;
- lower levels of grade retention and placement in special-education classes, leading to cost savings in elementary and secondary education;
- improved employment and earnings of mothers of the children receiving early childhood education services;
- reduced probability of smoking and improved health; and
- reduced use of social assistance.

The costs of providing intensive high-quality child care in the Abecedarian program were high. For infants, there was one staff member to every three children; for 2- and 3-year-olds, there were two staff members for every seven children; for 4- and 5-year-olds, the ratio was one to six. All staff were paid competitive public school salaries. Nevertheless, the value of the benefits, discounted back to the present, was found to be considerably higher than the costs. At a discount rate of 3%, the project provided a 4 to 1 return on the investment of public resources targeted at a disadvantaged group (Masse and Barnett, 2003).

The advent of a universal 4-year-old prekindergarten program in Tulsa Oklahoma has demonstrated the strong positive cognitive and language effects of a well-designed prekindergarten. Nationally normed test instruments (Woodcock–Johnson subtests for letter-identification (prereading), spelling (prewriting), and applied problems (premath)) found effect sizes, from 1 year of a very good-quality prekindergarten program, of 0.79 standard deviation for prereading, 0.64 standard deviation for prewriting, and 0.38 standard deviation for premath. Strong positive effects were found for both disadvantaged and middle-class children, and children from different racial and ethnic groups (with, in general, somewhat larger effects for disadvantaged and both Black and Hispanic children, but substantial positive effects for all children).

The Oklahoma results were partly due to the very high quality of prekindergarten services provided. Prekindergarten services were provided in the schools by teachers who had both a teaching certificate and a certificate in

early childhood education, and who were paid at public-school rates. Classroom sizes were capped at 20 children, and, with one lesser-trained assistant, this meant that staff-child ratios were 1:10 (Gormley *et al.*, 2005).

A similar pattern has been found in prekindergarten programs in five states: Michigan, South Carolina, New Jersey, West Virginia, and Oklahoma. Some of these programs are universal and some targeted, but not as well resourced as the Tulsa program. In all five states, there were substantial gains in both prereading and premath skills (Barnett *et al.*, 2005).

Of course, these latter results are for prekindergarten (generally provided in schools), rather than child care or other preschool. However, there is good evidence that child care can have positive cognitive effects too, as long as it is of adequate quality. Recent studies in the USA conclude that the effects of quality are relatively small (0.04–0.08 of a standard deviation on cognitive outcomes for children), but that, in addition, use of center-based care in the third and fourth year of a child's life has an independent effect of about 0.25 on cognitive and academic-achievement outcomes. Taken together, the effect of a good quality center-based program would be substantial (less than half the size of the effects of parenting or home environment or being in poverty, but still sizeable) (NICHD-ECCRN and Duncan, 2003).

Other studies of center-based programs include various studies of Head Start in the US. Head Start children are a targeted low-income group with heterogeneous programs delivered to approximately 1 million children per year.

These studies are well designed to account for selection bias; the main technique used is sibling fixed effects. In other words, the control group for the effect of Head Start is composed of the sibling of each Head Start attendee who did not attend Head Start. This controls for unmeasured family characteristics that might affect both Head Start enrolment and child outcomes. Currie and Thomas (1995) found long-term (i.e., into the early school years) positive effects on school achievement for white Head Start attendees, but not for African-American children, apparently because of the later negative effects of their schooling. In a second paper (1999), Currie and Thomas found long-term positive effects on school achievement for Hispanics (Currie and Thomas, 1999). Examining the long-term effects of Head Start programs when children were in their early 1920s, Garces *et al.* (2002) found that white children who attended Head Start were more likely to complete high school, to attend college, and to earn more than other white children who did not attend Head Start. African-American children were more likely to complete high school and less likely to be arrested for criminal activity than similar children who did not attend Head Start.

Finally, a recent study examines the long-term effects of the introduction of universal access to ECEC for 3–6-year-olds in Norway in the 1970s. A difference-in-differences

design, based on differential implementation of the program by municipalities, finds strong positive effects on long-term child outcomes. An increase of 17 500 child-care spaces results in about 6200 additional years of education measured 30 years later. There are also significant increases in labor-market participation for these children when they grow up, and reduced welfare dependency (Havnes and Mogstad, 2009).

In summary, there are good reasons to believe that some forms of center-based child care/preschool/prekindergarten can have important positive effects on children, whether these children are disadvantaged and low income and from lone-parent families or whether these children are from middle-income and two-parent families. The effect sizes appear to be dependent on two main factors: the quality and type of child care/early education they receive, and the quality (support and stimulation) of the care the children would have alternatively received (often related to the family situation of the child). The age of the child moderates both of these factors, and the persistence of improved child outcomes will depend on later classroom experiences (Magnuson *et al.*, 2007a).

It is possible that child care can also have some negative effects on children that have to be weighed against the positive cognitive, academic, and language effects (Magnuson *et al.*, 2007b; Baker *et al.*, 2008). Recent US studies have found evidence that more hours in a child-care arrangement is associated, at 24 and 54 months and in kindergarten, with various behavior problems. Initial research found that more hours in child care up to age 2 were associated with more negative interactions with peers and more behavior problems as reported by caregivers, and less social competence as reported by mothers. Measured cumulatively up to 4.5 years, more hours in child care was associated with more negative play, less social competence, and more externalizing behaviors. Higher amount of hours in child care was associated with more teacher-child conflict in kindergarten. These effects were moderated by the quality of child care and the quality of parenting received by the child, but were still statistically significant and quantitatively important after controlling for these influences (NICHD-ECCRN, 2003).

The effects on behavior do not appear to be related to a threshold level of hours. However, it is only children in child care for more than 30 hours per week who, on average, had more than normal behavioral problems, and only children spending over 45 hours per week over the whole period from 3–54 months who displayed high levels of negative externalizing behaviors. The weight of these negative effects is uncertain. One recent comprehensive study (Duncan *et al.*, 2007) found that while math and reading skills and ability to pay attention at the time of school entry can matter dramatically for later academic success, internalizing and externalizing behaviors had no independent effect.

Effects of ECEC on Parents' Employment Situation

The way most societies have evolved, it is generally the mother's role to take the primary responsibility for both the provision of care to young children and the making of day-to-day decisions about their lives. Accordingly, it is nearly always the mother's career that is foregone if someone stays home with the children; it is the mother who works part time when children are young, who declines opportunities for advancement, and who neglects the acquisition of skills that might permit moving to a higher income. Of course, young children make life forever different for fathers as well; often fathers may work harder or longer hours, and there is a considerable amount of off-shifting, where fathers and mothers adjust work schedules to avoid having to hire paid caregivers while both work. The evidence, however, seems overwhelming that changes in ECEC policy will have more dramatic direct effects on the daily lives of mothers, and on fathers, more indirectly.

Several different dimensions of female labor-market behavior are potentially affected by changes in ECEC policies (1) labor-force participation, (2) hours of work, (3) acquisition of general labor-force experience and company-specific seniority, (4) human-capital acquisition, (5) earnings, and (6) occupational status. There is a considerable research literature on the effects of child care costs on mothers' labor-force participation, much less on hours of work, and very little on other dimensions of labor-market experience.

There is an approximate consensus among researchers that the price that parents have to pay for child-care services will negatively affect the mother's employment decisions. However, there is considerable difference on the size of this effect. Blau (2003) analyses a range of studies and concludes that the possible positive effects of public investment in ECEC on participation in the labor force and hours of work are both small (an elasticity of labor supply to child-care price of probably less than -0.20).

Several natural experiments have been studied to provide information about effects of the price of child care on mothers' employment. For the USA, Gelbach (2002) analyses the impact of public kindergarten. His estimates indicate that access to free-of-charge part-day kindergarten increases the probability of the mother being employed by 4–5 percentage points. Cascio (2009) finds that the introduction of (typically half-day) state kindergarten programs in the 1960s had a strong positive impact on the labor supply of single mothers with no younger children, but not on other mothers.

However, a natural experiment which began in 1997 in Quebec (Canada) has produced substantial labor-supply effects on the mothers of preschool children. The policy change involved several family policy measures, including

provision of free full-school-day kindergarten for 5-year-olds and center-based or home-based child care for \$5 per day for children from 0 to 4. Lefebvre and Merrigan (2008) find that by 2002, the policy changes had increased the labor-force participation rate of mothers with young children by about 13%. Annual hours worked and weeks worked had risen by even greater percentage amounts, driven by an increase in full-time work. Mothers' earnings were up correspondingly. Baker *et al.* (2008) confirm this general pattern using a different data set.

There is not much evidence about how ECEC costs, convenience, and quality affect whether a mother works full time versus part time. Powell (1997) reports on Canadian evidence suggesting that full-time work is quite sensitive to child-care costs, while part-time work is less so.

Government ECEC Policy Issues

Even when governments agree on the importance of public investment in ECEC, there remain important differences over the forms that public policy should take. One issue is whether public intervention will occur on the demand side or on the supply side. Usually, this decision comes down to a debate over the importance of maximizing parental choice versus maximizing control over the quality of ECEC provided, and about the effectiveness of alternative ways of improving quality.

It is important to keep in mind that the most important component of the early care of the young child will occur within the child's home and will be provided by the child's parents. Even the most extensive ECEC programs currently in operation generally provide no more than 40–50 hours a week of ECEC to children, implying that the rest of the day and nighttime hours (120 or more) are provided by parents. Most studies of child outcomes identify parents as the most important factor in determining how children turn out. A central concern for ECEC policy will be to determine the appropriate boundary between parental care and ECEC services outside the family. In particular, a decision needs to be made on what age is most appropriate to begin ECEC services, and what supports are necessary to families prior to that age to allow them to provide family care. Currently, countries vary widely in the nature of the parental and child-rearing leave programs they provide, and in the extent to which those programs encourage mothers and fathers to remain in the home to care for their children when they are very young.

There is no one best funding mechanism for all circumstances. However, it is often the case that disagreements on funding that appear to be only technical also reflect differences in philosophy. For example, individuals (and governments) may differ on the appropriate role of the state in setting standards for the care of children, and

on the appropriate roles for men and women within and outside the family. Different funding mechanisms will be consistent with a larger role for the market or for the state in ECEC and these different approaches may be more or less consistent with practices and beliefs of the party in power in different countries.

Concluding Observations

The evidence on the benefits and costs of ECEC does not suggest that all and any expenditure of public money on ECEC will generate benefits greater than costs. The precise design of ECEC financing programs matters. In particular, the ratio of benefits to costs is clearly affected by the quality of ECEC services available; benefits to children rise with quality level, not just up to some point, but apparently without obvious limit (Lamb *et al.*, 1998). However, costs also rise, in general, as the quality level of ECEC services rises. The ratio of benefits to costs is similarly affected by the degree of employment support for mothers that ECEC programs provide. Programs should be designed to maximize the excess of benefits over costs for any child, and should include all children and families for whom benefits exceed costs.

Introduction

Early care and education programs for infants and toddlers can be defined by the wide variations that exist across countries and regions. Social attitudes to very young children will influence the type of education and care provision available and the priority that is given to programs for infants and toddlers. Increasingly research has highlighted the importance of the first 3 years and as knowledge of the social infant grows, there is increasing pressure to design programs that will have the greatest potential to support beneficial outcomes for children's development, growth and well-being. There is an increasing respect for the communicative competence displayed by infants and toddlers, and also a renewed emphasis on the family as a cultural unit, on work–family integration and demands on family members as current or future workers.

There are multiple agendas that early care and education programs are expected to meet. These include physical care, appropriate stimulation to support growth and well-being, family and workforce support, educational advantage, and early intervention for children, families and sometimes whole communities identified as disadvantaged. Infants and toddlers are no longer viewed as individuals who can easily be profiled by describing their developmental performance. Views have expanded as children are also seen as part of the culture, albeit novices, as citizens with rights and as communicators who can establish reciprocal relationships with those in their immediate environments. This powerful image of the child has come from theorists such as Malaguzzi, Magda Gerber, Piaget, and Vygotsky and examples of practice influenced by this image can be seen in the design of early childhood programs around the world, including Sweden, Italy, the United Kingdom, America, China, Australia, and New Zealand.

Globalization has altered some of the debates about group programs for infants and toddlers, which have abounded over the years. These include questions of education and care, demands for investment and regulation, development of a national curriculum appropriate for the age, increased research and a spreading of ideas about child development. Since the 1970s, there has been a demarcation in many countries about what constitutes care and education. This situation is changing. Language is changing as well to reflect recent thinking. In Spain, centers for the very young are now called *escuela infantil* emphasizing the educational role of childcare institutions. Denmark has developed training for a pedagog that combines care and education as inseparable units and the pedagog works with people from birth to old age. Many countries have integrated education programs for children from birth to school including Brazil, England, Scotland, Norway, New Zealand, and Sweden. Increasingly, early education and care is promoted as an economic consideration that is seen as an investment. Child-development theories, seen by many as a Western concept, have been more widely adopted as international agencies, such as the World Bank, Asia Development Bank, United Nations Educational, Scientific and Cultural Organization (UNESCO) and United Nations Children's Education Fund (UNICEF), support early education, health services, and the gathering of research data across the globe. Given the context of changing times, this article has been divided into the following sections:

- changing patterns of early care and education;
- research;
- changing family contexts for childrearing;
- prevailing theories, policies, and practices; and
- conclusion.

Changing Patterns of Early Care and Education

Depending on family circumstances, many infants and toddlers today are under nonparental care and education arrangements for a significant number of hours each week. Relative care is the most common, followed by home care by a nonrelative, and center-based care is the third in countries like the United States, United Kingdom, Canada, and Australia. This move outside the home for many babies has been accompanied by a renewed interest in the impact of the first years on a child's growth and well-being. There are two prevailing approaches to this acknowledgment of the value of positive experiences in the early years. One is a neoliberal view of the child as an asset to society, promoting the need to invest in early childhood services. The other is a participatory approach that would place children as protagonists in their own development, reciprocal members of the culture, and social partners establishing learning relationships.

The first approach to early care and education views the child as an asset to society and gives rise to investment models. One of these models is based on human capital theory, the proponents of which claim that high-quality education and care experience in the early years will aid the acquisition of skills for the individual and that skill begets skill. The cost of providing for children in the first 3 years will be beneficial to the individual and the society. This is an economic and political methodology and is characterized by language like scientific, evidence based, targeted interventions, learning outcomes, and mixed-mode funding. The latter may involve state money, sometimes as vouchers, being paid to the private sector along with users contributing to the service through the payment of fees. There has been criticism from the Organization for Economic Cooperation and Development (OECD), through the Starting Strong 1 and 11 reports, that these funding arrangements threaten quality, cost, and accessibility of children's services. Such an approach to the delivery of early childhood services may be favored by politicians. Targeted intervention is supported if the market cannot provide programs for all and particular populations, identified as needy, can receive services. Policymakers may find it ideologically easier to support the idea that infancy and toddlerhood are in the family domain and therefore are a private not a public good. Targeted interventions can support such a stance. The role of the state and whether early childhood services for infants and toddlers are a public good is a debate for the early childhood field, policymakers, politicians, and electorates.

A participatory approach is best known in early childhood literature through exemplary programs such as Reggio Emilia and the New Zealand early childhood curriculum *Te Whāriki*. *Te Whāriki* encompasses four principles: empowerment, holistic development, family

and community relationships, and five interwoven strands of well-being—belonging, contribution, communication, and exploration. The metaphor used is that of a woven mat. *Te Whāriki* was written as a bicultural, bilingual curriculum with space to promote a diversity of voices. The other example, the infant/toddler centers of Reggio Emilia, *nidos*, have as their cornerstone an image of the strong, competent, social infant. These infant/toddler centers have received much international attention as they have been designed for children specifically within the birth–3 age range and are an impressive example of articulating a social image of the child through physical surroundings, materials offered, and the documentation of relationships among babies and between babies and adults. This is one of the few examples of infant/toddler care that can claim to be strongly theorized for the particular age group.

There are many other approaches to group care for children from birth to age 3. A prevalent model that has had an international following is a health-focused model that emphasizes routines, health and nutrition, cognitive and language stimulation, and early intervention. Many early childhood programs are eclectic in the use of the theory on which to base practice. In England, part of the Sure Start initiative saw the establishment of local programs such as the Sure Start Local Programs (SSLPs), which integrated services, had multidisciplinary teams, and catered for local needs. Services, like those of Pen Green, combined concepts of children as protagonists in their own learning with a family-centered model and an interventionist approach to try to alleviate disadvantages within the targeted population.

There have been criticisms of psychologists having supremacy in relation to the design and establishment of early care and education programs. This may be justified as most of the theorists who have been influential in the early education field have been psychologists or from a related discipline. Among these, Piaget was particularly important as he emphasized the enormous development that occurs before formal language has become established. This led to an acknowledgment of infants as individuals who have preferences and desires. From the contributions of scholars like Piaget and Vygotsky observing and planning for very young children now has a broader base.

Infant and toddler education and care group programs are historically recent. Many of the theoretical influences are shared across borders as curriculum discourse becomes increasingly international. In the last 40 years, there has been a massive movement of people around the world and changing work demands as well as cultural interaction that have impacted upon traditional nuclear and extended family patterns. Such changes have brought about a need for out-of-home care for children as the families can no longer sustain care of the young and meet new demands. The growth of formalized childcare has occurred as a response to social change. As social

change in a globalized world is a reasonably recent phenomenon, the design of care and education programs for infants and toddlers is occurring simultaneously across the globe. Many similar influences impact on policymakers and scholars who respond to international research findings and economic demands to support the workforce and help provide the best start in life for the next generation. Current shared debates address the role of the state in providing services, issues of quality care and education, economics and social welfare, cultural and linguistic inclusion, and acknowledgment of a growing diversity of populations sharing the same services.

Research

Areas where research can support the growth and development of the early child education and care ECEC field include: (1) exploring the implications of the relationship between the environment, genetics, nature, nurture, and culture, and (2) studying the role of relationships in the development of social competence and resilience. Quantitative and qualitative research is necessary along with the emerging concept of mixed-mode research. Mixed methods research has the advantage of integrating quantitative and qualitative data to achieve sophisticated research study designs as well as combining data based on social science research and experimental psychology. For infants in group care, an advantage of combining methods has been the adding of the concept of well-being as a lens to view everyday happenings. Infants can therefore be studied in cultural contexts with an emphasis on what they can do and how they feel, and the lens includes both physical and psychological experiences. There is a greater awareness of infants' learning capabilities and how stress will affect physical and emotional growth, as well as perinatal risk factors that may impact on brain function and cognitive functioning.

In recent years, there have been a number of trends driving research impacting on infant and toddler programs. One is an emphasis on research to support practice and policy so decision making can be more evidence based. Such a research approach was enshrined in legislation in the United States in the No Child Left Behind Act of 2001. Since this legislation, there has been a revisiting of the concept of human capital theory encapsulated in the High/Scope Perry Preschool research of the 1960s and 1970s, as well as lessons from more recent scientific advances. Neuroscience, known in the field as brain research, has highlighted the threats that poor environments bring in the first 3 years and the impact upon the developing brain. Results can be measured by costs to the society in terms of skills, income, education levels, and even incarceration. This emphasis on empirical research and the privileging of the language of empiricism by

politicians and policymakers have had a profound effect. Canada and Australia have applied an early development index to aid the identification of populations at risk, warranting additional targeted interventions. Education systems have favored outcomes-based approaches, with concentration on goals, measurable standards, and the need to develop curriculum statements for early childhood settings, including those for babies and toddlers.

At the same time, qualitative research has become increasingly sophisticated and popular among educational researchers as naturalistic, interpretive inquiry designed to build understandings about meaning making in daily contexts. Qualitative research provides tools for exploring the meanings people attach to their actions and interpret their worlds. There is also a growing body of practitioner research and an interest in giving the child, including the preverbal child, a voice in the research process. This latter research has the potential to support the concept of rights as a living, active process in everyday experience.

Changing Family Contexts for Childrearing

Given that most nonparental care and education for very young children are carried out by relatives, with nonrelatives and formal institutional care being secondary forms of care, parenting programs for grandparents and others caring for infants and toddlers (and facilities like playgroups) are promoted by many governments and agencies. Research into grandparent care, for example, has highlighted gaps between services offered to parents caring for their children and other family members or friends who may be fulfilling a child-caring role. Grandparents are often the carers of choice when parents are working; however, there is an emerging pattern from the research suggesting that grandparents have their own special needs.

Changing demographics also impact upon parental care and education. Fertility rates are a concern of governments with reproductive levels driving some policies related to families. For example, China's restricted child policy has implications for early childhood experiences and family arrangements. Further, in response to low fertility rates, governments may endeavor to support and provide early childhood services as an impetus to population growth. In countries like Australia the advent of older mothers, higher education attainment, and smaller families have also led to a demand for better-quality services. However, what is high quality for infants and toddlers is a debated issue. Developmental psychologist Penelope Leach has long maintained that the best environment for the infant is home with a parent, although she acknowledges that this may be a luxury not open to many families. She argues that governments should take more responsibility

to ensure parents and babies can form strong relationships in the early months by making paid parenting leave available. Toddlers benefit from group programs, Leach claims, if they have a strong relationship with their parents.

The question of how best to support the development of babies and toddlers involves debate about paid parental leave, the quality of services, grandparents as carers, nannies and in-home services, the number of hours children are in centers, and possible developmental effects on children. There have also been studies of early childhood teachers' attitudes to infants and toddlers being placed in programs at such a young age. The prevailing wisdom is that it is the quality of early childhood programs that matters. The most considered quality factors are structural and organizational: staff training and child:staff ratios, the use of space, and the size of groups and industrial considerations about the work of childcare. All these become crucial for families seeking to ensure the right of their infants and toddlers to high-quality care and education in the early years.

Prevailing Theories, Policies, and Practices

A range of theories of childhood impinge upon local and global ECEC policies. The most dominant theories for infant and toddler programs follow the developmental approaches. Major theorists who belong to this school are Piaget, Vygotsky, and Bronfenbrenner. Piaget studied the growth of knowledge in the developing child. He viewed children as active learners who, through interactions with their surroundings, developed key concepts and understandings. Piaget's stage theory, based on children's intrinsic interests in their environment and the motivation to explore, has been criticized for taking too little notice of the role of culture in development. Whereas Piaget acknowledged the child in the culture and observed connections between language learning and culture, his key stages were predominantly based on cognitive understandings. As Piaget promulgated a theory of child competence and an awareness of the communicative nature of the infant, his theory has been associated with the cognitive revolution in education and developmentally appropriate practice (DAP), an early childhood framework promulgated by the National Association for the Education of Young Children (NAEYC).

In contrast, Vygotsky became known for promoting the concept of the social and cultural nature of learning wherein development consists of the use of signs and mediated understandings that occur through joint activity with other members of the culture. The preverbal child is communicative and can use signs. Vygotsky's work identified the developmental tasks of joint attention in infancy and toddlerhood that involved shared attention and engagement with another, for example, through eye gaze

of infants from a few weeks, and exploring objects from a few months, or pointing and social referencing by 9 or 10 months and the emergence of the first words, about the end of the first year. All of these signs are important steps in symbol use and are supported by more able members of the culture interacting with the infant. In the second year, the child consolidates the use of language as decontextualized symbols that can extend experience beyond the concrete present.

Bronfenbrenner suggested a theory of the ecological nature of human development. This model is often presented as a series of concentric circles with the infant in the middle circle. This infant is nested in an ecology which embeds relationships and experiences that gradually get further and further from the child's immediate family. The child's daily environment, and those members of the culture with whom the child shares frequent interactions, are described as the microsystem. This theory includes a number of systems. Some, such as a parent's workplace, are physically removed from the baby, yet will have an impact on its development. The macrosystem is the culture and society at large. For the infant and toddler, group education and care programs are potentially an important part of the microsystem and relationships within the setting should support the child's need for reciprocal interactions with others. Bronfenbrenner strongly supports the idea of a responsible state that will support families in their childrearing tasks.

These theories have a complex relationship to policy and practice as there is eclectic use of theory and stakeholders have divided opinions and different models. Educators often use a mix of Piagetian and Vygotskian theory with references to Bronfenbrenner, Dewey, Malaguzzi, Montessori, or Steiner. A growing discourse is on curriculum and academic outcomes, which has the potential to threaten the play-based practices that have been popular since the early twentieth century. Curriculum documents that are inclusive of infants and toddlers are becoming commonplace.

Internationally, the concept of curriculum for the early childhood years, birth–8, has become increasingly popular. This move toward formalizing learning experiences in the early years has implications for the birth–3 years where practices have not been strongly theorized. Other impacts on the efficacy of curriculum guidelines are the diversity that is found among care settings and the differing levels of experience and training of staff. Studies have found that curriculum statements on their own will not necessarily improve quality or enhance pedagogy. As learning and development occur in the social milieu, relationships are the most important attribute of the infant and toddler's early childhood experience.

The idea of lifelong learning has also had an effect on infant and toddler programs. Many countries include infants and toddlers in the learning continuum. However,

for children under 3, services can be a patchwork of care arrangements. Often in the private sector, services may attract poor regulation and have low standards and staff have little training. These factors are likely to produce poor-quality provision. As pedagogy for infants and toddlers is argued to depend for quality on positive, reciprocal relationships, the training, work conditions and child to staff ratios have to be considered core to positive pedagogies. Therefore, pedagogy has come to constitute relationships that exist between young children and other members of the culture, including ideas of agency and of the infant, or toddler, as a protagonist in their own development.

A further concept in the education discourse is the concept of rights. This is especially relevant to preverbal children in out-of-home care. These children are especially vulnerable to the social constructs of infancy. The most useful international instrument for the promotion of children's rights is the United Nations Convention on the Rights of the Child (UNCROc). This is the most ratified of the UN conventions, fostering a global discourse about rights and children and a level of political consensus that gives the convention universal relevance. The UNCROc can be divided into four sections, promotion, provision, protection, and participation, known as the four Ps. For ECEC programs, all sections are important but it is provision and participation that can be most closely linked to daily experience. In relation to provision, the UNCROc acknowledges that many parents work and a child is entitled to childcare services and facilities (article 18), all children have a right to benefit from early childhood services, (article 3, best interests of the child), and regulated high-quality care should be a right.

The participation rights espoused in articles 12, 13, 14, 15, 16, and 17 are the most innovative of the convention and it is these articles that promote the child's right to a point of view and to be heard. For infant/toddler programs, it is the responsibility of the government, the community, parents, and staff to ensure that the children's rights are upheld. Staff need to be well trained in child development, sensitive to individual children, and aware of the significance of a positive social context. Professional staff are expected to reflect on children having meaningful choices, respect a child's communicative competence, and work in partnership with families and other members of the child's culture. A rights perspective has the potential to reframe social images of the child and transform everyday relationships and practice.

Conclusion

This article has discussed ECEC programs for infants and toddlers and some of the major influences on changing patterns of care. The ECEC field, focusing on programs for children under the age of 3 until recently, has been

under theorized. Most of the attention has been focused on children in the preschool age group, 3–6 years. The terms pedagogy and curriculum are applied to everyday practice with infants and toddlers. These words need definitions specifically in relation to children of this age if they are to have meaning in the field.

The dominant theories for early childhood services are developmental theories, including Bronfenbrenner's ecologic approach. Seventeenth-century neoliberalism and economics theories favoring human capital development are also influential with governments and policymakers. An economics-oriented approach has also been presented in conjunction with the findings from the neurosciences so that both scientists and economists agree that the first 3 years are the most significant in relation to return on investment or developmental interventions.

Research to supply an evidence base for policy and practice has become more important, prompting new understandings of young children. Qualitative, quantitative, and cross-disciplinary research has brought new insights, not the least being that brain research, which confirms the first 3 years as of enormous developmental significance. Contemporary research efforts profile different voices, including those of infants and toddlers, raising awareness of the communicative competence of preverbal children. Finally, a concept of rights-based practice has been foreshadowed as a new direction for education and care programs for children from birth to age 3.

Introduction

In recent years, educators have looked for new ways of thinking about organizing learning for young children (e.g., Anning *et al.*, 2009). Hedegaard (2007) argues that children make sense of their environment within the context of their daily lives. Learning is situated. Children may act intuitively or enact a particular known routine during their everyday life. Through this lived experience, children build culturally relevant practices and develop working theories and concepts. However, at the psychological level, how these everyday concepts develop into literacy and numeracy concepts for preschool aged children is less well understood.

According to Vygotsky (1987), concept formation occurs when children can work with both situated everyday concepts and the academic concepts which make up the conceptual systems of literacy and numeracy. For example, children visiting a food market may not think conceptually about shopping places as being organized around a particular classification system (conceptual knowledge of comparison, systems, and sorting) or realize that they are using important literacy concepts when following arrows and pictorial cues on signage (conceptual awareness of print and symbol systems). At an everyday conceptual level, the children will draw upon their lived experience of moving around the food market simply looking for a product until they find it. However, if children have a mathematical concept of a classification system, they can be more systematic about how they move about the food market. If they have an understanding or concept that print holds meaning, then they may pay attention to the signs, and use these to guide them to the product they wish. Vygotsky (1987) argued that for children to develop conceptual understandings, they need experiences of both everyday concepts and academic or preschool/school-learned concepts of literacy and numeracy (e.g., those labeled in curriculum documents). Importantly, preschool children need knowledgeable adults who simultaneously help them pay attention to everyday contexts and who introduce them to the concepts which give meaning to their lived experiences in their moment-by-moment lives.

Hedegaard and Chaiklin (2005) state that these concepts inherent in our literacy and numeracy system of knowledge are empirical. Empirical knowledge is concerned with a single phenomenon abstracted from its context. Being able to consciously apply empirical knowledge already learned,

to an unfamiliar or new context is very useful for children. For example, knowing that a measuring instrument such as a ruler can give comparative and accurate information means that children can measure a table to see if it will fit through a doorway, rather than physically trying to move it through. The concept of measurement is developed as children experience informal and formal measurement through lived experiences, such as hearing about being a size six, or using measuring cups when cooking.

For young children, empirical knowledge that has not been connected to children's lives, or embedded in a child's world is of limited immediate worth. Children may be unable to consciously draw upon empirical knowledge in their everyday world, as they do not yet know what this knowledge can do for them. For example, learning to recognize and name single words at school or learning about classification in preschool through sorting beads assumes abstract concepts that are separated from everyday practical experiences in the real world. Learning isolated words is not necessarily going to be helpful when seeing print on a notice board in their community.

In this article, we draw upon everyday concept formation and academic concept formation in literacy and numeracy for a better understanding of how the learning of these knowledge systems can be best supported in the preschool years. We begin this discussion by drawing upon Vygotsky's (1987) theoretical works and those that have developed these ideas (Hedegaard, 2007) and discuss the importance of the adults in children's lives for mediating concept formation. We also review research literature which suggests that this is an area that has not been effectively undertaken in the past in preschools.

Concept Formation in Early Literacy and Numeracy

Hedegaard and Chaiklin (2005) suggest that in acquiring understandings of a literacy or numeracy knowledge systems, children need to gain an understanding of the central concepts that characterize particular forms of knowledge. For example, when a child understands classification, it has gained relational understandings of comparison, systems, and sorting.

To understand these important or central concepts, children must develop a conceptual model which shows the relations between the concepts that make up the

system of knowledge. In working through different, but related examples, children develop theoretical knowledge of the central concept, while keeping the related concepts visible in everyday practice. For example, in examining how to locate picture books in the local library, children learn about the classification system of their library, and develop a conceptual model for a classification system. The model can then be used in other contexts to navigate around other complex collections. That is, the children have acquired not just an everyday understanding of a library, but theoretical knowledge that libraries have classification systems to help people find specific items. As such, a child can go to any library and take into account the classification system in operation, thus transforming how it engages with its environment.

In drawing upon the work of Davydov (1988), Hedegaard and Chaiklin (2005) have advanced the theoretical idea of a double-move approach, which specifically emphasizes the “relations among children’s already acquired everyday concepts, subject-matter concepts (e.g., numeracy), and local knowledge” (p. 69). The double-move approach illustrates how educators can bring together literacy or numeracy concepts with children’s personal knowledge and their lived experiences. For example, a teacher notes a child’s everyday concept such as seeing a sign on a door (one move), at the same time as considering the academic knowledge she wishes the child to acquire such as print holds meaning (second move). By explicitly linking everyday concepts and academic concepts (double move), it is possible to develop core concepts, and through this, develop theoretical knowledge (Davydov, 2008). This double-move approach recognizes that the motives of the society and the child’s personal motives can be connected in everyday preschool and school practices:

The school child becomes oriented to topics that are valued by his [sic] parents, by the community, or that the child finds new and exciting to explore. (Hedegaard and Chaiklin, 2005: 80)

Others promote similar ideas for making literacy and numeracy learning meaningful to children. When a society specifically values literacy and numeracy, as is evident now in many industrialized communities, early childhood professionals are increasingly called upon to address specific academic concepts.

The Role of Adults in Everyday Practice

Along with children’s natural curiosity, persistence, and motives which are oriented to learning, what children learn during their first 4 or 5 years is not learned in isolation. A concept cannot be disembedded from the other known concepts which together give meaning for action.

Infants’ activities are complemented by relationships that encourage their gradual involvement in the activities of the family and community (see Rogoff, 2003). Caregivers may arrange the environment to promote learning (Schaffer, 1977: 73). A great deal of research has been conducted on how to guide children’s understanding and actions in new situations through emotional cues about the nature of the situation, nonverbal models of how to behave, verbal and nonverbal interpretations of events, and verbal labels to classify objects and events in everyday experiences (Rogoff, 1990, 2003; Walden and Ogan, 1988). Successful caregivers make efforts to build on what children know and extend their competencies by providing supporting structures (or scaffolds) for the child’s performance (Bodrova and Leong, 2001). Through bringing together everyday concepts and scientific concepts, adults are seen to be:

- supporting children to make sense of an activity by suggesting and talking about strategies that will help govern the number of steps required to solve a problem;
- engaging children in learning by making it meaningful, and keeping their attention through motivation and direction of the activity;
- encouraging and providing support for problem solving using scaffolding techniques that minimize frustration and risk, including telling and revealing;
- reinforcing the processes of problem solving and demonstrating the solution by providing examples, sharing ideas, and revisiting the process as a whole; and
- making conscious for young children the concepts that are embedded in their lived experiences, and setting the stage for abstract thinking in other contexts.

Along with these aspects of cognitive growth, social opportunities influence learning. Feeling that one is contributing something to others appears to be especially motivating (Schwartz and Brandsford, 1999). For example, young learners are highly motivated to tell and write stories of their own, and draw pictures that they can share with others. Some argue that effective mediation of young children’s learning appears to require adults to match their strategies to children’s intentions, knowledge, and understandings, and to phase in and out of more or less directive roles. Others have suggested that effective mediation occurs within the context of complete performances with more experienced others, as a form of guided participation (Rogoff, 1995).

Literacy and Numeracy: Opportunity and Development

Children’s literacy and numeracy behaviors develop as a result of social processes that are embedded in their relationships, activities, and everyday events. The vast majority of children today encounter a world of text and

numbers, and people using them. As Hall and Robinson (2000) point out, they are not confused by this symbolic world and in their own way are developing means of making sense of it. This is made easier for children because all around them are people who demonstrate the uses of literacy and numeracy – when they use it, what they use it for, why they use it, and how it is used. Adults and older siblings do this not by being explicit teachers, but simply by getting on with their daily lives.

Everyday activities embed opportunities for children to learn and develop through observation and apprenticeship. Young children learn through observation of and participation in the purposes, styles of interaction, and activities around literacy and numeracy. Yet, opportunities vary according to the community into which children are born. For instance, Neuman and Celano (2001) in their study of four neighborhoods asked the question: “What is the magnitude of the differences in access to literacy materials and resources across different income groups?” They found three times the number of retail outlets selling books, magazines, comics, etc. in the middle-income neighborhoods; and they found 44 times the number of different titles available to these children. In the schools there was twice the number of books available for children living in the middle-income neighborhood, four times the number of computers and trained librarians, while there were no trained librarians working in the low-income neighborhood. However, these researchers noted that resources alone are unlikely to improve achievement. Nevertheless, we would argue that differences in settings are likely to contribute to the considerable variations in patterns of early literacy and numeracy development, through the differential opportunities for mediated interaction with resources.

Descriptive studies of children’s early experiences of numeracy/literacy learning offer critical insights into the process of making sense of experiences with print and numbers, and of others’ attitudes toward numeracy/literacy (Heath, 1983; Purcell-Gates, 1996). Even rich environments provide limited opportunities for growth if children do not know how to interact with the artifacts around them. The modeling and demonstrations provided by surrounding adults are significant and important for children’s learning.

From a different perspective, with respect to print literacy, Heibert *et al.* (1998) from the Centre for the Improvement of Early Reading Achievement (CIERA) and other reviewers (e.g., Adams, 1990) indicate that powerful predictors of reading achievement are letter-name knowledge and phonemic awareness. However, in order to apply this knowledge in learning to read, children need to understand first the purposes and conventions of reading and writing. Merely teaching letter-name and sound knowledge without the child having an understanding of the alphabetic principle (Pearson, 1999) will not by itself make the difference.

As Clay (1975) observed:

As children learn to read and write there is a rich intermingling of language learning across levels, which probably accounts in some ways for the fast progress which the best children can make. A simplification achieved by dealing firstly with letters, then words, and finally with groups of words, may be easy for teachers to understand, but children learn on all levels at once. (p. 19)

The complexity of this intermingling of language levels that advances development in spoken and written language indicate that there will be more than a single route to literacy achievement (Konold *et al.*, 1999; Clay, 1998). This will be true for the early years of childhood and in formal schooling. For instance, with struggling readers, teachers may be tempted to postpone advanced and independent aspects of comprehension skills until lower-order skills and strategies such as fluency and accuracy are fully in place. Nothing can be more damaging to the comprehension growth of struggling readers. Indeed, Gray’s work (Gray, 1999) and that of Scull (2008) demonstrate clearly that both young children and older struggling readers benefit from explicit strategies which reveal the links across levels of language. With meanings embedded in text, this style of pedagogy addresses simultaneously, fluency, accuracy, and comprehension of what is being read.

Early Literacies and Preschool Practices

The role of the adult in children’s literacy and numeracy learning is highly significant, both at home and at preschool. However, teacher beliefs about the role of teaching concepts, determine whether or not literacy and numeracy concepts are used to give meaning to children’s everyday practices.

Demonstrating Interest/Awareness

In a study of UK preschool teachers, Hannon and James (1990) reported that the teachers surveyed did not see literacy as a central concern of the preschool curriculum. They were aware of parents’ interest in their children’s literacy development but worried about parents using inappropriate methods of teaching their children to read, and about parents putting too much pressure on children. Similar findings have been reported by Raban and Ure (1999) in Australia and Lynch (2009) in Canada. Preschool educators hold mixed views about preparing children for school. This has implications for their programming either in general or with respect to developing literacies. Clay (1998: 42) points out that some preschool teachers are committed to having children learn their letters, while others leave children unaware of such things prior to

entry into school. In research by Ure and Raban (2001), of a 156 preschool centers which were invited to join a literacy project in Australia, only 40 agreed to join the project because many centers saw literacy development as the domain of schooling and of no concern to them.

Reviewing Materials and Supports for Learning

In a US study of 3–4-year-olds and their access to literacy learning within prior-to-school contexts in Philadelphia, Neuman (1999) reported centers who refused to participate in a book-flood program. Of the 100 rooms included in the study, 21 rooms had book corners, 25 had bookshelves, 84 rooms showed print in the form of signs, alphabet letters, numbers, color names, and the like, with some of these signs at the children's eye-level, but most were not and only two rooms had writing centers.

Neuman concluded that young children need not only rich and diverse reading materials, but these need to be shared with more knowledgeable others, in order to acquire the complex set of attitudes, understandings, and behaviors associated with early literacy development.

In such print-enriched environments, however, young children were not merely passive recipients bombarded with stimuli. Rather, they appeared to be active agents in their own development; exploring, discovering, and using the physical environment as an important medium for transactions. Numerous observations often indicated that it was the children, even more than the adults, who generated the reading activity. Earlier studies also claim similar findings (Neuman and Roskos, 1990; Vukelich, 1990; Noble and Foster, 1993). The inclusion of literacy-enriched play centers increased, often dramatically, the amount of literacy-related activities in which children engaged during play. When materials only, and materials coupled with adult scaffolding were compared (Pickett, 1998), children engaged in significantly more literacy-related play when adults were present and involved.

Using Appropriate Pedagogy

The Preschool Literacy Project (Raban and Ure, 2000), conducted in 40 preschools in Australia, aimed to increase preschool teacher understandings of young children's early literacy development. Resources and activities designed to stimulate interest were introduced to give children literacy experiences that would promote their preparedness for school. Typically, primary school children in these areas of the state failed to achieve acceptable levels of literacy to support their further learning at school. However, by working with these preschool teachers over a 2-year period, supporting them in their growing understanding concerning young children's early literacy development, providing them with resources, discussion, and feedback high levels of student literacy were noted. Follow-up data reported by Raban and Coates (2004) revealed that

children from these project centers achieved higher scores on measures of both spoken and written language after 2 years in their primary schools.

In a study reported by Fleer and Raban (2006), undertaken in a childcare center to examine staff awareness of the literacy and numeracy concepts embedded in everyday center practices, it was found that the teachers could identify broadly based concepts, but many admitted that they did not actively stimulate or support literacy or numeracy learning through mediation. Rather, they assumed the resources alone would provide the learning. Evidence supporting the active role of adults has been shown in the UK Effective Provision of Preschool Education (EPPE) longitudinal study (Siraj-Blatchford *et al.*, 2002). The learning outcomes were linked to interaction strategies including sustained shared thinking time where teachers engage and extend the child's thinking, giving formative feedback during the activities in real time.

In the Harvard Home-School study, 74 young children from low-income families were followed through their preschool years from age 3 to high school. In synthesizing this study, Dickenson (2001) argues that preschool teachers who spent more time listening than talking supported children's superior language development. Successful preschool teachers were those who inclined to speak to children in ways that extended children's comments. Conversations around shared books that addressed issues such as the setting of the story, the attributes, and motivations of the characters, the order of events, and the like, also were found to be supportive of children's literacy development. The extent to which preschool teachers engaged children in intellectually challenging conversations around ideas and the meanings of new words were strongly related to measures of early literacy.

The study also found that preschool teachers were identified as of paramount importance – how they viewed their role, how they conversed with children, and the supports they provided for the children using language and literacy in varied ways. In line with the findings of Siraj-Blatchford (2004), successful preschool teachers exhibited a deep understanding of what children needed, they were skillful in providing appropriate experiences for children throughout the day, and they illustrated a willingness to expend the energy needed to support children's development. This UK research group identified these characteristics as the qualities of intentional and deliberate conceptual interactions for the early years. However, the preschool teachers in this study revealed little understanding of the developmental nature of early literacy development, of the place of oral language in supporting literacy, or of the critical role they as teachers played in fostering children's long-term language and literacy growth.

Conclusion

This article examined research literature to determine the importance of linking preschool children's everyday

concepts with early literacy and numeracy concepts. Critical for concept formation within the systems of literacy and numeracy is the close relations between children's everyday concepts they enact in practice, and the concepts that are central to literacy and numeracy knowledge. Children come to acquire conscious awareness, through deliberate and intentional interactions with adults that lead to learning and development. The theoretical writings of Vygotsky (1987) provide an important direction for understanding how concept formation can occur in the preschool years, and what kind of role the adult should take.

The literature demonstrated that successful learning in literacy and numeracy occurs when preschool teachers are active agents in:

- analyzing the everyday concepts children are experiencing through their play-based programs (as related to their everyday home and community experiences); and
- making academic literacy and numeracy concepts conscious to the child within these everyday situations.

However, the literature also showed the difficulties with promoting conscious realization of concepts in practice because the philosophical position of teachers tended to focus on taking a less-active role in concept formation. Rather than assuming that the resources or the experiences alone will provide concept formation for children, the research shows that the more knowledgeable others (early childhood professionals and families) have an important mediation role. Significantly, the research supports interactions which promote shared sustained thinking (Siraj-Blatchford, 2004) about the literacy and numeracy concepts that the children are experiencing in their everyday lives.

Participation in Early Childhood Education and Care Programs: Equity, Diversity and Educational Disadvantage

M Vandenbroeck, Gent University, Gent, Belgium

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Child-centered curriculum – A curriculum or educational project that starts from a holistic view on the child and takes the child's needs, experiences and its context as its focus. It is often used in contrast to adult-centered curriculum.

Early childhood education and care – A generic term to define services for children from birth to compulsory school age, including both family based (family day care or childminders) and centre based services (e.g. child care centers and kindergarten)

Socio-economic status (SES) – A generic term, varying in how it is defined, but mostly including demographic variables such as income, educational level and profession.

Vouchers – Benefits for (most often low-income) families, that aim at enabling them to purchase ECEC places in non-funded provisions.

Introduction

In different countries, the Programme for International Student Assessment (PISA) studies have profoundly shocked the educational communities as well as policymakers – not only in cases where results were disappointing, but especially where they were showing a societal gap in educational achievements. This gap seems to run along socioeconomic and ethnic-cultural lines: children from ethnic minorities and children from poor families (and these are often – but not always – overlapping categories), more often, perform less well at school. Such findings threaten social cohesion. In postindustrial societies, social success tends to be associated with (or may be reduced to) one's possibilities on the labor market and these possibilities are increasingly dependent on educational achievement. In short: widely differential education outcomes (re)produce social inequality. A positive finding is that quality early-childhood education and care can make a difference, yet, it often does not. In this article, a first look is taken at why this is the case, or in other words: What is the problem? Then, an examination is undertaken of what quality care – in the context of equity and diversity – may mean for policy and practice.

The Problem: Disadvantage and Inequalities

According to Leseman (2002), in all Organization for Economic Cooperation and Development (OECD) countries, nearly 10–20% of the children are children with presumably normal potential, but who show developmental delays or are at risk for educational failure due to socioeconomic, cultural, and/or socio-linguistic factors. It is well documented that poverty impacts on children's development and readiness for school (for an overview, see, for instance, the UNICEF Report card 8 or Vandenbroeck, *et al.*, 2008). Poverty is harmful to the developing child – across all areas of development, and early childhood is a particularly important stage. One of the more salient examples is that children from families with low socioeconomic status (SES) at age 3 have a vocabulary of less than 500 words, while children of families with high SES have a vocabulary of almost 1200 words at the same age. It is troublesome that this gap tends to grow, rather than to reduce in school age. Recent research in neuroscience tends to confirm that the early years are crucial for the later development.

Many studies have shown the potentials of early-childhood education and care (ECEC) on children's development – especially for those who are at risk for educational disadvantage. In the US, the most renowned example is the National Institute of Child Health and Human Development-Early Child Care Research Network (NICHD-ECCRN) study showing beneficial effects on different domains of cognitive and language development (e.g., Vandell, 2002). In the United Kingdom (UK), the extensive, longitudinal Effective Provision of Pre-School Education (EPPE) study also showed that children accumulating several risk factors thrive well at school, when – prior to school – they have attended high-quality ECEC (Sylva *et al.*, 2004). These converging studies make it even more salient that the quality of care that young children receive outside their homes is one of the important pathways through which income affects children (Duncan and Brooks-Gunn, 2000). Indeed, despite the potential beneficial effects of ECEC, children from ethnic minorities and children from lower-income families are to be found, more often, in lower-quality care than those from middle-income and higher-income families (Phillips and Adams, 2001; Pungello and Kurtz-Costes, 1999). Over the last decades, it has been extensively discussed why this is the case. Whereas, initially, some scholars thought that

parental choices may explain these differences, it is now clear that reality is much more complex. Parents from all classes and ethnicities attach importance to good-quality care, but parental choices for a specific type of ECEC or for a specific provision are, to a large extent, molded by environmental constraints. Moreover, parents tend to stick to the choice they have made and tend to appreciate what they receive. Differences in preferences, in fact, reflect restricted childcare options and there is a need to criticize the concept of free choice in this matter. Put more bluntly: parents can only choose what is available to them and resign themselves to that (restricted) choice (for a more elaborated account of this discussion, see Vandenbroeck *et al.*, 2008). Wall and Jose (2004) have shown, for instance, that quality care is hardly accessible for immigrant families in Finland, France, Italy, and Portugal. Vandenbroeck *et al.* (2008) have shown that – in the case of Belgium – quality childcare is more readily available in affluent neighborhoods and that the priorities set by the management of the ECEC provisions favor double-income, white, middle-class families. The unequal distribution of quality care is also to be found in The Netherlands (Noailly *et al.*, 2007). These findings can be summarized by saying that early-childhood education and care can make a difference in the lives of young children, but that it very often does not.

Policy Matters

In conclusion, it might be said that accessibility of services is one of the first-quality criteria to be met – from the point of view of equity. Accessibility as a quality criterion includes availability, affordability, and desirability (Shlay *et al.*, 2005). This, obviously, is a matter of ECEC policy (Weinraub *et al.*, 2005). Some countries have, traditionally, considered ECEC as a private matter in which states are not supposed to intervene. Provisions mainly operate on the private market and local or central authorities complement or compensate the market mechanisms with voucher systems. This is the case for diverse countries, such as Chile (Camoy, 2002), the United States, Hong Kong and Taiwan (Lee, 2006; Yuen, 2007), and The Netherlands (Noailly *et al.*, 2007). Other countries consider ECEC as part of the formal education system (e.g., Sweden) or of the welfare system (e.g., Denmark) – in which every citizen is entitled to quality ECEC, entirely funded by local or central authorities. Many continental European countries have a mixture of both systems (OECD, 2006). Despite the claims of the former (private market-oriented) system, it is clear that – from the point of view of equity – it does not keep its promises (Moss, 2008). A first reason has to do with availability. Privatization of ECEC tends to increase the number of provisions in more affluent and more urban regions – leaving rural and underprivileged areas behind (Noailly *et al.*, 2007). A second reason has to do with quality.

One of the most important conditions for quality is the level of staff qualifications (Sylva *et al.*, 2004), while independent studies in different European countries have shown that private provisions tend to hire lower-qualified staff in order to reduce the costs (e.g., Misplon *et al.*, 2004; Osgood, 2004). The Netherlands is a case of a country where policy has shifted recently. Since 2005, ECEC provisions operate entirely on the private market. Longitudinal studies show that the quality – as measured with Infant/Toddler Environment Rating Scale Revised edition (ITERS-R) and Early Childhood Environment Rating Scale-Revised edition (ECERS-R) decreased since the privatization – especially on those items that have to do with the educational interaction between staff and children. The number of groups with an unsatisfactory quality – according to international standards – has risen from 6% to 30% (Vermeer *et al.*, 2005). In the case of the US, subsidized childcare also seems to be more efficient and effective in reaching disadvantaged children than private arrangements (Weinraub *et al.*, 2005). This is not to say that inequality is inexistent in countries that traditionally adopt a policy of state-funded ECEC (e.g., Sweden, Denmark, and France). The problem in these countries, however, is a shortage of places and a possible unequal distribution of ECEC provisions – especially for the youngest children (babies and toddlers). From an equal opportunities point of view, the solution is, rather, more subsidies than privatization.

Quality Matters

Early-childhood education matters, but not every early-childhood education matters in the same way. As the EPPE study (Sylva *et al.*, 2004) made perfectly clear, only high-quality ECEC makes a difference. The average is just not good enough. However, what constitutes high quality in a context of diversity? The EPPE study included qualitative observations in those centers that made a difference for children's outcomes. According to Siraj-Blatchford (2006) – a leading researcher in this study – respect for diversity is one of the quality criteria that correlates most with positive outcomes for disadvantaged children. This is not surprising. Although what constitutes good practice with respect for diversity may vary substantially from one setting to another (Vandenbroeck, 2007), some guidelines may be set on what exactly quality – in this matter – may be. Since the famous works of scholars including Bronfenbrenner and Vygotsky, and also thanks to the work of Barbara Rogoff and colleagues (e.g., Rogoff *et al.*, 2005), we know that cultural context plays a major role in learning processes. Laevers (1997) puts it this way: children only learn when they feel well and when they are involved in activities. Well-being and involvement are two major criteria for educational quality. This implies that children should have a feeling of belonging to the ECEC center. For many children, their introduction

with ECEC represents their first step into society. It presents them with a mirror on how society looks at them and thus how they may be looking at themselves – since it is only in a context of sameness and difference that identity can be constructed. It is in this public mirror that they are confronted with these essential and existential questions: Who am I? Is it OK to be who I am? A positive self-image is closely linked to well-being. Different scholars have documented that these essential and existential questions, with regard to identity, may be problematic for children from ethnic minorities and also how important it is that ECEC providers take into account family cultures in the curriculum (Vandenbroeck, 2001). Children are confronted with many messages about how it is to be who they are. These messages are, often, unconscious and unintentional. It may be that a child does not feel represented in all children's cultural items, such as books or dolls or other play materials; that the child's own language is not recognized as valuable; that the child's eating or sleeping habits are considered as strange; or that his or her family composition is never represented. Therefore, a child-centered curriculum is always also a family-centered curriculum. In practice, this implies that the curriculum needs to balance between two pitfalls: denial and essentialism (Preissing and Wagner, 2003; Vandenbroeck, 2001). Denial of diversity would imply that one treats all children the same. It may be common practice among educators valuing equality – especially in contexts in which a strong separation between the public and the private domains is welcomed, precisely in order not to discriminate any children (Brougère *et al.*, 2007). Yet, it is obvious that every child is different and an equal treatment, therefore, would imply that every child is treated differently. Moreover, in practice, treating every child the same may imply that the educator addresses what she (or once in a while he) considers to be an average child. Most often, this average child is what is constructed as an average through the dominance of developmental psychology: a middle-class, white child, living in a traditional nuclear family (see, for instance, Burman (1994) for a critique of this developmental average). This may easily lead to what is, sometimes labeled as racism by omission. The other (and opposite) common pitfall is essentialism. This implies that a child is reduced to its (ethnic or cultural) background. It may be common practice in traditional multicultural programs that wish to celebrate cultural diversity. It assumes that there is such a thing as Muslim practices or African culture – denying not only the huge diversity within cultures, but also the agency with which parents, as well as children, shape their own multiple belongings or multiple identities (Beck, 1997; Vandenbroeck, 2001). One cannot simply assume that a child of North African descent loves to eat tajine, refuses to have pork meat, or that her parents would appreciate that the staff addresses her in Arabic. Consequently, the curriculum of ECEC cannot be constructed upon the belief that the provision should be a

home away from home, as many parents precisely choose ECEC for those things in which it differs from the home (Vandenbroeck, Roets, and Snoeck, forthcoming). On the other side, an ECEC curriculum cannot be built on constructions of the average child either. This has far-reaching implication for daily practice. There is, indeed, a major difference between asking a child's parents to bring some music from their culture to the center, or asking them if there is any music they often play at home and they would like to share with the group. As this simple example shows, child-centered curricula can only be constructed with the participation of the child's family. A good summary of guiding principles for a respectful curriculum is given by the European Diversity in Early Childhood Education and Training (DECET) network. ECEC provisions need, according to DECET, to be places where:

Every child, parent and staff member should feel that he/she belongs. This implies an active policy to take into account family cultures when constructing the curriculum.

Every child, parent and staff member is empowered to develop the diverse aspects of his/her identities. This implies that the curriculum fosters multiple identity building and multilingualism by building bridges between the home and the institutional environment as well as with the local community.

Everyone can learn from each other across cultural and other boundaries

Everyone can participate as active citizens. This implies that staff develops an explicit anti-bias approach and takes appropriate action to involve all parents.

Staff, parents and children work together to challenge institutional forms of prejudice and discrimination. This includes a critical study of availability and access policies and structural inequities.

A Final Note on Participation

A shallow reading of the literature on anti-bias education or respect for diversity may lead to a plea for parent participation, followed by the complaint that some parents do not participate as they should. It is important to distinguish between involvement and participation. Participation may be considered as one specific way to involve parents. Very often, it entails group sessions – meetings in which one is expected either to listen to experts or to express oneself aloud. These meetings may be extremely valuable to discuss the curriculum as well as daily practices in ECEC. However, self-expression may be more common in some families than in others and, therefore, it may privilege the already privileged and reproduce existing power relations in subtle ways (Tobin, 1995; Vandenbroeck and Bouverne-De Bie, 2006). Involvement includes a wider

variety of possibilities to exchange with one another. A close, qualitative, semilongitudinal study of experiences of immigrant mothers shows that the first weeks prior to, and following upon, the start of ECEC play a significant role in constructing reciprocal relationships of trust (Vandenbroeck *et al.*, forthcoming). This first – mutual – habituation period also appears to be crucial for the construction of a sense of belonging, both for children and their parents. Involvement is, then, understood as the continuous daily negotiation of educational practices between staff and parents. Another example of how involvement goes far beyond participation is described eloquently by Dahlberg and Moss (2005), referring to pedagogical documentation and the practice in Reggio Emilia (see also Rinaldi, 2005). Pedagogical documentation means the concrete documentation of daily practices, making practices visible, and, therefore, subject to reflection within staff meetings as well as with parents. Dahlberg and Moss describe it as democratic practices, in which parents and staff try to make meaning of these practices, acknowledging that there are always multiple perspectives to look at educational practices. This asks for a reflexive, researching attitude from the staff, since pedagogical practices do not have a meaning by themselves – an essence – but meaning is made or created through the perspectives of the (multiple) people involved. This may very well be at the core of what building a curriculum – based on equity and diversity – may mean, when we acknowledge that respect for diversity is not about tolerating what is deviant from the norms, but about problematizing the norms that create deviance.

Glossary

Curriculum differentiation – The provision of differentiated curriculum experiences as a response to the identification to the specific needs of individual or small groups of children.

ECERS-E – (Early Childhood Environment Rating Scale: Extension) A rating scale of Four subscales which assesses pedagogy and the curriculum within the setting, including the areas of mathematics, science, literacy, and diversity (whether staff plan to meet particular/individual needs).

ECERS-R – (Early Childhood Environment Rating Scale: Revised) A rating scale consisting of seven subscales which provide an overview of the preschool environment, covering aspects of the setting from furnishing to individuality of care and the quality of social interactions.

Formative assessment – The process whereby information is collected to identify the extent of children's learning, and subsequently applied in the provision of feedback and in adapting the curriculum and pedagogy to provide for their particular needs.

Multilevel modelling – A methodology that allows data to be examined simultaneously at different levels within a system (i.e., young children within preschool centres/primary schools, within LAs), essentially an extension of multiple regression.

Pedagogical content knowledge – Different pedagogic techniques are often required to make different forms of knowledge, skill, and understanding accessible to young children. In teacher education, the identification of appropriate strategies is often referred to as 'pedagogical content knowledge'. Requires knowledge of the 'subject' being taught and the child's level of learning.

Pedagogical interactions – Face-face interactions practitioners engage in with children; they may take the form of cognitive or social interactions.

Sustained shared thinking – An episode in which two or more individuals 'work together' in an intellectual way to solve a problem, clarify a concept, evaluate activities, extend a narrative, etc. Both parties must contribute to the thinking and it must develop and extend.

Systematic observations – Analysis from the timed *Target Child Observations*.

Introduction

This article summarizes the key findings of two major English studies related to teaching and learning in early-years centers. The Effective Provision of Preschool Education (EPPE) project identified centers that demonstrated good-to-excellent child-developmental outcomes, and the Researching Effective Pedagogy in the Early Years (REPEY) project (Siraj-Blatchford *et al.*, 2002, 2003) extended the EPPE analysis in an effort to identify the working practices that contributed most significantly to those outcomes.

The EPPE research project was initially funded as a 5-year longitudinal study following the progress of approximately 3000 children – from the age of 3 – in 141 preschools across England. (The studies were both funded by the Department for Education and Skills (DfES, 1997-2003). Subsequent funding has extended the study of the EPPE cohort and the current investigation is the Effective Pre-school, Primary and Secondary Education (EPPSE 3-14) project.) In addition to the range of quantitative data collected about children, their families, and their preschool centers, 12 effective preschool settings (selection based on child-developmental outcomes) were identified in the EPPE multilevel analysis for intensive, in-depth qualitative case study. The case studies were to reveal those teaching practices that are associated with better child outcomes. The REPEY study provided an opportunity to extend the case-study analysis further with both naturalistic and systematic observations, interviews, and focus-group discussions. Together, the studies provide a large-scale, sequential and explanatory mixed-method research-design investigating pedagogy in each of the Foundation Stage settings (at that time, providing for children in the age range of 3–5 in England).

This research has shown that the most effective pre-school settings (in terms of intellectual, social, and dispositional outcomes) enable children to spend two-thirds of their time in child-initiated activities – further achieving a balance between the pedagogical efforts provided for children in teacher-initiated group work and in the children's freely chosen (and potentially instructive) play

activities. The analysis also shows an association between children's outcomes and the frequency of sustained shared thinking observed between an adult and a child (or small group). Each of these features was found to contribute to the cognitive challenge. The evidence suggests that the better a setting does on each of these dimensions of pedagogical practice, the more effective it will be.

Researching the Effectiveness and Quality of Center-Based Practice

Children (and their families) were recruited into the EPPE study when they were 3 years old – the age at which many enter their first Foundation Stage group setting. Developmental progress was assessed regularly – beginning when the children entered the study and continuing through school entry – and at the end of their first and second years. Quantitative analysis (multi-level modeling) was applied to assess the contribution of the preschool setting to a child's cognitive and social/behavioral development – having controlled for child factors (e.g., gender, health) and family background characteristics (e.g., socioeconomic status, mother education). Full details of the research design may be found in EPPE Technical Paper 1 and in the Researching Effective Pedagogy in the Early Years (REPEY) Project Report (Siraj-Blatchford *et al.*, 2002).

The representative sample of 141 preschool settings were drawn from a range of providers (local authority day-nursery, integrated centers, playgroups, private day-nurseries, maintained nursery schools, and maintained nursery classes). A sample of home children (who had no, or minimal, group preschool experience) was also recruited to the study at entry to school for comparison with the preschool group. Analyses of the quantitative data collected on every child in the study revealed that, in some preschool centers, children made progress as expected, or better (or worse) than expected, given their individual and home characteristics. Settings for the case-study research were, therefore, selected based on their child-outcome data. This enabled an examination of the variation in child outcomes between centers – and the range of outcomes within centers – on eight identified cognitive and social development outcomes.

In addition to investigating the effects of preschool provision on young children's development, EPPE explored the quality of provision using the Early Childhood Environment Rating Scale: Revised (ECERS-R: Harms *et al.*, 1998) and the Early Childhood Environment Rating Scale: Extended (ECERS-E: Sylva *et al.*, 2003). EPPE has, therefore, been able to demonstrate the positive effects of high-quality provision on children's intellectual and social/behavioral development by describing gains during the preschool period (see Sammons *et al.*, 2002, 2003). Medium- and high-quality provision, as measured by the ECERS-E, has

continued to show a significant influence on attainment through to age 11, when disadvantaged children, in particular, have been found to benefit in terms of literacy and mathematics (Sylva *et al.*, 2008).

Quality and Diversity

In assessing the quality of provision, EPPE employed two rating scales – the ECERS-R and the ECERS-E. The ECERS-E was devised after wide consultation with UK experts and extensive piloting of the instrument. The word environment in both rating scales is taken in its broadest sense to include social interactions, pedagogical strategies, and relationships between children as well as adults and children. The construction of this new scale provided an opportunity to address the issue of the quality of provision for inclusion and diversity. The instrument was, therefore, developed to include a Diversity sub-scale along with those rating the provisions made for literacy, mathematics, and science.

The Diversity sub-scale recorded provision and planning for individual and cultural needs, and for the provision of positive role models. High scores on this sub-scale reflect a recognition of the importance of having high expectations for all children irrespective of socioeconomic class, ability, gender, or ethnicity. In reporting on the associations found between the qualities of provision for diversity made by the 141 preschools, and the children's cognitive and social outcomes, EPPE has provided the first evidence of the overall effectiveness of these curriculum approaches.

The study found that most early-childhood settings provided a relatively low-quality learning environment for children in terms of diversity (Sylva *et al.*, 1999). However, the quality of diversity provision was highest in combined centers (those that fully integrated care and education) and in some nursery schools where the overall ECERS-E scores were also relatively high. In terms of outcomes, strong patterns of association were found between the ECERS-E sub-scale for Diversity and children's attainment in Early Number and Non-Verbal reasoning. A positive relationship with prereading was also verging on statistical significance. In terms of social/behavioral outcomes, high scores on the Diversity sub-scale were also found to be correlated with Independence and (not quite significantly) with Co-operation and conformity. Diversity was, therefore, found to be associated with as many as five of the nine attainment outcomes. This was higher than for any of the other ECERS-R or ECERS-E sub-scales.

The Qualitative Case Studies

All of the settings selected for case study demonstrated a range of practices and all of them demonstrated some

above average outcomes. The settings were chosen from a range identified as good (if their children made slightly more developmental progress than expected based on their individual child and home characteristics) to excellent (where children made significant developmental progress above their projected developmental progress). The report, therefore, consistently refers to settings throughout as good (above average) or excellent (well above average), based on the child-outcome data.

In conducting the case studies, trained researchers – who were already familiar with the centers – spent 2 weeks in each center. Case-study data came from multiple sources to allow for assessment by source and the method of data collection. Data from policy documents was triangulated with manager and parent interviews, extensive naturalistic observations of staff (over 400 h), and systematic, focal, child observations of children (254 target child observations; Siraj-Blatchford *et al.*, 2002, 2003). The initial analysis was grounded and carried out blind, and this was, subsequently, built upon in an iterative process of triangulation with the ECERS quality, and other quantitative findings. Further details of the analytic procedures may be found in Siraj-Blatchford *et al.* (2003) and Siraj-Blatchford *et al.* (2006). This systematic process of iterative triangulation characterized the general approach that was taken in adopting a sequential explanatory mixed method approach to the study (Creswell, 2003).

A number of significant correlations were, in this way, identified between particular sub-scales and items in the ECERS, and the setting residuals (the complex value-added, multilevel model) analysis for each outcome (see Sammons *et al.*, 2002, 2003). This analysis has gone a long way in providing explanations for the patterns and associations between particular practices (as measured by the ECERS) and developmental outcomes (see Sammons *et al.*, 2002, 2003). Four patterns of association were identified for special attention, and a closer analysis of the data from systematic observations suggested that each of the following practices should be investigated further:

- Adult–child verbal interactions.
- Differentiation and formative assessment.
- Discipline and adult support in talking through conflicts.
- Parental partnership with settings and the home-education environment.

Pedagogical Practices Producing Improved Child Outcomes

Adult–Child Interactions

The excellent settings encouraged sustained shared thinking. This refers to an episode in which two or more individuals work together, in an intellectual way, to solve a

problem, clarify a concept, evaluate activities, extend a narrative, etc. Both parties must contribute to the thinking and it must develop and extend thinking. The research found that this does not happen very frequently. In excellent settings, there were significantly more sustained shared-thinking interactions occurring between staff and children than in the good settings. When it did occur, it extended children's thinking. Investigations of adult–child interaction have suggested that periods of sustained shared thinking are a necessary prerequisite for the excellent early-years practice – especially where this is also encouraged in the home through parental support.

In the excellent case-study settings, the importance of staff members extending child-initiated interactions was also clearly identified. In fact, almost half of all of the child-initiated episodes which contained intellectual challenge included interventions from a staff member to extend the child's thinking. The evidence also suggests that adult modeling is, often, combined with sustained periods of shared thinking, and that open-ended questioning is also associated with better cognitive achievement. (The process where early years educators provide a model in terms of their language, behaviors, skills, and/or attitudes for young children to imitate.) However, open-ended questions made up only 5.1% of the questioning used in the 14 case-study settings.

In the excellent settings, the balance of who initiated the activities (staff member or child) was nearly 2 times child initiated, revealing that the pedagogy of the excellent settings encourages children to initiate activities more often than the staff. In addition, staff regularly extended around two-thirds of all observed episodes and around one-half of all child-initiated activities, but did not dominate them. However, the children in reception classes experienced a different balance of initiation – with a much greater proportion of staff-initiated episodes. In all of the case-study settings, children spent most of their time in small groups. But observations show that sustained shared thinking was most likely to occur when children were interacting 1:1 with an adult or with a single peer partner. Freely chosen play activities, often, provided the best opportunities for adults to extend children's thinking. Adults need, therefore, to create opportunities to extend child-initiated playful learning as well as teacher-initiated small-group work – as both have been found to be important vehicles for promoting learning.

The findings reveal that qualified staff (i.e., almost all trained teachers) provided children with more experience of academic activities (especially language and mathematics) and they encouraged children to engage in activities with higher cognitive challenge. While the most highly qualified staff also provided the most direct teaching (instruction through demonstration, explanation, questioning, modeling, etc.), they were the most effective in their interactions with the children, using the most

sustained shared thinking. Furthermore, less well-qualified staff were found to be better pedagogs when they worked alongside qualified teachers.

Differentiation and Formative Assessment

The analysis of teacher observations suggests a positive association between curriculum differentiation, formative assessment, and the process of selecting activities to provide optimal cognitive challenge, and sustained shared thinking. The practice of adults modeling (or demonstrating) positive attitudes, behaviors, and the appropriate use of language, has also been identified as a valuable pedagogical strategy to be employed in early childhood. The best case-study settings maintained good records and engaged with parents with regard to their child's progress on a weekly or monthly basis. However, there was little evidence of detailed formative feedback to children during tasks. Feedback is a pedagogical strategy known to be effective in advancing cognitive outcomes in primary education.

Discipline and Adult Support in Talking Through Conflicts

The excellent settings adopted discipline/behavior policies that engaged staff in supporting children to rationalize and talk through their conflicts. In other words, a more problem-solving approach was taken. Three settings with positive social and behavioral outcomes had strong behavior-management policy which supported this practical approach. In settings that were less effective in this respect, observations showed that there was, often, no follow-up on children's misbehavior or conflicts and, on many occasions, children were distracted or simply told to stop.

Parental Partnership

The case studies indicate that, where a special relationship in terms of shared educational aims had been developed with parents – and pedagogic efforts were made by parents at home to support children – sound learning can take place even in the absence of consistently good pedagogical practice in the preschool setting. The excellent settings shared child-related information between parents and staff, and parents were often involved in decision-making concerning their child's learning program. This level of communication was particularly the case in private day nurseries. While settings providing for the needs of children from the higher socioeconomic groups benefited especially from this, the potential benefit of adopting a combined approach (good pedagogical practice within the setting and support for the home-learning environment) in settings serving more disadvantaged areas is also clear.

In more disadvantaged areas, staff in settings had to be proactive in influencing and supporting the home-education environment in order to support children's learning.

The evidence suggests that the excellent settings in disadvantaged areas recognize the importance of – and were proactive in – encouraging strong parental involvement in the educational process, by taking the time to share their curriculum, pedagogical strategies, and educational aims with parents. They offered advice on how parents could complement this within the home-learning environment and how this impacted on young children's development.

Some Overriding Conditions for Success

Knowledge of the Curriculum and Child Development

The case studies show that practitioners' knowledge and understanding of the particular curriculum area that is being addressed, are vital. Different pedagogical techniques are, often, required to make some forms of knowledge, skill, or understanding accessible to young children. A good grasp of the appropriate pedagogical content knowledge is a vital component of pedagogy and is just as important in the early years as at any later stage of education. Even in these good and effective settings, there were examples of inadequate knowledge and understanding of curriculum areas, especially in the teaching of phonological skills and science.

The study reveals that early-years staff may need support in developing their pedagogical content knowledge in the domains of the Early Learning Goals. Educators who demonstrate good pedagogical content knowledge display a firm knowledge and understanding of their curriculum content, but crucially, the most effective educators also demonstrated a knowledge and understanding of what part of that content was most significant and relevant to the needs of the children that they were teaching. They were also able to draw upon knowledge of the pedagogical strategies found to be most effective in teaching any particular content.

Management and Staff

The data showed that all the case-study preschool settings had strong leadership and long-serving staff. Most of the managers and staff had been in the settings for over 3 years. The private nurseries in the case-study sample had stability of staffing with retention between 3 and 9 years. In the other settings, staff – especially senior management – had been in their post even longer, and 10–20 years of service was not uncommon.

All the managers took a strong lead – especially in curriculum and planning. In most of the settings, the leadership was characterized by a clear philosophy for the setting that was shared by everyone working in the setting. The managers of the excellent centers also had a strong educational focus, valued the importance of

adult–child interaction, and supported their staff to develop better ways of engaging children. In excellent centers, the staff were encouraged to attend staff-development sessions. Although there was a great deal of variation in the training offered and what staff were able to access.

Summary of Findings

In summary, effective pedagogy – in the early years – was found to involve both the kind of interaction traditionally associated with the term teaching, and also the provision of instructive learning environments and routines.

The excellent settings provided both teacher-initiated group work and freely chosen, yet potentially instructive, play activities. Children's cognitive outcomes appear to be directly related to the quantity and quality of the teacher/adult-planned-and-initiated focused group work for supporting children's learning. The settings that viewed cognitive and social development as complementary, managed to achieve the best outcomes for children. Trained teachers were most effective in their interactions with children, using the most sustained shared-thinking interactions. Less well-qualified staff were better pedagogs when qualified teachers supported them.

The research showed that the best outcomes for children are linked to early years settings that:

- View cognitive and social development of children as complementary and do not prioritize one over the other.
- Have strong leadership and long-serving staff (3 years plus, this was even the case in the private day-care settings where the turnover of staff is normally the highest).
- Provide a strong educational focus with trained teachers working alongside and supporting less qualified staff.
- Provide children with a mixture of practitioner-initiated, small-group work and learning through freely chosen playful activities.
- Provide adult–child interactions that involve sustained shared thinking and open-ended questioning to extend children's thinking.
- Have practitioners with good curriculum knowledge combined with a knowledge and understanding of how young children learn.
- Have strong parental involvement, especially in terms of shared educational aims with parents.
- Provide formative feedback to children during activities and provide regular reporting and discussion with parents with regard to their child's progress.
- Ensure behavioral policies in which staff support children in rationalizing and talking through their conflicts.
- Provide differentiated learning opportunities that meet the needs of particular individuals and groups of children, for example, bilingual, special needs, and girls/boys.

Conclusions

The case studies have shown how diverse the early-years settings are in England. They have shown that there is no level-playing field, in terms of the training of staff, staff salaries and conditions of service, adult–child ratios, resources, or accommodation. EPPE identified moderate-to-excellent settings from among all the types of providers. However, few playgroups and local authority day-care settings demonstrated better child outcomes. Given the variation in staff pay, training, and development, this is unsurprising. In spite of this, the case-study centers all projected a positive ethos:

1. All case-study centers had a warm, caring, safe, secure, and supportive approach to their children. All the settings engaged children in a range of different groupings, individual and group play, group-focused table-top activities, interest areas, and class snack and story times.
2. All case-study settings had a welcoming appearance. The displays on the whole reflected the children's work. Children were, generally, treated with respect. The centers were warm and inviting places. The Staff appeared calm and engaged well with the children. All these centers were fairly well resourced and, although not always ideal, had enough space. However, the outdoor play environments varied greatly.

Many of the EPPE and REPEY findings echo those reported by Hohmann and Weikart (1995) and may be considered broadly consistent with the High/Scope curriculum program that emphasizes interaction, reasoning, reflection, and responsibility for self-learning. In High/Scope, efforts are made to ensure that learning experiences are developmentally appropriate for each child, and appropriateness is defined as the extent to which a learning activity:

- Exercises and challenges the capacities of the learner.
- Encourages and helps the learner to develop unique patterns of interest, talents, and reach goals.
- Presents experiences in which the learner is able to master, generalise, and retain concepts, skills, and knowledge and which relate to previous experiences, whilst linking to future learning expectations. (Adapted from Hohmann and Weikart, 1995:15)

Indeed, there are common characteristics in several, particularly popular and successful international early-childhood education (ECE) models of Early Childhood Education that may be considered consistent with the EPPE findings. If one considers the accounts of the three ECE models most clearly identifying their pedagogy in the Starting Strong Report (see **Table 1**; OECD, 2004), it can be seen that the particular strategies applied according to these accounts of the models by Ferre Leavers (Effective Early Learning), David Weikart (High-Scope), and

Carla Rinaldi (Reggio Emilia) correlate very closely with the evidence from EPPE and REPEY:

Of course, each of the approaches should be considered ideal types and the practices in many settings will involve a combination of all of these approaches. The challenge for early-childhood educators is to provide a gradual and supportive transition – as the children become more capable – that stimulates learning and development while avoiding any risk of regression or failure.

The Early Years Foundation Stage (EYFS) guidance in England promotes a pedagogy which involves negotiating and co-constructing the curriculum through playful processes of sustained shared thinking that may be initiated by either the adult or the child. The question of who initiates this sustained shared thinking is actually irrelevant as long as both parties are committed to playing an equal part in determining its focus and direction (i.e., its co-construction) in collaborative free flow. In a sense, initiation is taken in turns as different material and symbolic resources are drawn upon, and each play is extended as a more or less unique improvisation. As children develop the capability and are motivated to play with peers, the EYFS guidance encourages one to continue to provide children with a rich range of experiences and resources to draw upon in their play and to support them in developing a greater awareness of their development and learning. Ultimately, children take pleasure in learning for its own sake and restrict their play to scheduled playtimes, more disciplined creative activities, and their involvement in a variety of games with more formal rules (Siraj-Blatchford, 2008; 2009).

Glossary

Collective economy – A form of enterprise under the planned economy in China where the investments were collectively made and owned by a group of people, rather than by the government. Such entities are generally organized among households in the vast rural areas for farming, and among those in urban community with low skills to support themselves.

Large state syndicate – A group of companies combined to undertake a joint project. Here it refers to the dependence of state-run enterprises on state in the planned economy in China.

Self-kept profit – The portion of the business profit allowed to be kept by the state-owned enterprises to cover operating and nonoperating costs. It is based on the notion that all state-owned enterprises (to which no taxation applied) are supposed to hand over their business profits to the government under the planned economy in China.

Working institution – An institution under the planned economy in China where you worked and were entitled to a wide range of welfares, including housing, ECEC for children, pension, etc., in addition to the salary, which generally is quite limited. It might refer to a government agency, a public institution (academy, school, hospital, etc.), or an enterprise.

transition, as its concepts and institutional framework are being affected by stakeholders, market forces, governments, and the reflection on the overseas models in ECEC. China's ECEC has also to conciliate among many objectives, such as social compensation, equity, facilitating women's employment, and rural areas development. Given this, it is easily subject to changes in national social development policies or innovations of reform by the local governments. This article offers a description of the patterns of ECEC in China from three perspectives, that is, the origin of ECEC in China, its evolution and the propelling forces behind, and the driving and restrictive factors in formulating China's ECEC provision in future.

The Recent Origin of ECEC in China

The idea of ECEC had been introduced to China as early as 1920s, when the progressivist education campaign first came to settle in China, and it had even entailed some practices in few metropolitan cities.

However, China's ECEC service was officially launched only after the founding of the People's Republic of China in 1949, partly out of government's effort to help to liberalize women, that is, the focus of the ECEC then was more on enabling women to work, rather than on early childhood development alone. It was clearly stipulated in Article Two of The Provisional Regulations for Kindergartens, which was issued by the Ministry of Education in 1952, that the mandates of the kindergartens are to ensure the preschool children to have a sound physical and mindful development by raising them according to

Early Childhood Education and Care (ECEC) in the People's Republic of China is presently experiencing a

the New Democratic Guidelines on Education; and in the mean time, to enable their mothers to participate in the political life, production, and cultural and educational activities by easing their burden in childbearing. The Circular on Several Issues on Nurseries and Kindergartens, which was jointly issued in 1956 by the Ministry of Education, Ministry of Health, and the Ministry of Interior Affairs, emphasized the guidelines for the development of nurseries and kindergartens and pointed out that in order to help more mothers solve the problem of looking after and educating their children, the number of nursery and kindergarten needs to be increased.

The strategy to achieve the above objectives through ECEC provision under the planned economy was incorporated into the fundamental social organizational and management system, which was basically categorized into working institutions (the institutions where you work), the urban communities, and rural villages; that is, almost all aspects of life, for example, political and economic activities, as well as social welfares (including ECEC, housing, medical insurance, and pension) were organized or provided by one of these three categories of organizations. This social welfare system was the basis where the ECEC reform could set its orientation and tasks.

Financial and staffing support were arranged for such a system with working institutions and urban communities and rural villages as the ECEC service providers. As ECEC is basically regarded as a kind of work assurance and social welfare for the staff, its cost is part of the operating expense of that institution, with the ECEC staff also being the formal employees in that institution. At the time when the Directive No. 41 by the Ministry of Finance was issued on 15 May 1973, the ECEC cost was listed as a nonbusiness expense, affirming the notion that kindergartens come under the logistic expense and the public welfare nature of ECEC therefore enhanced. Until the 1970s China had improved and perfected a preschool education system which conforms to the planned economy mechanism. The ECEC run by urban communities and rural villages is financed and staffed at their own expenses.

In brief, until economic reform was later launched, ECEC had been clearly defined as part of the welfare offered by an institution for enhancing women's employment. In fiscal terms, ECEC expenses, being incorporated into the welfare and cost of fringe benefits, were deducted from the profit which is supposed to be handed over by an enterprise to the government. Such dispersed funding for ECEC was based on the notion of accounting the whole society as a large state syndicate, where enterprises and businesses also take on some government functions. Therefore, it made no difference whether ECEC was listed as an expense by enterprises or by the government. The implementation of the concept of the socialist market economy releases the individual institutions in

the state syndicate as independent accounting entities, by requesting enterprises to test their products or services in the market. This change shook the foundation of the accounting system of listing the expense of the welfare (including ECEC) offered by enterprises as nonbusiness expenses, and China's ECEC has thus been engaged into the process of economic reform.

Evolution of ECEC in China and the Propelling Drives Behind

The Reform and Opening-up policy that has been adopted since 1978 in China has profoundly affected the whole society and China's ECEC provision has also experienced significant changes, which can be categorized into three stages.

From 1978 to 1993: Consolidation of ECEC Provision

Since 1978, the society was going through an era of overall restoration and restructuring of orders in the aftermath of the Cultural Revolution, so was the ECEC as part of education undertakings. The Summary of National Working Meeting on Nurseries and Kindergartens (1979) reaffirmed the allocation of functions between the Ministry of Education and Ministry of Health. The Ministry of Education has been designated to be accountable for ECEC for children over 3 years, reflecting a focus on the education aspect in early childhood development. The Summary of National Working Meeting on Nurseries and Kindergartens stressed the principle of cooperation under the coordinated leadership, and proposed for the first time to coordinate with the civil construction and housing authorities so that nurseries and kindergartens could accommodate the demographics of the localities. It also requested the ECEC provided by enterprises to be open to the public. All this implies that the concept of open services of ECEC was starting to take root, alongside the strengthening of service provision. The Regulation for the Work of Urban Kindergartens (1979), and a number of comments on the Development of Rural Pre-school Education by the Ministry of Education (1983) clearly defined the standards in curricula, facilities, staffing, etc. in the urban and rural areas. Through all these professional efforts, the education aspect of ECEC was enhanced while its role in facilitating women's employment lessened. Till then, China's ECEC was still based on the dispersed funding and staffing by businesses and public institutions but with a unified professional guidance. Nevertheless, its adjustment in orientation provides the base for further reform of ECEC in China.

From 1993 to 2002: Market Economy Weakened the Funding Basis of China's ECEC

Under the planned economy, till 1993 when the government initiated the reform toward modern enterprise system, the public fund was channeled into ECEC in three ways. First, for ECEC services run by the government and army agencies, and by the public institutions, their operating cost was incorporated into the overall budget scheme in line with the total staffing quotas and service standards pre-approved by the government. Second, for those ECEC services run by the businesses, the funding of their operation was supported by part of its business profit that is allowed to be kept by that business for its own expense, while the majority of the business profit was taken by the government as public revenue. Such self-kept profit practice was featured in the planned economy as an incentive for a business to sustain its welfare services, including ECEC. Third, for ECEC services run by the urban communities and rural villages, their operation relied on the funding by the local communities drawn from the community-owned businesses. Their ECEC staffs are cost and paid at the level equivalent to the similar jobs.

In 1993 when the government started to build up the market economy system in China, all businesses were compelled to launch their transition toward the modern enterprise system by realigning their relations with the governments, easing off some social welfare functions so as to reveal real operation expense. Given this, the route to channel public funds to enterprise staff for welfare benefit was blocked and the funding base for business-run ECEC removed. Many enterprise-run kindergartens were compelled to close their businesses or operate at their own cost. It is estimated that a total of 10 800, or around 80%, of enterprise-run kindergartens were closed during 1995–2005, and most remaining enterprises-run kindergartens were transformed into kindergartens with other, sometimes uncertain, funding nature. That's why currently some ECEC institutions in China are referred to as kindergartens in transition, by which it implies that they are yet to come into a final classification. Probably these

kindergartens ought to be transformed into not-for-profit organizations; but respective laws are necessary to regulate them in governance, funding, operation, and quality assurance. Under the planned economy, the urban communities and rural villages ran their collective-owned enterprises and pay for their own welfare. These collective enterprises, most of which were small, welfare-based businesses, had also to face the fierce competition of the market economy, and many drowned in the ocean of the market economy, owing to their lack of competitiveness and/or ineffective governance. The land reform in the rural areas is another reason for the fading of the collective economy. Hence, the funding basis for ECEC services run by the urban communities and rural villages collapsed along with the collective economy. Only the ECEC services run by the governments, army agencies, and public institutions are still receiving steady public funding through government budgets. Not only did they survive the funding crisis, but also gradually evolved as the high-quality ones, by availing of the resources to which they are entitled.

In summary, the transition to the market economy has in some ways removed two out of the three funding sources for China's ECEC services. This is how we have come to the present pattern where the public funding is only made available to the ECEC operated by the governments and army units, public institutions, which is under frequent criticism.

From 2002 to the Present: Private Providers are Emerging as a Major Player in China's ECEC Services

While the market economy weakened the public ECEC provision, it has created enormous space for the market players, and, on the whole, the supply side of service capacity has increased dramatically. Since 2000, the private ECEC service has increased 52.6%. Currently, private ECEC providers make up around half of the total ECEC institutions, and children enrolled in private ECEC account for one-third

Table 1 China's ECEC provision under the planned economy and at present

<i>ECEC providers</i>	<i>Funding source in the planned economy</i>	<i>Funding sources at present</i>
<i>Run by working institutions</i>		
by Government and army agencies	Government budget	Government budget
by public institutions (academies, hospitals, universities, etc.)	Government budget	Government budget
by businesses/enterprises	Self-kept profit	Removed
<i>Run by collective economy</i>		
by urban communities	Profit by its business	Removed
by rural villages	Profit by its business	Removed
<i>Private</i>	Nonexistent	Private

of the total, emerging as an important supplier of ECEC in China.

Owing to the lack of basic rules to regulate the market supply, there are many problems associated with private ECEC services. First, the accounting norms currently in use in China do not make a clear distinction between for-profit and not-for-profit ECEC providers, and, as a result, much capital enters ECEC services trying to obtain the dual benefits by making profits while enjoying tax exemption. Second, private ECEC is spread on either the high or the low end of the market. The former is facing blames for its unwarranted high prices, while the latter frequently arouses safety concerns and poor quality, resulting from the low cost.

Uncertain Reform of ECEC Provision Ahead in China

Along with the launch of the second-stage piloting work by the Central-Government-owned enterprises to disengage from social functions in 2002, the reform of ECEC provision has also set out on an uncertain voyage. Here, it is referred to as uncertain in four senses. First, the goal of ECEC reform is still unclear. There has been no consensus as to whether it shall aim to strengthen the government's responsibility in ECEC provision, or to better align the current funding structure to improve the ECEC provision. Second, the balance between the role of government and market has not been resolved, owing to obscure expression of this issue in the Law for Non-Government Education. Third, given the multidiscipline nature of ECEC, no certain government agency has so far been designated the role as the focal point or as the leading authority for management and regulation of ECEC in China, thus causing difficulties in policymaking and coordination. Fourth, the early education part is having an upper hand over the child-development part in both urban and rural areas as people are anticipating an ever-fierce competing and globalized society, and the need in facilitating women's employment is often being overshadowed by various professionalized early education efforts, which are mainly concerned with how to impart knowledge and skills to early children.

One of the significant features in the transition period is the transformation and alternation of new and old systems and mechanisms. In the transition of ECEC provision from a working-institution-based model to a socialized and diversified model, the benefits of some social groups are harmed; in particular, the collapse of enterprise-run ECEC has negatively affected the welfare of the enterprises' staff, whereas the benefits of those who can access kindergartens operated by government bodies and public institutions have remained unchanged. The ECEC for urban communities and rural villages have succumbed to the market, given their collapsed funding base.

Economic reform has propelled ECEC into a reform pathway which has raised many urgent issues for attention. It is a justifiable objective to separate the social services of enterprises to allow them to perform their economic functions. However, the removal of social services from enterprises raises the question of how to redefine the nature of existing ECEC providers, and how to secure the working conditions of ECEC teachers. At once, private investment in ECEC raises the issue of how to regulate the nongovernment kindergartens. Another case: in some newly developed communities, ECEC services, unlike other public services such as primary schools, post offices, hospitals, and groceries, are yet to be provided. This is largely caused by the lack of a leading authority for ECEC development in the local government, as mentioned previously in this article, and thus no public funding available being allocated. All these problems in ECEC provision in China reflect the challenges for the government in adapting to the changed context in their delivery of public services to the society.

Some of these problems require urgent response by the education administration. For example, some ECEC teachers appealing for assistance, social resentment toward the unwarrantedly high price for some private ECEC services, escalating safety concerns over some other private ECEC services owing to the overcompetition among themselves through lowering the cost and quality, and the difficulties of enrolment to ECEC in some newly developed communities owing to the mismatched facilities. All these conflicting issues seem to leave no enough time for reform to take place in an easy manner.

Conclusion

At present and in the years to come, China's ECEC has to evolve in the mixed context of the planned and market economic circumstances. On the one hand, the welfare offered by the working institution under the planned economy will be further eroded, and on the other, the government has to become accustomed to managing the emerging players in ECEC under the market economy. It is likely that China can neither deter the transition of the publicly funded ECEC service, nor effectively manage the emerging private or transformed ECEC providers. In view of such a mixed and diversified provision in the context of lacking basic regulation, ECEC in China faces the hardship of long-term evolution: to clarify the objectives and make realistic choices. The new system should be built in a carefully discussed conceptual framework and on a clear and rational base of public service provision. Regulation and funding issues are more important than technical issues for ECEC in China at this time.

Glossary

ECEC – Early-childhood education and care.

ES – The abbreviation for effect size, calculated as the difference between the experimental group and the control group, expressed in standard deviations. In the social sciences, values of approximately 0.20 are considered to indicate small effects. Effects of 0.50 are considered medium, and effects of 0.80 or higher are considered large.

Meta-analysis – The statistical method of summarizing the results from different studies by aggregating outcomes over individual studies.

Introduction

Children from disadvantaged families are generally less successful in school. Early-childhood education and care (ECEC) intends to prepare these children for a more favorable school career. The central thesis of ECEC is that the environment of disadvantaged children can be enriched in order to optimize child development. Specific goals include preparing children adequately for primary education. General goals include offering children opportunities to escape from their detrimental circumstances.

ECEC includes a diverse array of facilities and projects in different parts of the world. In addition to the famous and extensively researched Head Start program in the USA, other historic forerunners in early care, early education, and early intervention have focused on the development of young children in disadvantaged situations. Preschool and day care are but two of the many forms that are covered by ECEC, which also includes the half-day play groups of the Anglo-Saxon world, the French *école maternelle* (nursery school), the German *Krippe* and *Kindergarten*, home instruction for parents of preschool youngsters (HIPPY) projects from various countries, the internationally renowned Italian *Reggio Emilia* centers, the Japanese *yochien* (private preschool) and *boiku-en* (full-day programs), Kenyan community-based rehabilitation centers, and various early-childhood projects that have been initiated by the United Nations, United Nations Educational Scientific and Cultural Organization (UNESCO) and the World Bank in various parts of the world. The heading of ECEC

covers extensively documented and scientifically evaluated, small-scale demonstration projects from the USA, as well as the less-frequently described, large-scale *anganwadis* centers in India, in which 4.6 million children receive health check-ups, in addition to education (see Boocock, 1995; Guralnick, 2005; Odom *et al.*, 2003 for a few international examples).

According to the ecological model (Bronfenbrenner, 1979), biosocial developmental contextualism (Ramey and Ramey, 1998), the developmental-systems approach (Guralnick, 2005), and other theories, early intervention offers multiple pathways to improving the development of children. Some programs influence the parents; others provide direct educational experiences to children, and still others do both. Three corresponding program types have been distinguished in the literature: home-based, center-based, and a combination of home-based and center-based delivery (each of these types is discussed in more detail below). In addition to differences in the location of operations, these types of programs also differ according to the chosen manner of entry into the ecological system to combat disadvantages. Program characteristics vary widely within each of these three broad categories (home-based, center-based, and combined). Without any attempt to provide an exhaustive list, examples of these characteristics include the age of the children at the beginning and end of the program (and therefore the length of the program); the involvement of professionals, paraprofessionals, or volunteers; the application of an individual or a group approach; and program intensity, as measured by the average number of hours per week and weeks per year.

Effectiveness of ECEC

The effects of early-childhood interventions have been studied in a number of areas. At the level of the child, outcomes have been investigated in the cognitive, affective, behavioral, and physical domains. Longitudinal designs, in which children are followed for longer periods, often reveal a shift in the domains that are measured. The initial measurement usually involves scores on academic achievement tests or school-readiness tests, while later measurements focus on school marks and information involving the school career (e.g., grade retention, placement in special education, attendance, and dropout rates), in addition to social career and citizenship across the life span (e.g., income, criminality). Some studies also

include other types of variables which illustrate the diversity of programs and reflect the values that are promoted in different societies (Boocock, 1995; Odom *et al.* 2003). For example, a Swedish evaluation study concludes that early entrance into day care predicts a creative, socially confident, popular, open, and independent adolescent (Boocock, 1995: 102). Boocock also mentions in her international overview variables such as sharing and cooperating (Singapore) and a group-oriented sense of self (Japan). In places where ECEC programs also include health education and nutrition supplements, the studies have measured the effects on physical growth and infant mortality. The majority of research focuses on the effects of such programs on children, although outcomes for parents have also been charted for home-based programs with parent-education components. Interestingly, a growing body of research is emerging that charts the long-term retention of program effects.

Some older publications sketch an optimistic image of ECEC, based on a few results that were achieved in successful projects and on sometimes high expectations (see Evans, 1994). In the recent scientific literature, which has been enhanced by many empirical results, ECEC is often discussed from a more balanced perspective. According to Boocock (1995), recent reviews of studies (predominantly from the USA, but including research from other countries as well) clearly show that intensive center-based and combined programs reduce educational disadvantages, although they do not resolve them. While ECEC does contribute positively to the development of children in disadvantaged circumstances, it does not resolve disadvantages either completely or definitively. Meta-analytic studies report statistically significant but modest cognitive effects, with effect sizes ranging from small to medium ($ES = 0.18$ in Sweet and Applebaum (2004) for home-based programs; Blok *et al.*, 2005: 0.32; and Anderson *et al.*, 2003: 0.35–0.43). Effects are smaller in the socioemotional domain, which tends to be less prominent in program goals and conducted evaluations ($ES = 0.10$ for home-based programs in Sweet and Applebaum (2004); 0.05 in Blok *et al.* (2005); and 0.38 in Anderson *et al.* (2003)). Other important effects (e.g., in the social and medical domains), are yet to be investigated sufficiently to allow any strong conclusions (Anderson *et al.*, 2003).

According to some hypotheses, ECEC may have ripple effects (i.e., a positive effect in a specific domain has a positive influence on the development for a different domain) or even sleeper effects (i.e., effects that become apparent only over time). A rival hypothesis, however, predicts that immediate effects will fade over time, as the continually changing school environment continually calls for new competencies. For example, Farran (2000) emphasizes that most programs focus on concrete skills related to readiness tests, even though profound curricular changes

take place in the third and fourth grades. Similar argumentation is conceivable with regard to home-based programs. Various developmental psychologists have asserted that growing up represents a series of continually differing developmental tasks for children. This implies that parents are confronted with changing parenting tasks throughout the process of raising a child, and these tasks call upon different parenting skills.

Several reviews have indeed provided evidence that the positive results of early intervention tend to fade over time (Blok *et al.*, 2005; Farran, 2000; Gilliam and Zigler, 2000). It is nonetheless important to note that, although the positive effects are likely to fade, they do not disappear entirely. The classic and often-used term fade out is misleading in this respect. Moreover, longitudinal research shows that programs whose positive effects on cognitive test scores fade can have ripple effects in other domains. For example, children whose scores on school-readiness tests improve immediately after ECEC programs are less likely to be held back or referred for special education (Barnett, 1995).

Home-Based Programs

For home-based interventions (also known as home-visitation, home-enrichment programs, parent education, parenting programs, or maternal teaching programs), professionals, paraprofessionals, and in some cases, volunteers without special training visit parents in their homes over a period that lasts between 1 and 3 years, beginning when the children are young (between birth and 3 years of age). In some cases, the program starts while the mother is still expecting. Internationally recognized examples include the HIPPI projects and the parents-as-teachers program. Home-based programs are highly diverse and include an array of interventions that vary widely in goals, methods, and target groups.

Proceeding from the assumption that parents mediate the development of their children, home-based programs rely on indirect methods of stimulating children's development, and they often assume a cascading set of influences. It has been hypothesized that home-based programs lead to a change in parental attitudes, behavior, and school involvement. These changes result in more and higher-quality parent-child transactions and family-orchestrated child experiences, all of which have positive effects on the child. According to the philosophy of home-based programs, therefore, parent education goes hand in hand with child development.

Recent reviews of available evidence of the effects of home-based programs are not overly optimistic (Brooks-Gunn and Markman, 2005; Farran, 2000; Gomby *et al.*, 1999; Halpern, 2000; Sweet and Applebaum, 2004). The conclusion is that, while home-based programs do bring

about changes in both parents and children, these changes are quite modest. A fundamental question therefore involves whether home-based programs are actually capable of generating significant improvements for families in disadvantaged circumstances. For example, in a meta-analysis of 60 programs, Sweet and Applebaum (2004) found relatively modest benefits for parents ($ES = 0.14$ for parenting behavior and 0.11 for parental attitudes) and for children ($ES = 0.18$ for cognitive outcomes, and 0.10 for socioemotional outcomes). The results are more favorable for programs that are more intensive and for those that involve working with professionals. A meta-analysis by Bakermans-Kranenburg *et al.* (2005) also reports modest effects for home-based programs, as measured with the frequently used homeschooling opportunities to maximize effectiveness (HOME) instrument ($ES = 0.20$). This meta-analysis further shows that randomized studies reveal even smaller effects ($ES = 0.13$). On average, the greatest effects are observed in the area of increased parental involvement ($ES = 0.19$), cognitive stimulation through the availability of educational materials (0.20), and the availability of various experiences (0.16). The interventions proved less effective for families from the most disadvantaged circumstances (e.g., families with low socioeconomic status and adolescent mothers).

According to Gomby *et al.* (1999), one explanation for the modest results is the vulnerability of home-based interventions when they are implemented in practice. For example, in some cases, only half of the planned home visits actually take place, and the visits that do occur are often shorter than planned (lasting between 28 and 50 min instead of between 45 and 60 min). In addition, some parents are not capable of completing the planned home assignments with their children, and too many families (between 20% and 67%) drop out before completing the program. The effective dose is relatively modest, involving approximately 20–40 contact hours.

Center-Based Programs

Center-based programs (also known as institutional ECEC services, preschool, early childhood education, childcare, play group, kindergarten, educare, or the child-focused approach) provide children with direct educational experiences in day care, preschool, or similar settings. In many countries, institutional ECEC services are divided into two separate systems: child-development centers (preschool) and childcare centers (care). Stimulation and preparation for primary school are important objectives for child-development centers, which have, historically, connections to school systems. Childcare facilities were originally established with the goal of facilitating the labor-force participation of parents with young children. A frequent point of criticism is that childcare centers pay insufficient attention

to stimulation (whether cognitive or in other domains). For example, according to an Organization for Economic Cooperation and Development (OECD) report titled *Starting Strong-II* (OECD, 2006: 16), “Children’s well-being and learning are core goals of early childhood services, but services for children under 3 have often been seen as an adjunct to labour market policies, with infants and toddlers assigned to services with weak developmental agendas.” On the other hand, some critics argue that child-development centers place excessive emphasis on this type of stimulation. The same OECD report identifies “the use of programmes and approaches that are poorly suited to the psychology and natural learning strategies of young children” (p. 13) as one disadvantage of the readiness-for-school approach that is common in English and French-speaking countries.

Center-based programs are based on the idea that providing direct stimulation to children is the most effective strategy. It has been proposed that center-based programs should begin relatively early, as children from disadvantaged families already show educational disadvantages upon entering primary school, and these disadvantages do not tend to decrease throughout the educational process. Many center-based programs begin in the toddler years and continue through the early grades. Each program has its own curriculum for addressing cognitive aspects such as early literacy and numeracy, and many address socioemotional development as well. Special center-based programs are usually carried out with relatively high structural quality. Caregivers in these programs have relatively high levels of education and special training; caregiver-to-child ratios are favorable, and the groups are usually small. As a result, these programs compare positively to other national center-based services, which are faced with less-advantageous conditions. The role of parents is less crucial in center-based programs than in home-based programs, although parents are often involved in the operation of center-based programs. For example, in child–parent center (CPC) projects and similar projects, parents can choose from a wide range of activities, including serving as classroom aides, tutoring children, performing clerical tasks, or accompanying classes on field trips. Other well-known examples of center-based programs include Success for All and Head Start.

Findings in this field have shown that significant effects can be achieved in the area of developmental competence and achievement-test scores at the end of preschool and into kindergarten. Increasing evidence also suggests that direct provision through center-based approaches is more effective than is indirect provision through home-based approaches. For example, in a recent meta-analysis using a statistical model with multiple predictors, Blok *et al.* (2005) found that cognitive effects were one half of a standard

deviation greater in center-based programs than in home-based programs ($ES = 0.48$).

Combinations of Center-Based and Home-Based Programs

There is a growing awareness in the field that effective programs should target both children and their parents in order to promote stable effects on child development. In line with this more inclusive view, a combination of home-based and center-based components is offered in combined programs (also known as mixed-models, two-generation programs, multistrategy programs, or a middle approach between home-based and center-based programs). The central assumption of combined programs is that the combination of the two delivery formats may create more pathways for positive change in families' lives and that they may have synergetic effects (Ramey and Ramey, 1998). Well-known examples include the High/Scope program and the Perry preschool project. Both programs comprise half-day classroom sessions and educational home visits, in which teachers attempt to engage mothers in learning activities with their children, paralleling the approach used in the classroom.

The parental component focuses on the parent as the primary caregiver, the parent as individual, or a combination of the two. In the first variant, the home-based component centers on the child, as the parental component is explicitly oriented toward child rearing, and parenting skills are central to the approach. In the second variant, the parental component focuses on the parents as individuals and therefore includes social, economic, and other forms of support (e.g., parent self-esteem, employment training, English-as-a-second-language courses or other forms of adult education). Combined programs with a dual focus on parents as primary caregivers and as individuals constitute the most extensive type of program, including both a center-based component and parental component that focuses on both parenting skills and the provision of social and/or economic support. The intensity of the parental component is a particularly prominent source of variation between programs. Some projects involve mandatory adult education, while the parental component of other programs consists only of a referral service. In other cases, a program involves multiple ways of carrying out the parental component in practice, due to local variations or customization by case managers who coordinate the program supply with the needs of individual families (see St. Pierre *et al.*, 1995 for an overview).

Both narrative reviews (Barnett, 1995; Farran, 2000) and quantitative reviews (see, e.g., Blok *et al.*, 2005; Karoly *et al.*, 2005) have found convincing evidence that combined programs produce favorable educational results at the child level. In a meta-analysis, Blok *et al.* (2005) report a statistically significant advantage of combined programs

compared to center-based and home-based programs ($ES = 0.42$ with regard to center-based programs and 0.90 with regard to home-based programs). In a meta-analysis by Karoly *et al.* (2005), however, the difference is not significant, although the trend is in the same direction ($ES = 0.33$ for combined programs, as compared to 0.21 for parent-training-only programs). There is evidence to suggest that the cognitive benefits for children are also greater when the parental component focuses on the parent as primary caregiver ($ES = 0.69$), which lends itself well to theoretical explanation. Parental components that focus exclusively on social or economic support yield no advantages in the area of cognitive child outcomes. According to Yoshikawa (1995), combined programs are also the most effective with regard to realizing advantages in the social realm and preventing delinquency at later ages.

At the parent level, positive effects have been reported in the area of parenting skills (i.e., for the child-focused variant), corresponding to the results of the previously mentioned home-based programs. Effects of adult education in combined programs are apparently more difficult to achieve. In a discussion of six US programs, St. Pierre *et al.* (1995) report that results are demonstrated only for outcomes that were closely related to the program (e.g., completion of certificates or more frequent use of food stamps or similar welfare benefits after having taken classes that refer to them). No transfer effects emerged in the form of improved performance on standardized tests, employment, household income, depression, or parental self-esteem. The conclusion that emerges is that impressive results have been achieved with combined programs by coordinated efforts in the home and the ECEC center. Nonetheless, the situation of the parents apparently did not change drastically, at least not in the short term.

Conclusion

The field of ECEC has developed considerably since the advent of the pioneering US Head Start program, center-based programs, and various home-based programs in the 1960s. Although program developers can build upon the experiences of the past, current times require new approaches in order to make a positive difference for children who grow up in disadvantaged circumstances.

Remarkably, the programs are ambitious and thus broader in scope. One important matter that is directly related to this involves coordination and continuity. Combined programs, which have proved to be effective, involve goals at both the child and parent levels, and they have various program components that must be coordinated with each other. There is also a demand for integrated and continuing program lines in which services are seamlessly coordinated with each other (see, e.g., Guralnick, 2005). From a theoretical perspective, enhancing continuity

regarding transitions between the most important social contexts of the young child (i.e., home, preschool, and elementary school) seems very important for the optimization of developmental and learning gains. The issue of coordination also relates to a completely different area – the coordination of vocational education with the occupational sector. Lessons that have been learned through practice should be translated into vocational education and career training, with special attention to ECEC in order to impart the appropriate vocational skills to future personnel (Klein and Gilkerson, 2000). Additional attention to vocational education is also important as research shows that targeted training is effective in improving essential interaction skills among professional caregivers who work with children in the day-care sector (Fukkink and Lont, 2007).

Limitations of Studies

ECEC has, generally speaking, positive effects. Another positive conclusion is that longitudinal studies continue to find effects years after completion of a program; ECEC therefore continues to work long after the end of the program. How large an effect must be before it constitutes a meaningful result remains an open question. Guidelines from the research literature are not the only important considerations in this regard; other considerations include the importance of the variables themselves, the necessary investments in terms of time and money, and the availability of alternatives. As emphasized by various authors, the results that have been found in ECEC evaluations are encouraging, while also calling for realistic expectations on the part of policymakers and directly involved parties.

Despite a growing body of literature, the modest knowledge base remains an important limitation in discussions of the effectiveness in ECEC. First, the internal validity of studies has traditionally been a topic of discussion in this regard. In addition to randomized studies, the literature includes results from quasi-experimental designs, which suffer from methodological weaknesses. Other questions can be raised regarding external validity. One issue involves the extent to which findings from predominantly US studies can be generalized to other countries that differ from the USA in many respects. Projects conducted in other parts of the world should be systematically evaluated and should receive more attention in the research literature, which is currently dominated by Western (and largely USA) studies. Another issue involves the generalizability of results from the past to the present and near future. The demographic composition of populations is changing continually, ECEC programs are in transition, and there are shifts in the participation of various groups in home-based, center-based, and combined programs.

A related question involves the determination of which approach is more effective – which approach works the

best? The steadily increasing database of ECEC evaluations makes it possible to use meta-analysis to identify characteristics that are associated with greater or lesser effects. This is also interesting because various program designs have been evaluated with differing results. These lines of research show that combined programs are more effective than center-based programs from the perspective of education, and that center-based programs in turn are more effective than home-based programs (Blok *et al.*, 2005). Correlations have also been found with improved training for personnel, more favorable child-to-staff ratios, and greater program intensity (Karoly *et al.*, 2005). For home-based programs, possible success factors have been shown to vary with regard to parent or child outcomes. When child outcomes are the focus, more intensive programs, working with professionals and single-site programs are more effective, although the associations that have been found are not strong (Sweet and Applebaum, 2004).

The meta-analytic line of research also involves a number of limitations. First, although the primary data from intervention studies are experimental or quasi-experimental (and thus aimed at identifying causal relationships), the study of these programs through meta-analysis is correlational. The classic adage “correlation is not causation” is applicable in this regard. In addition, characteristics of programs are usually confounded, thereby making it impossible to determine the unique contribution of a given program characteristic. For example, as could be expected, combined programs offer more services than do other types of programs, and they tend to be characterized by higher intensity and thus by a higher dose of the intervention than home-based programs are. The unique contribution of delivery model or intensity to effectiveness is therefore difficult to interpret unambiguously. An additional complicating factor is that there is sometimes too little variation in background characteristics. For example, many home-based programs pursue similar goals for similar populations, making it impossible to make a true comparison on these points (Karoly *et al.*, 2005). An additional limitation is that associations between program characteristics and effects are usually investigated with regression models under the assumption of linearity. Whether this assumption is always valid remains an open question. For example, it is questionable whether the effects decrease constantly over time or whether each home visit in a home-based program always adds a constant effect, as assumed by a linear model. It could be that the relationships are not linear or that it is necessary to consider threshold values below which effects cannot be seen.

Briefly summarized, the empirical research that has been conducted provides answers (at least tentatively) to three important questions in the field: Does ECEC work? How long does it work? What works the best? Nonetheless, authors unanimously emphasize that the empirical basis for home-based, center-based, and combined programs

continue to have limitations, despite the impressive efforts of various involved parties.

Integrated Early Childhood Education and Care Services – Care, Upbringing, Education and Health

S Colley

© 2010 Elsevier Ltd. All rights reserved.

In recent years, international researchers have recognized that integrating early childhood education programs will support the development of young children in a better manner. Integrated early learning and child-care programs include a range of services and systems that are attempting to blend governance and practice in a number of fields. Since the publication of the Organization for Economic Cooperation and Development (OECD) Report *Starting Strong* (OECD, 2001), many countries have focused on blending their education and child-care systems and services. Some countries have also attempted to integrate other services – health and social services – but this article focuses on integration between education and care.

The *Starting Strong* OECD Reports (OECD, 2001, 2006) identified eight policy directions to encourage equitable access to quality early childhood education and care (ECEC). The recommendations focused on supporting the social needs of families and strengthening the foundations of lifelong learning for all children. The second policy direction was related to the need for greater integration – a strong and equal partnership with the education system. Specifically, the OECD recommended that governments review their professional profiles, improve recruitment levels, and strengthen the initial and in-service training of staff in both kindergarten and child care.

Other studies have found positive results for child development as a result of their integration initiatives. One international study of early-years-integration projects concluded that integrated care and education programs were beneficial for children from birth to 6 years, particularly for children facing multiple risks (Penn *et al.*, 2004). The Ontario, Early Years Study cited integration as an important stepping-stone in the quest for improved child-development outcomes. One of the influential projects that impacted on it was the South-East Grey Community Organization (SEGCO) established in rural Canada as a delivery model that could offer accessible, sustainable child care, junior kindergarten, and family-support services in a rural community. The agency created a hub model to deliver programs and services tailored to the community's requirements. The UK Sylva *et al.* study of preschool education reported that children who attended integrated early learning and care programs and those who attended nursery schools made better intellectual progress by the time they entered primary school than children

who attended regular child-care centers, family child-care programs, or other combinations of nonparental care and early-education programs.

The Integration Continuum

There is a recurring question of what is meant by integration. Some programs consider themselves integrated if they offer separate services in one location (or close by) and have regular communication. Some services consider themselves to be integrated if they co-locate services to provide a one-stop shopping opportunity for local residents with some loose coordination and regular communication. Others consider integration to be a coherent service equally accessible to all potential users with a common budget, staffing, policy environment, and a pedagogic framework for all programs. Or, it may mean combining care and health (or welfare), but not care and education programs. To achieve positive outcomes, it is generally acknowledged that something more than coordination is required, but that attention needs to be given to both structural and conceptual integration. Researchers have generally concluded that service integration involves an ongoing process that involves a continuum of awareness, communication, coordination, collaboration, and consolidation even though it is not necessary to go through each stage. The focus is on the extent to which joined-up working and collaboration is occurring. (Cohen *et al.*, 2003)

A general distinction can be drawn between those countries that have administratively amalgamated their education, child care, and family-support systems under one ministry and those countries that have maintained the historical separation.

Countries with Administrative Amalgamation of ECEC Services

As early as the 1960s, several European countries began to integrate their child care and preschool education programs under one government department. Most of the Nordic countries integrated them into their welfare systems, while several Mediterranean countries integrated them into education. A new wave of integration began to occur in the 1990s when several OECD countries then

moved their entire ECEC systems for children from birth to age 6 (or older) under the umbrella of education. This process took place in some countries that had already experienced a measure of integration and in others that had previously maintained a total separation between child care and public education.

Of the countries that have administratively amalgamated their ECEC programs under education, perhaps the most well-known example is that of Sweden. In 1996, responsibility for child care in Sweden was transferred from the ministry of health and social affairs to the ministry of education and science under the School Act. Among a number of reforms, the government also introduced a uniform framework for training for child-care teachers, school teachers, and school-age child-care providers (known as leisure-time pedagogues). In this process, there were concerns expressed about preschool becoming rigid and formal, losing its emphasis on play and children's holistic development. Child-care teachers were anxious about the threat to their profession as a result of the shift toward education. Yet, at the time of the change, administrators and politicians were cognizant of the need for early child development philosophy to influence the integration process. Prior to moving preschool under the ministry of education, a national study urged Swedish schools to become more responsive to children's individual learning needs and styles. It was argued that integrating preschools with primary schools would allow the former to transform the latter. This point was taken into consideration in the revision of the school curriculum, which took on many of the pedagogical practices of preschools. Learning came to replace teaching, shifting the overall focus from teaching to learners. The Swedish Prime Minister, Göran Persson, set this approach in motion when he announced his vision of lifelong learning for Sweden in 1996, stating that preschool education should be a part of the country's lifelong learning vision. Nevertheless, concern persists about the degree to which early childhood programs have become too schoolified, with too much emphasis on cognitive skills and not enough emphasis on the other domains of development: physical, cultural, social, and emotional development (Choi, 2002).

Sweden was not alone in integrating the administration of its ECEC programs. New Zealand, Spain, Brazil, Slovenia, Iceland, Norway, England, and Scotland, as well as some of the Canadian provinces and the Australia states, also moved to unify services under education departments. In England, the central government not only administratively integrated its nursery school and child-care programs, but also endeavored to integrate health and family-support programs to better support children, families, and communities. The government established Sure Start to work with parents and preschool children to promote the physical, intellectual, social, and emotional development of children, particularly those who were disadvantaged. The aim was to

ensure that the children were ready to thrive when they arrived at school. In each area where there is a Sure Start project, locally based programs are encouraged to build on what already exists to ensure a range of core services including:

- outreach services and home visiting;
- support for families and parents;
- good quality play, learning, and child care;
- primary and community health care, and advice about family health and child development; and
- support for those with special needs.

Local communities may provide extra services according to local needs, such as skills training for parents, personal development courses, and practical advice and support such as debt counseling, and language or literacy training.

In New Zealand, some community organizations have developed their own initiatives toward multiservice provision. This is a result of a new policy encouraging ECE centers to offer parental support and development. In 2006, the Ministry of Social Development funded eight pilot projects of ECE Centre Based Parent Support and Development. Funding was extended to a further ten pilot centers in 2007 (Mitchell, 2008).

Countries that Have Maintained the Historical Separation Between Public Education and Child Care

Countries, such as the United States, Canada, and Australia, are beginning to explore ways to integrate ECEC services, often through the establishment of demonstration projects that may further influence government policy.

In the United States, several states are undertaking integration initiatives as part of the No Child Left Behind Policy. For example, Smart Start in North Carolina is a statewide initiative to enhance child-care center quality and ensure partnerships with family-support programs. Smart Start, a public-private initiative, provides early education funding to all of the state's 100 counties. Smart Start funds are administered at the local level through nonprofit partnership organizations. The North Carolina Partnership for Children, Inc. (NCPC) is a statewide nonprofit organization set up to provide oversight and technical assistance for local partnerships. Smart Start funds are used to improve the quality of child care, make child care more affordable and accessible, provide access to health services, and offer family support. Services at the local level vary depending on local needs. Approximately, 80 local partnerships have been established throughout the state to administer funding and programs. Smart Start has garnered much national recognition and is considered a model for comprehensive early

childhood education initiatives. In 2003, the Smart Start evaluation team examined the impact on program quality, development of cross-sectoral partnerships, and child outcomes and found that children attending Smart Start centers do better on measures of cognitive, language, and social skills regardless of family or ethnic background.

In Canada, the Toronto First Duty Project (2001–06) was a demonstration research project that aimed to integrate and expand early education, family support, and child care in five neighborhoods. The project was designed to demonstrate and study how existing early childhood and family support programs could be transformed into an integrated system for children aged 0–6 years. The five sites engaged in activities to bring together and integrate early-years services to children and families in their respective communities. The findings from this demonstration project indicated that parenting capacity (including confidence in helping learning at home and involvement with the school) was greater at the first-duty sites than in schools with similar socioeconomic characteristics and traditional early childhood programs (Corter *et al.*, 2007).

Within the context of the Australia-government approach to improve the proportion of children acquiring the basic skills for life and learning, South Australia, among other states, has developed a strategic plan that incorporates an integration perspective. Twenty-four children's centers for early childhood development and parenting are under development. The strategic plan further emphasizes the need to establish and network Aboriginal children's centers in remote communities. South Australia Action Plan for Early Childhood and Child Care includes the development of children's centers organized as hub-and-spoke models and linking children's services to a broad spectrum of support and referral networks. The plan also proposes to upgrade the qualifications of the early childhood workforce, building new competencies for an integrated multidisciplinary early childhood system.

The need to establish hubs and networks to support a variety of children's service needs has also been recognized in Canada. The Healthy Babies, Healthy Children (HBHC) Program was designed as a universal prevention/early-intervention program to improve the well-being and long-term prospects of young children. Using a community-wide planning and implementation process that involved most or all organizations and agencies that serve families and children (prenatal to age 6), HBHC's goal was to ensure an effective system of prevention, screening, and early-intervention services. It emphasized the early identification and prevention of problems and built on the strengths of families and community members. Central to this project was an integrated system of services and supports for healthy child development and family well-being (Ryan and Robinson, 2005).

Ingredients of Service Integration

Whether countries have already integrated their ECEC administration systems or not, there is widespread recognition that integration is a process that goes beyond jurisdictional integration. Moving toward integration requires a willingness to leave old identities behind – both professional and programmatic.

In countries, such as the USA, Ireland, Australia, and Canada, where spending on ECEC continues to be below the OECD average, insufficient government funding remains a huge obstacle to the optimum development of ECEC services. In those countries, there is a major challenge to ensure that government resources are sufficient to achieve the outcomes promised through integrated ECEC programs. An expectation of higher-quality programs and greater effectiveness, and the associated costs that accompany this, is enshrined in movements toward integrated ECEC provision. Consequently, government funding remains a key ingredient for future progress.

The structural elements – funding, legislation, and regulation, are essential, but not enough. Two key ingredients for reform are workforce reorganization and the curriculum (or pedagogic approach). These policy areas require a fundamental change in order to achieve full integration.

Reorganizing the Workforce

One indicator of the success of integration is the unification of a divided education and care workforce (Cohen *et al.*, 2004). In those countries that have made the most progress in integrating early childhood services, a core profession has emerged. These professionals work across the early childhood age spectrum from birth to age 5 or 6 and undertake all aspects of education and care.

The OECD recommended a review of professional profiles, improved recruitment levels, and strengthening of the initial and in-service training of staff. As early childhood centers become the foundation for lifelong learning, staff in these centers will be required to deal sensitively with cultural issues, respond appropriately to children with special needs, and provide individualized support to every child in moments of vulnerability or stress. The success of integrated early learning and care programs depends primarily on the excellence of the human resources employed. Most proposals for integrated or seamless ECEC identify human resources as the critical place for transformation if integration activities are to succeed.

A core profession has emerged in countries that have gone furthest in integrating early childhood services. Dedicated and qualified professionals work across the early childhood age spectrum from birth to age 5 or 6 or 7 and engage in all aspects of education and care. Examples include Denmark, Finland, New Zealand, Norway, Spain,

and Sweden. Some countries are still engaged in this transformation. For example, in New Zealand, all early childhood teachers are required to have a teaching diploma by 2012. Incentive grants and prior learning assessment, together with time for phase-in, make upgrading possible. In Norway, considerable resources have been dedicated to improving quality and hiring more qualified teachers.

In reviewing the training issues, the OECD has raised key questions:

- Is integration of the workforce possible? If so, who will be the core professional and what will be the balance between this professional and others working in the system?
- What educational requirements will this professional have?
- Who will pay for training and who will pay for a properly qualified workforce?
- What kind of phase-in period will be established for the new core professional?
- Will all staff be required to have the same training – as in New Zealand – or will there be a role for an assistant trained at a lower level but with access to opportunities to gain additional qualifications?
- How will the workforce be reorganized to accommodate longer hours, and a longer year?

However these questions are answered, without reform to ensure adequate core funding, governments' ability to provide proper remuneration, training, and development for a substantially underpaid and undervalued workforce will be severely compromised.

Integrating Curricular and Pedagogical Frameworks

A second key challenge for the successful integration of ECEC services centers on the successful blending of curriculum and pedagogy. As Bennett points out in **Table 1**, there are two distinct traditions of the pedagogical approach in the field of early childhood education. These often present themselves in the two separate spheres: a favoring of the preprimary tradition by programs originating in education jurisdictions and a favoring of the social-pedagogic tradition by programs oriented to the care of very young children. The social-pedagogy approach tends to emphasize broad development goals, which contribute to children's overall development. The preprimary approach tends to place more emphasis on focused cognitive goals such as mathematical development, language, and literacy.

Educators rooted in the social-pedagogic tradition argue that effective pedagogy involves the provision of enriched learning and play environments, freely chosen activities by children, and responsive accompaniment of children by educators who guide, inform, model, and instruct, but do not dominate the child's thinking.

Aware that children may be able to take on the challenge of a focused cognitive curriculum, these educators oppose the prescribed detailed literacy goals for all young children as it threatens to put undue pressure on educators and children. When begun too early, literacy instruction may actually harm the self-concept of young children, leading to anxiety, low self-esteem, and mediocre literacy results.

Table 1 Pedagogical goals

<i>The direct instruction tradition</i>	<i>The Swedish constructivist tradition</i>
<p>1. The early childhood centre: Often seen as a junior school, a place of instruction, socialisation and preparation for school</p> <p>2. Approach to curriculum: Centralised development of curriculum – stressing autonomy and competition</p> <p>3. Organisation of curriculum: Often prescriptive: clear targets and outcomes, detailed competencies. . . Learning is stepped (sequential) – see first draft EYFS curriculum</p> <p>4. Focus of work: A focus on learning standards, teachers, classroom environment, preparation for school, on literacy. . . Children can or cannot read. . . Teaching subjects privileged</p> <p>5. Approach to outputs: It is necessary to reach government standards. High stakes assessments and sometimes testing required</p> <p>6. A focus on competence in the national language, is sought. Technical approach and assessment: oral, phonemic. . . with some formal skills in writing and reading from an early age</p>	<p>1. The early childhood centre: viewed as a life space, a place in which children and pedagogues “learn to be, learn to do, learn to learn, learn to live together”</p> <p>2. Approach to curriculum: Conceived as a broad central guideline stressing fundamental aims and values - with local development of curriculum</p> <p>3. Organisation of curriculum: Broad orientations rather than prescribed outcomes: play, music, arts, project work, interaction with peers and nature – the natural learning strategies of the child. Learning occurs informally (and in many places) and especially within the planned holistic experience (rich project work)</p> <p>4. Focus of work: on a range of developmental goals and living together in a learning community of educators and peers. . . the competent child. Focus on communication, literacies. . . Culturally valued ‘topics of learning’ privileged. . . child interest</p> <p>5. Approach to outputs: Parental and child satisfaction predominate. Holistic goals for each child to aspire to are set with unobtrusive, developmental assessment</p> <p>6. A growing focus on individual language and oral competence. . . with much ‘play’ reading and writing</p>

Source: Bennett, Montreal, 2009.

A curriculum helps to ensure that staff cover important learning areas, adopt a common pedagogical approach, and reach for a certain level of quality across age groups and regions. As a result, support for a blended curriculum is critical to successful integration and is also necessary to guide the staff in centers, especially when they have low certification and little training. Curricular frameworks also help to involve families in curriculum development and implementation. Although knowledgeable about their children, many parents need professional assistance to support their children's learning and development.

It is not yet clear that any jurisdiction has determined the appropriate amount of literacy, numeracy, and scientific/technological knowledge in an integrated early childhood curriculum or how it should be ensured. But experts are clear that programs must be oriented to the broad developmental goals and not just focused on cognitive goals (Bennett, 2004).

New Zealand is a case in point. After Iceland, New Zealand was the next country to administratively integrate its child care and kindergarten programs under one department. An important element in the integration process was the development of an integrated, national early childhood curriculum, Te Whaariki, which was developed in partnership with Maori and after months of consultation across the country. The aims of Te Whaariki include: well-being, belonging, contribution, communication, and exploration. Implementation requires staff understanding of theory and reflective practice. It has been incorporated into teacher education, professional development, and ECEC resources. The New Zealand Government also developed a strategic plan emphasizing improved quality and collaborative relationships. Although divisions still exist, integration is based on theory, philosophy, research, and political action. Status, recognition, and support for ECEC have increased greatly and the system has moved from an *ad hoc* to a planned approach. Researchers have found that general support for the curriculum is high but, as observed elsewhere, current regulations and funding make it difficult for centers to meet the quality expectations (Carr *et al.*, 2002). Several training institutions have begun using Te Whaariki as a framework, and evaluation and assessments are now ongoing (Mitchell, 2008).

The challenge now is to bring practice in line with the theory. The essential ingredients required to meet this challenge include professional development of teachers and a strong policy framework to support enhanced materials and approaches to quality provision.

Conclusion

There are many structural, political, professional, and historic barriers to overcome before there is an integrated

approach to ECEC services for young children in many OECD countries. The goal of integrated services is to strive for collaboration, mutual respect between sectors and communities, and develop options based on collective imagination. Many countries have already made considerable progress toward integration of their ECEC programs. The pioneering efforts of these countries may provide some direction to other countries seeking to move toward integrated approaches to ECEC provision.

Glossary

Child care – Early childhood program designed to offer care to children but without a primary emphasis on providing educational services.

Early childhood education and care – Organized program offering educational services and/or care to children during early childhood. Here, we have focused on programs serving children from birth until entry into primary school.

Enrollment rate – Percentage of children from a pre-defined group who are on record as current participants in a school or early childhood education and care program.

Externalities – Spillover benefits of an early childhood program to people beyond those enrolled as children or their families.

Gross enrollment ratio (GER) – Percentage of children enrolled in the age group that corresponds to a particular grade in school.

Head start – A US federal government program providing education and other services to children in poverty, primarily from age 3 to 5, and their families.

Legal entitlement to education – Children with legal entitlements to education are guaranteed access to a program, typically based on their age.

Pre-primary education program – An educational program designed to serve children between ages 3 and the primary school entry age. These types of programs may be known by terms such as preschool, nursery education, infant education, prekindergarten, and kindergarten.

Targeted preschool education – Education program that is targeted to a particular subset of children within a given age range, often based on family income.

Universal preschool education – An education program available to all children within a specified age range (such as the year before kindergarten eligibility) whose parents wish to enroll them.

countries around the globe. There is consensus across a variety of fields that early childhood is a sensitive period of life, marked by development of critical cognitive, social–emotional, and physical skills. Over the past few decades, a large body of research has shown that participation in early childhood education programs can produce positive impacts on children’s development. Improvements in early learning and development in turn produce long-term improvements in achievement, educational attainment, and social behavior. Specific impacts shown in longer-term studies of high-quality preschool programs include decreased rates of grade retention and special education enrolment, increased school completion rates, and reductions in crime and delinquency rates.

Although the aims of ECEC initiatives vary considerably from country to country, a common priority of these programs is to offer educational services and/or care to children during the years prior to their entry into primary school, which occurs by age 6 in a majority of countries. Implementation of ECEC programs internationally has been marked by divisions between the types of services offered to children from birth to age 3 and those offered for children from ages 3 to 6. When government agencies are involved in the provision of ECEC, this age boundary is often replicated at the government level as well, with different agencies or ministries responsible for overseeing ECEC programs depending on a child’s age. Regardless of the level of government involvement, ECEC programs for children younger than age 3 tend to focus mainly on child care, while ECEC programs for children ages 3 and older tend to be conceptualized as pre-primary education.

Several Decades of Steady Growth in ECEC

Worldwide enrolment rates in preschool education programs have grown substantially since the 1960s. This rise in enrolment has occurred in the context of broad societal changes, including increased workforce participation by mothers of young children, higher numbers of single-parent households, decreasing birth rates, and urbanization. There has been burgeoning interest by both parents and governments in increasing the availability of educational opportunities for young children. One widely known example of an early government-sponsored ECEC initiative is the United States’ federal Head Start program, for young children in poverty and their families, which was started in 1965.

The Importance of Early Childhood Education and Care

Early childhood education and care (ECEC) programs for young children have become increasingly available in

Although many nations continue to target public resources on programs for disadvantaged children, there is a growing movement to ensure that all children can access preschool programs. Countries that were among the initial leaders in making ECEC widely accessible to all young children, regardless of socioeconomic background, include Belgium, France, and the Netherlands. In Belgium, nearly all children aged 3–6 were enrolled in ECEC programs by 1975. By 1980, almost all children in France aged 2–6 and almost all children aged 4–6 in the Netherlands were enrolled in ECEC. In general, differences in enrolment rates between countries have been diminishing, as ECEC becomes a higher priority internationally. Pre-primary enrolment rates are now about 3 times higher than in 1970, although rates are still low in less economically developed countries. Most countries in the Organization for Economic Cooperation and Development (OECD), which primarily counts industrialized countries as its members, are currently offering free pre-primary education programs of at least 2 years' duration.

Current Issues of Access to ECEC

International data on ECEC enrolment rates are gathered on an ongoing basis by the United Nations Educational, Scientific and Cultural Organization (UNESCO), which monitors progress toward a set of six Education for All goals adopted at the 2000 World Education Forum by 164 governments and 35 international institutions. These goals focus on increasing access to educational opportunities at all stages of life, as a human rights issue. The goal related to early childhood involves increasing access to comprehensive ECEC programs, and making improvements in these programs, with a particular emphasis on serving disadvantaged children. Data from UNESCO are reported in terms of the gross enrolment ratio (GER), a percentage of children enrolled from the age group matching a particular grade level in school. (A GER higher than 100% reflects enrolment by children whose age does not correspond to that expected at their current grade level, because they entered school at an atypical age or were retained.) The UNESCO data focus on enrolment in pre-primary education programs beginning at age 3 – programs offering a school-type, center-based environment, including programs variously known by such terms as preschool, nursery education, infant education, and kindergarten. Enrolment data for children from birth until age 3 are less widely available on an international level.

Pre-primary enrolment rates tend to be much higher in developed countries than in developing countries. The regions of the world with the highest pre-primary GERs in 2005 included North America and Western Europe (79%), Latin America and the Caribbean (62%), and Central and Eastern Europe (59%). In East Asia and the

^aEnrolment rates were calculated using national population data.

^bData are from a year other than 2005. In all cases, data from 2003 or later were used.

^cEstimated data were used.

For purposes of this table, gross enrolment rates exceeding 100% are capped at 100%. From United Nations Educational, Scientific and Cultural Organization (2007). *Education for All Global Monitoring Report 2008: Education for All by 2015. Will We Make It?* Paris: UNESCO.

Pacific, 43% of children were enrolled in pre-primary education; and in South and West Asia 37% of children were enrolled. Less than one-third of children were enrolled in pre-primary education programs in Central Asia (28%), the Arab States (17%), and sub-Saharan Africa (14%). From 1999 to 2005 (the years just after the adoption of the Education for All goals), pre-primary enrolment rates grew by 19% worldwide, with a 30% increase in transition countries, a 24% increase in developing countries, and a 6% increase in developed countries. Regions with the lowest enrolment rates at the beginning of that time period tended to show the greatest percentage increases, although these areas of the world continue to offer fairly limited access to ECEC programs for children between age 3 and primary school entry. See **Table 1** for country-by-country enrolment rates in 2005 from UNESCO. **Table 2** provides further details about enrolment in 20 OECD countries, focusing on legal entitlements and

enrolment rates for children from birth to age 3 and from age 3 until primary school entry.

Issues of ECEC Program Administration and Governance

Although, by definition, ECEC specifically encompasses services for young children starting at birth, the reality is that most policies and organized programs focus on children starting at age 3. Only about 53% of countries internationally have at least one type of program for children from birth to age 3; such programs are most prevalent in North America and Western Europe and are least prevalent in the Arab States and in Central and Eastern Europe. In countries that offer ECEC services prior to age 3, programs for older and younger preschoolers are often separately organized and administered, with those for younger children focusing on child care and those for older children focusing on education. Thus, programs for infants and toddlers may be separate from a country's pre-primary education programs rather than a downward extension of them.

The governmental divisions with responsibility for ECEC programs often differ depending on children's ages. From birth until age 3, ministries of health frequently administer child-care programs, whereas other ministries – particularly ministries of education – are more likely to be involved in ECEC for children age 3 and older. Research on early childhood education systems in France and Sweden suggests that as government education agencies took more responsibility for ECEC programs, this provided the resources for increased access for children and also helped to professionalize early childhood staffing.

The ways in which ECEC programs are paid for also tend to vary, depending on children's ages and whether the program is conceptualized as child care or education. For example, in OECD countries, governments bear the majority of the costs for pre-primary education programs. However, parents generally must contribute larger shares toward the total costs when their children attend ECEC programs for infants and toddlers or programs for older children that are considered to be child care. The parental share of costs for these programs can be very high in countries such as Canada and the United States, where parents may bear the entire cost unless they qualify for programs targeting families in or near poverty.

Pre-primary education programs are much more likely to be provided in public school settings than in private settings internationally. The use of private settings is most common in developing countries, where a median 47% of pre-primary education programs are in private settings. Less than 10% of programs in developed countries and almost none of the programs in transition countries occur in private settings. UNESCO reports that use of private

Table 2 ECEC programs from birth until primary school in OECD countries

<i>ECEC entitlements and enrolment rates</i>		
<i>Country</i>	<i>Birth to age 3</i>	<i>Age 3 until primary school entry</i>
Australia	There is no legal entitlement to ECEC. Child-care benefits are available for children enrolled in approved services. Accredited and family day care centers reach approximately 25% of children.	There is no legal entitlement to ECEC. Free or nearly free preschool is provided by most states at ages 4 and 5. Accredited and family day care centers reach up to 62% of 4-year-olds. Kindergarten or reception classes reach 17% of 4-year-olds and 84% of 5-year-olds. Primary school begins at age 6.
Austria	There is no legal entitlement to ECEC. About 9% of children attend family day care or crèche programs.	Children aged 3–6 have a legal right to fee-based kindergarten, and 80% are enrolled. Primary school begins at age 6.
Belgium	The legal right to schooling begins at age 2.5. Earlier, subsidized services are widely available, although supply is less than demand. In the Flemish community, family day care and crèches are most common, reaching 34% of children. In the French community, crèches and centers are most common, reaching 18% of children.	Children aged 2.5–6 are entitled to free school programs. At age 2.5, 90% of children are enrolled, and almost 100% are enrolled by age 3. Primary school begins at age 6.
Canada	Entitlements to schooling vary by province. In Quebec, the right to educational child care begins at birth, and 38% of children from birth to age 4 are enrolled. Programs are fee-based, though parent fees are very low. Outside Quebec, provincial support is weak.	Entitlements vary by province. Fee-based junior kindergartens enroll 40% of 4-year-olds in Ontario and 50% in Quebec. Free kindergartens enrol 95% of 5-year-olds in most provinces. Primary school begins at age 6.
Czech Republic	There is no legal entitlement to ECEC, and few crèche services are available.	There is no legal entitlement, but kindergarten programs are widely accessible. Beginning at age 3, 76% of children are enrolled. Free programs are available by age 4, with priority given to 5-year-olds. By age 5, 98% of children are enrolled. Primary school begins at age 6.
Denmark	Day care services for all children ages 1 to 5 are guaranteed by 87% of municipalities. Fee-based services may begin at 6 months and continue until age 6. Family day care centers enroll 45% of children, with an additional 15% in crèches and age-integrated facilities.	Until age 6, children may continue to attend day care programs. At age 6, children have a legal right to attend free preschool in a center-based setting or primary school. About 58% of children are enrolled in kindergartens from ages 3 to 6, and 98% of children are enrolled from age 6 until age 7. Primary school begins at age 7.
Finland	Beginning at birth, children have a legal right to enroll in a center- or home-based ECEC program. Family day care and municipal programs reach 28% of children from ages 1 to 2 and 44% of children aged 2–3. Programs are fee-based, with parents paying an average of 15% of costs in public day care programs.	Children have a legal right to enroll in a center- or home-based ECEC program. By age 5, 73% are enrolled. At age 6, preschool classes in centers and primary schools are free, and 96% of children are enrolled. Primary school begins at age 7.
France	There is no legal entitlement to ECEC, although subsidized services are widely available. About 30% of children are enrolled in various types of settings. Starting at age 2, about 35% of children are enrolled in free educational programs.	Children have a legal right to free ECEC services, and almost all children attend until primary school begins at age 6.
Germany	There is no legal entitlement to ECEC, but 37% of children in the former East Germany and about 3% of children in the former West Germany attend center-based crèche programs, for a total of 9% nationwide.	Children have a legal right to fee-based kindergarten programs from ages 3 to 6, and 90% are enrolled. Primary school begins at age 6.
Great Britain	There is no legal entitlement to ECEC. Under the responsibility of the Ministry of Education, 26% of children attend private nurseries or play groups, or are cared for by child minders.	At ages 3 and 4, children are legally entitled to enroll in a free, part-time ECEC program. At age 3, 95% of children attend play groups or nurseries, and at age 4 nearly 100% attend reception classes or nursery schools. Primary school begins at age 5.
Hungary	Children of working parents have a legal right to free ECEC at 6 months of age, but only 9% of children attend.	Children have a legal right to free kindergarten programs starting at age 3. From ages 3 to 5, 85% of children are enrolled. Compulsory kindergarten starts at age 5, and 97% of children are enrolled.

Continued

Table 2 Continued

Country	<i>ECEC entitlements and enrolment rates</i>	
	<i>Birth to age 3</i>	<i>Age 3 until primary school entry</i>
Ireland	There is no legal entitlement to ECEC. The majority of children are in family or informal child care, although 10–15% of children up to age 4 attend licensed family day care centers or nurseries.	Up to age 4, 10–15% of children attend licensed family day care centers or nurseries, and 4% of 3-year-olds attend pre-primary education. The legal right to free preschool begins at age 4, and 56% of children ages 3 to 6 are enrolled in public pre-primary programs. By age 5, enrolment rates are nearly 100%. Primary school begins at age 6.
Italy	There is no legal entitlement to ECEC. The majority of children are in family or informal child care, although 19% are enrolled in crèches.	Children have a legal right to enroll in school-based ECEC; programs in public settings are free. From ages 3 to 4, 98% of children are enrolled in regulated services (although rates vary by region); this increases to 100% from ages 5 to 6. Primary school begins at age 6.
Korea	There is no legal entitlement to ECEC. Family and informal child care are common, although 10% of children are enrolled in child care centers.	Four-year-olds from low income families gained a legal right to ECEC in 2006. Otherwise, the right to free ECEC begins at age 5. Child care centers enrol 31% of children ages 3 to 5. Ministry of Education kindergartens enrol 12% of children at age 3, 27% at age 4, and 45% at age 5. About 70% of 5-year-olds receive licensed services. Primary school begins at age 6.
Mexico	There is no legal entitlement to ECEC, and only 3% of children are enrolled in crèches.	Currently, more than 80% of children participate in ECEC at age 5, with enrolment rates for younger children much lower. Starting in 2009, free, school-based compulsory education will begin at age 3.
Netherlands	There is no legal entitlement to ECEC, although subsidies are available for children at risk. Family day care and child care centers cover 23% of children from birth to age 4, and another 5–10% attend municipal education services for children who are disadvantaged.	Although there is no legal right to ECEC until age 4, 89% of children aged 2–4 participate in play groups or receive other types of services. Nearly all children are enrolled in free pre-primary school starting at age 4, and pre-primary school is compulsory at age 5.
Norway	There is no legal entitlement to ECEC. Private and public kindergartens enrol about 48% of children.	There is no legal entitlement to ECEC. Private and public kindergartens are available in most areas, and about 88% of children ages 3 to 6 are enrolled in fee-based ECEC. Primary school begins at age 6.
Portugal	There is no legal entitlement to ECEC. About 13% of children are enrolled in crèche programs.	A legal entitlement to free ECEC programs begins at age 4. Average enrolment for children from age 3 to age 6 is 76%, with 60% of 3-year-olds enrolled and 90% of children enrolled from age 5 to age 6. Primary school begins at age 6.
Sweden	Beginning at 1 year of age, children of working or studying parents have a right to fee-based ECEC. Full-day programs enroll 45% of children from age 1 to age 2 and 86% of children from age 2 to age 3. Family day care programs enroll 8% of children from birth to age 6.	At age 3, bilingual children are entitled to free preschool. This right is being extended to all 5-year-olds and all 4-year-olds, progressively. All 6-year-olds are entitled to free preschool; enrolment in these programs is 91%, with the other 9% already in school. Primary school begins at age 7.
United States	There is no legal entitlement to ECEC. About 50% of children attend private child care centers or family day care settings. Of these children, 38% are in licensed settings.	There is no legal entitlement to ECEC. Most states offer free public prekindergarten at age 4, and sometimes at age 3 as well, but usually to targeted populations. At age 3, 40% of children are enrolled in some type of education program, and 70% are enrolled at age 4. Most school districts offer a year of free kindergarten at age 5, and more than 90% of children are enrolled. Primary school begins at age 6.

From Organisation for Economic Co-operation and Development (2006). *Starting Strong II: Early Childhood Education and Care*. Paris: OECD.

settings has changed little during the recent expansion of pre-primary education programs, with roughly equal proportions of countries increasing their use of private providers, decreasing their use of private providers, or

experiencing few changes in their use of private providers. Nevertheless, some countries rely heavily on private provision of ECEC programs during the pre-primary years. This is particularly the case in Arab States such as Bahrain,

Morocco, and Oman; Latin American and Caribbean countries such as Anguilla, the British Virgin Islands, and Saint Lucia; and some regions of sub-Saharan Africa including Ethiopia, Lesotho, and Uganda. In these countries, pre-primary education occurs almost exclusively in private settings. **Table 1** shows percentages of children in pre-primary programs who are enrolled in private settings by country.

Moving Beyond Enrolment Counts to Assure Access to High-Quality ECEC Programs

As mentioned previously, a substantial body of research indicates that children's early learning and development can benefit significantly from preschool education, leading to long-term improvements in achievement and educational attainment as well as in social behavior. Studies have found these results across a broad range of countries with more and less developed economies. There is some evidence that benefits are greater for more economically disadvantaged children and for those who are not native speakers of the language of the country in which they reside. Moreover, the precise benefits vary with the populations and with the characteristics of programs. These findings have two important implications.

First, it is not just the percentage of the population enrolled in ECEC that is important, but who is enrolled. Thus, international comparisons find that national average achievement test scores rise with preschool enrolment, but that the degree of inequality in scores begins to narrow only as enrolment rises above 60% of the population. One reason may be that high levels of enrolment are required to effectively reach most disadvantaged children. Another reason may be that there are peer effects from more socioeconomically mixed preschool classrooms and from a higher proportion of more able students in schools after preschool education.

Second, both the hours of preschool education and the quality of preschool education have implications for benefits. Longer hours are necessary if the programs are to facilitate parental employment and the increased income and productivity that result from this employment. Children's gains depend on what opportunities to learn are provided and how well these are provided. Programs that address children's needs more broadly have a broader range of positive effects. Thus, programs are more beneficial if they address both cognitive (academic achievement) and socioemotional (social behavior) development. Where children suffer from problems of inadequate health and nutrition, programs that address these needs as well as the need for education will be more beneficial. What teachers do in the classroom matters a great deal for the magnitude of

benefits to children's learning. As a result, the preparation, ongoing professional development, and supervision of teachers are important determinants of program benefits.

Very little comparative information has been reported about the quality of ECEC programs on a worldwide scale. However, due to differences in funding, policies, and standards, ECEC appears to be far from uniform with respect to both quality and quantity (age at start and length of day) both across and within nations. Program standards in ECEC are more variable than for K-12 education and often are quite low. Although some variation is to be expected because of variations in children's needs and the capacity of countries to provide for those needs, variations in which children are enrolled and in the characteristics of programs are likely to influence the effectiveness of early education in improving children's learning and development and supporting families.

Thus, it is important that monitoring of the national provision of ECEC programs moves beyond simply counting enrolment. Information should be available on enrolment for population subgroups – for example, children from low-income families, language minority children, and children of parents with low levels of education. Likewise, information is lacking on ECEC program characteristics including: program schedules, teacher education and training, class size, teacher–child ratio, the type and quality of children's classroom experiences, and other program services (e.g., nutritional supplementation). Direct measurement of program quality through observation of representative samples of classrooms is well advised, as classroom structural features are not strong predictors of actual practice. Conducting assessments of children's learning and development may also be useful, although practical limitations include the cost, difficulties obtaining valid assessment results for young children, and problems of attributing variations in children's assessment scores to particular program experiences.

Unfortunately, relatively few countries provide data on enrolment of subgroups, and quality data are rarely systematically collected and disseminated at national levels even in the wealthiest nations. The lack of detailed enrolment data is less of an issue, of course, in countries where enrolment is near universal. However, as mentioned earlier, even where enrolment is universal for older preschoolers it typically is far from universal for infants and toddlers. There are examples of private efforts to make such information available, including annual ratings of state preschool education programs in the United States by the National Institute for Early Education Research, and the Bertelsmann Foundation's ratings of preschool programs by state in Germany. Such efforts seek to inform both government policymakers and the general public. Examples of public efforts include government-sponsored rating systems for child-care programs that are provided

as guides to parents and may be linked to a schedule of government payments that vary with the rating attained.

Universal and Targeted ECEC Programs

Perhaps the most important policy decision governments make relating to the accessibility of ECEC programs is whether provision or subsidies for public programs should be limited to a particular population (typically, by means testing) or available to all. The arguments for targeting begin with the premise that the largest benefits accrue to children who are economically disadvantaged. If so, it is sensible to prioritize scarce public resources for those children. In addition, it is argued that governments are more able to provide higher-quality early education, with its higher cost per child served, if the total cost is kept down by serving a limited portion of the population. The arguments for public support of universal provision recognize that even if benefits are largest for disadvantaged children, the benefits to nondisadvantaged children may still far exceed costs and a universal program that serves all children together may better serve the disadvantaged children. Further, it is not always clear where to draw the line between children who are disadvantaged and those who are not. As the costs, takeup rates, and benefits of programs may vary by age and type of program (e.g., parenting education, paid parental leave, infant and toddler child care, and pre-primary education from age 3), countries may choose to target some programs and provide others to all children and families.

There are four major reasons to suppose that public support for universal preschool education may more effectively serve disadvantaged children. First, targeting has proven highly imperfect, and improving its accuracy is costly. In practice, universal programs can achieve better coverage of disadvantaged populations. When programs are targeted, there are costs of identifying and recruiting the intended population and excluding those who do not qualify. When means-testing is employed, the target population is constantly changing, as family income is not constant over time. A child who qualifies at the start of the year may not qualify 4 months later and vice versa. Frequent requalification of children for participation is costly and results in ineffective education if children are bounced in and out of an ECEC program during a single school year. This is the current policy in some programs that are operated primarily as child care. Moreover, any easily administered criterion such as means-testing fails to identify all of the children who are at elevated risk of school failure and other problems that preschool education might prevent or ameliorate. In addition, there may be social stigma associated with programs for the poor that lead some qualifying families to opt out. Second, because of the effects of peers on learning, disadvantaged

children appear to learn more when they attend programs that also include more advantaged children. Third, economic theory and experience suggest that the voters are more likely to support high-quality education if the program is available to all children and families.

Perhaps the strongest argument in favor of public support for universal preschool education is that all children benefit from high-quality preschool education, and there are substantial effects of subsidized high-quality child care on maternal employment in even the wealthiest countries. The externalities (spillover benefits to others that do not accrue to the child or parents) from high-quality preschool education are likely to remain significant for most of the nonpoor population. Even if benefits to more advantaged children are only a small fraction of those estimated for disadvantaged children, the benefits are likely to exceed the costs. If the effects on maternal labor-force participation and hours are somewhat smaller, this may be offset to some extent by the higher hourly earnings and higher taxes paid on those earnings of more advantaged mothers. In addition, countries seeking to support parents as a way of increasing the number of children born are likely to want this incentive to extend across the entire population. It should be noted that within a universal public program, the level of subsidy and intensity of service can be varied according to the individual needs of children and families. As with targeting, there are costs and practical difficulties in effectively delivering highly differentiated services.

One way of making ECEC programs universally available is by adopting policies that lower the mandatory school entry age to encompass the pre-primary years. UNESCO reports that by 2006, 30 countries had adopted policies for compulsory pre-primary education. This is a recent development, with fully half of the policies for required pre-primary attendance enacted since 1995. Countries that have lowered their school entry ages to include the pre-primary years are heavily concentrated in Latin America and the Caribbean, and also in Central and Eastern Europe. Attendance rates from countries with compulsory pre-primary attendance policies indicate that these countries, while signaling a commitment to ECEC, have not necessarily achieved universal attendance. In addition, a number of countries (particularly in Europe) offer universal programs with 4-year-old enrolment rates that exceed 90% even in the absence of mandatory attendance laws. Although national policies that address whether programs are universal or targeted offer an important starting point, other factors weigh in to accessibility of ECEC as well – including cultural attitudes toward early childhood education, government funding levels, whether ECEC programs are integrated within systems for primary education, and availability of appropriate ECEC facilities.

Conclusions

While international enrolment rates in ECEC programs have increased substantially over the past few decades, there is still wide variability across countries with respect to ECEC policies. Within this sector, countries have generally prioritized education programs for children beginning at age 3. There has been less emphasis on providing programs for infants and toddlers, and the initiatives that do exist have often focused on child care. As a result, much of the information about the availability of ECEC on an international level has focused on pre-primary education programs for children from ages 3 to 6. Most pre-primary education programs tend to occur in public settings around the world, although there is great variability from country to country, and some countries rely almost exclusively on private settings.

One complication in international comparisons of pre-primary education is that the primary school starting age varies considerably among countries. This is true even among countries where there is universal participation in the primary grades, with the compulsory primary school entry age ranging from age 4 (Northern Ireland) to age 7 (Finland, Sweden, and many other countries). Thus, 2 years of pre-primary education in some countries might still leave children with the same level of access to education as in other countries that start school at age 5 and have no pre-primary education. Interestingly, compulsory school starting age is positively related to international differences in test scores, but less strongly so than is the number of years of preschool education. This may be because universal preschool education policies to some extent compensate or negate the need for earlier compulsory schooling. At some point, the line is blurred between pre-primary and primary education, and what is important is the extent to which children can access programs and the content and methods of education rather than whether programs are administered within a primary or pre-primary education system, although the administrative auspices of a program may well influence who it serves and how it operates.

Based on the available international data, it is currently difficult to move beyond tallying enrolment rates from country to country. There is little comparative information available on a worldwide scale about which children are enrolled in ECEC, what specific services they receive, and the quality of programs they attend. These additional types of data are key to further examination of the educational opportunities available to children internationally, during the years before they begin primary school.

Kindergarten Transitions and Linkages to Primary School – Readiness Re-conceptualized

A Petriwskyj, Queensland University of Technology, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Horizontal transition – Transitions across one point in time such as within one day or week (e.g., kindergarten, therapy and outside-school-hours care).

Linkages – Connections between stakeholders (e.g. home and ECE, preschool and school) to share information.

Multi-faceted or multi-layered transition – Transition processes that take into account multiple changes in children's lives, and multiple strategies to improve continuity of experience.

Preparedness – Shared preparation of children, families, schools and communities for children's transition to school.

Readiness for school – Individual child characteristics such as maturity and pre-academic skills that are anticipated to enhance school adjustment and achievement.

Ready schools – Schools that have undertaken preparation to cater for the diversity of school entrants.

Structural provision – Organizational or system level provision such as set age of school entry, transition class, or transition curriculum.

System coherence – Consistency and communication between systems and agencies working with families and children.

Transition to school – On-going and non-stigmatising process of mutual adaptation by children, families, schools and communities to facilitate all children moving successfully from home and ECEC centres into and through the early years of school.

Vertical transitions – Transitions across time and between education levels (e.g., preschool, kindergarten and the first grade of school).

the growth of knowledge about children, learning, and achievement and adjustment. At the beginning of a new century, there is evidence of school entry and adjustment being conceptualized as longer-term and more complex processes. Traditional school-readiness concepts primarily focused on the individual child and normative expectations that were linked to child age. Contemporary constructions of transition have, to some extent, emerged as a response to the challenges teachers encounter as they work with the cohorts of diverse children entering a program, especially programs that use traditional age-based content. This article, therefore, primarily addresses the transitions of children from minority groups.

Since the 1990s, there has been increasing evidence of a re-framing of readiness for school toward the construct transition to school. Transition to school is thought to address more broadly the changes that occur as children move across early years' services and into school. Transitions can be broadly defined as border crossings that involve ongoing processes of mutual adaptation by children, families, communities, and schools (Ramey and Ramey, 1998). This article outlines some conceptualizations of transition to school that are apparent in early childhood education and care (ECEC) systems at this time including single time-limited change events, teaching practices, continuity of experience, multilayered and multifactorial processes, dynamic relationship-based processes, the engagement of children's resources, and the enhancement of resilience (Petriwskyj *et al.*, 2005; Dunlop and Fabian, 2007). The role of school readiness and preparedness is also discussed because readiness and preparedness constructs continue to have relevance in some systems, particularly in the US, Asia, and Australia.

Readiness and Preparedness

Attempts by professionals to ameliorate the perceived disadvantage of children from minority groups have focused on program content that is designed to optimize children's academic achievement and adjustment (Sammons *et al.*, 2004). For example, pre-academic programs, English-language instruction, and health or social-development programs have been used to enhance children's well-being and assist children's preparedness for formal schooling. Children with disabilities who have attended segregated early-intervention programs often receive specific instruction

Concern for the difficulties faced in the early years of school by diverse children, especially children from economic, social, and cultural minorities, and children with disabilities or learning difficulties is not new. Over several decades, a focus on individual children's readiness for school has altered in light of changing contexts and

in social and academic skills for school entry and social inclusion (Hanson *et al.*, 2000).

Child-readiness approaches emphasize a child's social maturation and content knowledge. An orientation toward child readiness is a feature of education systems within the United States and Australia. When political concern about the educational achievement of minority groups is addressed by focusing on child readiness, then children themselves become the primary targets for change (Burchinal *et al.*, 2002; Petriwskyj *et al.*, 2005). Support for readiness approaches is also apparent among Asian countries, and communities with Asian roots, where cultural expectations of a child's academic success may be high (Sy, 2003). The persistence of child-focused-readiness understandings among teachers, parents, communities, and policymakers can occur where there are also perceptions about school systems being inflexible, beliefs that each chronological age level requires the presence of uniform child-development outcomes and where there are understandings of preschool and kindergarten programs as getting children ready for school (Gill *et al.*, 2006). However, incompatibilities arise as readiness constructs, inclusive educational policies, and the use of selected, normative readiness assessments of young children coexist in an education system. In response, and sometimes to overcome problems related to individual assessments of risk or deficit, population-level assessments of child development may also be used to determine how best to allocate additional support resources for children in the early years. For example, in Canada, the early development instrument (EDI) and in Australia the Australian early development index (AEDI) are used to characterize communities that may benefit from enhanced school-readiness efforts.

There is evidence that some readiness-linked practices have generated equivocal results, including evidence that the practice of grade-retention harms child progress and self-esteem (Carlton and Winsler, 1999; Graue *et al.*, 2002). Increasing the age of school entry has not changed perceptions of advantage to older over younger members of a cohort, and delayed school entry has been challenged on the grounds that late school commencement may further disadvantage children in unfavorable home circumstances.

In the context of inclusive policies, there is pressure for schools to adapt to the diverse learning requirements of children rather than assume a set of prespecified academic and social skills that is required for young children at school entry. A shift in ECEC away from age-related approaches based on normative expectations of young children has prompted a reframing of readiness as preparedness (Dockett and Perry, 2007). Contemporary preparedness is interactionist in nature, context specific, and focused on the preparation of schools and families as well as children (Graue *et al.*, 2002). Both prior-to-school and school programs require attention to ensure preparedness. Shifting from a singular focus on the child to a comprehensive

analysis of the educational environment highlights the range of issues that affect transitions, children's subsequent learning, and their adjustment in new settings.

Transition as a Single Time-Limited Change Event

Transition to school can be construed as vertical steps: steps over time between different programs or program levels, for example, moving from child-care, through pre-school, and kindergarten class to the first primary-school grade. The step into a school-based kindergarten class from home or prior ECEC service is a key point of interest at system level, particularly with regard to children with perceived environmental or developmental disadvantage. Education systems vary in setting the age at which children must enter the statutory school education. A child's transition from informal preschool contexts to a formal kindergarten or primary school class can vary from age 3 to age 6 or 7 (Fabian, 2002; OECD, 2006). Transitions from a school-based kindergarten class into the first primary school grade may receive less attention, despite changes in expectations (Entwisle and Alexander, 1998), and further transitions throughout the early school years have only recently been addressed.

The construction of transition to school as a time-limited change event for children is consistent with an emphasis on initial adjustment to the school context, and to specific teaching practices that could improve adjustment. Some approaches to reducing the shock of this change event have reframed the prior preschool and kindergarten programs to be more school like. Other approaches have focused on supporting children's self-confidence, or have changed the first primary school year to achieve a more graduated change (Brostrom, 2002).

Short transition timeframes of a few days or weeks are evident in transition approaches that invest heavily in preparedness, single change events such as kindergarten entry and initial child-adjustment indicators. Longer transition timeframes are associated with practices that involve more sustained and complex processes surrounding learning continuity. These broader constructions of transition to school involve children, families, and schools and the processes shift from a primary attention to children's maturation and skills toward more complex interweaving of different facets of transition, including the structure and culture of family and school (Brooker, 2002).

Transition as Set School Practices

Concern for children's adjustment to school has resulted in a number of systems making structural changes that

include raising the age of school commencement and introducing transition classes in order to enhance school-entrant homogeneity. Accelerated school entry may also be justified in cases where commencement issues are substantial, such as for gifted children who encounter low-level curriculum relative to their skills. A focus on adjustment has given rise to various induction practices including prior-to-entry school visits by children or visits by school teachers to nearby preschools in order to familiarize the children and families with the local school context (Hanson *et al.*, 2000; Pianta and Kraft-Sayre, 2003).

Greater responsibility for induction is normally taken by the sending setting (e.g., kindergarten) than by the receiving setting (e.g., year 1 class). School-induction emphases may include introducing children and families to their local school, transferring information about children between teachers, and orienting children to the physical facilities and expectations of the new context (Dockett and Perry, 2007). These induction practices have been valuable in facilitating children's adjustment by enhancing confidence in the new environment, especially in situations where individual child support decreases at the same time as the social and academic demands increase.

Contemporary school-transition practices have incorporated wider communication linkages between families, schools, and ECEC services together with broader processes for supporting children as they move into kindergarten and primary school. Family-school interviews, family-induction meetings, and parent-orientation visits to school are also components of introductory practices (Brostrom, 2002). The unequal family-school power relationships implicit in some practices deserve careful consideration if diverse family circumstances are to be addressed. Sharing of information between teachers through meetings, transfer of children's assessment records, and other communication about individuals and curriculum are less frequent than parent-child orientation programs; yet they are valuable in the achievement of seamless transitions (La Paro *et al.*, 2000).

Transition as Continuity of Experience

Continuities in children's experiences as they move across ECEC and into school programs help children feel confident and secure. Although some level of dissonance can stimulate or positively challenge children, the negative impact of extreme discontinuity can threaten their progress in educational programs, especially children from social, economic, and cultural minorities (Dunlop, 2007; Podmore *et al.*, 2003). For example, the gap between ECEC and traditional school curricula and pedagogies can be significant. Efforts toward better curricula alignment continue to be made in many systems. These may involve changes to both ECEC and school curricula

(Brostrom, 2002; Neuman, 2001). There is awareness of the importance of pedagogy, especially achieving coherence of interaction style and language usage within and between ECEC and school programs. A focus on pedagogical continuity enables smooth transitions between the play pedagogies of ECEC and the more structured pedagogies of schools.

Another aim of systems that are sensitive to continuity is ensuring cultural coherence and inclusion. It is important to have in place program interactions that acknowledge diverse family-interaction patterns while also facilitating the development of common usage for learning in school settings. Ensuring cultural coherence across institutions and a continuity of experience for families and children are particular priorities in education systems working to facilitate the success of minority groups. Cultural variations and different expectations set within specialist and general-education services (e.g., early intervention program and kindergarten), can increase the challenge confronting children making transitions across the early years (Brooker, 2002). In many systems, there is a movement toward partnership with families, respecting continuity in learning home languages, and incorporating valued experiences of specific communities in the institutional settings (e.g., indigenous communities).

The need for increased overall system coherence has been raised in response to the lack of continuity of processes, policies, expectations, and quality between various ECEC and school systems. Where early childhood programs emerge from a range of agencies under different jurisdictions and with different mandates, discontinuities also emerge that may be confusing for families and children (Neuman, 2001). In the US, the full-service school or a school with a central community role has been suggested as a potential solution to this fragmentation. Approaches can also be made to integrate systems within a limited geographic area as a means of smoothing transitions although such approaches may assume family stability that is not warranted in times of increasing family geographic mobility (Fabian, 2002). In some European countries, more coordinated and systematically planned services and programs have been developed to ensure higher levels of system coherence for families and children (Neuman, 2001; OECD, 2006).

Transition as Multilayer Multiyear Process

Multilayered approaches to transition are grounded in a longer-term view of the transition period as a multiyear process. Recent literature frames transition into school as an extended process, ranging from 6 months to 3 years or an ongoing series of border crossings (Dunlop and Fabian, 2007; Raban and Ure, 2000). This longer frame of reference may have its foundation in the US experience of the

difference between short-term impacts on initial school adjustment and achievement and longer-term effects on developmental trajectories and life outcomes in programs such as Headstart (La Paro *et al.*, 2000; Peisner-Feinberg *et al.*, 1999).

The framing of school transition as a multiyear experience has occurred concurrently with the conceptualization of transition as a multifaceted process engaging a range of stakeholders (Graue *et al.*, 2002; Yeboah, 2003). The theoretical models of transition developed by Ramey and Ramey (1998), Fabian (2002), and Pianta and Kraft-Sayre (2003) share an ecological base that considers the interactions of factors in the child and family, the community, the school, and ECEC services. Conceptualizations of transition as both multiyear and multifaceted are also evident in recent investigations of the developmental trajectories of high-risk groups (Burchinal *et al.*, 2002). Such conceptualizations go well beyond earlier readiness issues toward a variety of ameliorating effects on educational disadvantage. Strategies include the provision of high-quality ECEC programs prior to school entry, high-quality educational programs in schools (Sammons *et al.*, 2008), and effective transition processes at a range of transition points.

Young children entering school undertake not only vertical transitions (from class to class) but also horizontal transitions, that is, across time within a class on any day (e.g., moving from general class lessons to specialist lessons such as music) or week (e.g., attending a regular kindergarten class part-time, a specialized class part-time, and an outside-school-hours care program). Horizontal transitions can pose challenges for children as they are added to other transitions in children's family lives and on vertical transitions (e.g., kindergarten into first grade) (Neuman, 2001). Children who are frequently withdrawn from their home classroom for learning support, additional language classes, extension programs, or behavior guidance may also spend undue time moving from place to place, thereby lowering their engagement in general classroom learning. Further, horizontal transitions between school and outside-school-hours care programs may involve substantial changes in expectations, location, relationships, and resourcing (Dockett and Perry, 2007).

Multiple transitions can cause stress by adding to the complexity of lives and increasing the chances of confusion (Neuman, 2001). Uncertainty about expectations in different settings has the potential to reduce the effectiveness of support programs and increase the likelihood of behavior challenges. Research that addresses the impact of multiple transitions is needed in order to guide policy development and educational practices. Teachers in the early years need to consider children's responses to multiple, overlapping transitions when planning curriculum and daily-program schedules.

Transition as a Dynamic Relationship-Based Process

Within both ECEC and inclusive education, dynamic, relationships-based transition processes have emerged, particularly in Europe (Niesel and Griebel, 2007). A key contribution of relationships-based approaches is their capacity to support young children and families who face multiple changes in their lives. The relationships considered include peer interactions, teacher–child relationships, family–school communication, linkages between teachers, and community involvement in the school. Within-school relationships have been the focus although wider support is now considered important (Dockett and Perry, 2007).

Studies of children's adjustment to school in Australia, New Zealand, and Europe have emphasized social and emotional issues, either because of the research emphasis on children from minority backgrounds with limited awareness of the rules and culture of schools or because of a perceived need to address academic readiness pressures from schools. There is some evidence indicating that teachers construct any atypical behavior of children who have delayed development or are from socially disadvantaged backgrounds as problematic (Skinner *et al.*, 1998). The contribution of social relations in the classroom and the playground, including both child–child and teacher–child relationships, appears to be vital not only to a child's social–emotional adjustment but also to academic achievement and self-esteem (Smith, 2002; Van den Oord and Rossem, 2002).

The continuity of children's friendships has been highlighted as important to a sense of security at school entry, meriting attention in class formation (Corsaro *et al.*, 2003). However, there is evidence that friendships alone do not necessarily make transition easier. Broader relationships issues require attention (Ledger *et al.*, 2000).

Greater involvement of the community in the life of schools is a feature of more extensive relationships-based transition processes. Community supports and connections that enhance bridging social capital improve the likelihood of successful transition to school (Dockett and Perry, 2007; Niesel and Griebel, 2007). Communities high in social capital may buffer and support children during transitions, through information networks, supportive webs of relationships, and reduction of social isolation for families facing challenges. Transition approaches that emphasize system-level coherence and integration of services reflect a democratic political view of transition as a community responsibility. This conception is powerful in government systems that emphasize more integrated national services, such as those in Scandinavian countries (OECD, 2006). In federated countries such as Australia and the US where ECEC and school policy and provision is segmented into separate federal, state, and local departmental jurisdictions (e.g., social welfare, education, and health), the community engagement challenge may be greater.

Child and Family Resource and Resilience

Reconceptualization of school transition has given rise to changes in the way successful transitions are determined and stakeholders are included. Successful school entry that was dependent on readiness as a maturational characteristic of the individual child, or a series of pre-academic skills, differs from more recent constructions of transition. Success is no longer defined solely as individual social and emotional adjustment and academic achievement against age-based curricula. Making successful transitions encompasses broader educational and personal purpose, taking into account the different participant groups (parents, teachers, and assistants) and learner diversity.

With greater recognition of differences in children's initial adjustment success at school entry, problems such as medium-term fade-out in achievement by some children over time, and the evidence of long-term improvement in broad life outcomes from effective ECEC programs, there is greater attention to the complexity of transitions.

It seems clear that successful transitions are important to ongoing progress, lifelong learning, and meaningful participation. There is an interest at this time in a new century to set more positive developmental trajectories for all children. Some shift in images of children from vulnerable toward competent has been accompanied by shifts in transition approaches from those emphasizing deficit and needs to those focused on personal and cultural resources and resilience (Dunlop, 2007). It is seen as important to capitalize on the resources children bring to the school in the transition process, ensure effective communication and collaboration with families and communities, and enact an outward-looking approach in both schools and communities.

Conclusion

Expectations of homogeneity in school entrants are giving way to recognition of the diversity in young children, families, and communities. Contemporary constructions of transition recognize the potential for child and family diversity to enrich teaching and learning. There is a focus on inclusive policies and a recognition that homogeneous classes of children ready for school entry denies the reality of young children's developmental, cultural, and linguistic diversity. A focus on single-transition issues such as teacher practices or time-limited change events has given way to more complex, multifaceted views incorporating a variety of transition points and a range of stakeholders. Studies of successful transitions now take into account long-term trajectories as well as initial adjustment to the school context. Alongside expanded conceptions of transition have come questions related to the coherence of curriculum, pedagogy and service

systems, and of authentic partnerships between families, communities, schools, and ECEC services.

There is also a persistence of attention to child-level readiness and preparedness at a policy, school, and community level. Teacher beliefs, public perceptions, and policy formation are resistant to change, and provision of universally accessible, high-quality ECEC programs confronts the continuing challenge of mechanisms that allow all children, including diverse minority groups, to succeed.

Glossary

Effect size – A number representing the magnitude of an effect in standard deviation units. One of the most common statistics for reporting effect size is known as Cohen's *d*; scores from 0 to 0.3 are considered small effects, 0.4 to 0.6 moderate, and 0.7 to 1.0 large.

Early childhood is a time of special vulnerability and opportunity. Because young children are particularly sensitive to environmental inputs, characteristics of early experiences, including the quality of parent–child interactions and home environments, potentially may have effects that last well into adulthood. Due to the importance of the early years and the fundamental role that parents play during this time, an abundance of research has focused on highlighting the specific ways in which parents influence their children. As a result, the notion that children's outcomes can be improved by altering parenting practices has become the fundamental belief at the core of parent-education programs.

Although parenting programs share a common goal of improving parental capacity in order to positively affect children, programs greatly differ with regard to their methods, staff, and the domains in which outcomes have been observed. Some are home based, while others consist of group meetings, child care, or combinations thereof. Qualifications of program staff range from paraprofessionals to public health nurses or social workers. Over the last several decades, as parenting programs have been implemented around the world, different patterns of results have been observed depending on the characteristics of the program and families served.

We now turn to a review that represents the wide variation in parenting programs, with international perspectives on parent training and supports for low-income families. The review has been organized to offer comparisons of programs around the world with similar programs in the United States. In order to focus the discussion on program effectiveness, we only consider outcomes within three domains: maternal parenting (warmth, sensitivity, and reduced harshness), child health, and children's

cognitive and social development. Whenever possible, we report Cohen's *d* to indicate effect sizes for significant findings.

Early Start and Healthy Families

Early Start, New Zealand

Early Start is a parenting support program in Christchurch, New Zealand that is part of the larger network of family support programs throughout the country. The program provides home-based services to families of infants and young children under age 5, with enrolment just after birth. Based on the Healthy Families America (HFA) model, those who are at the highest risk for poor parenting receive the most home visits, averaging an hour per month for up to 2 years. Services provided by trained family support workers (FSWs) balance the limitations and strengths of each family. FSWs who conduct the home visits have degrees in nursing or social work, and receive additional program-specific training. The program aims to build positive relationships, problem-solving skills, and provide support and advice to families throughout the preschool years (Fergusson *et al.*, 2005).

The randomized trial of Early Start included 443 families who were evaluated at 6, 12, 24, and 36 months after program enrolment. A number of significant effects were observed with respect to maternal parenting and children's health and development, with small to moderate effect sizes ranging from 0.03 to 0.31 (Fergusson *et al.*, 2005). Early Start families reported more positive and nonpunitive maternal parenting attitudes relative to control families. Children in treatment families were more likely to have had regular doctor and dental visits and had fewer accidental injuries than children in the control group. Early Start children also exhibited fewer behavior problems, particularly in the area of internalizing (Fergusson *et al.*, 2005).

Healthy Families America

After being initially developed in Hawaii, the HFA program has expanded throughout the US and Canada with help from Prevent Child Abuse America. The primary goal of HFA is to prevent child abuse and neglect by providing home-based supports to mothers of young

children. Trained paraprofessionals provide home visits to families who are considered at risk for abuse or neglect until the child is 5 years old or begins preschool.

Despite its popularity and fairly widespread implementation, randomized trials of HFA have identified few benefits associated with home-visiting services. In the initial evaluations of Hawaii Healthy Start, no significant program effects were found for either parenting behaviors or children's development. However, the evaluation of HFA in New York State has shown relatively small effects on mothers' use of harsh parenting. The observed effects were stronger for the most at-risk subgroups in the sample (DuMont *et al.*, 2008).

Early Start has roots in the HFA program. A key similarity is that families are screened for eligibility and offered services on the basis of family risk. Although both utilize home visiting as the method of service delivery, they differ in home-visitor qualifications. In HFA, paraprofessionals provide home visits, whereas in Early Start, visits are conducted by nurses or social workers. This probably accounts for the different pattern of results observed across programs.

Jamaican Home-Visiting Programs and Nurse–Family Partnership

Home Visiting, Jamaica

While many early education programs in developing countries contain parenting education components, few have been rigorously evaluated. In the 1970s, Powell and Grantham-McGregor began empirical tests of home-visiting programs for low-income families in urban areas of Jamaica. The programs aimed to improve early child development while teaching mothers more effective parenting skills; variations were based on program design (i.e., frequency of visits). Performed by paraprofessionals who were supervised by nurses at local health care centers, home visits typically focused on enhancing mother–child interactions and the self-esteem of both mothers and children. Home visitors modeled different ways for parents to engage their children through culturally relevant language, games, songs, and art activities (Powell and Grantham-McGregor, 1989).

Each separate home-visiting program was associated with beneficial effects for children's development. However, greater frequency of home visits was associated with the most positive outcomes. In one randomized study of 56 families who either received weekly home visits or were assigned to a control group, home-visited children displayed significantly higher scores on developmental tests 1 year after the intervention concluded. Despite the small sample, effect sizes were large in magnitude (0.52–1.09; Powell and Grantham-McGregor, 1989). Measures of maternal parenting were not examined, although parenting

was the hypothesized pathway by which children's development was impacted.

Nurse–Family Partnership, United States

The Jamaican home-visiting programs were not explicitly based on an American program, but they were similar to the Nurse–Family Partnership (NFP) – one of the most extensively tested home-visiting programs in the United States. The NFP employs public health nurses as home visitors in order to improve pregnancy outcomes, maternal economic self-sufficiency, and children's health and development by helping low-income parents provide sensitive and competent care. The first trial of NFP began in 1977 in Elmira, New York with a sample of primarily rural, white women. The Elmira study demonstrated long-term benefits of the intervention, but most effects were concentrated in the highest-risk subgroups (i.e., poor, single mothers). In particular, at the 15-year follow-up, nurse-visited families evidenced a 48% reduction in state-verified reports of child abuse and neglect. Although there were no other significant effects on maternal parenting or children's development, the 15-year follow-up also showed that adolescents of poor, single mothers who had received home visits had fewer arrests (0.20 vs. 0.45; $p = 0.03$) and fewer convictions (0.09 vs. 0.47; $p < 0.001$) than their counterparts in the control group (Olds *et al.*, 1999).

Two replications of NFP have been evaluated in Memphis and Denver. The Memphis sample included higher proportions of urban, African-American parents, whereas the Denver sample included more adult mothers. The pattern of results has largely been inconsistent across the three trials. Although both the Elmira and Memphis trials found evidence for fewer hospital visits for child injuries or ingestions (Olds *et al.*, 1999), this effect was not replicated in Denver. However, Denver was the only site that identified a benefit in terms of children's language skills ($d = 0.31$ at age 4; Olds *et al.*, 2004). A vast majority of program effects for NFP were isolated to the most vulnerable families within each site.

Since the use of public health nurses as home visitors is a central component of the NFP program, the relative effectiveness of nurse home visitors and paraprofessionals was examined in the Denver study. Although families who received home visits from paraprofessionals, in general, fared better than controls, nurse home visitors were associated with the most benefits (Olds *et al.*, 2002). Similarly, the Jamaican studies showed that nurse home visitors were associated with large benefits for children in the treatment group, relative to controls (average gain of 13 points on a developmental index). Since the effects with nurses were so large, subsequent programs employed paraprofessionals – resulting in smaller, but still significant, effects and a more cost-effective program that could be scaled to reach more families (Grantham-McGregor and Desai, 1975).

Sure Start and Early Head Start

Sure Start, United Kingdom

In 1999, the UK government initiated the Sure Start program as an early intervention strategy aimed at reducing child poverty and social exclusion (to address both financial hardship and access to civil, political, and social rights; Aber *et al.*, 2002). In order to limit social stigma associated with targeting less-advantaged individuals within communities, Sure Start was provided to all families with children under age 4, who lived in selected disadvantaged districts (Rutter, 2006).

Within the broad family of programs that comprised Sure Start, the government mandated provision of community-based supports for participating families and children, including outreach, home visiting, and quality child care and healthcare, with an emphasis on providing supports for families of children with special needs. Each Sure Start Learning Program (SSLP) had the autonomy to work with surrounding communities to improve existing services and create new initiatives where gaps existed. As such, SSLPs initially did not have prescribed curricula or standard services; individual programs greatly varied in implementation, content, and quality (Rutter, 2006).

The first phase of the National Evaluation of Sure Start was based on a nonrandomized, cross-sectional design in which 150 of 260 SSLP areas were randomly selected and compared to 50 areas waiting to be designated as SSLP. After less than 3 years of program participation, study families were randomly selected based on whether children were 9 or 36 months of age resulting in approximately 14 000 9-month-old and 5000 36-month-old children and their families. The evaluation focused on the effects of SSLPs on community service utilization, family functioning, child development outcomes, and program effectiveness (Belsky *et al.*, 2006).

The results showed small or nonsignificant effects of SSLPs on supportive parenting and child behavior. Among families of 9-month-olds, those in SSLPs displayed less household chaos than controls ($d = 0.14$). However, in some cases, Sure Start had adverse effects on the most-disadvantaged 3-year-old children and their families (Rutter, 2006). For example, children from unemployed and single-parent SSLP households scored lower on verbal ability than their non-SSLP peers (Belsky *et al.*, 2006).

From 2004 to 2006, SSLPs evolved into Sure Start Children's Centers, signaling a clearer set of program goals and more systematic services for families. With the maturation of Sure Start programs, a second phase of the National Evaluation was undertaken with a quasi-experimental comparison of 5883 families residing in 138 Sure Start areas to 1879 participants from the Millennium Cohort Study who resided in demographically similar, non-Sure-Start areas (Melhuish *et al.*, 2008). The results of the second phase of evaluation were more favorable than the first.

After 3 years of program exposure, children demonstrated more positive social behavior ($d = 0.19$) and greater self-regulation ($d = 0.17$) than nonprogram children. Parents in Sure Start areas also exhibited fewer negative parenting behaviors ($d = 0.44$) and provided more stimulating home-learning environments than comparison parents ($d = 0.27$). Further, the effects on parenting partially mediated the effects of Sure Start on children's social behavior (Melhuish *et al.*, 2008).

Early Head Start

Implemented 4 years prior to Sure Start in 1995, Early Head Start (EHS) was created by the US federal government to serve pregnant women and children under age 3 in disadvantaged populations (initiated in 1965, Head Start serves 3- and 4-year-olds and their families). In order to best tailor services, Early Head Start performance standards provide four program options—home based, center based, a combination of the two, or locally designed alternatives. The home-based programming includes weekly home visits and biweekly group meetings, while the center-based model incorporates center-based care and education with at least two annual home visits (Love *et al.*, 2005).

More specific than Sure Start's core components, the EHS performance standards mandate that programs explore language and culture; encourage parent involvement and positive consistent relationships with children; and promote healthy development along with early detection and prevention of developmental concerns. EHS is required to serve children with disabilities; facilitate smooth transitions into Head Start; and collaborate with other providers in order to enhance services (Love *et al.*, 2005).

With evaluation built into the federal program since its conception, a randomized control trial began in 1996 with a diverse sample of 3001 low-income families in 17 programs from urban, suburban, or rural communities. Overall, the study demonstrated positive, but small, effects of EHS participation for parenting and children's cognitive, language, social, and emotional development at 3 years. Parents who received EHS services were more emotionally supportive than control parents, demonstrated greater warmth, and provided more language and learning stimulation ($d = 0.15$, 0.09 , and 0.10). While EHS had smaller impacts on hostility and insensitivity, parents who participated in the program were less likely to use physical punishment as a means of discipline ($d = -0.14$). EHS children performed significantly better than controls in both cognitive and language development ($d = 0.10$ – 0.13). The children also scored higher on emotional engagement and sustained attention and lower in aggressive behavior ($d = 0.20$, 0.16 , and -0.11). The greatest impacts were in programs that offered a mix of home-visiting and center-based services that fully implemented EHS performance standards (Love *et al.*, 2005).

Despite being based on EHS and Head Start, the results of Sure Start were not as positive as those seen in the US. The main reason for the differences is likely due to the greater specificity of EHS services. Since Sure Start was so flexible across areas, different patterns of success likely emerged in different regions. Differences in treatment may have only been exacerbated by not having a randomized comparison group for examining program effectiveness, as was the case with EHS. However, results from smaller studies of Sure Start within particular areas, which used a set curriculum, yielded more positive results. We now turn to a discussion of the Incredible Years, and the results associated with it in Sure Start areas in Wales.

The Incredible Years

The Incredible Years is a prevention-oriented intervention that has received extensive empirical support for changing parenting practices that lead to reductions in child behavior problems. The program trains parents in positive communication and child-directed play skills, consistent and clear limit setting, and nonviolent discipline strategies. The Incredible Years promotes parental self-care, social and emotional child development, and secure attachment, while educating parents on how to teach children problem-solving skills and anger management (Barth *et al.*, 2005). The curriculum for Incredible Years parent programs is based on child age: babies and toddlers (0–3), Basic early childhood (3–6), Basic school age (7–12), and Advance (6–12). The Advance curriculum is an adaptation of the BASIC school-age program that has a special emphasis on problem solving, anger management, and support systems. Employed in different populations within New Zealand, Canada, Norway, the United States, and the United Kingdom, modified Incredible Years videos are available that are diverse in terms of ethnicity and language (Webster-Stratton, 1994).

The Incredible Years, Wales

In Wales, a randomized trial was conducted based on 11 programs that implemented the Incredible Years Basic within the Sure Start framework. In contrast to the results of the first phase of the National Sure Start Evaluation, this study showed benefits for Sure Start families relative to controls in terms of both positive parenting practices and fewer behavior problems for children (Hutchings *et al.*, 2007), suggesting the benefits of utilizing a systematic, evidence-based curriculum. Specifically, the evaluation demonstrated significant improvements in positive parenting ($d = 0.57$), decreases in child antisocial behavior and hyperactivity ($d = 0.30$ and 0.41), and increases in child self-control ($d = 0.38$) for those who had participated in Incredible Years (Hutchings *et al.*, 2007).

The Incredible Years, United States

Providing additional support for The Incredible Years model as an approach to altering parenting practices, randomized controlled trials with Head Start populations in the United States have demonstrated that harsh discipline and criticism were reduced ($d = -0.27$ and -0.18) and positive parenting behaviors were enhanced ($d = 0.17$) after program completion (Reid *et al.*, 2001). Parents who participated in The Incredible Years Advance Program showed increases in marital problem solving and their children improved in social problem solving as compared to controls and to those who received the Incredible Years Basic, with most effects retained for at least 1 year (Gross *et al.*, 2003).

Home Instruction Program for Preschool Youngsters

Founded on the belief that parents are children's first teachers, Home Instruction Program for Preschool Youngsters (HIPPY) was created at Hebrew University in the late 1960s. Over the past decades, HIPPY has spread to 12 countries, serving more than 22 000 families worldwide, and has built an international support network providing program-related services, including curriculum development and coordination of research efforts. HIPPY parenting education follows a coordinated approach employing local coordinators to train paraprofessionals who, in turn, use role-playing methods to educate parents (Westheimer, 2003). HIPPY strives to enhance home literacy environments, parent-child communication, and parental ability to support early learning, using a 2-year structured curriculum targeted to 4- and 5-year-olds. There are two core elements of the program. First, home visits by paraprofessionals and group meetings with parents, paraprofessionals, and local HIPPY coordinators occur on alternate weeks. These sessions include role-playing, sharing questions and concerns, meeting other parents, and enrichment activities such as presentations by school officials. Second, HIPPY includes 30 weeks of educational activities for parents to complete with their children. Age-appropriate materials are designed to support language, sensory, and perceptual development, as well as the visual-motor coordination and problem-solving skills that children need to succeed in school (Baker *et al.*, 1999).

Introduced in the United States in 1984, HIPPY-USA has program sites in 25 states and the District of Columbia. The primary US evaluation involved two cohorts of HIPPY and comparison families at sites in New York City and Arkansas. In New York, a diverse sample of 182 low-income families was recruited across both cohorts of the randomized control trial. As the Arkansas trial was quasi-experimental and replicated the New York results, we report only outcomes from the New York evaluation (Baker *et al.*, 1999). With effect sizes ranging from 0.56

to 0.76, children who participated in HIPPY performed significantly better on measures of cognitive skills in kindergarten, reading comprehension at the end of first grade, and classroom adjustment in first and second grades. However, these findings were not replicated in the second cohort and subsequent analyses could not account for the differences in results. Although data regarding parent participation are not available, it has been suggested that cohorts differed in the level and quality of parental engagement (Baker *et al.*, 1999).

Turkish Early Enrichment Program

In Turkey, the HIPPY curriculum has been incorporated into a larger program known as the Turkish Early Enrichment Program (TEEP). TEEP focuses on families with children ages 3–5 to promote cognitive and socioemotional development through maternal education. Paraprofessionals conduct home visits and group meetings in order to model strategies for active engagement with children. The program also seeks to cultivate human capital by building agency and communication skills in mothers (Kagitcibasi *et al.*, 2001).

The randomized longitudinal evaluation included 255 families who were studied over a period of 4 years and then followed up 6 years later. In the first year, baseline data were collected, then mothers were randomly assigned to treatment ($n = 90$) and control groups. In the second and third years, mothers in the treatment group participated in a 60-week, home-based training that used HIPPY materials and focused on maternal support and child cognition (Kagitcibasi *et al.*, 2001). In the fourth year, parent and child outcomes were evaluated.

Children whose mothers had received TEEP training had higher intelligence quotient (IQ) scores than children in the control group ($d = 0.55$). However, the picture regarding academic achievement and grades was more mixed. Treatment group children scored higher on tests of general ability ($d = 0.27$), but not on math or Turkish. The effects on grades were moderate among 5-year-olds ($d = 0.36$ – 0.47). Program mothers reported higher levels of self-efficacy because they were able to act as their children's teachers and interact more effectively with their children by being less punitive, more responsive, and more cognitively stimulating. Program effects were also observed at a 6-year follow up with superior academic performance among children in the treatment group ($d = 0.43$ – 0.47 ; Kagitcibasi *et al.*, 2001).

Parenting Support and Education: Lessons Learned

The picture that emerges when taking a broad view of parenting education and support programs is that the

effects are neither strong nor consistent across programs, domains, or even within programs. Some programs, based on similar models of intervention, find very different patterns of results. For example, while the NFP showed minimal effects on children's development, the Jamaican Home-Visiting programs showed large effects. However, the NFP results were strongest among the most high-risk families in the sample. Similarly, Jamaican families were at such high risk that even scaled-back versions of the intervention produced significant effects. In another case, the reason that Early Start in New Zealand showed more positive effects than HFA is likely due to the fact that despite utilizing the same program model, HFA employed paraprofessionals to deliver the intervention, whereas Early Start used nurses and social workers.

The programs with the fewest overall effects were those that lacked a strong theoretical model tied to the curriculum. Sure Start, with its flexibility to meet the needs of individual communities, produced very few results. Similarly, one of the reasons that Early Head Start has shown few effects is likely also due to its lack of a clear focus as the program was implemented around the country. The Incredible Years demonstration in Wales clearly showed that the Sure Start model had stronger effects when a specific curriculum was put in place than when no structured curriculum was utilized. Similarly, the theoretically based HIPPY curriculum has been associated with benefits for children and families in Israel, the United States, Turkey, and in several other countries. The differences in programs and their effectiveness can be translated to unique points of consideration for future research on parenting education and support programs.

The majority of the programs that were discussed in this review have been conducted on a large scale. One potential problem in offering services broadly is that relatively swift program expansion without adequate resources can hinder quality as well as impact. Bringing programs to large-scale implementation can pose challenges to maintaining fidelity and consistency in program quality, especially when a component of program effectiveness is flexibility. This was one of the primary problems of Sure Start – programs were rolled out across the country without a clear structure or plan. In contrast, the NFP programs have been slowly adding program sites in order to expand services, at the same time maintaining quality and strict adherence to the program model.

Another important consideration in applying research on parenting programs is understanding the cultural context in which the program was designed and will be applied. Research has suggested that although culturally adapted parenting programs may have positive effects, the effects may be reduced or observed in different domains than what would have been identified in the original program (Kumpfer *et al.*, 2002); caution is warranted when attempting to transfer intervention programs across cultures. It may be

that programs are not carried out in exactly the same manner in different contexts, or that they are experienced differently by families from different cultures. One of the reasons that programs such as HIPPY and the Incredible Years have been successful in different contexts is that adherence to their theoretical models was not compromised while cultural adaptations were made.

It is important to recognize that the research on parenting programs does not suggest a one-size-fits-all approach. Even so, tailoring programs to the needs of families within a specific community should not outweigh the importance of utilizing specific curriculum and targeting specific behaviors. The research on parenting programs to date shows that the most effective programs are those that target families with specific needs and use theoretically driven curriculum to enhance family and child functioning. Although most parenting programs have stronger effects on parenting practices than on children's development, it remains to be seen how the effects of parenting may continue to positively alter the child's experience into adolescence.

Glossary

Early-learning guidelines – The documents that describe standards for what children should know and be able to do before they enter grade school/ kindergarten. Most commonly refer to standards for very young children (infants and toddlers), see also Early learning standards.

Early-learning standards – The documents that describe standards for what children should know and be able to do before they enter grade school/ kindergarten. These are sometimes called early-learning guidelines.

Early Learning Standards (ELS) – documents that define expectations for what children from birth through to age 5 should be know and be able to do – are increasingly common in the United States. Since the beginning of this century, every state in the country as well as the District of Columbia has developed ELS for preschool-age children. A majority of states have – or are developing – similar documents for infants and toddlers. This article explains why ELS have become so common within the field of early care and education in the United States, how the documents have been developed, the content that has been included in the ELS, and how they are being implemented.

The Momentum of the ELS Movement in Early Care and Education

Standards-based education has been the norm within the United States' K-12 education arena – the educational system

serving older children – for almost two decades. Starting in the late 1980s, states developed standards to define what teachers should teach, what students should learn, and what should be assessed to determine the degree to which schools have been effective in helping students learn the content articulated in the standards. For several years, the early-care and education field was excluded from the effort to define standards for what children should learn, but this changed shortly after the turn of the century. Educators and policymakers began to focus their attention on developing ELS for use with children before they enter the K-12 education system.

The shift to developing ELS for younger children emanated from four developments:

1. extension of the standards-based education movement downward to younger ages;
2. increasing investments of public funds in services for young children, which led policymakers to ask what child outcomes should be expected from the public investments in early care and education;
3. increasing recognition of the potential benefits of early care and education in closing the achievement gap noted among children who enter school behind their more advantaged peers; and
4. increasing knowledge – with regard to the capabilities of young children – gained through research and articulated in seminal publications such as *Eager to Learn*, a report prepared by the United States Department of Education and published in 2001.

Taken together, these factors created a climate that was ripe for work on ELS, and the federal government added to the momentum by introducing the Good Start, Grow Smart early-childhood initiative in 2002. The Bush Administration's Good Start, Grow Smart initiative directed states

to include plans for developing voluntary early-learning guidelines in the areas of language and early-literacy skills as part of their plans for their Child Care Development Funds (CCDF), the plan states submit to describe how they are using childcare funds received from the federal government. Good Start, Grow Smart specified that these voluntary early learning guidelines should be aligned with K-12 standards and should be written in a format that would be applicable in various childcare settings. A combination of policy-related developments – combined with developments within the field of education – led states to develop ELS.

The momentum to develop ELS was not, however, without critics. Standards to define what very young children should know and be able to do seem inherently at odds with several long-standing tenants of early-childhood education. First, it has long been recognized that development at this age proceeds in an uneven and episodic manner. Individual children, typically, develop faster in some areas of development than others, and their development may proceed unevenly – with periods of rapid progress, followed by periods where their development seems to lag or not progress rapidly. Furthermore, children's development is highly influenced by their environment and their experiences – which vary tremendously from one child to another. Children who experience an enriched environment where they are exposed to stimulating materials and interactions at home and/or in an early-care-and-education setting will exhibit vastly different progress than children who experience impoverished or unstimulating environments. Given the high degree of variability expected in children, critics wondered how ELS that define uniform expectations for children's development could be written, and pointed out great potential for misuse of the documents. Some educators feared that standards to define expectations for children's learning and development before they enter kindergarten would be used inappropriately to make judgments concerning individual children or to keep children who do not demonstrate that they have met the standards from entering kindergarten.

ELS also seemed to be at odds with traditional early-childhood pedagogy – which emphasizes individualized learning experiences planned for children based on observations of the children's interests and their current knowledge and skills. Critics wondered if the rich tradition of developmentally appropriate practices – based on the tenets of learning experiences that are individually, culturally, and developmentally appropriate – could continue in a standards-based education approach. While the field has accepted the importance of program standards to define basic requirements for the services provided through early-childhood programs, the idea of using ELS to define what children should learn seemed counter to traditional early-childhood pedagogy. Some educators

worried that early-childhood curricula would become increasingly focused on academic skills, giving less attention to the developmental orientation and leaving little room for individualization.

Despite these concerns, many educators within the field recognized the potential benefits of high-quality ELS that are implemented appropriately. ELS that define appropriate expectations for young children can be used to educate teachers/caregivers with regard to child development, to engender more intentional teaching practices, to establish credibility and the importance of learning that takes place before children enter school, and to offer common goals that could be shared across the many different types of programs serving children before they enter school. Recognizing the tremendous potential benefits as well as the potential risks of ELS, two national organizations joined forces to call attention to the importance of ELS and provide guidance on issues related to ELS. In 2002, the National Association for the Education of Young Children (NAEYC) and National Association of Early Childhood Specialists in State Departments of Education (NAECS/SDE) published a position statement to guide states as they develop ELS. The position statement addresses the process that should be used to develop ELS, the content of such standards, and how the standards should be used.

Development of ELS in the United States

There has been a tremendous momentum toward developing ELS within the United States. Whereas in 2002, only 27 of the 50 states had published ELS documents for preschool-age children, in 2008, all 50 states, plus the District of Columbia, had published ELS for preschool-age children. What is more, the momentum has spread to programs serving younger children. While, in 2002, only four states had ELS to define expectations for infants and toddlers (most commonly called Early Learning Guidelines for children at this age), in 2008, 22 states had developed infant-toddler ELS and ten were in the process of developing such documents. By the close of 2009, all 50 states and the District of Columbia will have ELS for preschool-age children and well over half of the states will have infant-toddler ELS. This section provides information on how these documents have been developed and the resources that are available to states as they develop ELS.

ELS Development Process

In 2002, a national study was conducted to collect data on how states were developing their ELS. The authors

interviewed multiple informants from each state to collect data on the standards-development process. Results indicated that the process varied from state to state, but that most could be described as highly collaborative and lengthy.

States varied in their reasons for initiating the standards-development process. In nine states, there was a legislative mandate to develop ELS, and in four states, there was a directive from the state's department of education (the agency responsible for the K-12 education system). In 14 states, the process did not begin with a mandate from the legislature or a governmental agency, but emerged because early educators felt the need for ELS. In some cases, respondents indicated that starting the ELS-development process was a preemptive move. Early educators in their state believed that a mandate for ELS was forthcoming from policymakers and started the process in order to be proactive and have more control over the process than they would if they were responding to a mandate.

Irrespective of how the process started, most state respondents noted that, as the standards development work unfolded, it was inclusive of stakeholders. Committees were formed that included representatives from the state's department of education, local school districts, department of social services, higher education faculty, parents, content experts from a variety of disciplines, and resource persons – such as children's librarians. Respondents indicated they felt it was important to include a wide array of stakeholders in order to ensure that the ELS reflect the values and priorities of their own state. Furthermore, typically states engaged the public in the development process – seeking input via open forums and public hearings. Input from parents took different forms – with parents engaged in committee work in some states and serving on advisory committees or participating in focus groups in others.

Respondents to the survey reported that the typical timeframe for the ELS development process was 1–2 years, with one state reporting that it took 5 years for them to develop their ELS. Given the number of stakeholders involved and the complicated nature of the task, it is not surprising that the development of ELS required a lengthy process. The ELS-development process also required significant resources – both in terms of personnel time and financial support. Although respondents from three states indicated that there were no funds earmarked for standards development, the majority of states did procure financial resources to support the process. Typically, states combined funds from several sources – often using the federal Child Care and Development Block Grant (CCDBG) and Individuals with Disabilities Education Act (IDEA) funds. The state's department of education was the most common source of funding cited for the development process, and some states used private sources of funding – such as grants from foundations or corporations.

Resources Used to Develop the Content of ELS

State work-groups, typically, consult a variety of resources when developing their ELS. The mostly commonly cited resource is the state's own K-12-standards document. ELS-development committees consult their state's standards for kindergarten as they develop the ELS for prekindergarten-age children to promote consistency between expectations for prekindergarten-age children and kindergarten-age children. State committees developing ELS also review the work of various developmental theorists, national frameworks or standards, such as the Head Start Outcomes Framework, the work of the National Education Goals Panel, and publications from the National Association for the Education of Young Children as they define ELS. In addition, committee members developing ELS, often, seek to learn what other states have addressed in their ELS. Committees writing ELS, often, look at ELS documents from another state, and, sometimes, use standards from other countries or provinces – particularly British Columbia – as examples.

A number of other resources are available to states that are developing or revising the content of their ELS. Starting with the NAEYC/NAECSSDE position statement, in 2002 (NAEYC & NAECSSDE), various national organizations have developed resources to assist states as they write or revise their ELS documents. The Council of Chief State School Officers (CCSSO) maintains a website that catalogs standards developed by each state and provides online linkages to each state's document. The National Center Child Care Information and Technical Assistance Center (NCCIC) also posts lists of ELS from states and has developed several documents to describe issues ELS writers might need to address. Zero to Three convened a national panel of experts to offer guidance to state agencies developing infant–toddler ELS. The resulting document – entitled *Early Learning Guidelines for Infants and Toddlers: Recommendations for States* – is available on the Zero to Three website. As the number of states that have published ELS documents has increased, so too has the number of resources available to support the development process. Websites for these resources are listed at the end of this article.

The Content of ELS Documents

The advent of ELS is a relatively new development within the field of early care and education in the United States. Given the potential use of the documents in early-care and education programs, it is important to understand the content of these documents. Two studies have been conducted to examine the content of ELS. One looked at the content of ELS written for

preschool- or prekindergarten-age children, and the second study examined the content of ELS written for infants and toddlers.

The Content of Preschool ELS

Content analyses were conducted on 46 ELS documents published as of January 2005. An analytic framework that explicated various elements of development and learning within five developmental domains – physical and motor development, social and emotional development, approaches toward learning, language and communication development, and cognition and general knowledge – was used to analyze the content of the ELS documents. Each individual standards item within each of the ELS documents was coded according to where the content of the item fit on the analytic framework. The percentage of ELS items coded for each of the five developmental domains, and for specific indicators within each domain, was then calculated and analyzed.

States have, generally, focused more attention on two domains of learning – cognition and general knowledge, and language and communication. On average, approximately 40% of states' ELS items addressed children's cognitive development and knowledge they need to acquire about the world. ELS coded within this category included children's knowledge of factual information such as naming colors, mathematical skills, and their knowledge of social conventions. By far, most of the ELS items coded within this domain addressed knowledge of the physical world and knowledge related to mathematics. On average, approximately 30% of the ELS items addressed the language and communication domain – which includes skills and knowledge related to receptive and expressive language development and early-literacy development. The ELS standards within this domain most frequently addressed children's social uses of language, their writing skills, and their knowledge of print.

ELS written for preschool-age children have also addressed the remaining developmental domains (physical development, social-emotional development, and approaches toward learning), but to a lesser extent. The physical development domain was addressed least often, with only about 8% of the ELS items addressing this domain. Social-emotional development and approaches toward learning have been addressed to a greater extent, but each of these two domains account for only ~11% of the ELS items. Within the ELS items written for children's physical development, the vast majority addressed children's motor development. Social skills with peers, emotional expression, and self-concept were most commonly addressed within the social-emotional domain. Within the approaches toward learning domain, states have most often addressed children's ability to reflect and interpret information, their curiosity, and their creative abilities.

The Content of Infant-Toddler ELS

Similar analyses were conducted on 21 infant-toddler ELS documents to examine the content of ELS written for infants and toddlers. The analytic framework used for the preschool-age ELS-content analyses was modified significantly to reflect the learning and development of infants and toddlers. Each of the ELS items written for infants and toddlers was coded according to where it fit on the framework, and then percentages were calculated in the same manner as they were in the preschool ELS study.

The content of the infant-toddler ELS items included in the analyses was relatively balanced across four of the five developmental domains. The mean percentage of ELS items coded as physical development, social-emotional development, language and communication development, or cognitive development, ranged from 20% to 25%. The balance of ELS items across the four domains differed, however, by the age for which the ELS were written. Physical and social-emotional development tended to be emphasized more heavily in ELS written for children ages birth through 18 months, while language and communication and cognitive development were the domains emphasized most within ELS written for children ages 19–36 months.

Far fewer ELS items addressed children's approaches toward learning within the infant-toddler ELS documents. On average, only about 5% of the ELS items addressed children's approaches toward learning. It is unclear why the state ELS for infants and toddlers have not addressed the approaches toward learning domain to the same extent as other domain areas. It is possible that the committees developing the infant-toddler ELS did not see children's approaches toward learning – characteristics such as interest in the environment, persistence, and problem solving – as important for children of this age, or perhaps they considered these types of skills as so much a part of the development of children of this age that they did not need to address this area in the ELS.

Implementation of ELS

State agencies develop ELS with the intention of improving the quality of care and education children receive in various early-education settings. By defining the skills and knowledge that are important for young children, ELS developers hope to improve the knowledge and skills of teachers, and engender more intentional teaching in early-education classrooms. To this end, state agencies that develop and implement ELS intend for teachers to use the documents in their curriculum planning. Prekindergarten programs operated with state funding are

most commonly required to use the ELS. States have also promoted the use of early-learning standards in a number of other programs, including private childcare, Head Start, IDEA programs serving children with disabilities, and Even Start family literacy programs, but the use of the ELS in these programs is typically on a voluntary basis. States make the documents available to other programs and encourage them to use the ELS, but, most often, it is the state's pre-kindergarten programs that are required to use them.

In addition to requirements that programs use the ELS, state agencies have developed various types of resources to support teachers in their efforts to use the documents. New in-service training initiatives have been developed to introduce teachers to the content of the ELS, and more in-depth training has been developed in many states to teach teachers how to use the ELS to plan intentional, goal-directed learning activities for children. Several states have also developed online and print resources to help teachers and administrators learn about the ELS. Often known as a Tool Box, these materials provide teachers with access to information with regard to the ELS and with suggestions on how they can use the ELS. Several states have developed resources for parents. These documents are intended to help parents understand the content of the ELS, and to learn how they can help children make progress in the areas of child development described in the ELS.

The ELS have also been incorporated into the preservice professional development provided in many institutions of higher education. Early-childhood teacher-education programs have incorporated the documents into courses, with some faculty using the ELS as a required or recommended textbook in their courses and others requiring that students use the ELS in the lesson plans they write as part of their course assignments or practical experiences. One relatively new development within the field of early care and education is the advent of standards that define what teachers should know and be able to do in order to teach effectively. These documents – generally known as professional competencies – articulate the content knowledge, pedagogical knowledge, and skills that the state requires of teachers in order to be credentialed. To encourage the use of the ELS in preservice professional development, more than half of the states have developed or revised their professional competencies based on the content of the ELS. Teachers are required to learn about the ELS and to demonstrate teaching skills that will help children make progress in the areas described within the ELS. ELS have become a central component of the in-service and preservice professional development offered in many states, and are being used to define requirements for the competencies teachers are expected to demonstrate.

Summary

ELS are a recent and important development within the early-care and education system within the United States. Within the past decade, all 50 states have developed ELS for preschool-age children and over half of the states have similar documents to define expectations for infants and toddlers. States have invested significant efforts in developing these documents, convening stakeholder groups to develop standards and collecting public input on draft documents. The content of preschool-age ELS tends to focus more attention on content related to children's knowledge about the world and their language and literacy development. The content of infant-toddler ELS is more balanced across the developmental domains, with roughly equivalent numbers of standards to address children's physical, social-emotional, language, and cognitive development.

ELS are an important component of efforts to improve the quality of programs serving young children. States have developed in-service training and are incorporating ELS into courses offered in institutions of higher education to teach teachers and caregivers how to use the ELS in their curriculum planning. The hope is that using ELS can improve the quality of teaching and learning in early-childhood-education settings by engendering more intentional teaching practices to address the content of the standards.

Along with these developments within the United States, ELS are increasingly common in countries around the globe. It stands to reason that the content of ELS developed by different countries may vary, but the purposes of the documents may be common across the countries. ELS are viewed as a strategy to help adults foster the skills, knowledge, and characteristics within children that are valued and expected. As such, they have great potential to shape the course of early care and education in the United States and around the world.

Glossary

Early childhood development – The age span below 8 years.

Early learning and development standards – Statements of expectation for what children should know and be able to do.

Validation – Methodology to determine accuracy of information.

Internationally, early childhood development (ECD) is coming of age, accompanied by a growing recognition of the importance of the early years. Fueled by the latest developments in science and a host of recent reports on ECD, attention to the field is rapidly burgeoning. This work has indicated that a majority of children, 8 years of age and under, are not developing to their fullest potential. These children primarily reside in the developing world and bear the greatest burden of poverty, disease, and violence. The staggering statistics, coupled with the empirically grounded importance of the early years, have led to a call for action in discovering the most effective and optimal approaches to improve outcomes for young children across the globe.

Going Global with Early Learning and Development Standards (henceforth referred to as Going Global), an initiative rooted in Early Learning and Development Standards (ELDS), is one such approach that resonates with this call for action. Standards, in general, are statements that specify an expectation for achievement. ELDS are statements that describe expectations for children's behavior and performance across multiple dimensions of learning and development, reflecting 'what children should know and be able to do.' For supporting countries engaged in the development and utilization of ELDS, Going Global is a culturally grounded, inclusive, and child-centered approach to standards. It uses a partnership model, between government, the development agencies, primarily the United Nations Children's Fund (UNICEF), the private sector, academia, and other relevant stakeholders to develop and implement ELDS. It posits that, once developed and validated, the ELDS can be used for multiple purposes, from improving the quality of learning environments and supporting parenting, to providing data for policy decision. In so doing, the ELDS not only address the needs and rights of children, but also foster a truly integrated approach to ECD.

In this article, we provide a conceptual background to the Going Global initiative; briefly describe the process of developing and implementing ELDS; present a brief status report on the countries participating in this initiative and their achievements; and finally present a set of lessons learned from this initiative.

Conceptual Background of ELDS

Standards, in and of themselves, are not a new concept. They have been the *norm-de-rigor* of efficiency and accountability in several industries, including many human services. In education, they made their appearance in the early 1980s and by the late 1990s were being considered by early childhood educators. Given the newness of the concept of standards to the field of early childhood, there has been confusion around this concept, both in terms of the different types of standards applicable for ECD and the uses to which these standards can be put to improve child outcomes. To that end, in work for the National Governors Association in the United States, Kagan sought to distinguish among different kinds of standards and developed a typology of standards, germane to ECD, as follows:

Type I: ELDS. These are typically a set of statements that inform various audiences about children's learning and development accomplishments. They are statements that indicate what children of specific ages should know and be able to do.

Type II: parenting standards. These define what parents should know and do to advance their young children's health, development, and education. Parenting standards provide information on parenting behaviors, caregiving practices, stimulating and supportive experiences, and opportunities for learning, for example, standards, such as the frequency of shared book reading, or the presence of printed materials in the home.

Type III: teacher standards. These define what teachers should know and do to advance their students' learning. Teacher standards provide information on teaching practices, educational interactions, pedagogy, and creating opportunities for learning. An example of teacher standards is: all teachers should know how to assess their students' competence and report such findings to parents.

Type IV: social indicator standards. These are those that yield information about the overall social and economic

conditions of children and their families. For example, social indicator standards can include the number of children living in poverty, the number of children born to single parents, or the number of live births.

Type V: access to services standards. This reflects the nature of services that exist and the access that children have to these services. Examples include the percent of children who have access to preschool services, the percent of children living in families that receive income subsidies, and the percent of pregnant women with access to prenatal care.

Type VI: system effectiveness standards. These define the degree to which services and programs work together to improve their effectiveness. For example, the degree to which early childhood programs, launched by a ministry of health and a ministry of social welfare, might work together to improve the learning and development of young children and family functioning.

Using this typology as a guide, the Going Global effort focuses on type 1 standards or ELDS (what young children should know and be able to do). This focus is predicated on the understanding that the heart of all standards should be child based. Once type 1 standards are developed and used, other types can be created, thereby providing an integrated approach to ECD. A second key premise underlying ELDS is that it is rooted in cultural and national expectations of what children, residing in a given country, should know and be able to do at predetermined ages. Standards emanate from the socioeconomic, cultural, and political context within which the children live. No single set of standards is, therefore, suitable for all of the world's countries. The standards-based approach is founded in research and scientific knowledge of the processes and outcomes of early learning, taking into consideration cultural, linguistic, and socioeconomic differences, as well as children with special needs. A third key premise of ELDS is that it must respect holistic child development and therefore must embrace multiple domains, including, but not limited to, physical and motor development, social and emotional development, cognitive development, language development, and approaches toward learning.

Process for Developing and Implementing ELDS

As the ELDS can be used for so many purposes and because they need to include a variety of domains, an inclusive, systematic process of development is recommended. The four-phase process includes:

1. making initial decisions;
2. drafting the standards;
3. validating the standards; and
4. implementation.

With the understanding that the skill set required for each phase might vary, all phases must be highly inclusive with representation of multiple sectors and disciplines.

It should be noted that the process of developing ELDS commences with a reflective and critical dialog about country cultural, social, and political values. The values conversation focuses on articulating country and cultural traditions, heritage, and ideals that should be carried forth through future generations, the place of early childhood and view of young children in the country. Other concomitant values questions are discussed during this phase. The goal of this prerequisite stage is to arrive at a set of value statements that will help guide the content, development, and implementation of ELDS.

Phase 1: Making Initial Decisions

The foundation of ELDS is laid at the initial decision-making stage with four decisions that are undergirded by country values: guiding principles; domains of development; ages covered by ELDS; and how ELDS will be used.

Decision 1: Guiding principles

A set of principles needs to be developed that provides the answer to the question, 'What principles should guide our work?' or, 'What do we believe in?' Principles can be developed for several aspects of the ELDS – content, development process, implementation, and utilization.

Decision 2: Domains of development and learning

Domains are the broadest conceptualization of an area of learning and development and are then decided on the basis of culling together the values and the scientific literature on ECD. The literature is used to provide a framework for amalgamating the values into a scientifically recognized typology of domains, while also providing the rationale for inclusion and substantiation of values. Therefore, domains of development, included in a set of standards, could be considered a reflection of a country's priorities and expectations for their young children.

Decision 3: Ages covered by ELDS

The age-range and age-grouping decisions are linked to several factors, such as country values, the developmental literature, the national policies and service provision structure in a country, and the purpose for which the standards are being developed. Given that standards are statements of what children should know and be able to do, specifying the ages of the children is of pivotal importance, as expectation is intrinsically linked to age. An important set of decisions, regarding the age ranges to be covered by ELDS, relates not just to the overall age coverage, but also to the age groupings that will be addressed by the indicators (an element of ELDS).

Decision 4: Uses of ELDS

As stated earlier, ELDS can be used for several purposes:

- *Improve instruction.* Standards can form the basis for revising the educational program for young children according to their needs and progress.
- *Support parenting skills and behaviors.* Standards can be used to help parents see what is and can be realistically expected from young children.
- *Improve curriculum.* Standards can be used to guide the development and revision of curriculum of early childhood and preschool programs.
- *Improve teacher preparation.* Standards can guide the development of curricula for teacher-training programs by providing information about what teachers of young children should know and be able to do in their roles as teachers.
- *Evaluate program effectiveness.* Standards can form the basis for selecting or developing instruments for assessing children's progress as part of a comprehensive evaluation of a program's effectiveness.
- *Monitor national progress of children and families.* Standards can be used to collect national data on performance of children to determine how the nation's children and families, as a whole, are doing.
- *Improve public knowledge of children's development.* The standards can be used for public information materials, for example, television, newspaper, and public service announcements.

The decision regarding uses is an important one because many of the subsequent stages of development are guided by the primary uses. However, it should be noted, given the versatility of standards, that they could be developed for several purposes.

Phase 2: Drafting the Standards

After the foundational decisions are made, the standards document is drafted. Country standards are articulated in a document that provides a framework for understanding the expectations for what children should know and be able to do. Typically, the ELDS document provides background information on the process of development, a brief statement of values, and lists guiding principles. The framework for presenting the standards contains several components, such as the domains of development and learning; the standards statements themselves; indicators, which are measurable and observable, and are linked to the standards; and some preparatory learning activities for the adults that would help the children achieve the standards (see **Table 1** for an example). Several standards are required per domain and several indicators per standard.

In general, the process of developing standards is iterative, going through stages of review, reflection, and revision prior to finalization.

Table 1 Example of an ELDS framework

<i>Domain 1:</i> Language and literacy development.
<i>Standard 1:</i> Children develop skills in listening and in understanding language.
<i>Indicator:</i> Child is able to follow directions that involve a two- or three-step sequence of actions.
<i>Preparatory learning activities:</i>
1. Give oral directions and play a game like caregiver says.
2. Make the children give simple directions to each other.

Phase 3: Validation

The final stage in the development of standards is validation. With reference to ELDS, validity refers to the extent to which the standards are what they say they are. Validation, a cornerstone of good practice in the development of standards, measures, and instruments, is essential for ensuring the accuracy of the standards. Therefore, before standards can be implemented, they need to undergo a process of validation to ensure that the content and age expectations of the standards are accurate and valid for the children of the country.

The ELDS validation model has three tiers which build sequentially on the previous tier, and also increase in level of methodological sophistication. There are three types of validation, recommended for ELDS, linked with the uses of the standards. The model has been built on the empirical literature with applicability for the many uses of the standards.

Tier 1 of the model ascribes that content validation be conducted for all seven uses of ELDS. Content validity is the extent to which the ELDS represent national values, expectations, and the scientific conceptualizations of child development. The rationale for conducting content validity is to ensure, that for all uses to be nationally relevant, the content has to be accurate and valid. Therefore, content validity is required for all uses.

Tier 2 of the model is required for all uses, except for building public knowledge and will power. Two types of validation are required: content (described previously) and age validation. Age validity is the extent to which the indicators are age appropriate for most of the population. Age validation is concerned with the age appropriateness of the indicators (e.g., Are they too easy, too hard, or just right for the children of a given age?), based on a consensually predetermined percentage of children that can attain them. The rationale for conducting age validity is to ensure that expectations for children's learning and development are correct for their age, given the uses for education, parenting, program evaluation, and national monitoring.

Tier 3 of the model is the most advanced and is required for national monitoring and program evaluation. Three types of validation are required for these two uses: content, age (describe above), and predictive validity.

Predictive validity, with respect to ELDS, is defined as the extent to which the indicators demonstrate a significant degree of association with future desired outcomes. Data from national monitoring, which reports on the status of children, are typically used for policy mobilization. Most ECD programs are based on the premise that they are preparing children for future success in life, and, most immediately, to succeed in school. Consequently, indicators, selected for program evaluation and national monitoring, should have demonstrated predictive validity.

Scientifically accepted methodologies are recommended for conducting content, age, and predictive validation studies, in keeping with the resources and capacity in the country to conduct such work.

Phase 4: Implementation

Once ELDS are validated, they are ready to be implemented for one or more of the several uses, outlined above. Typically, the process of implementation requires the selection of a set of standards, most appropriate for use, and transforming them in implementation tools. For example, if standards are to be used in parenting programs, standards most applicable for the age which the program is targeting and the aspects of parenting which the program focuses on, are selected from the ELDS document, through a systematic item-selection process, and converted into parenting materials, such as brochures, posters, and pamphlets. The process of conversion from the ELDS document to the implementation document is dependent on the use and, therefore, varies considerably from country to country. In addition, ELDS are also implemented in alignment with other sets of existing standards, such as program standards and curriculum standards.

Status Report on Countries Participating in ELDS

Going Global, a multi-country initiative, was launched to create integrated systems for ECD. In each country, this initiative has been adapted in keeping with the economic-political context and sociocultural ethos. However, several basic tenets of the initiative have been maintained. The initiative took roots in 2003 with six pilot countries: Brazil, Ghana, Jordan, Paraguay, Philippines, and South Africa. These countries represented geographic and economic diversity. Currently, in 2008, this initiative is alive and contributing to the ECD landscape in almost every region of the world: East Asia and Pacific (e.g., Cambodia, China, Fiji, Thailand, and Vietnam); South Asia (e.g., Bangladesh, Maldives, Nepal, Pakistan, and Sri Lanka); Central Europe and Commonwealth of the Independent States (e.g., Bulgaria, Georgia, Kosovo, Moldova, and

Tajikistan); and Latin America (e.g., Chile and Uruguay). (This is not an exhaustive list of countries. Examples have been listed to highlight regional diversity and expansion of the initiative.) The number of countries participating in this initiative continues to grow and expand, in real time, thereby precluding a final tally count.

The countries are at different stages of development and implementation with their ELDS. Most of the six original pilot countries have completed the development of their standards, including validation and are currently implementing them for multiple uses. For example, ELDS are being used: to revise preschool and ECD curricula in Ghana, Philippines, and South Africa; to inform parenting programs in Jordan, for National Monitoring in Jordan; and to revise teacher-preparation curriculum in Ghana.

The second cohort of countries to join this initiative was primarily from East Asia. Most of the countries in that region are nearing the end of validation, and many have begun implementation in uses beyond those envisioned by the initiative. For example, in Cambodia, the ELDS standards have been used to ensure that the educational programming for children on television is rooted in the standards, and thereby, ensuring cultural relevance and allegiance to the country's values.

The next set of countries in Central Europe and the Commonwealth of Independent states are near the end of the development process, with interesting applications emerging in some of the countries. For example, Moldova has created a comprehensive set of standards and measurements tool to align child and instructional standards used in preschool classrooms.

The newest set of countries from South Asia are either just beginning the process (e.g., Nepal) or are at the writing (e.g., Bangladesh) or validation phase (e.g., Pakistan). It is anticipated that, in 2009, several countries from East and South Africa will join this initiative.

Lessons Learned

The lessons learned from the initiative hold valuable recommendations for future direction not only for ELDS, specifically, but also for ECD programs and policies in general. The following aspects are discussed: conceptual; procedural; and implementation.

Conceptual Gleanings

Each country has been developing their ELDS, rooted in their values, cultural ethos, and child development research, through an inclusive broad-based process. As a result, we now have a large corpus of standards that provide a window into interesting and unique conceptualizations of ECD. Initial, and informal content analyses have revealed, while many similarities are noted across

country conceptualizations of ECD (e.g., motor development and language development), unique domains of development have also emerged (e.g., national values and moral development). This corpus has tremendous potential to widen our vistas on ECD and create a South-to-North transfer of knowledge regarding our conceptualization of ECD.

Another valuable insight gained during the course of this initiative is the varied reaction to the term standards. In some parts of the world, where standards were part of the system, the term met with no resistance, whereas in other parts of the world, it has been off-putting. As a result, countries have elected to use their own lexicon and terminology to label their ELDS, including benchmarks, competencies, and guidelines.

Procedural Gleanings

A key ingredient of success in the development and implementation of ELDS has been government involvement and support. If the initiative occurred in the absence of government participation, the process either was disbanded or implementation was limited. Other factors that made for success were consistent and solid leadership, inclusivity extended to all traditional and nontraditional stakeholders, and finally, and most importantly, a need for ELDS in the country.

Through the processes of developing ELDS, participating countries derived many benefits. First, by making standards development an inclusive process, capacity for ECD is built in the country. There is now a large cadre of professionals, not just those with an ECD background, but also those who are knowledgeable about latest developments and the importance of ECD (e.g., Philippines). Second, ELDS has generated a base for implementation support. By information from professionals across sectors, there is far greater synergy and integration in addressing ECD issues (e.g., Ghana). Third, data collected during the age validation phase of the work could be used as comprehensive baseline data for children's development (e.g., China). In addition, the process used for age validation provided the platform for future national data collection. These byproducts have worked toward the success of this initiative in individual countries.

Implementation Gleanings

ECD implementation challenges, in most parts of the world, are instructive. First, by linking ELDS to other ongoing initiatives, the linkage not only smoothens the implementation process, but also creates for integration across programs. For example, in Cambodia, ELDS were used to create expectations for children school readiness, thereby linking a successful preschool program in the country to primary school entry. In Thailand, as part of the national

policy plan, ELDS have been linked to family development and gender development programs. By creating this alignment, it has become possible to train 30 000 caregivers to improve the quality of those programs, based on ELDS.

ELDS, also has valuable lessons for ECD in general. Internationally, school readiness is gaining rapid currency and is built upon three pillars of readiness – children ready for school, schools ready for children, and families and communities ready for school. The application of ELDS simultaneously (for multiple uses – curriculum, instruction, teacher preparation, and parenting programs) addresses these three pillars of school readiness, holistically.

Finally, ELDS has been a positive experience in countries, as noted by the evidence. Many countries report that ELDS has set a historic precedent by bringing together multiple sectors in a shared vision for ECD. The highly inclusive process has pushed ECD policy and advocacy among broad-based communities, including health, education, labor ministries, and community leaders. This approach is a lasting legacy in many countries.

Acknowledgments

We would like to thank UNICEF for the funding they have provided for the Going Global initiative. We owe a debt of gratitude to the UNICEF staff and members of the ELDS teams in countries that are part of this initiative.

Rethinking Early Childhood Education and Care: Implications for Research and Evaluation

Introduction

Evidence from a diversity of research studies in developmental neuroscience and developmental psychology provides a consistent, strong, and compelling argument for the role of early experience in directing children's trajectories of achievement and well-being (Shonkoff and Phillips, 2000; Schweinhart *et al.*, 2005; Center on the Developing Child, 2007). Early experiences affect the child's developing brain architecture. The range and quality of early experiences determine the strength of neural foundations set for future learning, social behavior, and relationships. Early learning experiences establish the pathways for children's motivation for school learning and long-term scholastic attainment, while early interactions and relationships with adults and peers establish pathways for their emotional security, sense of agency, self-regulation, and social behavior.

Early Childhood Education and Care (ECEC) programs present an important opportunity for improving the quality of early experience and affecting long-term outcomes. Randomized control trials of early education programs among disadvantaged children have demonstrated a causal relationship between early education and life course (Schweinhart *et al.*, 2005; Reynolds, 1994; Campbell and Ramey, 1994). Longitudinal tracking of participants in these trials indicates that, in adulthood, children who received well-resourced preschool education had more life successes (e.g., high school completion and higher lifetime earnings) and experienced less adversity (e.g., need for special education, participation in crime, early parenthood, and unemployment) than comparable children who had not experienced an early educational program (see Schweinhart *et al.*, 2005). A key question for research is how these findings might apply for all children. There is a need to understand how the potential of ECEC programs demonstrated in these studies of targeted populations might generalize to broader applications of educational policy and practice.

In this article, we examine the question: What ECEC programs, and which of their components, most effectively deliver optimal outcomes for children and society? We examine the conceptualizations and policy directions in English-speaking Western economies, propose an evidence-based approach to define optimal program outcomes, and

outline approaches to conducting research exploring the quality and effect of programs.

Changing Interests in ECEC Programs

The evidence that ECEC programs can have a long reach into adulthood has provoked a rethinking of their place in early childhood development and learning. In English-speaking developed economies (e.g., USA, Australia, and UK), until recent times, early education and child care provisions have been conceptualized separately, serving two quite separate functions often with different political and governance structures (see OECD, 2006). In this article, we refer to this as a differentiated service orientation. The provision of care (child care) has been constructed primarily as delivering the immediate goal of enabling parent participation in the paid workforce. The benefits for children have been viewed as indirect; preventing the adverse effects of poverty and contributing to the material well-being of the family. Commensurate with this focus, the regulation of child care has favored attention to aspects such as safety and hygiene, giving relatively little attention to a child's education. In contrast, early education or preschool programs, in English-speaking countries, focused on short-term goals: particularly preparing children for formal schooling. The role of preschool has been seen by many as providing children with social experiences and cognitive preparation for literacy and numeracy learning on entry to school. Further, many of these programs operate in sessional or part-time modes, making it difficult for working parents to ensure a child's attendance and assure that a care program is available for the remainder of a working day. This dual system of child-care (care) and preschool (education) provision has contributed to inequities and served to create a tension for parents between providing for their children's material needs and their children's educational needs. Research questions, mirroring the dual nature of provision, have tended to focus on either child care or preschool provision. Those focusing on child care have been concerned with the effects on children and asked whether nonparental care causes harm. Research on preschool education has predominantly focused on the narrow remit of school readiness.

The alternative conceptualization to a differentiated service orientation is a comprehensive program orientation. This orientation focuses on the evidence from developmental science, particularly longitudinal studies, that has highlighted the capacity of early education to benefit the child, families, and the community in both the short term and across the life span by promoting economic productivity (through human capital formation) (e.g., Keeley, 2007) and social inclusion and participation (through social capital formation) (Schweinhart *et al.*, 2005; Reynolds, 1994; Campbell and Ramey, 1994). To this end, all programs, regardless of their stated goal, are assessed in terms of this broader framework. Evidence clearly shows the potential for substantial benefits to be accrued through the provision of programs at this early developmental stage. Further, if the opportunity to maximize these benefits is forgone in the cost of achieving the same benefits later in life are greater, there is a high opportunity cost associated with achieving the same benefits later in life (Heckman, 2007).

Figure 1 illustrates the theorized difference in lifelong effect when ECEC programs are offered within the above-mentioned paradigms of either differentiated service orientation (a dual system of care and education where programs are offered primarily to meet the single goals such as parental labor participation or school readiness) or an comprehensive service orientation (where both short- and long-term goals are being addressed and

the rights of children to optimal educational experiences are enhanced).

Competing policy interpretations have grown as a result of viewing ECEC in the long term and adopting a comprehensive conceptualization of ECEC: targeted and universal provision. Targeted provision focuses available and limited resources to ensure the provision of programs for disadvantaged populations only (Penn, 2005). This interpretation is a direct application of randomized control trial studies to new settings and is underpinned by a compensatory approach in which poorer home environment is supplemented by rich educational experience outside the home. In contrast, universal provision takes a broader view of existing research findings and directs focus to social equity by highlighting the potential benefit of programs for all children alongside the relatively greater effects for those who are disadvantaged. In this construction, access to educational programs is presented as the right of all children (OECD, 2006).

Targeted provision is proposed on the premise that it is cost effective, best serves those with greatest need, and more effectively reduces social inequity (e.g., see Rutter, 2006). However, success of programs may be undermined by poor access or poor uptake by those groups who might benefit. Evidence from Early Head Start (Love *et al.*, 2002) and Sure Start UK (NESS, 2005) indicates that the most disadvantaged were less able to benefit. For example, teen parents, lone parents, and

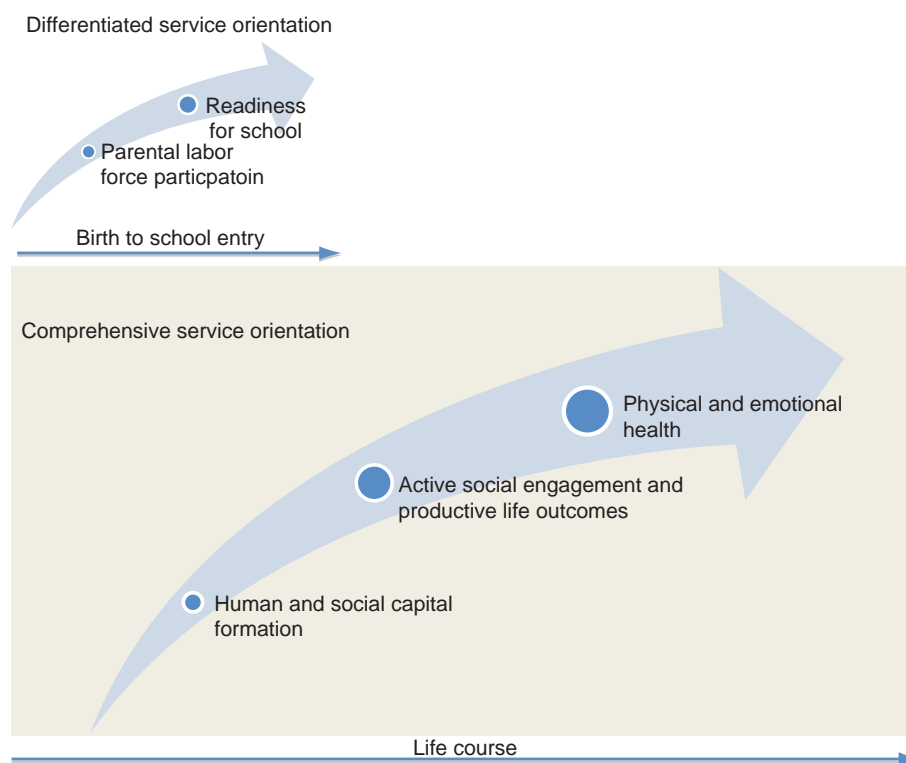

Figure 1 Two conceptions of the ECEC policy framework associated with the effect of programs over the life course.

workless households living in Sure Start UK intervention areas were found to make poor gains or even regress relative to others (NESS, 2005). These findings are likely to reflect poorer uptake and access by the most disadvantaged. Targeting is criticized for being potentially stigmatizing, and it may also be inaccurate. Rutter (2006), for example, argues that one difficulty with Sure Start is that it targeted geographical areas statistically defined as disadvantaged when in the UK many disadvantage families reside within statistically advantaged areas. Moreover, clustering targeted groups in educational programs may exclude social and learning opportunity. When the social composition of an early childhood class is more socially diverse, greater positive effects have been found for children's scholastic and social learning (EPPE, 2002).

Universal provision is based on the tenet that ECEC benefits all children and that when programs are presented as normative, access is increased and uptake by marginalized groups is more likely to be achieved. Hustedt and Barnett argue that it is not the percentage of enrolment in ECEC programs but who is enrolled that makes a difference to social equity. They state that a minimum of 60% of the population should have access before a program is effective in reducing inequality in achievement scores because greater coverage of the population as a whole is required to reach the most disadvantaged. Thorpe *et al.* (2004) report that free and universal provision of a full-time program for 4-year-olds improved performance of all children. In addition, such provision closed the gap in social and cognitive achievements across a school year between disadvantaged children and others. Thorpe *et al.* (2004) proposed the effects reflect improved access for disadvantaged groups into a universal, free program that engages the whole age cohort.

Currently, there are no studies examining the impact of population-based ECEC programs with outcomes into adulthood. The Effective Provision of Preschool Education (EPPE) study provides longitudinal data on the effects of a range of ECEC programs that were delivered to children in the UK. Results of the study have been tracked through to the middle years of school. These findings indicate that not all early education programs deliver positive outcomes in the long term; some have little or only short-term effects (EPPE, 2007). A key task for research is to clearly define outcomes and learning standards for ECEC programs and then identify the programs, as well as features of these programs that best meet these goals.

Defining Optimal Outcomes

We propose, on the basis of a comprehensive conceptualization of ECEC, that there are four outcome criteria against which the success of ECEC programs should be assessed:

1. Access.
2. Benefit to all children.
3. Long benefit.
4. Wide benefit.

Access

Evaluations of ECEC programs very often do not take account of access and yet a program, no matter how well resourced, cannot be of benefit if it is not attended by those for whom it was designed and implemented. The randomized control trials of preschool education conducted in the USA demonstrate the stark effects of not accessing preschool education among disadvantaged populations. In these studies, children who did not access programs had significantly poorer achievement and social outcomes across their lifetime. In a nonexperimental setting, where there is likely to be lower impetus to attend an ECEC program, one key criterion of success is the level of uptake and sustained attendance in the program across the diversity of the population. Access is particularly pertinent when considering marginalized groups and developing ECEC programs as potential meeting places for diverse social groups (see OECD, 2006). For example, in the EPPE study, the children who did not access ECEC programs were a select subgroup with very different characteristics when compared to children who experienced ECEC programs. Children in the EPPE study, who did not experience ECEC programs, were more likely to be from an ethnic minority, have English as an additional language in the home, come from larger families, and have mothers with no formal qualification (EPPE, 2002). Similarly, in Australia, there is disproportionate nonattendance at preschool for Indigenous children (Biddle, 2007). Location and physical access to program may also affect access and need to be considered as part of the features that define a program's quality – that is, its reach. In the Australian context, for example, where 38.5% of the population of 3–4-year-olds do not access preschool education (OECD, 2006), geographical barriers are almost certainly a factor. Cost, timing (number of days per week), and availability (hours per day) of program may also serve as barriers particularly if there is a disjuncture between hours of program provision and the needs of working parents (Thorpe *et al.*, 2004).

Benefit to All Children

Not all ECEC programs deliver benefit to children. Further, the magnitude of benefit varies considerably across programs (Thorpe *et al.*, 2004; EPPE, 2002). The success of a program should be assessed by measurement of the degree of impact on all children from a given sampling frame or community of interest from baseline measurement through repeated measures after the course of the program and to a nominal point in the future. Measurement must take account of other factors that may influence

children's development, including family background and home learning environment (Duncan and Gibson-Davis, 2006; Hungerford and Cox, 2006). The outcome measures would include a range of social and attainment outcome domains. Snow and Van Hemel (2008) suggest a categorization of child outcomes that includes:

1. physical well-being and motor development;
2. socioemotional development;
3. approaches to learning;
4. language (and emergent literacy); and
5. cognitive skills, including mathematics (p. 58).

Long Effects

A key premise of the comprehensive approach to early education is that the early years are vital foundation years that direct life chances. The test of a successful program, therefore, is that its effects endure beyond the course of the program or the period of school entry which follows immediately after: the effect must be sustained. The effects may have direct pathways in which early numeracy and literacy preparation support higher levels of scholastic achievement into the school years. There may also be moderating or mediating effects. For example, the EPPE study indicates that higher-quality education programs served to make children more resilient to poor educational experiences in the primary years of school than those who had poorer forms of provisions (EPPE, 2007).

Wide Effects

Early successes increase the likelihood of future successes in a range of related areas, while limitations on learning can increase the likelihood of compounding difficulties. Language development provides a good case in point. Analyses of the 1970 British birth cohort parsons *et al.*, 2009 indicate that children who had receptive language difficulties at age 5 yet achieved, through educational experience, competence in reading at age 10 were more likely to have an easier pathway into adulthood and to achieve higher levels of socioeconomic status than those who did not achieve reading competence at age 10. Language difficulties have also been shown to link to poorer mental health: the pathway being through decreasing levels of achievement and increasing social exclusion (Rutter and Mawhood, 1991). Assessment of program success should therefore capture not only direct child outcomes (see Snow and Van Hemel, 2008) but also the indirect pathways to other life attainments. Little attention has been paid to long-term health outcomes that might derive from ECEC programs but, given the high association between health and social economic status, this would be an important new direction for assessment of the wide effect of ECEC programs.

The effects of ECEC programs also extend beyond the achievements and well-being of the individual child to include family, community, and societal effects. Engagement between home and school may serve to not only benefit the child (Thorpe *et al.*, 2004) but also engage families in social participation. This is a less studied effect of ECEC programs but one identified by the Organization for Economic Cooperation and Development (OECD) as a potential benefit, and worthy of inclusion as a measure of outcome. The potential societal benefits of ECEC programs are perhaps best demonstrated in the experimental studies. The long-term effects measured were wide and included the prevention of a range of negative outcomes. The reduction of such negative behaviors spills over to produce communities with both tangible and intangible improvements. An example of tangible improvements includes the reduced costs of repairing damage caused by crime and associated lower insurance costs. Intangible benefits can include a better sense of community or safer environment. These are examples of ECEC's ability to produce positive externalities realized as societal benefits.

Identifying Optimal Programs

The claim that high-quality early education delivers positive and enduring outcomes, at least for disadvantaged groups, is ubiquitous in the early education literature. Yet there is, at best, only partial empirical evidence to enable the definition of relevant models of quality ECEC that can be applied to a broad population rather than specific at-risk groups. It is not yet known what model or models of ECEC delivered in a general population yield optimal outcomes relative to each other. This is a key agenda for current research focus.

We propose that a three-staged analytic strategy is required to provide a strong evidence-base for any universal delivery of ECEC programs:

1. Deriving a model of quality in ECEC.
2. Testing alternative delivery and access modes for the model.
3. Evaluating delivery of the derived model.

Deriving a Model of Quality in ECEC

The experimental studies of ECEC have tested the effects of single models of highly resourced ECEC programs against counterfactual conditions (the children in the control group do not receive the experimental program, but may have other educational and care experiences outside the home). The outcomes of these studies indicate that the programs have been extremely successful against three of the four criteria set out in this article for success

in an ECEC program: all report immediate, long, and wide benefits but data on access are limited. High/Scope Perry Preschool Study reported a 69% full-attendance rate but none of the early intervention experimental studies reports on attrition rate (Wise *et al.*, 2005). Despite the gains made and attributed to the treatment condition (model program), these studies cannot provide evidence that the model tested is the most effective model of ECEC even within the population they target. The experimental programs implemented are informed by anecdotal evidence, subject-matter experts, and literature; there is no empirical analysis of the components of program that are most efficacious or produce the greatest effect when combined together. These experimental designs test the efficacy of a model program rather than the best model program. To empirically define quality in ECEC requires comparison of alternative models of ECEC provision and examination of their relative effects. Variability between models of program (contrasting different approaches to ECEC delivery) and within models of program (contrasting different ECEC delivery of the same type) need to be exploited to identify program components and combinations of components that most effectively deliver successful outcomes to a given population of interest. To this end, the use of effectiveness designs, in which the performance of multiple existing ECEC programs are compared against each other, may be a more potent first step before the rollout of experimental designs testing specific models of ECEC delivery.

Unlike experimental designs, where randomization to groups is used to ameliorate potential systematic bias on observed and unobserved variables, effectiveness designs use the natural assignment to ECEC programs that occurs in the community. While this has the advantage of allowing the examination of access and uptake of programs, it also means that statistical approaches are needed to control for selection bias. The National Institute of Child Health and Human Development (NICHD) Study of Early Child Care and Youth Development (NICHD henceforth) is the most significant example of a nonexperimental design in ECEC. NICHD looks at variability within a program model to estimate the effect on quality in predicting child outcomes. NICHD has tested several approaches to accounting for the effect of background characteristics that lead to selection bias and have categorized them in the groups of: characteristics of the child, of the home, and characteristics of the family. Some of these approaches, such as the difference model, also account for unobserved differences within these categories. By controlling for these background characteristics, it is possible to begin to disentangle the effects of nonrandom selection into groups from the effects of the program on children's outcomes (NICHD and Duncan, 2003; Duncan and Gibson-Davis, 2006). Similar approaches have been used in the Australian Preparing for School study (Thorpe *et al.*, 2004) and also in research

conducted across multiple studies of preschool education in the United States (Early *et al.*, 2007; Mashburn *et al.*, 2008).

Although effectiveness designs have been criticized for their inability to make inference of causality (National Forum on Early Childhood Program evaluation, 2007), they provide the much needed data on the relative effect of program and allow the empirical definition of program quality. Such an approach allows the specification of an optimal model of quality that can be translated into a program. This minimizes the likelihood of falsely concluding that a program does not have an effect (type II error) or of understating the effect of quality ECEC on children's development in a universal population.

Evaluating Alternative Delivery and Access Modes for the Model

As access to programs and maintenance of attendance is a key success criterion to ECEC programs, understanding how any apparent barriers to access might be overcome is an important issue to be addressed by research. Effectiveness designs, because they compare existing programs, are able to identify barriers and biases in uptake across the various program provisions. The identification of key success elements presents the possibility of experimentation with provision to overcome barriers that might relate to geographical, time, and cultural barriers. For example, in the Australian context, the need to examine ways to deliver preschool education to those in remote locations while retaining core quality components could be investigated. Thus, increased attendance at preschool programs by indigenous children in Australia has been found to be associated with the presence of an indigenous preschool worker (Biddle, 2007). Core elements of quality would be trialed alongside component additions and different access modes, depending on the context. This stage does provide an understanding of the functioning of identified high-quality or successful programs in different contexts and populations.

Evaluating Delivery of a Derived Model

The National Forum on Early Childhood Program Evaluation (2007) indicates that experimental and regression discontinuity designs (RDDs) are the gold standard for testing the success of ECEC programs. (RDD uses exogenous variation such as an age cutoff or policy change to allocate participants to groups in a way that approaches random assignment. Such designs can be used to make causal inferences.) Although studies, such as the EPPE study in the UK, have demonstrated that effectiveness designs can be powerful in their own right and make important contributions to the field, the use of experimental and RDD methods are able to provide estimates of causality and are powerful in evaluating the independent

effect of a model program or intervention. It should be acknowledged that implementing experimental research designs of ECEC programs is not free of difficulties. There are ethical dilemmas about the rights of those randomized to the control conditions. There is also difficulty in specifying the control condition as it is seldom that parents of young children would withhold all out-of-home ECEC experiences: unless the experimental intervention is specified as a particularly efficacious program there is potential that parents may source equally good or better ECEC elsewhere. The alternative, RDD designs require conditions that exploit naturally occurring cut-points in provision (e.g., children who sit either side of an age criterion for inclusion/exclusion or introduction of a new program). Although appealing, these require the model program to be implemented such that a hard cutoff point is established. This is often not the case in noncompulsory ECEC, particularly at the pre-K level. In the Preparing for School study (Thorpe *et al.*, 2004), many transgressions of set age criteria were noted in the two preschool programs that were compared. It is therefore vital that robust and powerful model ECEC programs be specified before progressing with experimental designs – failing to do so weakens the cogency of the research conducted.

Conclusion

Despite significant evidence of the potential positive benefits of ECEC programs, there remains no empirical framework from which to design model programs that can be distinguished from other forms of provision as being more powerful or of having a greater impact on children's development. This is particularly true in the general population: quality programs are currently defined by what has been historically seen as important, the subjective inputs of experts (academics, teachers, governments, and businesses), and by imitating programs found to be successful in at-risk populations. The task for research is to determine those programs and program conditions that allow access for all children and deliver benefits that yield enduring and far-reaching outcomes for children, families, and society. We propose that a first stage is to empirically define key components of quality in ECEC through comparison of the effectiveness of existing programs. In addition, research studies need to explore barriers to access and sustained attendance in diverse contexts. From such work, model programs can be specified and tested experimentally. Under such conditions, it is possible to comment on the potential efficacy of ECEC programs in general rather than simply that of programs touted to be high quality but with little evidence of their relative superiority in a wider context.

Diverse Families

The traditional nuclear family of a married mother, father, and two or three children has been a model for much policymaking in the global North (Jenson, 2008), but it is a global experience that families are becoming more diverse. There are more parents choosing not to marry; more divorce, more second marriages, and more single parents; more role reversals between men and women, with men choosing to stay at home, and women choosing to work outside of the home; and there are more older mothers, with more educated women choosing to have families later or not at all. There is more mobility within and across countries (Bianchi *et al.*, 2003, Heymann, 2006). Even in the global North, caring arrangements for children may fluctuate considerably in accordance with family needs and societal circumstances. In the global South, family life has generally been much more communal and shared (DeLoache and Gottlieb, 2000), but the most significant change in the South is migration–urbanization – where men and women from the countryside migrate to towns and cities. Stripped of their rural support networks, they struggle to make a living and bring up children in the shanty towns that surround every city of the South (UNFPA, 2008). Discontinuity of caring arrangements in migrant or disrupted societies may be the norm and young children may move between people and places – even continents. Newman – writing about South Africa, for instance – comments that “commonly households are in a state of flux with the children moving between the relatives that are best able to care for them at particular times of their lives” (Newman, 2006: 1121).

Working Mothers

One of the biggest changes that has taken place in developed countries has been the rise of women in the workplace. In such countries, gender equity has become a major issue (OECD, 2006; EU, 2007, 2009). Maternity, paternity, and parental leave policies – along with the availability of early education and childcare provision – are crucial in

enabling women to try to reconcile their position in the workforce with familial obligations. The number of mothers in the workforce differs considerably across countries. This is, partly, for historical and cultural reasons, but, partly, also that if childcare and other benefits are not available, mothers are less likely to work.

One reason for encouraging mothers into the labor market in developed countries is that social security payments to single mothers and mothers in low-income households are regarded as a drain on the national economy, but once in work, such mothers contribute, instead, to tax revenues. Another is that the poorest households tend to be workless households, and encouraging mothers to work critically augments family income. Evidence from diverse countries suggests that governments have an interest in encouraging mothers to work outside of the home, and in providing childcare to facilitate their entry into the workforce (Kucera and Bauer 2001, Cleveland and Krashinsky, 2003).

However, a recent study in Australia, by Craig (2007) on mother's time-use, illustrates how a woman's work impacts on her time, and how – without compensatory social policies such as adequate childcare – most mothers who attempt to combine work and childrearing do so at considerable personal cost – lack of sleep, lack of leisure, and high levels of stress – whereas a father's employment status is likely to make little difference to the organization of his daily life. Meda (2001) using European data reaches similar conclusions. Children have a highly differential impact on mothers, fathers, and, indeed, other family carers. Role reversal is, of course, possible, with fathers shouldering the burden of childcare, but, typically, it is women whose economic and social position changes with childrearing (Paull, 2007). Although the word parent is commonly used in order to avoid gender stereotyping, it also obscures very real gender differences. Where possible, mother is used, in this article, in preference to parent for this reason.

As Heymann (2003) points out, these circumstances are exacerbated in the global South – where there are few state benefits, and employment is largely informal. In her four-country survey, 29% of working mothers in shanty towns left their children unattended or in the care of siblings.

It is both – for equity reasons, that is, to reconcile family life with employment, and educational rationales, that is, to improve children's school performance and outcomes – that the expansion has come about in early education and care services, and to the growth of a professional cadre of people who are concerned with children's cognitive, social, and emotional well-being.

The Intimacies of Caring

Caring, by itself, is an activity arising out of consanguineous relationships. Studies of caring – and of mothering, in particular – suggest that mothers focus on the material and emotional welfare of their children, that they pursue a different ethic of care from that of teachers. Mothers' knowledge of their children and relationship with them are not scientific and generalized, but anecdotal, subjective, *ad hoc*, and continuous – developing and changing over time within a specific context. It is also intensely physical. Care requires responsive ministration to physical as well as emotional and cognitive demands. It is this dirty physical work – feeding young children, keeping them clean and maintaining their bodily functions, and guarding them against danger – that has paradoxically led to care activities being devalued. Mothers have intense and intimate relationships with – and knowledge of – their children, especially when they are very young (Ebtehaj *et al.*, 2006, Noddings, 1984).

Caring is also a reciprocal relationship, in which the person caring and the person cared for offer each other feedback and support – albeit of differing kinds (Noddings, 2003). Mothers care for their children and expect love in return. The sociobiologist Sarah Hrdy argues that mothering has a strongly protective function, and that infants – in turn – reward their caretakers in a virtuous cycle of physical intimacy.

Maternity is inextricably inter-twined with physical sensations, and it is an infant's business, through grunts and coos, touches and smells, to make the most of Mother Nature's reward system, which conditions a woman to make this infant a top priority. Evolutionary logic is firmly on the side of mothers who enjoy the sensual side of mothering for its own sake. (Hrdy, 1999: 538)

Hrdy – drawing on her work with primates – also argues that the work of infant rearing is burdensome, too much for a single individual, and infants who are reared in multiple-female households – aunts, grannies, and cousins – in evolutionary terms, stand a better chance of survival.

Teachers and professionals, on the other hand, tend to hold more abstract, norm-related knowledge and expectations of children, unrelated to context, and without expectations of reciprocity or continuity. They are not

swayed by the storms of the moment, and they limit physical care (nursery education, formally, begins in almost all countries when children are no longer incontinent). They are more professional and detached. Teachers and other professionals operate in public institutionalized settings, mothers and carers in the private enclosed setting of the home. This boundary between public and private is a sensitive frontier which both professionals and parents cross with caution (see below). For example, in the 1970s, in the UK, the eminent psychologist Jerome Bruner argued in favor of the playgroup movement, and for mothers to be involved with their children:

when we are planning for the care of our young children we must also enable care in its widest sense to be given to those who have day to day responsibility, their parents and in particular their mothers. (Bruner, 1980: 231)

Countries with maternalist welfare traditions (i.e., holding beliefs about the natural role of women as mothers and the importance of mother-child attachments in early childhood) have encouraged mothers to stay at home with their young children and, until relatively recently, discouraged the use of alternative services except on a very part-time basis (Schweie and Willekens, 2009). Some commentators – who have attempted to extrapolate from neuroscientific studies of the brain – argue that the mother's role as a responsive carer is a key one in stimulating cognitive growth, although others are considerably more skeptical about the use of such studies in justifying particular approaches to parenting (Bruer, 1999, Thompson and Nelson, 2001).

In a classic study in the UK, Tizard and Hughes (2003) tape-recorded the conversations of 3-year-old girls at home with their mothers and compared their conversations with those they had at nursery school. They found that whatever the background of the child – working class or middle class – and however limited the conversation, the child's language at home tended to be richer, more extended, and drew on a much wider range of events, and showed more evidence of logical thinking than any talk that took place in the nursery school. This conversation happened in a leisurely, almost casual way in the course of everyday activities and in getting on with daily life – they were not scheduled play sessions, in which mothers focused exclusively on their children's talk. The researchers discuss the complementary roles of home and school and conclude that “the school's problem, as we see it, is to foster, harness and satisfy the curiosity which children show at home . . . instead of the emphasis on fostering play, on devising ingenious ways of using play materials, and on questioning children about their play, a higher emphasis would have to be given to widening the children's horizons, extending their general knowledge, and listening to them talk” (2003: 219). This finding – although powerfully evidenced – has been,

generally, ignored by professionals, possibly, because it is perceived to undermine their expertise in fostering children's cognitive and linguistic development. The study was originally carried out in the early 1980s, and it may also be the case that more recent changes in family life and conduct – the reliance on television (TV) and, in some areas, increasing drug use – have meant that the kind of intimate talk recorded by the researchers is less frequent.

Mothering Styles and Children's School Outcomes

The evidence suggests that mothers from poor homes do worse in preparing their children for the specific requirements of school – irrespective of ethnicity or any other variables. Ermisch (2008), an economist, has analyzed the Millennium cohort data in the UK, and concluded that differences in cognitive ability and behavioral development at age 3 are correlated with parental income. The lower the parental income, the poorer the scores are on standard cognitive and behavioral tests. Using a production-function framework, he argues that these differences can be partly explained by parenting styles – with low-income parents demonstrating less interest in cognitive-promoting activities such as reading. Sylva *et al.* (2007) reach a similar conclusion in their EPPE study (EPPE, the Effective Provision of Pre-School Education), arguing that parental style is a more powerful determinant of subsequent child outcomes than any educational intervention – although early-education interventions also do make a difference to outcomes. Feinstein *et al.* (2008) argue that a mother's educational level and social class are correlated with child outcomes. The differences in the willingness or capabilities of families to take advantage of educational opportunities exacerbate social class differences and limit actual equality of opportunity. Feinstein argues, for instance, that mothers from poor families have the least resources to deal with children who have learning problems, and as a result, their children are disproportionately disadvantaged (an estimated one in six children from across the social spectrum has some kind of disability or problem that may temporarily or permanently disrupt their learning). These three longitudinal studies come from the UK, but on a broader level, the Organization for Economic Cooperation and Development (OECD) argues that inequality and educational outcomes are linked; the more unequal a society, the more marginalized groups, and the higher the rates of poverty, the poorer the educational outcomes (OECD, 2008).

If the mother's parenting style – or, rather, the interface between expectations of school and home – plays a crucial role in determining a child's initial progress and subsequent readiness, it makes sense to focus on the home environment

and home-school relationships in the early years. The importance of the home environment – and, in particular, the vulnerability of children from poor and/or dysfunctional homes – have led some countries to invest heavily in home visiting and parental education programs – most notably, the Sure Start program in the UK. However, recent evidence summarized by Waldfogel (2004) suggests that home visiting and parent education do not significantly affect children's outcomes, although they may, in some cases, alter parental behavior. In addition, the investigation of such outcomes is problematic, since it is unclear what psychological mechanisms are at play in producing change when mothers receive support from home visitors or other support programs (Rutter, 2002, 2006). Poverty and inequity severely depress expectations both for mothers and their children (Bradshaw and Bennett, 2007), and poor parenting is likely to be multicausal, not merely a matter of improving mothers' emotional relationships with their children or assisting mothers to engage in cognitively stimulating games with them. In addition, the mothers most likely to be visited at home are those about whom there is concern – mostly from low-income households – whereas the professionals carrying out the visits are, by definition, middle class or at least trained and skilled in knowing about and interpreting the norms and expectations that their society has of children.

Training for Work with Young Children

There has been some discussion concerning the extent to which these different kinds of responsiveness to – and knowledge about – children are distinct or overlap (Noddings, 2003; Lynch *et al.*, 2007). Looking after one's own children requires a particular kind of contextual knowledge, responsiveness, and protectiveness, on a continuous 24-h basis, but these mothering skills cannot be easily generalized to other nonrelated children who may only be with the carer or educator for a relatively short period of time. Most countries choose to emphasize the importance of training for work with children, even for those women who are childminders or family day-carers working from their own home (OECD, 2006).

Training for workers in some – mainly English-speaking – countries reflects the different traditions of care (substitute mothering including physical care for those unable to care for their own children) and education (developing children's cognitive, linguistic, and other crucial skills in preparation for mainstream schooling). Generally, care training is at a low, mainly vocational level, and poorly paid. Education training tends to emphasize degree or postdegree standards. However, models of training also vary on a continuum between social pedagogic models which explore and emphasize the emotional relationships which underpin learning, and teacher models which

emphasize the knowledge content of what is to be learned. Overall, there is considerable variation between countries on the knowledge content, pedagogical methods and length of time, and the academic standard required for training to work with young children; in other words, there is no consensus with regard to what constitutes professionalism in the field. OECD (2006) has produced a comparative table of training which indicates the range of variation. Some countries have chosen to emphasize age-related training, with particular skills being required for particular age groups, and an emphasis on caring skills for younger children. In yet others – most notably in the famous groups of nurseries in Reggio Emilia, Northern Italy – the emphasis is on in-service training, on learning from, and reflecting continuously on daily practice with children.

New and Cochran (2007) review training initiatives across ten countries, including China, Japan, Brazil, and Sweden. Training, in these countries, is also firmly located within national policies and traditions, and there is considerable variation in the expectations of what professionals will provide, and the level to which they should be trained.

In all countries, working with young children is a profession which attracts women rather than men. Although there is considerable rhetoric about the importance of male role models – especially for children from female-headed households – hard evidence of the impact of gender inequity among professionals on young children or on their mothers or carers is lacking thus far.

Multidisciplinary Working

Welfare, health, and educational professionals, all have a role with respect to young children's upbringing and well-being, and – in some countries, most often those with relatively fragmented and low levels of services – multidisciplinary or multiprofessional working is considered to be the key to successful practice. The health and nutritional status of young children has always been regarded as an important aspect of child development, particularly in countries where child poverty is rife. The recent UNICEF-IRC (the United Nations Children's Fund-Innocenti Research Centre; 2008) report *The Child Care Transition: a League Table of ECEC in Economically Advanced Countries* gives ten benchmarks for a decent level of service, which include a spectrum of support for parents – parental leave arrangements, the need for a national integrated plan for young children, specified levels of service for children aged 3 and 4, antipoverty strategies, and health-outreach work. A country that successfully serves young children needs to have all these aspects of provision in place. Arguably, the most well-integrated schemes were those to be found in the ex-communist countries – where it was routine practice to

provide weekly health checks in kindergartens, exercise and rest regimes, and where nutritional intake was closely controlled.

Some of the current discourses about multiprofessional work take their cue from the activity theory of Engstrom (Anning and Edwards, 2006). Engstrom's theory – derived, in turn, from Vygotskian cultural theory – emphasizes client-focused cross-disciplinary collective problem solving, rather than co-ordination of specific areas of professional expertise, which is what is usually implied by multiprofessional work (Sanning *et al.*, 2009). In the case of early years, the argument has been whether to create a core professional whose training encompasses a wide range of disciplinary approaches – albeit at a relatively basic level – or whether to try to create projects where a range of professionals come together to share their expertise in dealing with the complex circumstances of childcare, early education, and family life (OECD, 2006).

Mothers and Professionals Working Together

Historically, parental involvement had a narrow meaning for professionals; a mother's (and occasionally father's) role is to be a loyal supporter of the activities of the nursery or school, or to carry out those tasks which the school deems especially suitable to foster learning, such as reading with the child or going to the library. Professionals, frequently, see themselves as in possession of knowledge and expertise in the field of child development and schooling, which mothers – especially poor mothers – lack. From this point of view, the challenge for professionals is to impart such knowledge and skill to mothers – hence parenting classes, early stimulation, and many other special lessons for mothers. Communication is one-way – from the school or setting to the mother – rather than mutual.

Bouve (2007) discusses moves in France to increase family involvement in services, and notes that the process has been rather different for working-class and upper-class families. For the former, the dominant ethos has, historically, been social control and normalization, whereas better-off socioeconomic groups have been able to exert a stronger influence on the pedagogy and other aspects of the *ecoles maternelle* system. Penn (2004) also notes a similar historical class division in the UK. The OECD report *Starting Strong* (2006) stresses that social equity and a higher standard of service education and care services are more likely to be achieved where the priority is universal services for all children, rather than targeted services for certain classes of children and their families. The take-up of universal nursery education in most countries is very high, but mothers are much more ambivalent about using targeted services which they, often, see as stigmatizing or patronizing.

However, others have cast the challenge of parent–professional relationships rather differently. Given the pressures mothers – especially working mothers – encounter, the challenge for early-childhood services is how to support mothers (and fathers and other carers), especially those living in vulnerable circumstances, by acknowledging their rights as mothers/parents and their intimate contribution as carers. Dahlberg and Moss (2005) have argued that services should ideally recognize the mother's and father's rights within services; their right to be informed, to comment, and to participate in key decisions concerning their child. This echoes Dewey's idea of the school as a democratic institution where citizenship is actively learned and practiced (Pring, 2007). From this point of view, early-childhood services are democratic spaces trying to forge mutual discussion and decision-making between mothers, fathers, and professionals – and, indeed, with children themselves – with regard to the range and quality of the service they use or practice in, or attend, or rely on. This ideal is a demanding one – although, for example, the services in Reggio Emilia and other towns in Northern Italy do manage to operate on this basis (Bloomer and Cohen, 2008). Many early-childhood services in the Nordic countries have also devolved and have democratic decision-making at the level of the nursery and view mothers and fathers as rightful partners in the joint enterprise of care and education of young children (OECD, 2006).

The Tensions of the Marketplace

In market-driven early education and care services, the notion of parental involvement has become conflated with parental choice. In a situation where early education and care is purchased within the market – as is increasingly the case in neoliberal economies (Penn, 2009) – parents can choose between one kind of care rather than another, but they are essentially customers making a purchase between satisfactory or less satisfactory options, rather than partners who might help shape the service they use. Vincent and Ball (2006) have demonstrated how such choices are also class driven. Middle-class parents have the resources – both financial and social – to make strategic choices of education and care, whereas working-class parents are not only financially constrained, but make choices on the basis of the local and familiar. The result is that, in a market-driven situation – where parents are funded directly through tax credits or vouchers in order to choose early education and care (as opposed to supply-side funding where services are directly funded) – social stratification becomes amplified. The rich go in search of what they consider to be the best, whereas the poor stay put and take whatever is on offer locally.

In the global South – where most early education and care provision is provided by local entrepreneurs, and relies entirely on parental fees – cost is directly related to quality; the poorer the mother, the less that can be afforded. Those who can pay get relatively good services, but those who cannot do so get the poorest quality services – thus, increasing inequity (Penn, 2008).

The financial transactions over children between the parents and the teachers or child-carers who look after them, are frequently characterized by fracture and dissension. Staff are ambivalent about working mothers and feel exploited, while mothers try to prioritize an untroubled relationship with staff – even when they are unhappy with what seems to be on offer. On the other hand, mothers may also seem to devalue the work of those in charge of their children (Vincent and Ball, 2006). For example, the UK practitioner magazine *Nursery World* increasingly carries articles concerning disputes over fees between nursery owners and parents (Penn, forthcoming).

In a marketplace, early education and childcare are products which are bought; and the child will lose his or her place if the mother and father are unable or unwilling to continue with the purchase.

Conclusion

This article has very briefly considered some of the theories and debates on the topic of child rearing and early education. Conceptual distinctions have been made between the care offered by mothers and other carers, and that offered by professionals; however, in rapidly changing family environments, new accommodations need to be made. This is especially true with respect to working mothers. The growth of a substantial private market in many countries has been a further complication. Although the debate on mothers, fathers, and professionals, has mainly derived from the global North or rich countries, many of the considerations are also pertinent for the global South.

Policy Context

There are different legislative frameworks and qualifications for Early Childhood Education and Care (ECEC) practitioners within the four countries of the United Kingdom. In 1999, devolution of powers to the national governments of Scotland, Wales, and Northern Ireland resulted in complex layers of legislation. For example, in Scotland, in the area of early years and child-care policy, education, and health are devolved. Yet employment and the Department for Work and Pensions, including the child benefits system, as well as maternity and paternity leave, remain the remit of the UK government. Childcare Tax Credits, designed to promote a consumer demand-led approach to developing child care, are UK-wide. Aspects of workforce qualifications are both UK-wide and specific to the four countries, depending on the workforce and level of qualification. The complex legislative arrangements result in complex administrative processes in the ECEC field in the United Kingdom.

However, the context of redefining ECEC professional profiles in the four nations is similar. There is common inheritance of occupational segregation, low pay and status, and a predominantly female workforce. Social services have had responsibility for day care, child-minding, and child protection. Education has had responsibility for nursery (for 3-year-olds) and reception classes (for 4-year-olds) in primary schools (catering to 3–11-year-olds) and a few nursery schools (catering to 3–4-year-olds). The voluntary sector has provided preschool playgroups and many family support services. Health authorities have had responsibility for universal, statutory home visits, health checks to newborns and toddlers (through midwives working from hospitals), and health visitors (working from general

practitioner doctors' surgeries). Responsibility for play services has been with the recreation/leisure services. Each agency has had distinct training routes, qualifications, pay and conditions, knowledge and skills bases, beliefs, values, and languages. As a result, professionals working for these agencies hold different beliefs about the causes of problems presented by families and they have prescribed different treatments to put them right.

Since 1997 'Education, Education, Education' and 'Joined-up Thinking' have been mantras driving the Labour government reforms of children's services. However, within as well as outside government and its agencies, interpretations of these slogans have been multiple and contradictory. There have been disputes over the purposes and definition of early childhood education: Is it preparation for life, for school, for employment, or a phase in its own right? (Dahlberg *et al.*, 1999). There have been disputes as to what should be joined up and how: How infrastructures and funding streams should be redefined? How different pay and conditions of service reconciled? Also, How settings should be reshaped?

Overarching the rhetorical aims has been an ideology of public-private initiatives. These are to fund new developments to replace public sector services, and to reorientate the work of employees, including the use of short-term contracts, commissioning out, and employment of corporate rather than specialist agencies to manage the strategic planning and delivery of services (Ball, 2007).

Policy

In the United Kingdom, national policy aspirations have been to address poverty and inequalities by providing

high-quality, universal, integrated services for families. The justifications for investing in early years services were on social justice grounds (redressing the widening gap in life chances between the rich and poor) and for economic gain (money spent at the early stages of a child's development is likely to enhance life trajectories in health and education, enhance employment outcomes, and, ultimately, reduce government spending).

Many initiatives were launched to address these aspirations. In the late 1990s, Early Excellence Centres (EECs) were set up as one-stop shops to model services for the education and care of children under four, the training and employment of their parents, the health and welfare of the whole family, and support for parenting. From 1998 (eventually more than 500) 'sure start local programs' (SSLPs) were established as a flagship antipov-erty program in the most disadvantaged areas of England. They provided outreach and home visiting, support for families with preschool-age children, good quality play/early learning/childcare, primary and community health-care, and support for families with young children with additional needs and disabilities. The mode of delivery of SSLP services was through multiagency teamwork. In 2004, the 'ten-year strategy' made a commitment to providing 2500 children's centers by 2008 and 3500 by 2010. In 2006, partly in response to disappointing early findings on impact from the National Evaluation of Sure Start (NESS, 2005), SSLPs were rebranded as Sure Start Children's Centres. Further, primary schools are expected to take on a broader role in working with families with children aged 4–11 years as they expand into extended schools. Extended schools will provide before- and after-school care, leisure activities, family support services (including parenting advice and training and signposting to employment opportunities), and provision for children with additional needs and disabilities. Social work and health professionals are required to work closely with those delivering education and care services.

Children's trusts within all English local authorities (the bodies responsible for commissioning, coordinating, and monitoring the delivery of all services for local communities) are expected to ensure a suitably diverse range of providers of children's services. They must commission services of uniformly high quality equitably from the private, voluntary, and maintained sectors, in line with parental choice (Her Majesty's Government, 2006). In sum, the policy context has generated major structural reform of the ECEC field, impacting the professional profiles of all those engaged.

Legislation to Support Policy Change

Reforms in education and care services were bound together by a seminal Children Bill and Children Act in 2004 which enacted principles outlined in the Green Papers

Every Child Matters (DfES, 2003), the Ten-Year Strategy (Her Majesty's Treasury, 2004), and *Every Child Matters: The Next Steps* (DfES, 2004). There are five key principles embedded in the outcomes specified in the legislation: being healthy; protection from harm and neglect; enjoying and achieving; making a positive contribution; and economic well-being. The principles are embedded in the Office for Standards in Education (Ofsted) affirming the inspection of all settings delivering education and care for children from birth to school-leaving age. In 2007, an ambitious children's plan was launched by the Department for Children, Schools and Families, with goals to improve schools and the way families and children are supported.

Education

For children aged 3 and 4 years, there is an entitlement to two-and-a-half (soon to be three) hours of free pre-school education a day for 38 weeks a year. There is currently a pilot scheme offering part-time, free daycare for 2-year-olds from families in poverty. The entitlement may be delivered by a range of providers. The Early Years Foundation Stage, which was introduced in 2008, replaces earlier legislation, and provides a statutory curriculum framework for children from birth to 5 in early years provision.

Under the duties of the Childcare Act 2006, practitioners in England are required to complete a Foundation Stage profile for each child, recording the child's progression in physical, intellectual, emotional, and social development against 13 assessment scales. By the start of compulsory schooling (at age 5), children are expected to attain a set minimum score in the personal/social/emotional and the communication/language/literacy scales. Local authorities are required to return data to the Department for Children, Schools and Families at institutional level. There is heightened concern by staff about accountability for the results and increased scrutiny of ECEC professional profiles.

Childcare

Reforms have included a National Childcare Strategy (in 1998), a Ten-Year Strategy for Childcare in 2005 (DfES, 2005), and the Childcare Act in 2006. (These reforms have enabled the expansion of child-care services, mainly through the private sector, to ensure that parents (in particular those on benefits) can return to work.) The Neighbourhood Nursery Initiative was launched in 2000 to increase the supply of day care in poor neighborhoods with a requirement that their funding should be commissioned from the private sector. In 2007, in England, 80% of child care was provided by the private sector. The globalization of corporate child care has resulted in new risk: How will the imperatives of social justice be reconciled with those of making profit? (See Williams (2004), for a discussion of the ethics of social care.) There is concern that

recruitment and retention of more highly educated and better-trained professional staff will be incompatible with a private system which aims to make profits and where parents are usually responsible for paying a high proportion of the costs.

Either the government will have to subsidize equitable salaries between comparable professionals, such as Early Years Professionals (EYPs), and qualified teachers, or private providers go out of business as parents will not be able to afford the fees or staff careers and salaries will be dictated by the settings in which they work. Those with guaranteed salaries and career structures, such as teachers in maintained schools, will be reluctant to retrain to work in new (private?) multiprofessional settings where there are no such protections.

Integrating Early Years Care and Education

For a brief period (1997–2003), there appeared to be a possibility of developing a new concept of integrated care and education with a new working-framework, structures, and curriculum. Initiatives such as EECs and SSLPs had been seen as moving toward such integration. The extension of children's centers from targeted disadvantaged areas to all areas, through the ten-year strategy, appeared to recognize that providing integrated early care and education was good for all families. Aspirations were for "high quality provision with a highly skilled childcare and early years workforce, among the best in the world" (Her Majesty's Treasury, 2004: 1). However, the implementation of these ideas indicates that since 2004 forces driving care and education apart have strengthened. Even though new structures were set up with the purpose of integrating children's services, schools and teachers (including nursery teachers) were left outside them.

When there is emphasis on children of all ages and the integration of all children's services, the strategic scale of the work may be so great that it risks destabilizing and overlooking or alienating core subgroups to the extent that more positive outcomes are compromised. At the core, professional work in integrated services must translate into practical actions that advance the outcomes of children and families.

Multiagency and Transdisciplinary Teams Provision and Settings

Partly by chance and partly because of government commitment to offering choice to consumers, policy reforms in the United Kingdom have ensured service users have a mixed menu of provision. Three types of settings exist: private-for-profit provision (private schools with day care and nursery education attached, day care, and childminders), voluntary sector provision (preschools and family

centers), and publicly funded (maintained) nursery schools, Sure Start Children's Centres, and early years units in primary schools. The settings differ in whether they offer full-day care or sessional care, and whether they provide free educational entitlement.

Many young children attend several types of provision before they enter formal school. This has consequences, given the variable quality of experiences provided in preschool services. Very young children may encounter inconsistencies in carers, frequent changes in routines and familiar places, and exposure to changing cultures and values in settings. Parents and carers have to make complex arrangements for children, taking part for varying durations, in different types of settings.

The nature of the setting has consequences for the type and qualifications of staffing. A significant driver of quality is the level of qualifications of the workforce and yet the level of qualifications in the ECEC workforce is still low. For example, in maintained nurseries, 80% of the staff were found to be qualified with A levels, or National Vocational Qualification 3 (NVQ3) or higher, while for voluntary and private sector nurseries levels fell to 51% and 46%, respectively (Coxon *et al.*, 2007).

Workforce Reform

An aim coordinated by the Children's Workforce Development Council (CWDC) is to upgrade the workforce qualifications so that all supervisors of full day-care provision hold a relevant level 3 qualification and at least 50% of the remaining child-care staff are qualified to level 2. In recognition of the complexity of managing integrated services settings, a master's level qualification (the National Professional Qualification for Integrated Centre Leadership) for present and potential managers was made available. Other initiatives include a 2-year foundation degree offered to the existing early years practitioners who have limited formal training with recognition of excellence as senior practitioner serving as an incentive for such staff to study. As a further encouragement to career progression, an additional 2-year route was offered to gain qualified teacher status. Further a graduate professional status aims to create an EYP for work in every children's center and in every full-day-care setting to provide an integrating role as well as taking responsibility for planning, assessing, and recording children's progress through the Early Years Foundation Stage. The training of teachers remains separate. In practice, teachers working in integrated settings, but trained to work in schools, have found the transition into a different working culture difficult. For many, the birth of EYPs raised the specter of a different kind of teacher – one for example where the training, unlike teacher training, is assessed through attaining competency standards which do not include being supervised while interacting directly with children (CWDC, 2006) and can result in lower paid staff

for children under the age of 5 in English preschool settings. There are currently fierce debates in England at central and local government levels about applying a common funding formula to all settings providing education and child care.

In England, development of an Integrated Qualifications Framework is emerging, described as a climbing frame of qualifications, which will allow staff working with families and young children to move within and across occupations. The aim is for clear career pathways and qualifications not only for a chosen job, but also for routes to move, for example, from being a nursery nurse in a preschool setting to becoming a care assistant in a children's home – without having to start all over again.

Working in Multiagency and Transdisciplinary Teams

'Joined-up Thinking' that has underpinned workforce reform in the last decade has left questions. There is confusion about the nature of teams working together in integrated service settings. Teams may be labeled as multiagency with the team made up of some specialists and some generalists. Within each agency team there may be workers from several disciplines (e.g., in a hospital-based team representation from psychology, medicine, and speech and occupational therapy). Each layer within agencies and disciplines provides differing levels of challenge to those charged with working together.

There is evidence of four common dilemmas in making multiagency teams work (e.g., Anning *et al.*, 2006; Anning *et al.*, 2007; Siraj-Blatchford *et al.*, 2007). The first relates to the structural features of the team. For example, some professionals are seconded to multiagency teams for short periods or on part-time contracts. Those appointed as core members of a team may be on time-limited contracts. Where a professional feels peripheral due to their working hours or contracts, full commitment to a team may be compromised. Arrangements for professional appraisal and supervision may have remained with the agency from which staff were released. There can be tensions between the priorities of their lead agency and those of the multiagency team. For example, a health visitor may be expected to take on a more active role in offering parenting support in her multiagency team, to the point where she feels her attention is diverted from her mainstream agency role of monitoring children's health and well-being. The tensions between core and peripheral team members are often exemplified in the allocation of space and resources for staff to carry out activities.

The second dilemma is ideological. A social worker may have different constructs of children and families, ascribing blame for problems with children's behavior to society, while a teacher in the same setting ascribes blame to parents. The cultures of medicine and preventative health workers may collide; the medical model focuses

on diagnosis of the medical condition and applying treatments in line with scientific evidence, while the health worker may see the patient within the social network of a particular culture, community, and family. For professionals expected to work in a joined-up way, considerable time may be spent clarifying the distinct beliefs and values of team members. It can be challenging for many (particularly those in lower-status occupations) to have to articulate why they do things in certain ways and how this relates to what they know. They may never have been asked to do so before. Opening up to possibilities, especially when they are cloaked in professional jargon, involves a real effort and can destabilize a professional sense of self. Yet, exploring the knowledge and beliefs of those from other agencies and disciplines can be rewarding, leading to the generation of new and more expansive forms of knowledge both for individuals and the whole team. This is a benefit to service users.

A third set of dilemmas are procedural, related to the nitty-gritty of daily activities of delivering services. The pace of change in children's services may cause stress. The distinct approaches of staff from different agencies to documentation and record keeping, and related attitudes to confidentiality of information can exacerbate tension. Different work cultures can make workers particularly anxious about sharing information. Yet, one of the pivotal aspects of making interagency collaboration work is sharing information. At one level, this is about professional skills and expertise and the knowledge base underpinning actions, and, at another, this concerns the specifics of individual cases for whom the team is responsible. A further concern is how specialist and generalist staff are deployed. For those with specialist (and by implication higher-status) training and qualifications, taking on generic team functions may feel like being de-skilled. An example is when a teacher in a children's center is scheduled to take on routine, caring aspects of work with children, whereas their perceived primary role is that of an educator. Carers may feel stressed about expectations that they should teach. Such perceptions underline the difficulties of trying to introduce a new role.

Specialists may question the competence of generalist workers to take on aspects of work they perceive to be the preserve of specialists. An example is when a speech therapist is charged with training mainstream nursery nurses or teaching assistants to support children with language delay or impairment. In this female-dominated workforce, there is also discomfort with confronting disagreements and conflicts. Where individuals and teams are not guided by skilled managers in how to deal with conflict, teams continue to work in parallel with each other, each defending their own disciplinary and agency boundaries inherited from their past working lives, thereby not moving the promised gains of genuine multiagency teamwork.

The fourth set of dilemmas relates to building inter-professional relationships over time. The speed at which

multiagency teams is formed and expected to operate, the rapid shifts in professionals' roles and responsibilities (often without training) can leave individuals feeling that their professional identity is at risk and their job satisfaction eroded. A professionals' sense of self, of 'Who I am', is deeply embedded in their work – 'What I do'. Leaders and managers need to support professionals when they feel destabilized by workforce reforms and be aware of tensions arising from the differing pay and working conditions of their team members. It is not unusual, for example, for a teacher in an integrated service setting to be earning more than her (social-work-trained) center manager and yet still be entitled to the long holidays and short working days afforded to teachers.

Professionals may need to retain links with their specialist agencies, in order to ensure a career trajectory in the home agency. This means that managers have to make judgments about reconciling the training needs of a whole multiagency team with those of individual members of the team.

Implications

Proposals for reforms in service provision and workforce qualifications for ECEC are visionary and show commitment to improving the life chances of young children and providing day care for parents wanting to return to work.

As we have argued, the case study of ECEC reform in the United Kingdom indicates that there is a risk that the Every Child Matters agenda and, more recently, the Children's Plan have been over ambitious. For example, the commissioning of services by Children's Trusts to ensure a diverse range of providers is a challenge when day care is largely in the hands of the private sector and education in the hands of the maintained (public) sector; and to afford to staff and resource its services to deliver the Early Years Foundation Stage. There is growing evidence of tensions between running a for-profit service and maintaining high-quality provision of day care, and of the challenges of regulating services offered by independent companies. In England, the maintained sector, offering most of preschool education services, is better resourced and, in particular, has more highly qualified and expensive staff than the day-care sector. Voluntary, private, and maintained sectors are subject to rigorous monitoring, regulation, and inspection. But how equitable are services for families using different types of provision?

The creation in England of a new EYP raises unanswered questions about how they will be integrated into the current workforce. For example, how will an EYP equate to an Early Years Teacher? At a more visionary

level, how will a new breed of ECEC professional drawing from the sectors of health, education, care, and family support learn to work together for the benefit of families with young children if there is little clarity about training at initial service level or retraining at in-service level? Who will fund the new qualifications and enhanced salaries?

Early Childhood Education and Care Staff Support: Mentoring and Professional Development in Finland

P Lindberg, National Institute for Health and Welfare, Helsinki, Finland

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Curriculum in ECEC – A learning and teaching plan including developmental aims, pedagogical processes, and contents. In the Finnish context, a framework or guidelines for implementing ECEC based on the society's values; enhances child's rights and well-being.

ECEC (Early childhood education and care) – A holistic system that covers both the day-care arrangements offered to families and the goal-oriented early childhood education open to children. Care and education are brought together in an integrated way also in the daily pedagogical activities.

E-learning / working environments – Learning environments that use specific software to provide web-based tools to aid learning processes. Also referred to as virtual learning environments (VLE).

E-mentoring – Electronic mentoring that is carried out by using electronic forms of communication, such as emails or media using Internet connection.

Group mentoring – Mentoring where the mentor is a learning leader of a team or a group. In a group mentoring situation everyone can benefit from the diverse knowledge and experience of the learning leader.

ICT – Information and communication technologies; may also be referred to as information technologies (IT).

Open source – Open source is a development method for software that enables access to the source code and free distribution.

Peer mentoring – A form of group mentoring where each participant is equal and benefits from the mentoring situation. Participants in peer mentoring complement each others' knowledge and skills in a reciprocal dialogue.

Reflection – Critical way of observing and evaluating actions in the working community. It helps to develop practices by questioning current ways of working. Reflection makes values, tacit knowledge, and experiences more visible.

The Need for Staff Support

Well-educated staff with ongoing access to professional development opportunities have been raised as a core element in the provision of high-quality early-childhood education and care (ECEC) services (OECD, 2006). The foundation for professional knowledge is laid during the initial education of the staff. However, policies focused only on increasing teachers' education level cannot suffice for improving quality. To keep the professional skills of the staff in balance with the changing context and situation of the society, professional development should be a continuous and intentional process. This process should be formed by a number of relevant support measures and clear structures for staff development.

The required staff competencies are numerous. Staff should have knowledge of what is needed to foster the well-being, development, and learning of children and be aware of the rights and potentialities of young children. Staff should also be skilled for operating in partnerships with a variety of parents from a number of social, cultural, and educational backgrounds, and with other professionals in schools, healthcare, and social services. Many children have special needs. Furthermore, families may have problems that require either support from the staff, or at least advice on where to get support. In the information-based global world, ECEC staff also need to be capable of using new technologies – such as computers and other digital equipment. Furthermore, staff in ECEC should have reflective skills and they should be competent in team work.

The Organization for Economic Cooperation and Development (OECD) (2006) demonstrates that ECEC staff, in many countries, face several practical challenges in accessing in-service training. There are too few professional development opportunities available – both in the public sector and in parts of the private sector. Considering this, it is important to develop support models that can be brought closer to the ECEC practice, for example, by utilizing modern technologies, or by applying methods where the expertise of the staff and other regionally available sources can be employed. Moreover, the everyday working environment of the ECEC staff should be used in the development of support measures because it forms an important context for building expertise.

Mentoring provides a functional means for holistic professional learning, taking into consideration the different developmental needs of staff. Mentoring can also have an impact on the development of ECEC quality by providing an instrument for knowledge transfer, translation, and reflection. The initial education of the ECEC staff provides a theoretical basis for the work, while mentoring may augment the reflective element that affords a means to deepen the understanding of the theories-in-use and, thus, improve the intentionality of the actions taken.

This article adopts a perspective of mentoring as staff support in ECEC. A brief introduction into mentoring, in general, is given, but the focus is on the development of working communities, and e-mentoring. To provide practical illustration, two examples of how different mentoring models have been used in professional development in Finland are presented.

Mentoring in Professional Development

Mentoring is a versatile method used for professional development in a variety of areas. In general, mentors are seen as more experienced and competent people who – in different contexts – can act as facilitators for the less experienced. In this article, only work-related mentoring – in the context of education – is discussed, although mentoring has been used also for other purposes, such as supporting young people to realise their potential in life.

Mentoring has been used extensively in the rapidly changing business world – the environment in which many of the mentoring theories were originally developed. In the education sector, mentoring is widely used – especially as a method for teacher students and for beginning teachers in their early career development (Scherer, 1999). Observation of the Internet pages of a number of universities and other teacher education providers demonstrates well the contemporary relevance of this support method. Staff-support methods using different forms of mentoring have also been applied in ECEC in many countries. Mentoring has expanded from the more traditional one-to-one mentoring processes into a variety of models for deepening the expertise of entire working communities. Mentoring provides a tool for employing local experts as mentors in the professional development processes (Lindberg, 2007).

What is Mentoring?

Over time, there has been an array of definitions on mentoring. Due to the multilateral nature of mentoring, a simplified categorization of different mentoring models is difficult. According to Clutterbuck (2004), the differences in definitions derive from the purpose of the relationship, the

expectations of the mentoring pair, and the context in which they operate. The two main mentoring traditions – the US and the European tradition – originate from different assumptions concerning the role and nature of mentoring.

Kram (1985) – who represents the US tradition – has divided mentoring into two main categories: career and psychosocial mentoring. Career mentoring – which is also called sponsorship – is a top-down model where the mentor is typically in a higher position in the same organization with the mentee and has power to influence the mentee's career. The mentor's tasks include coaching, protecting, and supporting the mentee, arranging challenging tasks, and helping the mentee to meet important people. Psychosocial mentoring is about strengthening the mentee's identity, self-respect, and feeling of competency, with the mentor being a role model, guide, and friend. Even if the mentoring task would focus only on one of these categories, in most mentoring cases, the other category is included at some stage of the process.

Meggison *et al.* (2006) – who represent the European tradition – view mentoring as a relationship where one person helps another to develop in the process of knowledge, work, and thinking. The mentor is often more experienced than the mentee, but not necessarily in a direct supervisory position. The focus of the mentoring process is on providing the time and space to take a wider view, and on helping the mentee to find his or her own solutions. The mutuality of learning between the mentor and mentee is emphasized (Clutterbuck, 2004).

Mentoring redefined

Many of the contemporary definitions seem to point out that the distinction between the mentoring traditions has diminished as the North American tradition has become closer to the more holistic European one. The mentoring process is more reciprocal than in a traditional apprenticeship model, and the mentor's role has changed from being an expert and adviser to a listener and promoter of reflective thinking (Boreen *et al.*, 2000). The mentor is also seen as a learner and, subsequently, the mentoring relationship brings advantages to all parties: the mentee, the mentor, and the organization. (Kram and Hall, 1996).

Group and peer mentoring

In addition to the traditional one-to-one mentoring models, alternatives have been developed. This has been important especially when organizations have become flatter and the individuals more self-reliant. In group-mentoring, the mentor is a learning leader of a team or a group. In a group-mentoring situation, everyone can benefit from the diverse knowledge and experience of the learning leader. Group-mentoring, often, also includes peer mentoring – where each participant is equal and benefits from the mentoring situation. Participants in the

mentoring complement each others' knowledge and skills in a reciprocal dialog (Kaye and Jacobson, 1996).

E-mentoring

E-mentoring is – at least partly – a virtual process. It is carried out by using electronic forms of communication, such as emails or other media using Internet connection (Kasprisin *et al.*, 2003). In synchronous e-mentoring, the participants in the mentoring process are online simultaneously. The interaction takes place using tools that enable immediate response and feedback – such as telephone, chat-channels, the Skype, or video conferencing. In asynchronous e-mentoring, the mentoring parties are engaged in the mentoring process at differing times, for example, via email, blogs, or discussion forums.

E-mentoring offers an option for a mentoring relationship, especially when there are no opportunities for face-to-face mentoring. E-mentoring is easier to access – being independent of time and place – and it is more egalitarian than traditional mentoring. It can also be less costly, at least from the point of view of the mentoring process (Bierema and Hill, 2005). However, its cost-effectiveness has been a point of debate, since setting up websites and creating software is time consuming and expensive.

E-mentoring is, increasingly, used to strengthen the relationship between education and working life. In addition to one-to-one mentoring using web-tools and email, the development of e-learning and e-working environments enables virtual group and peer mentoring. Especially in the ECEC field – where professional isolation may occur and where there may be a lack of local experts to support professional development – e-mentoring can offer better opportunities for finding mentors and bringing mentoring processes within the reach of the staff. Internet environments enable the involvement of a greater number of people in the mentoring processes.

Mentoring and reflection

For an individual, the development of expertise means responding to challenges and deepening understanding by being open to new ideas, by continuously seeking more information, and by learning from others in dialog and reflection. This is, however, not an easy task. First, a long working history does not necessarily guarantee improved expertise. Instead, it may lead to routines that create resistance to change and restrains development (Hakkarainen *et al.*, 2004). Second, acquiring new information and theoretical knowledge is made easy at present, with a variety of sources – such as educational courses, reading, conferences, or workshops – being available. New information may seem relevant and useful. However, linking theory and practice is not easy, and thus it is important to ask how new ideas and information might create new thinking and change practice.

According to Argyris and Schön (1974), theories of action are used to link our thoughts with our action. Theories of action can be espoused (those we know) or they can be theories-in-use – which are tacit in nature. One problem with transforming new ideas into practice is that the behavior of staff is governed by theories-in-use. To develop the working communities and to proceed in professional development, the tacit theories-in-use have to be made explicit by interaction and reflection in the working community.

When adopting reflective practices, the ECEC personnel start to think more of the implications their choices have for different children. Consciousness in the educational process means that the staff members are capable of examining their own pedagogical thinking and view of learning, that is, the capacity to ponder over what is best for the child, how the child learns, why they are doing what they are doing, what are the aims of education and the methods to reach the goals.

To achieve progress in the reflective practices, a promoter appears to be needed. This is where a mentor can play a fundamental role. The mentor can be internal or external to the work setting. Especially when the mentor's task is to promote change, the distance of an external mentor from the organization, sometimes, allows better handling of challenging and difficult issues. An external mentor works as an outsider who questions trivial issues, and who initiates dialog and common reflection in the working community. Sometimes, the use of internal mentors – who may be too committed to the working community's ways of action – can halt the development of working practices and values (Arhén, 1991), especially in the early-childhood field where the development of new thinking often collides with a this-is-how-we-have-always-done attitude. Even where members of the staff want to be reflective and begin to develop their practices, it may prove difficult. In the hectic daily working situation, old habits and routines easily take over if there is no one to support and encourage the process of change. A mentor can help to sustain the reflective atmosphere and support the systematically progressing change.

Mentoring the Working Communities

Mentoring brings certain advantages to professional development compared to traditional staff-support methods. Different mentoring models can help to develop staff competencies when there are no options for organizing other long-term staff educational programs. Using local expertise in mentoring can promote reflection processes among staff, especially when there is variation in the educational background of the staff members – both in the level of education and in the knowledge and skills they hold. In geographical areas with long distances and

low population density that often also have shortage of qualified staff, using external mentors from nearby locations or exploiting e-mentoring may be helpful in the provision of staff support. The National Research and Development Center for Welfare and Health in Finland developed two mentoring programs for ECEC, supplying national and regional processes for professional development. To better understand the function of these models, it is worth knowing that, in Finland, over 90% of the ECEC services are publicly provided. The services are regulated nationally and provided by municipalities. Services include center- and family-based ECEC.

A Coordinating Mentor in the ECEC Curriculum Process

Finland's national curriculum guidelines provide a frame for the content of the ECEC that has to be discussed and reflected upon at the municipality and individual service levels. The idea of the guidelines document is to promote an ongoing development process at each level, to increase the professional awareness of ECEC staff, and to, thus, raise the quality of the services. To implement such a framework curriculum, requires a well-structured professional development program – including both the provision of theoretical and practical knowledge, and multiple staff-support methods. The ambitious goal of the curriculum framework is to go beyond the daily discussion of functions, and to argue what is important in ECEC and how a vibrant community of children and adults can be built. (Lindberg, 2007).

The structure of the mentoring models

As a structure to support the professional development of ECEC staff throughout the country, a mentoring-network approach was developed. The mentors in this network were municipal ECEC experts with high qualifications and long-term working experience. The core of the approach was formed by eight 2-day mentor training sessions organized at the national level at the beginning of the process, in 2003. During the training sessions, the mentors were educated about both the content of the

curriculum and providing support for the ECEC staff in the implementation process.

Following the training, the mentors had two main tasks in the curriculum process to fulfill: (1) to start a networking project in their own municipalities or in larger geographical areas with a number of municipalities; and (2) to act as a group and peer mentor for the mentees in their areas. Thus, in addition to being experts to guide the staff for the content of the curriculum and to start reflection processes to change their practices accordingly, the mentors were coordinators of the municipal curriculum processes. The municipalities adjusted the group mentoring in accordance to the size and local needs into three different models. All models had several layers, the number of them depending on the size and other features of the municipality (Figure 1).

Model 1

Model 1 utilized group mentoring where one municipal mentor mentored several mentees in the municipality. Depending on the size and resources of the municipality, each mentor could have one or several groups of mentees. The mentoring inside the municipalities was organized using one of two alternatives: (1) the groups of mentees were usually staff from center-based ECEC settings (one group = one center) or a group of family child-minders; (2) each of the ECEC centers sent one or more members of staff into a mentoring group to be inducted into the mentoring process. They then became mentors for the second mentoring layer. Usually, a family child-minder (family-day care) coordinator also belonged into this group. The second layer of mentoring was then formed inside the centers between the mentor who participated in the induction meeting/s and other members of staff. This model was, especially, utilized in large cities.

Model 2

In model 2, a single mentor took care of several municipalities. This model was mainly used in small municipalities that did not have enough critical mass of adequately trained experts to run individual municipal mentoring programs. The municipalities combined their resources

Figure 1 Local-level group-mentoring models.

and educated one mentor to co-ordinate a larger area of several municipalities. Often, each of the municipalities on the area had only one center, or their system consisted only of family child-minders.

Model 3

Model 3 effectively combined group and peer mentoring. Each mentor in the network had their own municipalities to mentor. In addition, mentors from several municipalities formed a network that utilized peer mentoring among the mentors by organizing their own meetings and training.

For example, in Northern Finland the regional Social Competence Center coordinated a model where 22 municipalities formed a network, together with the regional university – which, in this case, provided the mentors. Some of these municipalities were very small and did not have their own experts.

The mentors

The municipal mentors were skilled professionals with long-term working experience. Many of them had higher education than ECEC staff, in general – often possessing a master's degree in early education. Many mentors held day care-center leadership positions, and – especially in the smaller municipalities – had municipal-level leadership positions. In addition to being the process organizers, the mentors were the supporters of groups. These tasks demanded strong organization skills and extensive knowledge and experience in ECEC work. The leader or senior-expert positions held by these mentors gave them more credibility to mentor the other staff members.

Many of the staff members participating in the process as mentees were also highly educated and skilled with long-term working experience. This made the mentoring processes challenging and created a pressure to even more reciprocal reflection processes – based on dialog and peer mentoring.

Web-based support

The mentoring network was provided with its own extranet environment within the national public ECEC website. The extranet contained all training material, other important information, and a discussion forum. Via the extranet, the mentors had the opportunity to interact with mentors from different municipalities. They could, thus, share their visions and understanding, as well as problems, with the network. The open website also had an essential role in providing working tools and content material to assist the municipalities in their own curriculum processes.

Promoting Professional Development by Group-Based E-Mentoring

An e-learning environment for the professional development of ECEC staff was piloted in 2002–04. The environment consisted of material and process tools to promote

professional development in center-based ECEC settings. The centers were from four municipalities in the South of Finland – 12 centers in all. The primary goal was to offer the centers an opportunity for self-reflection with the help of the tools and e-mentoring. The process involved all the staff in the centers, and thus also aimed at increasing the sense of belonging in the working community. The e-learning environment, as a whole, supported professional development processes and encouraged reflection among members of staff – evidenced by the content of each center's documentation using the preset documentary tools.

E-mentoring was provided within the learning environment by a network of seven mentors. All the mentors in the network were experts working in the municipalities that took part in the process, and were highly educated with long-term career background. Each of the mentors also had a specific topic of expertise – such as children's special needs. The mentors' tasks were twofold:

1. To follow the documentation of the centers and to provide the centers help by offering reflective questions, comments, information, or suggestions for material to be utilized. All these contacts were made on an asynchronous discussion channel inside the learning environment. All activities were open to the centers involved, which allowed the centers also an opportunity to support each other in the form of peer mentoring.
2. To respond when a center actively asked for support in the form of questions for the network of mentors.

The mentors acted as a team. One of the mentors at a time took the main responsibility for reacting to questions posed on the network, for coordinating the discussion in the network, and for ensuring that the answers were completed in time. A rota of biweekly periods was arranged for this. The mentors also had their own forum inside the learning environment where only they had access. This allowed mentors themselves an opportunity for peer mentoring: to discuss and analyze the issues, expand their knowledge, and thus provide better support to the centers.

Developing working communities

A common feature in each mentoring-model example is that they emphasize the importance of reflection, dialog, and reciprocity in all actions taken. The mentors' tasks are to support the self-reflection of the mentees in ways that encourage them to reach their own conclusions and to find their own solutions within the working communities. The mutual dialog within the working communities is of crucial importance in the process. This dialog covered issues such as the basic values of the work, the importance of the being clear about the goals of education and the effect of pedagogical choices for the child's well-being,

learning, and development. These were seen as the key issues in promoting the development of the ECEC work.

Conclusion

The ECEC systems in different countries are strongly socially and culturally bound. It would be overly simple to claim that there can be universally suitable staff-support methods to promote professional development. However, certain aspects of mentoring can offer well-functioning tools for professional development programs in different countries, especially when combined with other staff-support methods.

In the ECEC sector, e-mentoring has much to offer in the future. However, it faces a number of challenges that have to be resolved if e-mentoring is to reach full potential. Contrary to face-to-face mentoring programs that can be set up – for instance, by a single center – e-mentoring needs a coordinating organization to fund and build the mentoring environment, and to manage and develop it. Although the problem of building the environment can be overcome by using environments based on open source, resources to educate the staff about effective use of the environment are required. In many countries, ECEC staff is not yet proficient in the use of information and communication technology (ICT), which creates further pressure for these kinds of proceedings. Asynchronous e-mentoring may be an easier and less expensive option to commence. Most ECEC professionals are familiar with email and discussion channels, and, therefore, the threshold to use them is lower.

An important aspect in building successful mentoring models is the training of mentors. Many of the websites providing information about mentoring in the education sector pay substantial amount of attention to mentor training. As mentors in ECEC communities are, mostly, professionals who have no formal education for adult teaching, educating the mentors is a crucial task for successful mentoring processes. One of the important aspects in the presented Finnish professional development processes was to help the mentors to understand, clearly, the idea of mentoring: what does it mean to become a mentor, what are the mentor's obligations, and how time consuming mentoring is. Mentors need support in their work and various peer-mentoring options can help give this support. It is also important for mentors to feel they belong to their respective working communities, even if they are external mentors.

Personality and individual skills and knowledge are important elements concerning professional expertise. In most of the current mentoring theory and discussion, mentoring supports an individual's professional development – either by providing help in one-to-one relationships or in groups. Less attention has been paid to the development of the entire working community, its values, and core ideas.

These aspects, however, should not be exclusive, because, on one hand, the working environment has an important role in the development of professional expertise (Karila, 2008) and, on the other hand, each individual has an effect on the working environment, its culture, and its course of development. Instead of viewing mentoring only as a process – where an apprentice is mentored into the existing, unchangeable working culture – mentoring can provide tools for change and learning. To realize the potential of mentoring, members of staff are required to have the courage to think, to take intellectual risks, and to exchange ideas with others openly in the process of developing expertise (Hakkarainen *et al.*, 2004). As such, mentoring can be an empowering process for the individual members of the working community.

Mentoring can decrease resistance to change by providing support and encouraging reflection and open dialog. In this way, mentoring helps to create an intelligent working community based on mutual, continuous learning.

Glossary

Health-related quality of life (HRQL) score –

A numerical valuation of life in a given health state anchored between 0 (death) and 1 (perfect health). These scores are used to adjust life years to quality-adjusted life years (QALYs). Thus, a year of life lived at an HRQL of 0.7 is equivalent to 0.7 QALYs (or 0.7 years of perfect health).

Medical expenditure panel survey (MEPS) – An annual survey of around 40 000 households in the United States. It includes a household component with demographic and health information of the participants. It also contains a provider component that obtains the cost of medical visits from providers.

Prospective studies – The studies in which subjects are followed over time. Typically, this involves following subjects with and without putative risk factors for disease to ascertain who does and does not develop the disease.

Quality-adjusted life expectancy (QALE) – The life expectancy in perfect health. It is equal to the product of life expectancy and the age-adjusted health-related quality-of-life score.

Quality-adjusted life year (QALY) – A year of life lived in perfect health.

Randomized controlled trial – A form of experimental study in which subjects are randomly assigned to either a treatment condition or a control condition.

Risk ratio – The ratio of the probability of an event occurring in an exposed group relative to the probability of the event's occurring in the unexposed group.

Education and health together account for a quarter of the gross domestic product in the United States, and are perhaps the two most complex areas of domestic policy. They are also intertwined. Not only is health critical for learning, but also education appears to be a major determinant of health.

This article begins with a brief overview of the research exploring whether the relationship between education and premature mortality is causal. The primary causes of death from which the less educated are more likely to die are then explored. These causes of death point to six health risk factors associated with lower educational attainment: higher levels of stress, lower social standing, social deprivation, behavioral risk factors, lower health insurance coverage rates, and suboptimal cognitive skills.

Overview of Causal Relationships

It has been recognized since the time of Hippocrates that social conditions shape the ecological niche in which people live or die. Some 2300 years after Hippocrates, Horace Mann proposed that education might serve as a tool for repairing social ills. He observed that education is “the great equalizer,” providing people with the knowledge and technical skills needed to survive. While Mann was referring to income and social prestige, education also appears to be an equalizing force in health.

Evidence of a causal relationship draws upon a single, randomized, controlled trial, instrumental variable analyses, and a large number of prospective studies. The lone, randomized, controlled trial with long-term follow-up is the Perry Preschool Program, a study consisting of 123 students randomized to 2.5 h of preschool at ages 3 and 4 years or no intervention. Although the study was small,

children randomized to the preschool intervention were much more likely to report better health status and fewer behavioral risk factors for health (such as seatbelt use or smoking). By age 40, two of the children in the experimental group had died and five in the control group had died.

Most evidence arises from natural experiments, which primarily rely on instrumental variable analyses. Lleras-Muney (2005) conducted what is perhaps the best known of these studies, using compulsory schooling laws to examine the causal relationship between educational attainment and mortality. Her instrumental variable analysis exploits the fact that compulsory schooling laws should have a direct influence on educational attainment, but not on mortality rates. The analysis first examines the effect of compulsory schooling laws on educational attainment, and then estimates the effect of these laws on mortality. The ratio of the effect of the laws on mortality to the effect on educational attainment produces a direct estimate of the causal effect of educational attainment on health. Using a synthetic cohort derived from census data, Lleras-Muney (2005) found that compulsory schooling and child labor laws reduced mortality rates by as much as 60%. Given that adjustment for income or occupation produced little effect on the analyses, it was hypothesized that improved cognition, manifested as improved medical decision making, was the causal factor through which educational attainment produces health.

This same methodology has since been replicated in a number of other countries with similar results. It was also later explored using a larger census sample as well as using data from the Survey of Income and Program Participation (SIPP). This subsequent analysis of the census data raises concerns that the instrument might be picking up smooth cohort trends in educational attainment rather than discrete increases induced by more stringent compulsory schooling laws. Nonetheless, using the SIPP, a strong causal association between educational attainment and self-reported health was also found.

Beyond the handful of domestic and international natural experiments and randomized studies with proximal outcome measures, there are few studies specifically examining the causal association between education and health. However, there are a number of reasons to believe that the relationship between educational attainment and health is causal in nature. First, these studies do not reveal patterns in the relationship between health and third variables, those other than education, so little of the association is explained by unobserved heterogeneity in correlational analyses. Second, because children and adolescents have very low rates of chronic disease, sickness is not a major cause of low educational attainment. Thus, we can be more confident that most of the difference in life expectancy by educational attainment is explained by education rather than poor health. Third, the association is strong and consistent across cultures and time, and

fourth, the primary causes of death between those with more and less education can be readily explained by the very risk factors for diseases for which less-educated persons are most at risk.

The education–health association has been explored by epidemiologists, sociologists, economists, urban planners, social psychologists, and even neuroimmunologists. Once this work is connected, a rich picture emerges. Specifically, the risk factors most obviously linked to educational attainment are also risk factors for the diseases responsible for the 6–9-year gap in life expectancy between those with and without a high school diploma (Wong *et al.*, 2002).

These diseases include cardiovascular disease (35% of all deaths), cancer (27% of all deaths), infection (9% of all deaths), injury (5% of all deaths), lung disease (5% of all deaths), and diabetes (4% of all deaths). With the exception of injury, these risk factors overlap with respect to the diseases they cause (**Figure 1**). Many of these underlying risk factors are remarkably consistent with new evidence from the fields of psychology, neuroanatomy, neurophysiology, molecular biology, sociology, and epidemiology. Others, such as smoking or lower rates of health insurance, have been widely discussed. However, the interdisciplinary research helps us better understand and contextualize the linkages between these factors and educational attainment as well.

The following sections set the stage by discussing the relationship between poor health and poor education outcomes, then explore the evidence related to the six main pathways potentially linking education to health.

Health, Education, and Poverty

Before exploring each mechanism, it is important to consider the environmental factors giving rise to poor outcomes in both health and education. Poor health and poor education are tightly intertwined concepts. Native-born parents lacking a high school diploma tend to have lower than average income, less-healthy children, and children who are, themselves, at risk of dropping out of high school. Factors contributing to higher dropout rates among such children include attendance at poorly funded schools, exposure to lead paint, abuse, overcrowded living conditions, and a host of other health and environmental factors. The challenge, therefore, is to tease apart the primary ways in which education produces health independent of the influence of these factors on health.

For instance, a lead-abatement intervention may both improve health and educational attainment in children, but we would point to the lead-abatement program as the causative agent for any observed improvements in both health and education, not to the additional education received by the children in the abatement program. On the other hand, if a child received an educational

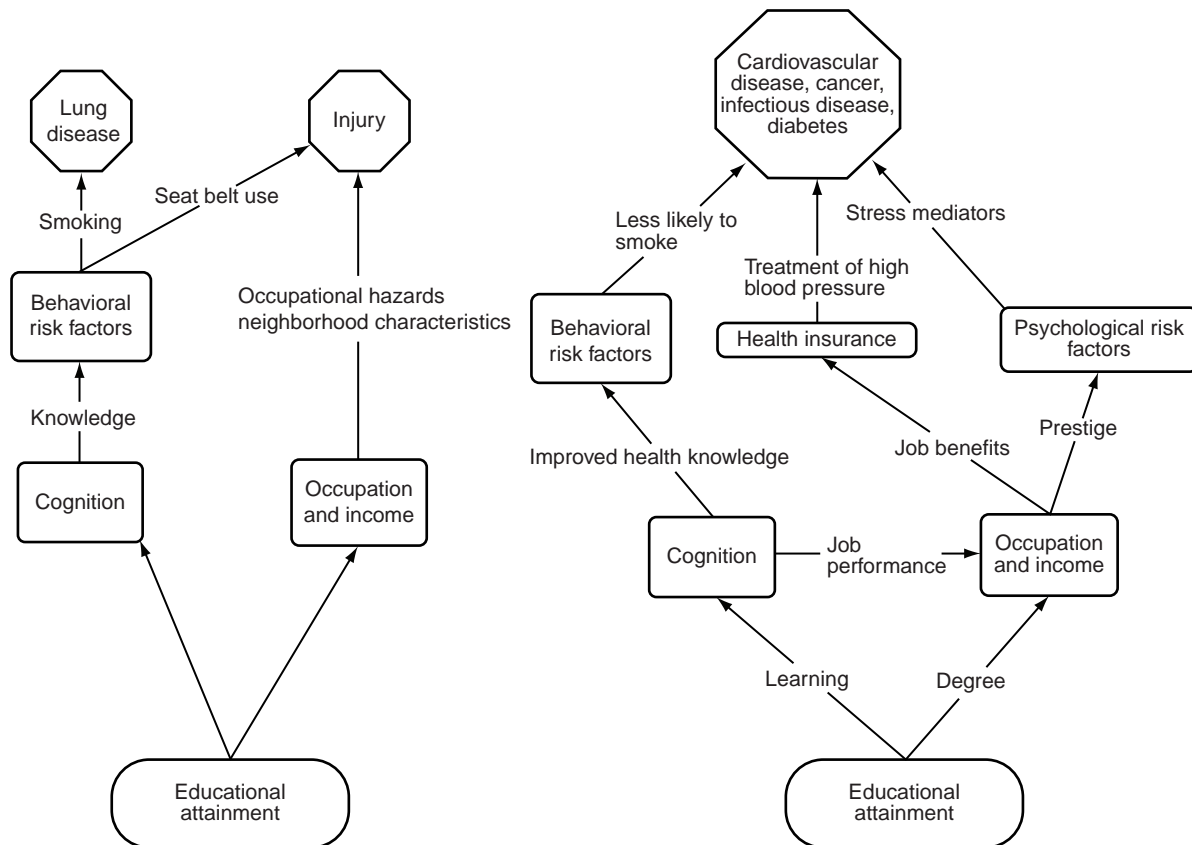

Figure 1 Selected plausible pathways through which education works to improve health.

intervention that induced him or her to graduate from high school, that individual will be more likely to obtain a quality job and enjoy the benefits of health insurance, a quality job, a lower-stress lifestyle, good housing stock, and other health-inducing social benefits. In the latter case, it was the education, not the intervention, which was central to the production of health.

Stress

Early associations between type-A lifestyles and heart disease led to the popular misperception that affluence and education naturally led to stressful lifestyles. Wealthier, more educated persons indeed have stress in their lives. However, while those with a postgraduate degree report higher levels of having too many things to do (relative to high school dropouts), nationally representative self-report surveys suggest that the better educated also have fewer concerns about money, health, leisure time, environmental noise, or problems with children. Self-report surveys also suggest that those with more education enjoy lower levels of anger, distress, aches, pains, and other factors that interfere with subjective quality of life than do those with less education. Finally,

those with more education are more likely to have fulfilling, rewarding jobs, a high sense of control in life, and higher levels of social support, all of which are associated with higher self-reported health and physical functioning.

If real, how might these differences in self-reported stressors and annoyances translate into poor health? Functional magnetic resonance imaging (fMRI) studies offer one view. These studies expose small numbers of subjects to stimuli that are intended to evoke an emotional response or a cognitive appraisal of an event. The scanner then detects which areas of the brain receive an increase in blood flow, and statistical testing is performed to ascertain which areas are significantly more active than others. fMRI studies suggest that, when one is exposed to a stressor, such as persistent horn honking or a difficult boss, parts of the brain that give these perceptions emotional valence become activated. These emotional centers, collectively known as the limbic system, in turn activate other circuits in the brain responsible for regulating heart rate, blood pressure, and the production of stress mediators.

We can observe the effects of these neural processes on the body by examining the relationship between levels of stress mediators in the blood and educational attainment (McEwen, 1998). When subjects of differing social class

(and, by extension, educational attainment) are exposed to mild stressors such as a line-tracing task, persons with a low income and low education tend to exhibit an abnormal stress response. Many of these stress mediators (e.g., cortisol, interleukin-6, catecholamines, C-reactive protein, and fibrinogen) are putative risk factors for cardiovascular disease, hypertension, diabetes, and infectious disease – four of the education-related diseases in **Figure 1** (Muennig, 2007). Nevertheless, it is possible that these stress mediators are merely markers of other processes or that their association with education-related disease is simply the result of spurious association.

In addition to leading to high blood pressure, diabetes, and disruption of the immune system, stress may cause oxidative damage, which increases the rate of human-cell aging and possibly increases one's risk of cancer. The first study in this area recruited unstressed subjects and compared them to subjects with a chronically ill child to ensure large differentials in self-reported stress (Epel *et al.*, 2004). They then examined a marker of cell aging, called the telomere, to ascertain whether there was an association between self-reported stress and cell age in the immune system. They found that subjects with high levels of self-reported stress show chromosomal changes that are consistent with an entire decade of additional biological life relative to those with the lower levels. This study was potentially confounded by their selection criteria; parents with a chronically ill child may be more likely to suffer from genetic disease and therefore be more prone to premature cell aging.

A subsequent study overcame this limitation by examining twins who had different levels of educational attainment (along with other markers of socioeconomic status (SES)). While the outcome measures they included in the second study were different, this group of researchers effectively confirmed the finding that stress increases cell aging. These authors found that the increased aging among less-educated, poorer twins could be accounted for by increased rates of smoking and obesity, and lower rates of exercise. While these authors did not fully disentangle these behavioral risk factors from psychosocial stress, the study raises the possibility that behavioral risk factors and stress are intertwined.

In a related series of studies, subjects with various forms of stress, including job-induced stress, were found to have higher levels of DNA damage and higher blood levels of a marker for cancer. This damage is thought to occur when the acute stress response causes the physiological release of oxidative chemicals into the bloodstream. A subanalysis of these data found that effective cognitive coping skills for stress (measured using a validated instrument) were associated with lower levels of DNA damage. Given that increased educational attainment is associated with improved cognitive coping skills and social network size, it is plausible

that education may reduce the incidence of disease though this association.

Social Standing

Social identity theory suggests that individuals tend to categorize other people on the basis of characteristics such as educational attainment as a means of self-comparison. Differences in relative standing – whether due to less education or less wealth – can be a source of anger, envy, or stress. The long human history of bloody wars fought over social class, such as the Bolshevik Revolution, suggests both that these feelings can be powerful and that they can have direct consequences for health and mortality. It has been suggested that the modern manifestations of lower social standing include both internalized physiological disruptions and crime. This hypothesis was initially drawn from heavily confounded ecological studies assessing the effects of income inequality on mortality and crime, but it is now supported by a stronger base of outcome measures and research designs.

The idea that social status affects health came to light in studies of government workers in England. These studies found that, among persons with good jobs in the same government department and equal access to healthcare, occupational class was still inversely linked to premature mortality. More surprisingly, this health gradient extended all the way into white-collar jobs; even those with high-level jobs were at greater risk of premature mortality than those in the most prestigious jobs. Similar gradients were subsequently found for income and education, and these gradients have been observed in a wide variety of cultural and economic contexts. In fact, it is possible that the social prestige conferred by an educational degree is a more important determinant of life expectancy than the skills acquired with each year of education (see **Figure 2**).

These findings are corroborated by animal studies. Primates, low in social standing, measured in part by the size of the animals and dominance behavior, have higher levels of cholesterol and higher levels of stress mediators. When a dominant male is removed, the subordinate's laboratory tests improve. Likewise, when a dominant male is put among still larger males, his laboratory tests deteriorate. Such findings are, of course, only consistent among stable social hierarchies. Dominant primates whose authority is constantly challenged show opposite results, but most human primate hierarchies (e.g., corporate or government offices) more closely resemble stable nonhuman primate hierarchies than unstable ones.

The implications of social-standing research for education policy are unclear. All of human society is hierarchical, and the top and bottom of the hierarchy may be better delimited by those in one's immediate environment than by the relative social distance between the wealthiest and poorest members of society.

Figure 2 Change in life expectancy with educational attainment among males. Life expectancy remains relatively flat between educational milestones, but increases greatly when degrees are conferred. Mortality risks were converted to life expectancy values. All data points are adjusted for age, race, household size, marital status, employment status, and occupation. A similar relationship is seen for females, but the data are not presented here for simplicity. Adapted from Backlund, E., Sorlie, P. D. and Johnson, N. J. (1999). A comparison of the relationships of education and income with mortality: The National Longitudinal Mortality Study. *Social Science and Medicine* 49, 1373–1384.

Social Deprivation

For children with poorly educated parents, the effects of social deprivation manifest early in life. Harlow's (1964) classical work on animal bonding suggests that an individual's psychosocial troubles can begin with poor parenting. For instance, socially deprived monkeys tend to be more hostile and have predilections that lead them toward risk taking and alcohol consumption in experimental situations. These problems show a dose–response effect, with monkeys raised by a furry stuffed doll that administers milk fairs better than those raised by a similarly equipped surrogate mother made of chicken wire.

These problems can begin before birth; behavioral problems are also observed among the offspring of monkeys stressed by prolonged physical restraint during pregnancy. Likewise, humans raised in busy orphanages with less social bonding tend to make few friends and exhibit more social pathologies. Nicolae Ceausescu famously relied on orphans to supply the Romanian Secret Police because they had few social contacts and he correctly judged that they would be able to kill without remorse.

From childhood to death, persons born into poverty face a series of psychological and social obstacles that often include neglect, abuse, failing schools, bullying, low graduation rates, low wages, and often multiple jobs. This does not portend a healthy psychological milieu in which children or adults can thrive. Educational and

economic deprivations such as these are associated with a cascade of biochemical mediators in childhood, which may lead to cardiovascular disease later in life. Many childhood events, such as exposure to lead paint and abuse, are largely irreversible and simultaneously affect cognitive development and health. Lead paint has long been known to be a neurotoxin, and even small quantities of lead cause intelligence quotient (IQ) deficits. Likewise, children who suffer from physical and emotional abuse have been shown to have smaller brain structures than children who do not.

It is possible that weaker social networks are merely markers for childhood deprivations, and that such traumas are the primary reason why weak social networks are associated with poor health. However, it is likely that poor social networks are also independent risk factors for poor health.

Social deprivations and their associated feelings of anger or hostility, like other psychosocial stressors, are associated with higher rates of cardiovascular disease, infectious disease, lung disease, and diabetes. Although speculative, risk taking and anger may also partially explain higher mortality; persons of lower educational attainment sustain significantly more injuries, and display higher rates of smoking and drinking. Data from the aforementioned Perry Preschool Program randomized controlled trial (along with many other quasi-experimental studies) confirms much higher rates of crime, injury, and death among those receiving less education.

The Perry Preschool Program randomized experiment suggests that these early deprivations are somewhat reversible with early intervention. By age 5, 67% of the children in the experimental group, relative to just 28% of the children in the control group, had a measured IQ greater than 90. By age 40, those in the intervention group were a third less likely to have multiple arrests and were a third more likely to have earnings over US\$20 000 per year. Relative to those who did not receive the intervention, males who received the intervention were nearly twice as likely to raise their own children, less likely to use drugs, and more likely to report satisfactory relationships with their children. Thus, the intervention appeared to modulate the intergenerational transfer of social pathology.

Likewise, one nonrandomized age-matched trial of 1539 children showed decreased arrest rates at age 20 years among those children assigned to a prekindergarten (plus family interventions and health services) intervention group relative to children receiving a less-intensive preschool intervention. While the rates of social pathology were reduced in both instances, it is unknown whether the benefits of these preschool interventions extended to other health measures.

Finally, there is evidence that other social interventions reduce social pathology as well. In one natural experiment, Costello *et al.* (2003) examined the effects of

a casino opening on social pathology rates among Native American on a reservation. The investigators examined the rate of mental health diagnoses among 1420 children in the community according to income level before and after the casino redistributed large amounts of cash to Native American families registered by the tribe. After 8 years of follow-up, results showed the rate of conduct and oppositional/defiant disorders, such as physical abuse, among the newly rich families fell to levels seen in families that were well-off before the intervention. On the other hand, rates of conduct and oppositional/defiant disorders remained high among those families not receiving the income distributions.

To the extent that educational attainment improves social networks and reduces social pathology, we would expect education interventions to improve health through reduced negative emotions and improved behavioral risk factors.

Behavioral Risk Factors

The combined effects of smoking, eating poorly, and lack of exercise are thought to explain somewhere between 12% and 50% of the association between educational attainment (or other socioeconomic risk factors) and mortality (Lantz *et al.*, 1998). About 44% of white males without a high school diploma and 32% of white males with a high school diploma (but no higher degree) are self-reported smokers. Although the overall prevalence of smoking is lower among Hispanics, African-Americans, and females, the percent reduction in smoking is similar across these populations among those who have a high school diploma relative to those who do not.

It has been pointed out that most people, regardless of their level of educational attainment, know that smoking, drinking, and eating greasy food is not healthy (Mechanic, 2002). One might speculate, however, that, in addition to reducing fatalism, education could increase the total exposure to preventative health information, thus normalizing it. Education might similarly improve cognitive appraisal of this information. For instance, people may be more likely to eat healthy food if they understand that cholesterol and saturated fat clog arteries, and can visualize these arteries, instead of just having a vague, abstract notion that these substances are harmful. Better-educated persons might also be better equipped to balance health information against messages from the fast food, tobacco, and alcohol industries.

As increased educational attainment improves income, it may also exert positive effects on health behavior through upward mobility to neighborhoods where healthier foods are available in stores and their consumption is normative. Given lower rates of crime, wealthier neighborhoods also afford more opportunity for exercise. One large, randomized, controlled multisite trial evaluated

the health, crime, and other social effects of vouchers for housing that allowed recipients to move out of low-income neighborhoods. Five years after randomization, those who received the vouchers had significant reductions in obesity and improvements in measures of mental health relative to those randomized to receive no vouchers.

Finally, prospective examination of the contacts that people make in their lives suggest that improved diet and exercise as well as reduced smoking and obesity rates are contagious. That is, when an individual develops a contact with a peer that does not smoke or drink, he or she is much less likely to smoke or drink (Christakis and Fowler, 2007). Thus, the effects of educational attainment on behavioral risk factors appear to be transmissible to less-educated peers.

Genetic Risk Factors

Individual characteristics are determined by a combination of genetic predispositions and environmental influences. Genetic predispositions that influence health behaviors may also influence success in school. For instance, twin studies suggest that a person's ability to cope with stress is partly determined by genetic factors; further, the probability of having a life event perceived as stressful in the first place has also been partly linked to genetic factors.

Environment also plays a role; while twin siblings reared apart show some concordance on measures of IQ and income, twins who fall on hard times socioeconomically have been found to have more cardiovascular risk factors (e.g., higher blood pressure and cholesterol levels) than identical siblings not raised in poverty. Twin studies strongly suggest that measures of health status and cognitive ability are partially environmentally determined. Unfortunately, such studies cannot produce a reliable estimate of the contributions of genes, environmental factors, or of the interaction of the two (Boomsma *et al.*, 2002).

First, twins reared apart are nonetheless exposed to similar environments *in utero*, and sometimes the same environment in childhood, both of which are strong predictors of adult mortality by SES and social pathology. Therefore, upon comparing adult twins reared apart, it is difficult to disentangle genetic effects from early environmental effects. For instance, fetal alcohol and lead paint exposure are both risk factors for delayed development, and both are strongly associated with parental educational attainment.

Second, virtually all of the conceivable genetic contribution to the education–health gradient described here can be attributed to a large number of genetic foci. The expression of these genes, in turn, is highly influenced by environmental factors in a dose–response manner. Consider a hypothetical experiment in which a group of

fetuses is randomized to ideal childhood conditions and another group is randomized to a harsh childhood. Among children with loving parents, excellent schools, and ideal nutritional intake, genetics will play a major role in determining which children do well in school and live a long and prosperous life. Among children with abusive parents and peers who are exposed to drugs, unhealthy food, lead paint, and bad schools, the degree of exposure to positive environmental conditions (such as preschool programs or mentors) will be a major determinant of their longevity and prosperity. In these latter situations, genetics play a small role in explaining educational attainment.

In a groundbreaking twin study, Turkheimer *et al.* (2003) set out to test this hypothetical scenario using biometric analyses. They examined the contribution of (1) genetics, (2) shared environment, and (3) nonshared environment on IQ as measured by the Wechsler Intelligence Scale for Children administered at age 7 years. Their models examined the interaction of these three characteristics and SES using the National Collaborative Perinatal Project data set. This prospective study included 48 197 pregnant women and their 59 397 children. Their measure of SES was based on a linearly combined measure of parental educational attainment, occupation, and income. Their intent was to measure the interaction between genotype and environmental conditions (as measured by SES). They accounted for the possibility that SES is genetically determined by including the main effect of the moderating variable in their model. They found that, among poor families, IQ was determined almost entirely by the childhood environment. Among wealthy families, on the other hand, genes were almost entirely predictive of IQ. Of course, this study's conclusions hinge on the assumption that SES is an adequate proxy measure of a harsh versus an ideal childhood environment.

In another compelling study, Korean adoptees – who were essentially randomly assigned to families of varying SES – were studied later in life (Sacerdote, 2004). Education and health outcomes were then compared with those of their new parents and siblings. Clearly, Korean children adopted into non-Asian families tend to stand out in social situations, and this likely exerts an influence on their development. Nonetheless, adoptees assigned to better-educated parents do better in school, go further, and are healthier by some measures than adoptees assigned to parents with less education. Most strikingly, adoptees were just as likely as their nonadopted siblings to take up smoking and drinking, providing strong evidence that these behavioral risk factors might not be inherited.

In sum, both genetic factors and environmental factors influence characteristics of individuals that are critical in determining both SES and health status later in life. Study design problems make it difficult to quantify the effect of genetics on health. However, both current scientific

evidence and logic suggest that genetic factors will be stronger determinants of health among more affluent children and much weaker determinants among poor children. Thus, intellectual capacity will be likely be optimized when educational interventions are targeted toward low-income families and schools in low-income communities. Clearly, to maximize environmental variables, it is also important to optimize other aspects of childhood and adult environmental conditions, such as access to healthy foods, good housing, safe transportation, and medical care.

Health Insurance

Of these childhood environmental characteristics, medical care for children has received almost as much attention as education interventions. Massachusetts, Pennsylvania, and California all have planned health insurance reforms that are primarily driven by concerns surrounding child health. Nonetheless, while it is clear that families with poorly educated parents simultaneously lack health insurance and suffer from poor health outcomes, there is as of yet limited evidence showing that the possession of health insurance is causally linked to improved health status.

Among 18–64-year olds, 7.3% of persons with at least a bachelors degree lack health insurance, compared with 27.6% of those without a high school diploma. This lower rate of insurance among those with less education is probably attributable to fact that less-educated persons tend to have lower-quality jobs, which usually do not offer health insurance.

Access to medical care increases access to medications and treatments that are known to reduce morbidity and mortality. Of those diseases prominent in the education gradient, access to medications that reduce cholesterol, blood pressure, and diabetes may be most important (see **Figure 1**). The best evidence of the efficacy of health insurance to date suggests that insurance may improve health through these modalities.

In the 1982 Rand health insurance experiment, 3958 healthy but uninsured subjects were randomly assigned to either receive a premium health insurance policy or a policy that required financial contributions on the part of patients before they could receive care (Brook *et al.*, 1983). Subjects were assigned to their insurance plans for 3 or 5 years, and then evaluated for health outcomes, including mortality. These authors found that mandatory patient contributions reduced healthcare utilization relative to those who had no such requirement, but this barrier to care only produced a calculated 10% increased risk of death among high-risk subjects with hypertension. No changes were found in other measures of health outside of an improvement in vision through corrective lenses.

This study is somewhat dated, however, and over the past 24 years, a wide range of medications that prevent

heart disease, infections, and cancer have become available (e.g., statins, vaccines, and smoking cessation technologies, respectively). These medications, being expensive, are almost exclusively used by persons with health insurance. Recent correlational analyses show a 25–67% reduction in mortality among the uninsured (Muennig *et al.*, 2005). However, this reduction in mortality might be explained by model endogeneity, or other factors associated with insurance, such as the economic protection and peace of mind that health insurance affords, rather than the benefits associated with receiving medical attention itself.

Given that preventive modalities, such as antihypertensive medications, seem to matter most, and that these modalities reduce the incidence of disease in the education–health gradient (**Figure 1**), health insurance seems a logical contender for an explanatory variable in the education–health gradient. If accurate, this 25–66% reduction in mortality would account at most 3–9 months of the roughly 6–9-year difference in life expectancy between those with and without a high school diploma. It should be noted though, that the effects of educational attainment on cognition should synergize with health insurance effects; in addition to improving access to medications, more-educated people are also more likely to comply with prescribed dosages and intervals.

In sum, in industrialized nations, healthcare likely plays a small but significant and growing role in reducing health disparities by SES. While health disparities by educational attainment are smaller in nations that offer health insurance, these countries also tend to offer more social services like childcare and parental leave, making it difficult to disentangle the effect of health insurance from the effects of other social programs on reducing educational disparities in health. Moreover, increasing health insurance would be significantly less cost effective than implementing effective education interventions, such as small class sizes (Muennig and Woolf, 2007).

Nonetheless, universal health insurance coverage may be one potential policy approach to addressing the health–education gradient. The findings of the Rand health insurance experiment notwithstanding, universal healthcare may in of itself prove to be an effective education intervention. After all, it is difficult for children to learn if they are sick. Moreover, while health may improve educational attainment, increasing educational attainment may improve the utilization of healthcare among those who are already insured.

Enhanced Cognitive Ability

Even among those with access to medical care, knowledge of screening test availability is predictive of the use of such tests. Those with more education are also more likely to be compliant with their medications and otherwise manage their disease better than those with less

education. In addition to increasing the uptake and proper use of health technologies, improved cognition also likely reduces day-to-day errors that can lead to automotive or household accidents. In addition to increasing one's access to health information and improving one's comprehension of the information, cognitive ability may also influence the so-called future discount rate, that is, a value assigned to consequences and events far in a person's future, such as retirement funds or smoking-induced lung cancer.

Conclusions

Lower educational attainment likely affects health both through a higher-stress lifestyle and through material deprivation. Social stressors both partially originate from, and are compounded by, a higher likelihood of exposure to social pathology, weaker social support networks, and lower social standing. Likewise, lower rates of health insurance, weaker cognitive coping mechanisms, lower job quality, and an inability to fully understand medical diagnoses or treatments all seem to play a role.

Less explored are the effects of fatalism, anger, and hostility among those with less educational attainment. These negative emotional styles may contribute to higher rates of smoking, drinking, and eating poorly among those with less education. Recent evidence suggests that influences from educated friends and family members also play a large role in behavioral risk factors.

In sum, the psychosocial factors linked to educational attainment are also major medical risk factors for cardiovascular disease, cancer, infection, injury, lung disease, and diabetes – the diseases contributing most to the 6–9 years of life expectancy separating those with and without a high school diploma.

Introduction

As research in economics of education moves toward causal research methods, the importance of high-quality data on educational institutions, students, teachers, and policies has increased significantly over time. This article offers an overview of the available national, state, and school district databases that might be of interest for researchers and policymakers alike. In doing so, we center our attention on US primary and secondary education data sources. (For a discussion of the different empirical research methods in education, see the article on empirical research methods in this encyclopedia. McEwan (2007), Barrow and Rouse (2005), Angrist (2004), Loeb and Strunk (2003), and Meyer (1995), also provide a thorough discussion.)

This article builds on Dee *et al.* (1999), paying special attention to national longitudinal surveys and state longitudinal administrative datasets. (The national longitudinal survey of youth (NLSY) and the panel study of income dynamics (PSID) are excluded from this review. Both have been extensively used and described in prior research studies. See, e.g., Brown *et al.*, (1996) for a description of PSID, and visit the NLSY website to access the NLS handbook that contains an overall picture of the seven cohorts of this survey.) Without intending to be exhaustive, it offers a comprehensive description of the main data sources that may be of interest to researchers in the economics of education field. It is organized as follows. We first present an overview of the different research questions that can be answered with the type of data systems described in this article. We then describe the most relevant nationally representative data systems. We follow it up with a description of state and district data systems that contain longitudinal information and briefly describe some international data systems. The last section offers concluding remarks.

Overview

Before describing the available datasets, it is important to provide a general overview of the type of research questions economists of education focus on, and how these data sources may be used to answer them. Some basic questions posed by economists of education are: (1) what are the effects of education inputs (e.g., class size, teachers'

qualifications, and professional development), competition among schools (i.e., vouchers), and accountability measures on academic achievement; (2) of cognitive abilities and education on earnings; (3) of pay incentives, school characteristics, and testing on teacher characteristics; and (4) of family background characteristics (i.e., income and parental education) on student academic attainment? In order to address these questions, researchers need state- or nationally representative data on student test scores, class and school size, characteristics of peers, teacher education and experience, incentives associated to the federal and state accountability system, and/or family background. In addition, researchers need to be able to link these different variables with each other, which means linking students to teachers, students to peers, and/or follow students over time. The different nationally representative datasets that are featured in this article, which are actively maintained by the National Center for Education Statistics (NCES), tend to specialize in some of the areas mentioned above. For instance, the National Assessment of Education Progress (NAEP) provides extensive data on student test scores, while the School and Staffing Survey (SASS) collects data on teacher-related topics. Therefore, being able to merge information across datasets is a basic prerequisite for addressing these research questions at a national level. In the case of state or district databases, generally a single data collection effort covers student, teacher, and school information.

National Data Systems

The observed emphasis on scientifically based research in education takes place within a tradition of extensive use and collection of data in the field. Since the 1980s, the US has used complementary approaches to analyze the education process from different perspectives. In this section, we present a brief description of the main nationally representative databases that are maintained by the federal government. We present some examples of empirical research that have used these data sources, and also provide relevant information on how to access these data.

CCD and SASS Databases

The Common Code of Data (CCD) is the information backbone of the US education system. It contains the list of all public primary and secondary schools in the country, as well as all public school districts. This database

identifies all charter, magnet, Title I, special education, vocational education, and alternative schools in the country. It also keeps track of enrolment figures by primary ethnicity, gender, and eligibility for free and reduced-price lunch. The number of classroom teachers is also provided. At the district level, staffing information is more extensive, including instructional, administrative, library, and support staff, as well as guidance counselors. At the district level, financial information is also available. (The fact that financial data are not available at the school level is probably one of the areas of this information system that should be addressed in the future. Without it, it is not possible to know in a systematic way how much additional resources are provided to schools under certain policy interventions.) NCES has also generated a district-level longitudinal data set – the Longitudinal School District Fiscal-Nonfiscal File – from 1989–90 through 2001–02.

Unlike the CCD, the SASS does not collect information on all schools in the country and across all years. It relies instead on a state-level representative sample of public schools. (SASS data are also representative at the private school affiliation level for private school respondents.) The trade-off for this smaller sample size is a rich dataset of teacher-related topics such as teacher shortage and demand, general characteristics of elementary and secondary teachers, teacher workplace conditions, and teachers' career paths (since 2003–04). In addition, SASS has a small longitudinal component called the teacher follow-up survey (TFS). A subset of the teachers surveyed in SASS is surveyed again the following year, even if they leave the teaching profession.

SASS goes well beyond teacher-related topics; it includes principal, school, and district's questionnaires. It also collects data on school programs and policies, admission requirements, tuition, student and class organization, special programs and services offered, and student instructional time, among others. The years covered by SASS have thus far been 1987–88, 1990–91, 1993–94, 1999–2000, and 2003–04.

Given the nature of SASS, it has been used extensively to analyze teacher-related questions. Ballou and Podgursky (1998) used this source of information to analyze teacher recruitment and retention in public and private schools. Angrist and Guryan (2004) studied the effect of teacher testing on teacher characteristics. Figlio (2002) addressed the question whether public schools could attract better-qualified teachers increasing teacher salaries, and Figlio and Rueben (2001) used these data to analyze the relationship between tax limits and qualifications of new teachers.

NAEP Assessment Data

Even though SASS, CCD and its private school counterpart, the private school universe survey (PSS), generate

rich information on student, teacher, and school characteristics, neither of them collects data on academic achievement. To fill this gap, NAEP provides assessment measures in mathematics, reading, science, writing, the arts, civics, economics, geography, and US history every 2 years. (Note that, since 1969, NAEP was carried out annually until 1979.) NAEP relies on a complex sampling design to ensure state- and national-level representativeness of academic performance estimates of public and nonpublic schools, as well as student subgroups by primary ethnicity, gender, and parental education for fourth, eighth, and twelfth graders. In fact, every 2 years, NAEP generates two different samples: one for state-level estimates used to compare state performances at a given moment in time, and another for national-level measures. (Not all subjects are covered in exactly the same years.) In addition, every 4 years a third sample is drawn with the purpose of identifying changes in academic performance of students, aged 9, 13, and 17 years, in mathematics and reading. This component of NAEP is known as the NAEP long-term trend (LTT) assessment. Of course, this long-term approach implies that assessment instruments need to be consistent over time, and therefore cannot change as the state and national cross-section NAEP assessments do, as they try to adapt to ongoing changes in curricula.

The increased emphasis on accountability since the 2001 No Child Left Behind (NCLB) Act has certainly influenced NAEP. Now states receiving Title I funding are required by law to participate in the state NAEP in mathematics and reading in grades 4 and 8 every 2 years. The accountability movement has also influenced the type of research questions that have been addressed using NAEP data during the last years. For instance, for cross-state comparisons of the percent of students meeting or exceeding proficiency (this is the key performance measure of the recent standards-based reforms) in a given subject to be consistent, it is crucial to know which states set higher standards than others. McLaughlin and Bandeira de Mello (2002) map state standards to the NAEP scale in order to compare them. Carnoy and Loeb (2002) use NAEP data to study the effect of accountability measures on student achievement.

National Longitudinal Studies: NLS-72, HS and B, NELS: 88, and ELS: 2002

Four longitudinal studies have been carried out in the US so far, including the national longitudinal study of the high school class of 1972 (NLS-72), high school and beyond (HS&B), the national education longitudinal study of 1988 (NELS:88), and the educational longitudinal study of 2002 (ELS:2002).

The first of them, the NLS-72, surveyed 21 000 high school seniors (i.e., twelfth graders) in 1972. This data collection effort not only gathered background information

on students and their schools, but also carried out cognitive tests during the base year. This cohort was resurveyed again in 1973, 1974, 1979, and 1986, as it entered higher education and the workforce. The first follow-up survey of 1973 also added 4500 new individuals to the sample. The second longitudinal study, HS&B, besides surveying and testing high school seniors, also collected information on sophomores (i.e., tenth graders). That is, it started collecting information of individuals earlier on in their life cycle. The younger cohort of HS&B was followed through 1992, and surveyed in 1982, 1984, 1986, and 1992. The high school senior cohort of 1980 was only followed through 1986 and surveyed every 2 years.

The third longitudinal study was initiated in 1988. The NELS of 1988 continued the trend of following individuals earlier on in their life cycle. The base year included a sample of about 25 000 eighth graders attending 1000 schools throughout the country. As the previous longitudinal studies, this sample was nationally representative of that particular cohort of students. Two years later the sample was expanded to allow national representativeness of estimates of tenth graders in 1990. The students were resurveyed in 1990, 1992, 1994, and 2000. The fourth and last longitudinal data collection effort, ELS: 2002, followed the cohort of tenth graders in 2002 over time. Again, student academic achievement was measured during the base year, as well as during the first follow-up in 2004. The last data point available (2006) followed this cohort into postsecondary education and the labor market.

The research agenda involving NLS-72 has focused extensively on the effect of college attendance on earnings. Frazis (1993) estimated the college premium trying to correct for selection bias, while Kane *et al.* (1999) proposed a methodology to identify measurement errors when schooling is self-reported (as it is in NLS-72 and HS&B), and analyzed its impact on the estimates of returns to schooling. Kane and Rouse (1995) studied the economic return of 2- and 4-year colleges. Altonji (1995) used NLS-72 to estimate the effect of high school curriculum on education and labor market outcomes. Finally, Acemoglu and Pischke (2001) used NLS-72, as well as HS&B, to analyze the link between family income and college education (Note that other research has been conducted using these data. This list is by no means exhaustive.).

The other longitudinal studies have provided invaluable information for analyzing other topics in the field. HS&B has been used by researchers to estimate the effect of Catholic schools on student test scores (see Coleman *et al.*, 1982; Coleman and Hoffer, 1987) and educational attainment (see Evans and Schwab, 1995). Other examples of studies involving HS&B are Murnane *et al.* (2000), which studied the impact of cognitive abilities on earnings, and Dee (2004), which addressed the question of civic returns to education.

The research using NELS: 88 has been somewhat more focused on teachers. Ehrenberg *et al.* (1995) used NELS: 88 data to evaluate the relationship between teacher and student ethnic and gender match and student learning. Goldhaber and Brewer (1995) studied the impact of teacher certification on student achievement using NELS: 88. Other researched topics with NELS: 88 have been high school size and academic achievement (see Lee and Smith, 1997), and the effect of unobserved school, teacher, and class characteristics on student achievement (see Goldhaber and Brewer, 1997). Given the more recent availability of ELS: 2002, its literature is very limited. Dee *et al.* (2006) used this data source to study the effect of school size on parental involvement in education.

Crime and Safety Surveys

An additional data source that may provide important contextual information on schools is constituted by the crime and safety surveys (CSSs) maintained by NCES. Two types of national surveys regularly address the crime and safety situation at American schools: the school survey on crime and safety (SSOCS), and the school crime supplement (SCS) to the national victimization survey (NCVS). These surveys collect data on frequency and type of crimes, disciplinary actions, prevention mechanisms, and the general safety climate at schools.

Accessibility

Extensive portions of all NCES databases are publicly available. Individuals and institutions can either download these publicly available data from the NCES website or request a CD-ROM at no cost. Researchers should note that some portions of these NCES databases are classified as restricted use, which means that researchers need to request a license in order to get access. Without this license, it is not possible to link school information in SASS to CCD or PSS, or analyze student-level records in any of the longitudinal surveys.

It is also important to mention that NCES is not the only institution involved in collecting and generating national education statistics. The US Census Bureau carries out the current population survey (CPS) and makes the public-use micro-data samples (PUMS) of the decennial census available. The CPS is a monthly survey of approximately 50 000 households, and NCES funds the October supplement survey, which collects data on educational attainment. Additional items in the CPS funded by NCES involve language proficiency, disabilities, computer use, student mobility, and private school tuition. The PUMS also contains data on a sample of households in the country. Education attainment estimates by age and race can be generated using this data source. For an overview of all these national education data systems please see **Table 1**.

Table 1 Summary of national data systems

<i>Dataset</i>	<i>Acronym</i>	<i>Link</i>	<i>Census or sample</i>	<i>Data frequency</i>	<i>Years available</i>
Common core of data	CCD	http://nces.ed.gov/ccd	Census	Annually	1986–87 through 2005–06 (for previous years contact NCES)
1. Public elementary/secondary school universe survey	CCD	http://nces.ed.gov/ccd/pubschuniv.asp	Census	Annually	1986–87 through 2005–06
2. Local education agency (school district) universe survey data	CCD	http://nces.ed.gov/ccd/pubagency.asp	Census	Annually	1986–87 through 2005–06
3. Local education agency (school district) finance survey (F-33) data	CCD/ F-33	http://nces.ed.gov/ccd/f33agency.asp	Census	Annually	1992 through 2005
4. Local education agency (school district) universe survey dropout and completion data	CCD	http://nces.ed.gov/ccd/drpagency.asp	Census	Annually	1997–98 through 2003–04
5. State nonfiscal public elementary/secondary education survey data	CCD	http://nces.ed.gov/ccd/stnfis.asp	Census	Annually	1986–87 through 2005–06
6. National public education financial survey data	CCD	http://nces.ed.gov/ccd/stfis.asp	Census	Annually	1987 through 2005
Schools and staffing survey	SASS	http://nces.ed.gov/surveys/sass	Sample	Every 3–5 years	1987–88, 1990–91, 1993–94, 1999–2000, 2003–04, 2007–08
Private school survey	PSS	http://nces.ed.gov/surveys/pss	Census	Every 2 years	1991–92, 1993–94, 1995–96, 1997–98, 1999–2000, 2001–03, 2003–04
Longitudinal school district fiscal–nonfiscal file	FNF	http://nces.ed.gov/edfin/finance_data.asp	Census	Annually	1990 through 2002
National assessment of educational progress	NAEP	http://nces.ed.gov/nationsreportcard	Sample	Annually until 1979, then every 2 years	1969 through 2006
National longitudinal study of 1972	NLS-72	http://nces.ed.gov/surveys/nls72	Sample	Variably	1972, 1973, 1974, 1976, 1979, 1986
High school and beyond	HS&B	http://nces.ed.gov/surveys/hsb	Sample	Variably	1980, 1982, 1984, 1986, 1992
National education longitudinal study of 1988	NELS: 88	http://nces.ed.gov/surveys/nels88	Sample	Variably	1988, 1990, 1992, 1994, 2000
Education longitudinal study of 2002	ELS: 2002	http://nces.ed.gov/surveys/els2002	Sample	Variably	2002, 2004, 2006
Crime and safety surveys	CSS	http://nces.ed.gov/programs/crime	Sample	Variably	1989 through 2005
1. School survey on crime and safety	SSOCS	http://nces.ed.gov/surveys/ssocs	Sample	Variably	1999–2000, 2003–04, 2005–06
2. School crime supplement	SCS	http://nces.ed.gov/programs/crime/student_data.asp	Sample	Variably	1989, 1995, 1999, 2001, 2003, 2005
Current population survey, October supplement	October CPS	http://nces.ed.gov/surveys/cps	Sample	Annually	1968 through 2005
Public-use microdata samples	PUMS	http://www.census.gov/main/www/pums.html	Sample	Every 10 years	1940 through 2000

State and School District Databases

With NCLB, the pressure for state and district officials to develop and maintain student-level longitudinal databases that track student progress over time has increased. In fact, according to a report in the *Education Week* (2006)

about the study of states' data, 39 states have longitudinal systems that can track individual academic progress and characteristics over time. As the quality of the data and the number of available years rise, we would expect to see an increase in the access and usage of these data systems. In this section we describe state and school district

administrative data systems that allow following students over time and that have been used to conduct empirical studies.

The National Center for Analysis of Longitudinal Data in Education Research

The Center for Analysis of Longitudinal Data in Education Research (CALDER) is a federally funded joint project of the Urban Institute and scholars at Stanford University, the University of Florida, the University of Texas at Dallas, Duke University, the University of Missouri, and the University of Washington. The mission of this center is to inform education policy leaders through analysis of longitudinal administrative databases on individual students and teachers. Their research focuses on how teacher policies, governance policies, and social and economic conditions affect teacher and student outcomes. One of the unique strengths of this center is the potential to explore similar questions across different states. This will not only increase the external validity of their findings, but also the reliability of their methodological designs and results. Having access to multiple data will allow them to test findings under different policy and context conditions. CALDER makes use of administrative longitudinal state databases that have been created and maintained by certain state officials, as well as state longitudinal databases that have been compiled by scholars. The states from which CALDER has longitudinal information include Florida, Texas, New York, North Carolina, Missouri, and Washington. The main characteristics of each of these databases are briefly described below.

Florida

Florida has been at the forefront of tracking individual students over time. The Florida Department of Education maintains longitudinal records on all Florida public school students and their teachers, from preschool through college, beginning with the 1995–96 school year. This education data warehouse (EDW) contains student information, such as test scores and student demographic data, course grades, courses taken, home language, disciplinary actions, and participation in programs designated for English learners. It also contains teacher information, such as education level, certification status, years of experience, and participation in professional development activities. In addition, it includes school and district financial records. These data have a unique characteristic. They can precisely link both students and teachers to specific classrooms at all grades, and at the same time, provide information on the percentage of time spent in each classroom. (Hansen (2006) provides a detailed account about the origins of Florida's comprehensive database as well as

how it has been enhanced and maintained by the Florida Department of Education.)

Florida longitudinal data have been used to address a wide array of policy-relevant questions. For example, Sass (2006) used Florida student information to study the performance of charter schools using student-fixed effects. Figlio (2006) investigated if schools employ discipline for misbehavior as a tool to increase student test performance. It is possible to obtain access to this confidential dataset by soliciting permission to the Florida Department of Education.

Texas

The Texas School Project (TSP) funded in 1992 by John Kain, is housed today at the University of Texas at Dallas. In 2007, the TSP was officially designated as a State of Texas Education Research Center. The TSP dataset combines individual-level information from multiple administrative datasets from state agencies and school districts. These data include student-level test scores starting with the 1992 third-grade cohort, enrolment information, demographic characteristics, and other K-12 public school data. They also contain community college and public university attendance and completion, teacher characteristics and teacher test scores, as well as higher education tuition and financial aid data.

Hanushek, Kain, and Rivkin have used these data in several articles. They have looked at the effects of charter schools, teachers' contributions to student outcomes, peer groups effects, the costs and benefits of switching schools, among others (Hanushek *et al.*, 1998, 2002; Hanushek and Rivkin, 2003). Interested researchers can gain access to these data by submitting a research proposal to the Texas School Project center, which will be reviewed for feasibility. The final decision is made by state authorities.

New York

Boyd, Lankford, Loeb, and Wyckoff have collected a dataset that follows teachers and administrators in New York State since 1969. This dataset contains state-level longitudinal teacher administrative records, City University of New York (CUNY) and longitudinal New York City student records. Teacher records include undergraduate institutions, teacher preparation programs, years of experience, education level, demographic characteristics, and certification area and scores, among other records. These data can be linked to New York City student-level test scores and demographics. This group of researchers has used these data to investigate the matching process of teachers and schools, the distance from where teachers attended high school to their first teaching position, and teachers' career paths, among others (see Lankford *et al.*, 2002; Boyd *et al.*, 2005). Interested researchers who would like to use New York data need to contact directly the New York Department of Education for approval.

North Carolina

The North Carolina Education Research Data Center (NCERDC), located at the Center for Child and Family Policy at Duke University, was established in 2000–01 to house several data sources in a unique location. The NCERDC stores data from the North Carolina Department of Public Instruction (DPI), NCES, and other agencies. The main goal of this center is to provide researchers with access to rich longitudinal data to inform policy-relevant research. These data have the capability to link students' test scores over time, analyze students' transitions to middle and/or high school, and identify students who move into different school systems (either charter schools or different LEAs), for example. Researchers can also link students to teachers, evaluate teacher's qualifications, payment and education levels, as well as follow teachers and identify their career paths.

Several researchers have used these data. For example, Bifulco and Ladd (2006) used North Carolina data to study the impact of school choice on racial segregation. Clotfelter *et al.*, (2004) studied the impact of the state's school-based accountability on the retention of high-quality teachers in low-performing schools. (NCERDC provides clear guidelines to access these data. Institutions of higher education, nonprofit research institutions, and government agencies can gain access to use their confidential data.)

Missouri

Missouri state education agencies maintain several administrative databases. For instance, the Missouri Department of Higher Education maintains student-level information on graduates from public higher education institutions. The Missouri Department of Elementary and Secondary Education maintains school-level K-12 information, as well as teacher-level data. Michael Podgursky, who is part of CALDER, has developed a panel data that matches higher education student-level data to teaching-level information. This dataset contains information on students enrolled in public 2- and 4-year colleges; it includes high school enrolment information, high school GPA scores, class rank, college entrance exams, college coursework, college major, and degree earned. Teacher information includes certification, salary, title, and demographic information. These data have been used to study labor-market decisions of recent college graduates, specifically their decision to enter the teaching profession (Podgursky *et al.*, 2004).

Washington

CALDER's website provides a description of a longitudinal dataset of Washington State that includes longitudinal teacher- and school-level information. However, official information about this dataset could not be found at the time of this article.

Other State and District Administrative Databases

In this section, we feature some additional longitudinal state and district databases that have been used to conduct empirical research. This list is by no means exhaustive. It intends to give an idea of the type of data that exists, and the steps some states have taken to build a longitudinal system.

Chicago

The Chicago public schools (CPS) database allows following students over time as long as they remain in the Chicago public school system. It includes test results (Iowa test of basic skills), students' demographic and family characteristics, language status, grade retention, summer school attendance, and special education eligibility. The district also maintains fiscal information, as well as teacher data that can be linked over time at the school level. Jacob and Lefgren (2004) studied the effect of remedial education on student academic achievement with CPS data.

Arizona

The Arizona Department of Education maintains longitudinally linked student-level data. These data contain the Stanford Achievement Test result, ninth edition (SAT9) starting in 1997, and demographic characteristics such as race, gender, grade level, number of absent days, years in the same district, and program participation. Solmon *et al.* (2001) used these data to evaluate the effect of charter schools on student academic achievement.

California

California does not have a statewide system to track students' performance over time. However, California has a myriad of databases that allow for school- or district-level longitudinal analyses, such as the standardized testing and reporting (STAR) program, the academic performance index (API) databases, and the California basic educational data system (CBEDS). California has already begun to take important steps toward building a student- and teacher-level longitudinally linked data systems. The state enacted Senate Bill 1453 to create the California longitudinal pupil achievement data system (CALPADS), and Senate Bill 1614 to create the California longitudinal teacher integrated data education system (CALTIDES).

Despite that a longitudinal data system is still not available statewide, the capability has existed in several school districts within the state. For example, Los Angeles Unified School District, Fresno Unified, Long Beach Unified, San Diego Unified, Oakland Unified, San Francisco Unified, Elk Grove Unified, and Santa Clara Unified, to mention some, have longitudinal student-level information going back, in some cases, to 1998. Some of these databases have already

Table 2 Links to international data systems

Dataset	Acronym	Link
Trends in international mathematics and science study	TIMSS	http://www.timss.org
Progress in international reading literacy study	PIRLS	http://pirls.org
Program for international student assessment	PISA	http://www.pisa.oecd.org

been used by researchers. For example, Parrish *et al.* (2006) used the Los Angeles Unified School District longitudinal data system to study the effects of Proposition 227 on the education of English learners.

Other states

Nevada and Alaska are following Florida's data system model and are in the process of implementing a state-wide data system. The state of Nevada has created the statewide management of automated record transfer (SMART) system, which tracks students over time. Alaska has also developed a student-level linkable database called the on-line Alaska school information system (OASIS).

International Data Systems

Even though this article has focused on the US, researchers might also want to carry out international comparisons. The Trends in International Mathematics and Science Study (TIMSS) compares math and science academic achievement of 4th and 8th graders around the world (in 2003, TIMSS involved 46 countries). It has been collected in 1995, 1999, 2003, and 2007. This dataset is complemented by the Progress in International Reading Literacy Study (PIRLS), which focuses, as its name suggests, on reading skills. PIRLS data for 2001 and 2006 are available. On the other hand, the Program for International Student Assessment (PISA) focuses on older students (15-year-olds), and includes assessments on math, science, reading, and the cross-disciplinary problem-solving subjects. More than 40 countries have participated in each of the three PISA studies carried out so far (i.e., 2000, 2003, and 2006). These three international data systems are somewhat equivalent to the topics that NAEP covers within the United States. Examples of research studies that have used these data are Hanushek and Woessmann (2006), and Afonso and Aubyn (2006). **Table 2** shows the link to each of these international datasets.

Conclusions

In this article we have centered our attention on US primary and secondary education data sources, and some major international data-collection efforts. However, additional longitudinal data sources can be often found in other countries. For example, Chile has been used to analyze the impact of a national voucher plan, Israel to evaluate the effect of teacher training and use of technology in the classroom, and Indonesia to study the impact of significant expansions of the education system. Of course, these are only some examples, but they highlight the importance of finding new sources of variation of education inputs and outputs beyond the frontiers of the United States.

Empirical Research Methods in the Economics of Education

P J McEwan, Wellesley College, Wellesley, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Empirical research in the economics of education often seeks to identify causal relationships between policies or investments, and a variety of school or individual outcomes. Do additional years of schooling cause individuals' earnings to increase? Does attending private instead of public schools cause students' test scores to improve? This article summarizes the methods used by economists to address these and other causal research questions. It is based on the more extensive description of empirical methods in McEwan (2008). The methods include regression analysis, but they are increasingly supplemented by experimental and quasi-experimental research designs.

Common Research Terms

The results of cause-testing research, regardless of the method, are commonly judged by two criteria: internal validity and external validity (Shadish *et al.*, 2002). A result is internally valid when it identifies a believable causal link between a policy or program and an education outcome. The policy or program is often generically called a treatment. A causal result is externally valid when it can be generalized to modified versions of the policy treatment, to alternate measures of student outcomes, to diverse populations of students or schools, or to different policy contexts. This article mainly emphasizes the importance of improving internal validity.

The causal effect of a policy treatment is the difference between students' outcomes when treated, and the same students' outcomes when not treated (commonly referred to as the counterfactual). Research methods are employed to "create reasonable approximations to the physically impossible counterfactual" (Shadish *et al.*, 2002: 5). Researchers estimate counterfactual outcomes by identifying a separate group of untreated students, called a control group or comparison group (the former term is reserved for randomized experiments, but is used loosely). Members of the control or comparison group should be similar to their treated counterparts, in every respect but for exposure to the treatment.

In practice, the groups are often dissimilar, in ways that affect the outcomes of interest but have nothing to do with the treatment (e.g., students' families have different incomes, because higher-income families were more or

less likely to choose the treatment). If this occurs, then the outcomes of comparison of students incorrectly estimate the counterfactual. Thus, a simple difference in the average outcomes of treatment and comparison students can yield a misleading estimate of the treatment's causal effect, and is said to suffer from selection bias. Selection bias is a pervasive challenge to internal validity, and the research methods discussed in this article are aimed at lessening it.

Economists use two broad approaches, usually in combination, to ensure that members of treatment and control/comparison groups are similar, on average. First, they make statistical controls for observed differences between students, often using regression analysis. Second, they influence how students are assigned to treatment and control groups. Cause-testing research is often lumped into three broad categories: experimental, quasi-experimental, and nonexperimental. The essential difference among categories is the degree of control exerted by the researcher over who is assigned to the policy treatment (whether students, teachers, schools, districts, or states), and who is assigned to the control/comparison group.

In experimental research – often referred to as a randomized, controlled trial (RCT) – the assignment is entirely determined by luck of the draw, as in a researcher's flip of a coin. In quasi-experimental research, the broadest category of research, assignment may contain elements of randomness or purposeful assignment by the researcher, but some might be due to the individual choices of students, parents, or administrators (called selection). In nonexperimental research, the researcher exerts absolutely no influence, and assignment is entirely due to selection. When greater control is exerted, the causal results often possess greater internal validity.

Methods for Answering Causal Questions

Statistical Controls for Observed Variables

Suppose that researchers collect nonexperimental data from students who attend either private or public schools, but were not encouraged or coerced to do so by researchers. The causal question is whether attending private school improves test scores. A naïve researcher would simply estimate the difference between the average test scores of private students and public students, and ascribe

it to the causal effect of school type. But the difference could be explained by preexisting differences in students that are the result of selection. For one, private students in tuition-paying schools have higher incomes, on average, which might be associated with higher test scores.

Regression analysis

Regression analysis is the first line of defense against this kind of selection bias. Here, regression analysis implies ordinary least-squares (OLS) regression. In education policy, it is common to apply multilevel or hierarchical models (Raudenbush and Bryk, 2002) that model error components and account for the potential correlation of errors within classrooms, schools, communities, or states. In so doing, they avoid understating standard errors of coefficients and overstating their statistical significance – the models do not necessarily, as is sometimes assumed, remove selection bias. Economists are more likely to report OLS coefficient estimates accompanied by adjusted Huber–White standard errors that allow for arbitrary correlations among units within clusters (Wooldridge, 2002). In comparisons, OLS with adjusted standard errors and other multilevel models yield similar results, though OLS with standard errors not adjusted for clustering can dramatically underestimate standard errors (Angeles and Mroz, 2001). This issue is not discussed further, but the research cited in this article generally reports cluster-adjusted standard errors. A basic regression model can be written as:

$$A_i = \beta_0 + \beta_1 P_i + \beta_2 X_i + \varepsilon_i$$

where A represents the test score of each student in the entire sample (the subscript i might range from 1 to 1000); P indicates whether a student attends a private school ($P = 1$) or public school ($P = 0$); (This assumes a binary policy intervention (treated or not), though the discussion can be generalized to continuously measured policy interventions (e.g., class sizes of 1–50).) X indicates the value of a control variable, like family income, that one wishes to hold constant; and ε is an error term unique to each student. The error term captures the notion that test scores vary, for unobserved reasons, even among students attending the same school type and with the same incomes.

Using the method of OLS, researchers estimate the regression coefficients β_0 , β_1 , and β_2 . In the absence of controls for X , the estimate of β_1 would be interpreted as the average difference between private and public students' achievement (the naïve estimate from before). Upon controlling for X , it is the average difference holding constant family income. The immediate question is whether the difference can now be interpreted as the causal effect of private school attendance.

The causal interpretation rests on an assumption of regression analysis: that private school attendance (P),

controlling for X , is uncorrelated with positive or negative shocks in test scores captured in the error term, ε . (Formally, the assumption is that $\text{COV}(P_i, \varepsilon_i) = 0$.) What could produce such correlations? Suppose that an unmeasured variable, M , gauges parent motivation. Further suppose that children of motivated parents disproportionately attend private schools (M and P are positively correlated, even controlling for X) and that the children of motivated parents obtain higher test scores (M and A are positively correlated, even controlling for X).

In regressions that do not control for M , the net result is that attending private schools tends to be accompanied by positive shocks in students' test scores, the (noncausal) influence of greater unobserved motivation among their parents. In this example, estimates of the coefficient β_1 would be too big because of selection bias, leading to overly optimistic causal conclusions about private school effects. Yet, selection bias could also work in the opposite direction, depending on the sign of partial correlations between the excluded variable(s), the dependent variables (A), and the key treatment variable (P). Omitting variables creates no bias in β_1 if (1) the omitted variables are uncorrelated with A , or (2) the omitted variables are uncorrelated with P (The goal of randomized experiments is to ensure that condition (2) holds by design.)

In nonexperimental research settings, researchers have few remaining options. One is to collect and control for additional variables in the regression, but that is cold comfort to users of existing data sets. Even controlling for hundreds of variables proves unconvincing in many contexts. For example, the archetypal nonexperimental study in education policy regresses student test scores on student, family, and school variables. The third category often includes a key policy variable such as class size or student/teacher ratio. Yet, test scores (say, at the end of grade 6) are the cumulative product of thousands of family and school inputs received by students from birth onward (Todd and Wolpin, 2003). Data sets can never fully and accurately measure all inputs.

In test score regressions, researchers often resort to controlling for test score measurements taken at earlier moments in students' careers (say, at the beginning of grade 6). By controlling for pretests in so-called value-added regressions, researchers hope to implicitly control for the all inputs that affected test scores until that moment, thereby reducing the scope of bias. Nonetheless, there is no guarantee that omitted variables during grade 6, or earlier ones not captured by error-ridden pretests, do not continue to bias estimates.

Propensity score matching

An alternative method of controlling for observed variables is propensity score matching. Researchers first estimate a propensity score for each student (or other unit) in the sample (Rosenbaum and Rubin, 1983). The score is a

predicted probability that students receive a treatment, given their observed characteristics. So, in the prior example, researchers would estimate probabilities, using a probit or logit regression, that students attend a private school, given their family income (X) and other observed variables thought to influence propensities.

In a common approach, private students would then be matched to similar public students, based exclusively on values of their propensity scores. If students cannot be matched to a counterpart, then they are discarded from the sample (e.g., this might happen if children of millionaires, or with other observed characteristics, always attend private schools). Estimates of private school effects are based on comparisons of average outcomes across students in propensity-score matched treatment and control groups.

The method's virtues are at least twofold (Ravallion, 2005). First, it imposes no arbitrary assumption of linearity on the relationships between outcomes, policy variables, and other controls, as in most regression models. Second, it removes treated (or untreated) students from the samples that have no obvious match in the other group. Intuitively, the observed uniqueness of such students implies that they are also unique in unobserved ways that could introduce selection bias. Yet, like regression analysis, the causal interpretation of propensity score matching results rests on the unverifiable assumption that no unobserved variables are correlated with outcomes and with the probability of receiving a treatment. In this regard, it is no panacea for causal research.

Randomized Assignment

In the 1990s, economists became disenchanted with the ability of statistical controls for observed variables to eliminate selection bias in nonexperimental data. (A growing literature finds that nonexperimental statistical approaches, including regression and propensity score matching, do a poor job of replicating experimental results (Agodini and Dynarski, 2004; Glazerman *et al.*, 2003).) A turning point was the widespread analysis and debate of results from a randomized experiment in Tennessee that identified the causal effect of smaller class sizes on student test scores (e.g., Krueger, 1999).

In the classic instance of randomized assignment, researchers flip a coin to determine which students are treated, and which are not (note that teachers, schools, districts, or even entire towns could also be randomly assigned). Thus, each student's probability of receiving the treatment is an identical 0.5. (A coin flip or similar mechanism is only the simplest approach to designing randomized assignment. The essential point is that students or other units have well-defined probabilities of being assigned to the treatment.) The virtue of this approach is that it balances the distribution of students' observed and unobserved characteristics across treatment

and control groups. The two groups are not identical, of course, but they should be similar, on average. Control group members are similar and therefore, except for their exposure to a treatment, they provide an ideal counterfactual estimate of outcomes.

To obtain an internally valid estimate of causal effects, one estimates the mean difference between the outcomes of treated and untreated units. One could further apply regression analysis to control for observed differences between groups. If randomization proceeded without a hitch, then doing so is not strictly necessary to eliminate selection bias, although it reduces the standard errors of estimates of causal effects.

Besides class size, randomized experiments have been used to explore the effects of many policy treatments on student test scores. For overviews of methods and findings, see Borman (2002) and Glewwe and Kremer (2006). Randomized experiments are not without pitfalls (for varied opinions, see Burtless, 1995; Heckman, 1995). One common critique is that attrition from treatment or control groups could reintroduce selection bias into experimental estimates. To be fair, attrition is a widespread problem in social science research, and is hardly confined to randomized experiments.

A second critique is that experiments, especially small-scale ones, yield causal conclusions of limited external validity (Shadish *et al.*, 2002). As one example, it is unlikely that treatments affect all students similarly. A typical randomized experiment identifies the average causal effect among heterogeneous students (some of who are strongly affected, and others not at all). Researchers with large enough samples can estimate causal effects within subsamples of students, perhaps dividing them by location, income, or race. Yet, even average effects in experimental samples may not be generalizable to the average student in the entire population, since initial samples are not always a random draw. In fact, many research studies pragmatically begin with volunteers, either students or schools. Results from volunteer students or schools may be harder to generalize to the broader population.

Discontinuity Assignment

One of the most credible quasi-experimental methods is the regression-discontinuity design (RDD) (Hahn *et al.*, 2001; Shadish *et al.*, 2002). In the RDD, researchers assign students to treatment or control groups on the basis of a single assignment variable – often a test score, but potentially any continuous variable – and a specified cutoff value. To provide an illustration, suppose that a thousand students vie for college financial aid by taking a pretest (the assignment variable). Students with scores of 50 or above (the cutoff) receive aid, and those with scores below 50 do not. Note that the assignment is not randomized, as in the flip of coin, but neither is it due to selection.

This provides sufficient leverage to identify the causal effect of financial aid on some students' subsequent outcomes.

The causal effect is estimated by comparing the outcomes of treatment and control students whose values of the assignment variables are close to 50 (van der Klaauw, 2002). The intuition is that such students should be very similar, not just in their values of the pretest, but in other observed and unobserved ways. At the very least, observed and unobserved characteristics of the students should not vary sharply in the vicinity of the cutoff. In short, control students (just to the left of the cutoff) provide a good counterfactual estimate of outcomes for treated students (just to the right). Thus, any sharp – or discontinuous – changes in outcomes near the cutoff can be attributed to the financial aid treatment.

A hallmark of recent papers is that researchers do not specify cutoffs or implement the assignment process. Instead, researchers take advantage of cutoff-based assignment that administrators used to allocate resources in a transparent, fair, or efficient way (i.e., needy or meritorious students receive financial aid, low-scoring schools receive assistance or sanctions, and high-scoring ones receive rewards, less-effective teachers receive training, and so on). The unintended usefulness of such rules to researchers has only recently been noted in many cases, even when discontinuity assignment has a long history.

What are the potential pitfalls of using discontinuity-based assignment? The most serious, related to internal validity, is that students, or others subject to discontinuity assignment, are familiar with the potential intervention, the assignment variable, and the value of the cutoff. If they have incentives to receive the treatment, or not, then they may well attempt to manipulate their values of the assignment variable (Lee, 2008). As in the nonexperimental context, the concern is that manipulation may introduce selection bias into estimates of causal effects. For example, suppose that students with rich parents are aware of financial aid assignment rules and obtain extra pretest tutoring for their children. The result is that treated children, just to the right of the cutoff, also happen to be somewhat wealthier, and perhaps more likely to attend college even without the treatment.

Precise manipulation of many continuous assignment variables is actually harder than it might seem (Lee, 2008). While most families can probably influence their child's pretest score, random errors in testing make it unlikely that they can affect it within a very narrow band of scores around the assignment cutoff. Students within this narrow band contribute the most to estimates of causal effects, implying that assignment variable manipulation must be very precise to bias regression-discontinuity effects. To test for manipulation, researchers typically search for suspicious clustering of students on either side the cutoff. They also compare students' observed characteristics near the cutoff, which should vary smoothly across the break, in the absence of manipulation.

Instrumental Variables

In the majority of cases, the assignment of students, schools, or other units to policy treatments is neither random nor based on values of an observed assignment variable. Besides controlling for observed characteristics, what remaining methods are available to identify the causal effect of policies on outcomes? One of most popular among economists has been instrumental variables (IV).

In nonexperimental data, the receipt of policy treatments is usually correlated with unobserved characteristics of individuals that affect outcomes. Therein lies the empirical dilemma. Yet, some individuals in the sample might receive a treatment because of luck or because they were encouraged to do so for reasons unrelated to outcomes. The challenge is to base estimates of causal effects entirely on clean variation in treatment status – that is, variation uncorrelated with unobserved characteristics that affect outcomes.

One must identify an instrumental variable, or instrument, that fulfills two conditions (Wooldridge, 2002). First, it must be strongly correlated with the probability of receiving an intervention. This condition, straightforward to test in the data, is needed to ensure that the instrument actually induces students or schools to alter their treatment status. Second, the instrument cannot be correlated with unexplained variation in the outcome variable (i.e., the variation in outcomes that remains after controlling for other independent variables). The validity of the second assumption, more complicated to empirically test, usually rests upon the compelling reasoning of the researcher.

In applications to education policy, instruments are often related to features of geography or students' location, which are assumed to be random in some regard, and thus viable candidates to fulfill the second condition. Toward estimating private school effects, for example, Figlio and Ludwig (2000) show that the availability of subway transportation in metropolitan areas affects the probability that families, especially poorer ones, choose private schools. Using this as an instrumental variable, their analysis suggests that private school attendance has strong effects on reducing some risky teenage behaviors. Given the second IV condition, they must assume that transportation availability is uncorrelated with student outcomes, after controlling for other variables like family income. The validity of this condition is hard to prove. For example, do metropolitan areas with extensive subways have progressive mayors that invest in public schools? In the most convincing IV analyses, there are *a priori* reasons to believe that instruments are uncorrelated with unexplained outcomes.

Difference-in-Differences

Difference-in-differences (DD) methods attempt to control for unobserved variables that bias estimates of causal

effects, aided by longitudinal data collected from students, school, districts, or states. Researchers employ two varieties of longitudinal data. Panel data track the progress of the same students or teachers in successive months or years. Repeated cross-section data follow different groups of individuals (e.g., second-graders in successive years) that are clustered within the same schools, districts, or states.

The logic of DD causal inference is best communicated with an example based on repeated cross-section data. Of two states, Massachusetts and Maine, suppose that the former implements a finance reform – increasing state financing of local public school districts – and the latter does not (Dee and Levine, 2004). To estimate the reform's impact on district outcomes in Massachusetts, a naïve approach would compare outcomes across states, within a single year of post-reform data. The comparison is likely biased by selection, since unobserved differences across states could also affect outcomes.

Now consider the same comparison of outcomes, but within an earlier, pre-reform year of data. Evidently any differences in outcomes cannot be attributed to a Massachusetts reform that is yet to occur. Pre-reform differences in outcomes are perhaps due to unobserved differences across states that contaminated the previous, naïve estimate. To control for these unobserved variables, the DD estimate of the reform's effect subtracts the second difference from the first. The remaining DD could be plausibly attributed to the reform. For this to be credible, the change in Maine's outcomes must be a good counterfactual for Massachusetts' outcomes. Yet, suppose that Massachusetts' outcomes rose more quickly than other states, even before the reform, because of economic growth due to a strong biotech industry. The DD will nonetheless attribute faster outcome growth in the treated state to the causal effect of reform.

In light of this pitfall, one of the best ways to assess the internal validity of DD results is to compare the trends of outcome variables across treatment and control groups before application of the treatment. Evidence of similar trends bolsters confidence in the DD assumption. Dee and Levine (2004) estimated the effect of Massachusetts' state finance reform on districts' per-pupil state revenues. As controls, they used districts in Maine and Connecticut, which did not apply reforms, over the same pre- and post-reform period. DD estimates showed significant effects of the reform on local revenues. To support the use of these comparison groups, they showed that the outcome variables had similar trends in the three states in years prior to the reform.

Researchers increasingly apply DD methods to student-level panel data on test scores, applying a similar logic of causal inference. Some students' outcomes are observed before and after exposure to a treatment. Their outcomes are compared to students never exposed to the treatment. Rouse (1998) provides an example of this approach in her

re-analysis of data from the Milwaukee voucher program. The treatment group consists of students, observed before and after their selection to receive a private school voucher. The comparison groups consist of (1) students that were denied a private school voucher or (2) students in public schools that never applied for one. The DD estimates suggest that treated students have faster gains in math scores, but not in reading, than students in both comparison groups. The necessary assumption, as in previous analyses, is that treated students would have had trends in achievement similar to untreated students in the absence of the treatment.

Combining Methods to Improve Causal Inference

Researchers often apply multiple methods in the same study to improve internal validity. Almost every study employs statistical controls for family and student characteristics that affect outcomes. DD methods are frequently combined with experiments (Skoufias, 2005), the RDD (Chay *et al.*, 2005), and IV methods (Kuziemko, 2006). Finally, researchers often combine IV methods with randomized experiments and the RDD, especially to address imperfect compliance of students with random or cutoff-based assignment to policy treatments. In New York City's voucher experiment, for example, students were randomly assigned to receive a voucher offer, but not all students accepted the offer and actually attended a private school (Krueger and Zhu, 2004). To recover an estimate of the treatment-on-the-treated (i.e., the effect of actually attending a private school), researchers used the voucher offer as an instrument for private school attendance. The resulting IV estimate provides a credible estimate of the effect of private school attendance on those induced to accept it by the voucher offer.

Conclusions

This article has described empirical research methods used to estimate the causal effect of education investments on outcomes. Some, like regression analysis with nonexperimental data, are common but not always capable of delivering strong causal conclusions. Others, like experimental and discontinuity research designs, are increasingly common in the economics of education and better suited to addressing causal questions. Finally, it bears emphasis that good causal research is a necessary but not sufficient condition for designing and implementing good policy, a point not always clear in recent debates over scientific research (US Department of Education, 2003).

Introduction

Over the past two decades, the economics of education has grown rapidly as a field. Previously, scholars and policymakers tended to view education and economics as separate realms, with economics applied to the study of private goods and education as a public good. Economics has been characterized as cold and impersonal due to its focus on firms, rational self-interested individuals, and cost-benefit decision making, all of which on the surface appear to be unrelated to the social and moral values associated with educating children. As school systems in developed countries have come under pressure to improve quality and scale, the distance between the two realms has narrowed. It is well documented that better-educated workers have more favorable labor-market outcomes than those with less schooling. Moreover, a well-educated labor force is critical for a nation to compete in an increasingly global economy that rewards knowledge and skills. Given concerns with the productivity of educational institutions and the fact that the study of incentives, choice, and competition lie at the heart of economics, economists have become more relevant to education-reform debates. They bring increased attention to resource allocation and decision making at the school level, take the view of educational organizations as potentially competitive enterprises, and those running them as entrepreneurs. The study of incentives lies at the heart of economics, and an understanding of how actors in large complex systems respond to incentives, and changes in incentives, helps shed light on how teachers might react to merit pay incentives or schools might react to increased competition from choice programs and charter schools.

In this article, we briefly review several of the most important theoretical concepts in the economics of education. First, we define economics and then review three of the most commonly used ideas – human capital, markets, and education production. We focus here on explicating the major underlying theories (in a nontechnical manner), rather than their application. All three have been utilized in numerous empirical studies. These are reviewed in greater depth elsewhere in the encyclopedia.

Economics Defined

Economics is often defined as “the study of the allocation of scarce means to satisfy competing ends” (Gary Becker

as quoted by Walberg and Bast, 2003:182). Economists study how individuals, organizations, and societies employ time, money, and effort. In the case of education, economists are interested in how society organizes and uses scarce resources to produce various types of knowledge and skills through formal schooling, and how these types of knowledge and skills are distributed to various groups in society. This broad definition means that many social and political issues and topics can fall under the purview of economics. John Maynard Keynes once wrote that economics was a “way of thinking” and it is this lens that has been brought to bear on a wide array of traditionally non-economics topics, including education policy.

Economists typically begin an explanation of observed phenomena by building a theory or a model in order to simplify reality and highlight key characteristics. A model contains a set of assumptions, and yields predictions, *ceteris paribus* (all other things being equal). Often this abstraction causes concern among noneconomists, but such simplifications are essential to understanding real-world settings. Economists would argue that what matters is whether the predictions of a model are correct on average rather than whether the assumptions underlying it are realistic. Economics, then, sits firmly within the tradition of theory-testing scientific method-based disciplines: a question is framed; a model/theory developed to explain behavior; and the hypotheses or predictions of that model/theory are then tested empirically using real-world data. It is often described as concerned with positive rather than normative issues, where the former are empirically testable and the latter are dependent on value judgments. The emphasis on hypothesis testing makes economists almost always use research designs that are quantitative in nature, attempting to discern whether predictions of cause and effect are valid, and the degree to which they are generalizable.

Economic theories are typically built on three basic foundations: scarcity, rationality, and optimization. Scarcity refers to the assumption that individuals and society will never have enough resources to completely satisfy their unlimited wants. Rationality refers to people's ability to make decisions in a systematic and purposeful way. It implies a “consistency of response to general economic incentives and an adaptability of behavior when those incentives change” (Ehrenberg and Smith, 2006: 4). The last assumption is the idea of optimization – either profit or goal maximization with reference to organizations or

utility maximization with reference to individuals. Individuals and groups have particular goals – be they happiness, profit, market share, or some combination of these or others – and will make choices that will maximize these benefits, subject to the constraints that they face (e.g., their income). This does not mean, however, that economists only care about selfish individuals; personal values are viewed more broadly, including all that individuals care about. Individuals behave subject to the constraints they face, the context in which they find themselves, and their perceptions of the consequences of alternative choices they make.

Economics provides a framework for understanding the behavior of individuals and organizations as they generate and allocate human, material, and financial resources. Using this perspective, economists have examined a wide range of education-related topics, and in the remainder of this article we discuss three of the major education questions of interest and the concepts that have been used to shed light on them. First, how much education (does and) should an individual acquire? This entails the notion of human capital. Second, how should education be produced and allocated by a society? This broad question examines conditions, characteristics, and behavior under alternative organizational forms, including both markets and hierarchies. Third, can we be more efficient and effective in organizing the production of education? The idea of ‘education production’ is helpful in answering this question. We discuss each of these in turn.

Human Capital

A primary research area within the economics of education is the association between schooling and individual outcomes, especially those associated with the labor market. Education (and training) is modeled as an individual investment decision that will receive a monetary return in the labor market, typically in the form of higher lifetime earnings. This notion of human capital has a rich history, with early economists such as Adam Smith, John Stuart Mill, and Alfred Marshall suggesting that individual’s skills could contribute to their economic status. In 1776, Smith laid the foundation for human capital theory when he wrote that human effort lies at the root of all wealth. In 1848, Mill built upon Smith’s notion; he considered human abilities as means to wealth (Sweetland, 1996). Modern-day human capital theory has further extended the central insight through the pioneering work of Schultz (1963), Becker (1964), and Mincer (1958, 1962).

Knowledge and skills acquired through educational investments increase human productivity. With each investment, one may incur costs in the form of out-of-pocket expenses, foregone earnings, and psychic costs associated with the pressure of studying and examinations.

Benefits accrue later in life through enhanced earnings in the labor market, access to better jobs, a higher likelihood of being employed, and better health. There are also psychic benefits from enhanced social status and the prestige associated with higher levels of education. Although individuals’ motivation for pursuing schooling may differ, and the psychic costs and benefits may be quite varied depending on personality, expectations of returns, and other traits, economists hypothesize that, other things equal, the more the education acquired, the higher the earnings achieved after the schooling is completed.

Prima facie evidence for human capital theory is to be found in the strong positive relationship between education levels and earnings that exist in almost every developed country. Generally, earnings rise with education level and they increase at an increasing rate in the immediate post education years, continue to increase at a slower pace, and then flatten as individuals approach retirement (Ehrenberg and Smith, 2006). This general pattern of earnings by education level holds for almost all subgroups, including men and women, and different racial and ethnic groups, but it is the differences among these groups that often fuels education policy debates about the distribution of education subsidies and services. Economists have devoted considerable attention to the challenge of estimating the returns to schooling taking account of these other factors. Analysis of such returns generally reveals a consistent positive relationship between investment in education and increased earnings for individuals, with an estimate of the average rate of return to an additional year of schooling of about 10% (Psacharopoulos and Patrinos, 2002). An overview of the empirical literature is provided elsewhere in the encyclopedia.

Economic research has also found nonmonetary benefits, both private and public, associated with educational attainment. Individuals who have invested in education and job training often have more job stability, improved health (e.g., exercise regularly, smoke less, and eat better), are more likely to receive employer-provided health insurance and pension benefits, are more inclined to vote, and have generally increased social and cultural capital that often enables upward mobility. These benefits are reviewed elsewhere in the encyclopedia.

Markets and Market Failure

There is general consensus that national investments in education lead to economic growth (for a review of the literature, see Sturm, 1993; Hanushek and Kimko, 2000). Countries spend a sizable percentage of their gross domestic product (GDP) on education each year. Educational spending can be undertaken by private individuals and by governments through public expenditures. The decision as to how education at different age levels should

be allocated is at its core an economic decision about how best to allocate scarce resources in order to maximize output (i.e., education).

Goods and services may get allocated in many different ways – for example, by tradition, force, or lottery. In modern societies, resources are allocated either by markets, by governments, or frequently through the interplay of both. K-12 schooling has traditionally been allocated by government at the federal, state, and local levels, with postsecondary education allocated by some combination of markets and government. As concerns about the effectiveness of existing schools have risen, policymakers have questioned the central role and functions of government in the allocation of educational resources, and turned toward market or market-related mechanisms.

A market is defined in an economic context as a collection of buyers who purchase and sellers who produce and sell goods and services; the interaction of buyers and sellers results in the possibility of exchange and, hence, in the allocation of goods and services. The transaction is facilitated through agreement on price. A graphical illustration of a market shows a downward-sloping demand curve and an upward-sloping supply curve. Sellers want to maximize profits, while buyers want to maximize satisfaction based on their preferences and budget constraints. The higher the market price, the more of a good or service a seller is willing to supply, but the lower quantity of that same good or service a buyer will demand, other things being equal. The function of a market is to adjust price to accommodate changes in supply and demand as efficiently as possible. When the price in a market reaches a level where the quantity that buyers want to purchase equals the quantity that sellers want to supply, then the market is said to be in equilibrium. Markets also act to keep prices low. Producers that fail to offer consumers what they want, or who charge too high a price, will lose business and eventually close. The dynamics of markets means a continuous process of adjustments that includes shortages and surpluses, and consumers and producers entering and exiting the market.

In many circumstances, markets are the preferred method for allocating resources because they are able to coordinate many buyers and sellers, give consumers considerable influence over price, characteristics, and quantity, and avoid relying on a handful of arbitrary decision makers. Under these circumstances, markets are an efficient mechanism for allocating resources, meaning that no more could be produced with the same resources, and the same output could not be produced with fewer resources. Efficiency is a specific criterion for judging an allocation mechanism. It does not say whether the resulting distribution of resources meets goals other than satisfying buyers and sellers (e.g., whether it is fair). Clearly, consumers of education have multiple goals (Gill *et al.*, 2001) and these need to be considered in deciding what is the

best mechanism for allocating education from society's standpoint.

When markets do not efficiently organize production or allocate goods/services to consumers, then market failure is said to occur. There are several reasons why markets fail. First, market power may arise when a supplier of a good/service has the ability to control price. A monopoly is an example of such market power. Perfectly competitive markets have many buyers and sellers, so no single buyer or seller has a big impact on price. While certain inputs to schooling may be more characteristic of perfect markets than others (e.g., school supplies), markets in K-12 schooling are quite imperfect.

A second type of market failure is when consumers have incomplete information about price and product quality, in which case the market cannot respond efficiently and correctly. Under incomplete information, parents may or may not choose schools based on outputs important for broader society. (There is some evidence, e.g., that many parents care not only about student achievement but also the social and racial profile of a school's students, preferring settings where there are most students like their own child.) Hence, although their preferences may be satiated in a market setting, some may judge that these preferences are not desirable from society's standpoint.

Third, externalities exist when consumption or production have an indirect effect on others that is not reflected in market prices. In the case of education, the decision maker (e.g., an individual student) does not bear all the costs or reap all the rewards from his or her decision about how much education to obtain. Even though society may benefit more from an educated person, the person making the educational decisions may not see those benefits as his or her own. Thus, the good (education) will be underconsumed from the perspective of the market. This presence of social benefits arising from basic education is perhaps the chief reason why governments have typically made schooling compulsory at elementary and secondary levels.

Fourth, markets may fail for public goods – those that can be made available to additional people without additional cost (nonrival), and once provided are difficult to prevent others from consuming (nonexcludable). Schooling is to some degree a public good. As with externalities, markets will tend to undersupply public goods.

The possibility of market failure, especially the underconsumption of education by private individuals from society's standpoint, as well as the importance of educational goals other than efficiency, has historically led to significant government intervention in the education sector through regulation, financing, and operation. Regulation can take different forms including setting safety standards, mandating curriculum or student assessments, and requiring teacher credentials. Financing can be in the

form of direct funding to schools or various forms of financial aid to individuals. Revenues for schooling may be generated from general taxation, rather than user fees, such that there is no clear relationship between receipt of the service and the payment for it. The government may also directly operate educational enterprises, which means that the delivery units are embedded within a larger government hierarchical infrastructure controlled by political mechanisms, owned by the state, and in which the employees are civil servants.

Typically, regulation, finance, and operation have been combined in a vertically integrated public sector system. Further, because government-operated schools have been designed to serve all students in a geographic area, in that locality they constitute a virtual monopoly. From a market perspective, this means that schools do not face competitive pressure to keep quality high and costs down. In addition, many families (particularly low-income and minority families) do not have much choice over the schooling options for their children. Recent educational reforms are to some extent characterized by an attempt to unbundle regulation, finance, and operation – ranging from tax credit schemes, to magnet schools, to controlled-choice programs, to charter schools, and voucher programs. Several of these are discussed in much greater depth elsewhere in the encyclopedia.

Education Production

Economists have sought to understand how education is produced. This has taken two different forms. One is to treat education as a production function wherein schooling inputs are processes from which outputs are produced. In this formulation of schooling, processes occur within a black box of the school system. The second approach explicitly looks inside the black box and examines the organization as a web of interpersonal contracts wherein individuals seek to coordinate others (and are in turn coordinated by others) in the performance of work. This latter arena is most often referred to either as transaction cost economics (accounting for the newly recognized costs of coordination or transactions) or as applications of principal–agent theory (seeking to capture the complex issues of delegation of decision rights between bosses or principals, and their subordinates or agents).

The production function approach uses an input–output framework to help think about schooling. The main inputs may include teachers, administrators, supplies, and facilities while the main outputs are student achievement (knowledge, skills). The relation between the educational inputs and outputs is usually statistically estimated using multiple regression techniques. While the education production function is simple in theory, it is very complex in practice (Goldhaber and Brewer, 1997). For example, it is hard to

identify and measure all inputs and outputs of schooling. Multiple outputs (e.g., basic skills, vocational skills, creativity, and attitudes) are valued, may accrue in a cumulative manner, and may only be discernable many years into the future. Inputs can be hard to measure, and the dimensions most easily measurable may not capture the important features of that input adequately. For example, the way in which a teacher interacts with students is important in the students' learning process; however, the characteristics of effective teachers may not be well captured by readily available proxies such as years of experience or qualifications. Nonschool inputs, such as peer influence and family background clearly affect how much students learn. Moreover, outputs are themselves joint products (i.e., students experience multiple teachers and carry with them knowledge from other classes and from home). The value of the production function approach, however, is as a framework for thinking about what resources, in which combinations, make a difference for student outcomes. Many studies have attempted to determine the relationship between inputs and outputs as currently exists in the United States and elsewhere.

The second economics-oriented perspective on organizations, achieved largely through applied principal–agent theory, was originally conceived by economist Nobel Laureate Ronald Coase in the early 1930s, who argued that markets and hierarchies, heretofore examined as separate topics, were in effect, substitutes for each other. The factors in a specific firm or division of a firm that made one alternative superior to another were often associated with the differing costs of coordination (the costs associated with transactions among individuals). This perspective has been extended to include a third substitutable form of organization, alliances or networks. In agency theory (Moe, 1984; Ferris and Winkler, 1991) principals (superiors in organizations, e.g., school superintendents) seek to ensure that agents (subordinates in organizations, e.g., school principals) carry out the principal's goals, in recognition of four primary factors that make this difficult. An adverse selection problem occurs when principals (e.g., school superintendents) are not fully informed about the abilities and values of the agents (e.g., school principals) and select agents that are not the best choice. A diverse objectives problem occurs when agents pursue their own objectives at the expense of pursuing the principals' objectives. This problem is compounded when compliance is achieved only by costly monitoring and controlling of the agents. An information asymmetry problem occurs when information within the accountability relationship is not evenly distributed. The agent typically has the information advantage. Finally, a weak incentives problem occurs when principals lack sufficient decision rights to cause the agents to either share principals' values or to behave as if they did. Although the full implications of agency theory and the

concepts embedded with it are still being explored, they have become common in analyses of current educational policies.

Concluding Thoughts

Economics, as a framework for understanding the allocation of resources, and human and organizational behavior more generally, has made important contributions to the study of education. The core concepts of human capital, markets, and education production have over several decades become increasingly common in education policy debates as well as familiar to practitioners. The contributions and the impact of economics on education (past and projected) are uneven. The concept of human capital, for example, is well established, and has expanded beyond simple rate of return calculations to considerations useful for policymakers – for example, in determining the relative contributions of different types of institutions or programs of study. The interplay between markets, regulation, and individual and organizational performance in education has attracted considerable academic interest, and that is expected to continue, albeit frustrated by the absence of large-scale demonstrations of different structures of the sort that would permit more definitive statements about what works. Applying economics to policies affecting the design of education organizations has been a mixed bag. With some exceptions, production function and cost effectiveness studies have had limited policy impact. Agency theory and transaction cost economics, intuitively appealing concepts, have not yet been rigorously applied to education organizations. However, as the education world begins to flatten this field should be expected to grow.

Economic Evaluation of Education

Cost–benefit analysis (CBA) and cost–effectiveness analysis (CEA) are the two main methods used by economists to evaluate educational investments.

CBA is an important method for evaluating educational investments and for deciding on the provision of public goods. CBA compares the costs and outcomes of alternatives. Critically, these outcomes must be expressed in monetary terms (Mishan, 1976). Both costs and benefits must be expressed in present values, that is, monetary values that take account of the difference between income received now and received in the future. At its most general level, CBA has been applied widely to evaluating educational investments at the national and subnational levels, most commonly in evaluating the ability of such investments to raise productivity and earnings.

CBA enables a direct comparison of the costs and benefits of an alternative or a comparison of their magnitudes with those of other types of social investments in education or in other sectors. Not only is it possible to ascertain which educational investment has the largest benefits relative to costs, but it is also possible to compare these results with investments in health, transportation, physical capital, such as plant and equipment, and other sectors. In this way, governmental units can use CBA to compare the desirability of alternative educational investments, as well as to determine the balance between investing in education and other sectors.

CEA is a method of comparing decision alternatives in which both the costs and the effects are taken into account in a systematic way (Levin and McEwan, 2001). The

method is used to compare the efficiency of alternative ways to achieve an educational objective. For example, if the objective is to raise the rate of high school graduation, this method of analysis can be used to determine whether investment in (as examples) preschool reading programs or smaller elementary school classes is more cost effective. In principle, the method is simple for each investment, the full costs are calculated (C) and the effect on graduation rates is identified (E); and so the most cost-effective investment is the one with the lowest C/E ratio.

Clearly, CBA and CEA are closely related to each other. The essential difference is that for CBA, the benefit must be measured in money terms and for CEA, the effect is measured directly in educational results. For example, vocational education programs are often solely intended to raise future earnings and are amenable to CBA. Alternatively, educational programs may be designed to improve, for example, reading skills as a desirable end per se, whether or not there is an associated monetary value. Sometimes, the effects of an educational program can be translated into monetary benefits: for example, a program that has the effect of raising the high school graduation rate will most likely also yield a benefit of thousands of dollars in extra income for the new graduates. The advantage of CBA is that – because the metric used is money – many more educational programs can be compared with each other. A program to boost reading skills may be compared to one that reduces grade retention rates; and more generally, investments in education can be compared to other social investments. However, many educational alternatives are dedicated to improving achievement or some other educational outcomes that cannot be easily converted into

monetary terms. When this is the case, CEA is the more appropriate method.

The purpose of both these forms of economic evaluation in education is to ascertain which program can achieve a set of particular objectives at the lowest cost. The implicit assumption is that different alternatives are associated with different costs and different educational effects or monetary benefits. By choosing those with the least cost for a given effect or benefit, society is using its resources more efficiently. That said, it is important to know if economic differences are large or small. If the differences are small, it may be wise to weigh more fully other criteria in deciding between educational investments (such as ease of implementation).

Methodology

The basic technique is to measure effects or benefits for each educational alternative using high-quality evaluation procedures, that is, ones that can causally identify consequences or ones that apply rigorous econometric techniques (Levin and McEwan, 2001). Separately, the costs for each alternative should be measured using the ingredients method (Levin and McEwan, 2001); these costs should include all the resources that are given up by society to implement the intervention. In practice, measurement of both cost and benefit/effects is challenging.

In order to adjust for the time pattern of costs, a discount rate is used to make past, present, and future costs comparable. A discount rate does not adjust for inflation in prices. What it does do is enable one to compare costs that have different time patterns by establishing their present values (Levin and McEwan, 2001: 90–94). The specific discount rate for public investments is a matter of some contention, although Moore *et al.* (2004) provide a strong argument for using a rate of 3.5%.

Measuring Costs

CBA and CEA both require that the costs of the investment are accurately measured using the ingredients or resource-recovery method (Levin and McEwan, 2001). The costs of an intervention are defined as the value of the resources that are given up by society to implement the intervention. These resources are referred to as the ingredients of the intervention, and it is the social value of those ingredients that constitute its overall cost. At a later stage, one can assess the distribution of these costs between the decision-making agency and other agencies. Accordingly, the method sets out systematically to identify and ascertain the value of the ingredients that are required for each alternative that is under consideration. From an economic perspective, the costs of an action are determined by the value of the resources that are entailed in their best alternative use.

This is known as opportunity cost, in the sense that it is the value of the best forgone opportunity that must be considered when one refers to the cost of the intervention. The ingredients method represents a straightforward way of estimating cost.

The ingredients approach to cost estimation entails three distinct phases: (1) identification of ingredients; (2) determination of the value or cost of the ingredients; and (3) an analysis of the costs in an appropriate decision-oriented framework.

The identification of the ingredients refers to the delineation of all of the resources that are required for the particular intervention that forms the basis for the economic analysis. For example, in the case of a study of expansion of technical education, the personnel, facilities, materials, and other ingredients required for the activity need to be identified. For educational programs, the main ingredient is often labor services of which the largest component is that of the teacher. Yet, teachers and administrators must prepare classes as well as manage the educational enterprise; so the ingredients are more than just their instructional time.

Educational interventions use not only these resources but also the time of the students who might otherwise be able to use their time productively in the workplace or through self-employment. Even the time of elementary school children is likely to have some value in developing countries in terms of household or farm tasks. If a student is required to spend four additional years in the educational system, those years could have been used for other productive activities that, when forgone, have a cost to both the individual and to society. Hence, student time is an important ingredient in economic analysis.

Once the ingredients have been identified and stipulated, it is necessary to ascertain their costs (Levin and McEwan, 2001). In doing this, all ingredients are assumed to have a cost, including donated or volunteer resources. That is, they have a cost to someone, even if the sponsoring agency did not pay for them in a particular situation. At a later stage, the costs will be distributed among the constituencies who paid them, but at this stage the aim is to ascertain the total costs of the intervention.

Ingredients can be divided into those that are purchased in reasonably competitive markets, and those that are obtained through other types of transactions. In general, the value of an ingredient for costing purposes is its market value. In the case of personnel, the market value may be ascertained by determining what the costs would be for hiring a particular type of person. Such costs must include not only salary, but also fringe benefits and other employment costs that are paid by the employer. Many of the other inputs can also be estimated using their market prices.

There are a number of techniques for determining the values of resources that cannot be readily priced in the market place. To cost out student time, the usual measure

is the earnings forgone by the student by enrolling in school or a training program rather than being employed in the workplace. This should approximate to the value of productive activity that was lost because the student was in school. Typically, the cost of student time is estimated from the earnings of persons of similar gender, race, and socioeconomic status who are in the workforce rather than in schools or training programs. Such estimates must be adjusted for the probability of unemployment.

However, the quality of costs data is often poor. Although the market prices of some ingredients can be obtained from accounting data for educational enterprises, such data are not reliable sources for ascertaining overall social costs. The accounting systems that are used by schools are designed for ensuring consistent reporting to state agencies rather than for providing accurate and consistent costs data on specific educational interventions. Important discrepancies are the costs of volunteers' time and other donated resources, as well as the costs of capital facilities that are typically charged to budgets at the time of expenditure rather than amortized over the life of the school. Besides, the issue of who pays the costs is important: decision makers may pay only part of the cost for one intervention, but the whole cost for another intervention.

Lastly, the issue of scale is important. In general, those alternatives with high fixed costs such as those with large investments in facilities and equipment will require a high enrolment or utilization to be most efficient. In contrast, alternatives that are constituted largely of variable costs such as personnel will have costs that are less sensitive to the scale of output. Thus, an economic evaluation of alternatives that differ in terms of their intensities of fixed versus variable costs may produce very different results depending on the scale of enrolment or output.

Benefits and Effects

Since CBA requires that the benefits be expressed in monetary units, it is only possible to apply this to interventions where this is feasible. CBA lends itself especially well to those alternatives or interventions in which the outcomes are market oriented. For example, educational and training programs that are designed to improve earnings or reduce poverty can be evaluated with a cost-benefit approach when the benefits are the additional earnings associated with the interventions. But all benefits must be considered. Yet, Herrnstein (1997) points out a saliency mismatch, whereby it is hard to envisage some of the benefits (or even some of the costs) and this may falsely diminish their significance.

Some studies have looked specifically at the monetary benefits of education, without directly relating these to the costs of a particular program that might influence education. An important early study was by Haveman and Wolfe (1984) which itemized the potential economic

benefits of education and derived a simple method by which these could be monetized. Research in an edited volume by Belfield and Levin (2007) shows in more detail the link between high school graduation and earnings, health, welfare, and crime; this volume also calculates the present value benefits for each additional high school graduate that is produced in the United States—these benefits are substantial.

For cost effectiveness, it is necessary to measure effects. For some programs, the average effect is of interest; for others it is the marginal effect of a program. In addition, many programs have multiple effects and these effects may not be found for all students. For example, some students may have higher test scores and others may exhibit improved classroom behavior or social skills. Deciding which effect is more important—or placing weights on each—is a challenge that might be undertaken using utility analysis (Levin and McEwan, 2001).

Examples of Applications

Cost-benefit analysis

The most popular area for CBA in education is that of preschool programs. Belfield *et al.* (2006) conducted an updated CBA of the High/Scope Perry Preschool Program, using data on individuals aged 40. Delivered in the 1960s, this program involved random assignment to a treatment or control group; the treatment was a preschool program. The treatment group received program provision for one or two short academic years composed of three parts: (1) a center-based program for 2.5 h per day for each weekday, with a child:teacher ratio of 5:1; (2) home visiting for 1.5 h⁻¹ weekday; and (3) group meetings of parents. Overall, the program represented a relatively intensive and structured investment in supporting the preschool development of the participants. The participants entered the study as 3- and 4-year-old African-American children, with no physical handicaps, but were selected on the basis of low parental education and disadvantaged background. Program costs were compared against treatment impacts on educational resources, earnings, criminal activity, and welfare receipt where these impacts were expressed in money terms. Net present values were calculated for participants, the general public, and society. Treatment group individuals obtained significantly higher lifetime earnings. For the general public, higher tax revenues, lower criminal justice system expenditures, and lower welfare payments easily outweighed program costs; they repaid US\$12.87 for every US\$1 invested. However, program gains were mainly in the form of reduced crime by males.

CBAs of preschool interventions have also been performed for other preschool programs, such as the Chicago Child-Parent Center program. This too showed a very high cost-benefit ratio: the total benefits were 10.15 times greater than the costs (Reynolds and Temple, 2007).

Another program, which also involved more comprehensive child care for younger children, is the Abecedarian Early Childhood Intervention. It also had a positive net present value where benefits greatly exceed costs (Barnett and Masse, 2007).

Potentially, CBA could be performed on any educational investment. For example, for the US, another example is by Bishop (1996), who estimates the costs and benefits of lengthening the school day and finds that the net present value of benefits is approximately five times the costs. Increasingly, CBA is being performed on educational investments in developing countries to guide state governments. However, ensuring that these economic evaluations are of high quality is far from straightforward (see Vawda *et al.*, 2003). An early attempt for rural Brazil – comparing different resource reallocation strategies – was performed by Harbison and Hanushek (1992). More recently, Machin and McNally (2007) calculated a benefit–cost ratio of the National Literacy Strategy in England; this reform changed the way literature was taught (with a focus on classroom management and effective teaching). As it was beneficial but relatively low cost, the reform yielded a very high benefit–cost ratio.

Further application of CBA

CBA is slowly being implemented, but it is still not a straightforward method to apply (e.g., for comprehensive school reform, see Levin, 2002). The main advantage from additional years of education appears to be in terms of the extra income a person can earn. However, this type of analysis is often done in the form of a rate-of-return analysis rather than a cost–benefit ratio or net present value (see Krueger's (1999) rate of return calculation for reducing class sizes in the elementary grades). That is, the income benefits are expressed in terms of the equivalent of an annual return on investment. Nevertheless, the basic data used to estimate rates of return can be used to calculate net present values (the difference between the present values of benefits and costs) or cost–benefit ratios.

Cost–effectiveness analysis

CEA can be applied to any educational interventions that have broadly the same objective. However, in practice its application has been very limited, not least because of the methodological challenges described above. Yet, this is in contrast to health economics, where CEA is much more prevalent (Muennig, 2002).

Curriculum is an area that is very appropriate for CEA. In the quest for educational improvement, schools face numerous ways in which they can organize the mode of instruction. Some are likely to be more effective than others, and there may also be substantial differences in resource requirements with respect to ingredients such as teacher time, materials, equipment, and so on. An excellent cost–effectiveness study of fifth-grade mathematics

curriculum was performed by Quinn *et al.* (1984). Their evaluation compared two approaches to teaching mathematics, a traditional curriculum and an alternative one. Using the ingredients method, the resources found that the alternative math program cost about 50% more than the traditional program, but the effectiveness of the alternative program was also higher. Depending on how student achievement was measured, the alternative program was found to be from 60% to 300% more cost effective (cost per point of achievement score) than the traditional program.

Levin *et al.* (1987) investigated four reforms for which there were adequate effectiveness data as well as a basis for estimating costs. These were: computer-assisted instruction (10 min of drill and practice per day); a longer school day (of 1 h divided equally between instruction in math and reading); smaller class sizes (changes in class size of various ranges from 35 to 20); and peer tutoring (of second-grade students for 15 min^{−1} day by fifth- and sixth-grade students).

Costs were estimated using the ingredients approach. The least costly interventions were reductions in class size of five students and increasing the length of the school day. The most expensive was peer tutoring because it requires adult coordinators. The costs of peer tutoring were about four times as great as reducing class size by five students or increasing instructional time by one-half hour per day per subject and twice as great as the daily sessions of computer-assisted instruction. In terms of effectiveness, peer tutoring showed the largest effects, nearly a year of achievement gain in math and about one-half year in reading. The longer school day and reduction of class size by five students showed the smallest effects. Computer-assisted instruction was associated with gains in the middle of the range of results. Cost–effectiveness was determined by combining costs and effectiveness in terms of the estimated annual costs to obtain an additional month of student achievement per year of instruction. Peer tutoring was the most cost-effective intervention and a longer school day the least cost effective; the former was almost ten times more cost effective in months of math achievement than the latter (and almost double for reading achievement). Computer-assisted instruction was almost as cost-effective as peer tutoring in terms of reading achievement, but reducing class size was very inefficient with respect to reading gains. Although class-size-reduction policies are very effective, they are also very expensive.

Further application of CEA

McEwan (2002) describes the many potential pitfalls and itemizes a set of technical criteria with which to evaluate cost–effectiveness studies. Clune (2002) evaluates the method as applied in 541 studies that refer to cost effectiveness; in over three-quarters of the studies the CEA is

rhetoric or minimal. A more recent exercise by Ross *et al.* (2007) yields a similarly low number of high-quality economic evaluations. The reasons for this are described in detail by Levin (2001).

Economic Approaches to Adequacy

J Imazeki, San Diego State University, San Diego, CA, USA

Glossary

Cost of adequacy – It is the minimum amount of money that school districts must spend in order to achieve some minimum-outcome goal.

Educational cost function – It is the estimated relationship between dollars per pupil, educational performance, and the characteristics of the school district and its student body.

Marginal costs of adequacy – They are the additional costs associated with specific student or district characteristics (such as poverty, English learners, and special education), above and beyond the base cost of adequacy in a district with none of these special needs.

Throughout the 1970s and early 1980s, school finance court cases and state-level school finance reforms across the United States focused primarily on the equalization of resources across districts. The underlying assumption of these efforts seemed to be that a more equal distribution of dollars would lead to a more equal distribution of educational outcomes. However, during the 1980s and 1990s, a growing awareness that equal dollars do not lead to equal outcomes led to new court challenges in several states, based on adequacy grounds. In these cases, plaintiffs maintained that states were required to ensure students had equal access to an adequate education, with adequacy defined in terms of some minimum standard of student performance or skills. In particular, these cases recognized the differential costs of education for schools serving different student populations, highlighting the fact that some schools require more resources than others to meet the same performance standard.

The cost of education can be defined as the minimum amount of money that a school district must spend in order to achieve a given educational outcome, such as reading at a grade-appropriate level. Costs generally differ across school districts for reasons that are outside the control of local school boards or state governments, such as the number of children with special needs. All else equal, districts with higher costs will need to spend more than districts with lower costs in order to achieve any given outcome. Thus, costs are specifically linked to outcomes. Costs are also distinct from expenditures. Actual expenditures in a district are influenced by costs

but they also reflect choices made by local school boards or district officials regarding how to allocate and organize resources to achieve selected objectives. Thus, a school district with below-average costs could have above-average expenditures because it chooses to offer a particularly broad range of advanced classes, or because it is relatively inefficient in its use of resources.

Measuring the Costs of Adequacy

Designing a school finance system that guarantees all students an adequate education requires information on the costs of providing that education in each district. To that end, an increasing number of costing-out adequacy studies have now been conducted in a large number of US states. (The literature discussed here focuses on cost studies conducted with data from the United States. For a review of the literature on costs in other countries, see Tsang (1988, 1997).) Researchers have used a number of different methodologies to estimate educational costs, but most studies involve one of four methodological approaches: professional-judgment, evidence-based, successful-schools, or the cost-function (or econometric) approach. As discussed extensively in Baker *et al.* (2004) and Duncombe *et al.* (2004), each of these approaches has distinct advantages and disadvantages.

Researchers conducting a professional-judgment study organize from one to several teams of educators within a state and ask them to design an educational program that will achieve the state's educational goals. Once team members have identified the required set of inputs, researchers determine how much money will be needed to fund those inputs; typically, the panels themselves are not required to consider how much their suggested program will cost. This has led to concerns that these panels tend to overestimate resource needs. The evidence-based approach is similar except that the sources of expert opinion are not panels of professionals but research evidence on strategies that have been proven effective. Both professional judgment and evidence-based studies have the appeal of transparency; that is, not only do they provide a total cost of education in dollars, but they specify how those dollars are to be spent. However, these methods focus on the selection of inputs, the estimated costs may be only weakly connected to specific outcomes. This could be considered a strength, as it allows for the consideration of performance outcomes that may be difficult (or impossible) to measure, but it could also be

considered a weakness in a policy environment focused increasingly on specific accountability standards. Finally, although some professional judgment studies address the issue of extra resources that may be required for certain types of students, such as those from low-income families or with limited English proficiency (i.e., marginal costs), it may be problematic to estimate costs for actual districts that differ significantly from the typical school or district for which the original program was designed.

Sonstelie (2007) modifies the professional judgment methodology to address some of the concerns with the more traditional approach. Using a large sample of California teachers, principals, and superintendents (rather than a few selected panels), these professionals are presented with a school budget and characteristics for a hypothetical school, and then asked how they would allocate those resources. Once that allocation is completed, these same professionals are asked to predict the performance level of students in the re-designed school. The researcher can estimate relationships between the resource allocations, school characteristics, and outcomes because of the large sample. Thus, this approach can produce cost estimates that are tied to a particular outcome level, generate estimates of the marginal costs associated with specific student characteristics, and also provide insights into how dollars should be spent. One drawback is that the estimates are still built on predictions of individuals who may have unknown biases, rather than on observed correlations between dollars and outcomes.

Cost studies using the successful-schools approach start by identifying a set of high-performing schools (with performance generally based on the state's educational goals). Estimates of the cost of providing a high-quality education are then based on the lowest level of per-pupil spending among this set of successful schools. This approach has the advantage of directly linking costs and outcomes, but generally says little about how resources ought to be allocated within the school or district. A few successful schools studies have addressed the issue of additional costs for low-income students by identifying high-performing schools among schools with high proportions of students in poverty but, as with the professional-judgment method, it may be challenging to extrapolate to districts that are significantly different from the original set of successful schools.

The cost-function, or econometric, approach utilizes data on per-pupil school expenditures, student performance, and various characteristics of students and school districts, from all school districts within a state. Following Bradford *et al.* (1969), the output of public schools is assumed to be a function of school inputs (e.g., teachers and textbooks), characteristics of the student body, and the family and neighborhood environment in which the students live. This relationship can be represented by

$$S_{it} = g(X_{it}, Z_{it}, F_{it}) \quad [1]$$

where S_{it} represents an index of school output, X_{it} is a vector of direct school inputs, Z_{it} is a vector of student characteristics, and F_{it} is a vector of family and neighborhood characteristics. The subscript i refers to the school district and subscript t refers to the year.

The amount that a district will need to spend in order to produce a particular level of output is a function of school inputs and the prices of those inputs. This is shown in eqn [2], where per-pupil expenditures, E_{it} , are considered as a function of school inputs, a vector of input prices, P_{it} , and ε_{it} , a vector of unobserved characteristics of the school district:

$$E_{it} = f(X_{it}, P_{it}, \varepsilon_{it}) \quad [2]$$

Finally, by solving the production function in eqn [1] for X_{it} , and plugging X_{it} into eqn [2], we arrive at the cost function represented by eqn [3], where u_{it} is a random error term:

$$E_{it} = b(S_{it}, P_{it}, Z_{it}, F_{it}, \varepsilon_{it}, u_{it}) \quad [3]$$

Once a functional form is chosen for eqn [3], it can be estimated with district-level data for a given state, using regression techniques. The resulting coefficients indicate the contribution of various district characteristics to the cost of education, holding constant the level of performance. The cost function can then be used to predict the cost of any given level of performance; this is done by multiplying the cost function coefficients by the actual values of the student and district characteristics while setting the performance variables equal to the desired level. Thus, for each district, the cost function can predict the minimum amount of money necessary to achieve various educational performance goals, given the characteristics of the school district and its student body. As discussed in Reschovsky and Imazeki (1997), these predictions can be used to generate an index that summarizes, in one number, the cost differentials for each district in the state. Such an index is then easily incorporated into a state foundation aid formula (Ladd and Yinger, 1994). The marginal costs of specific student or district characteristics are also easily determined since the coefficients quantify the additional spending required for higher values of a specific cost factor, holding constant everything else.

Although generally considered more complex than other methods, the econometric approach has the advantage of directly quantifying the relationship between outcomes and costs for districts with a variety of characteristics. This approach is particularly appealing for states such as California, Texas, and New York, which are quite large and have tremendous diversity in both student and school district characteristics. However, as with the successful-schools method, cost functions are black boxes that do not illuminate how districts should organize their resources. Cost

functions are also limited by the same problems that can plague any statistical analysis, including errors in estimation and availability of high-quality data.

Cost-Function Estimation

As discussed in Imazeki and Reschovsky (2005), any empirical analysis requires that the researcher make a number of choices. Even when the basic methodology is the same, different researchers may make legitimately different choices that lead to different results. For example, before estimating a cost function, one must first specify a functional form (e.g., linear, log-linear, etc.). Such choices have implications for the final cost function results and any subsequent cost predictions that are derived from those results. Imazeki and Reschovsky (2005) present a detailed comparison of two cost functions estimated using data for Texas (Imazeki and Reschovsky, 2004; Gronberg *et al.*, 2004) to highlight some of the more common decisions that must be made in cost-function analyses. These include the choice of which variables to include, how to measure them, and the functional form of the cost function; how to address school district inefficiencies; and whether and how to account for the endogenous nature of district spending and student performance.

Variables and Functional Form

Although guided by an underlying model of public decision making and assumptions about cost-minimization, researchers still have considerable latitude in choosing which specific variables to include, how to measure them, and what functional form to assume. First, as noted by Baker *et al.* (2004), “A central difficulty of performance-oriented analysis involves the politics of achieving consensus regarding *important outcomes* (emphasis in original) and the empirics of precisely measuring those outcomes” (p. 20). The vast literature on educational production functions tends to focus on student cognitive achievement as measured by standardized test scores. Thus, a commonly used measure of school output or performance is test scores from achievement tests administered to all students. However, cost-function studies differ in whether they use a value-added measure of performance (i.e., including a lagged value of the performance measure), as in Reschovsky and Imazeki (1998, 2003) and Gronberg *et al.* (2004), or a current level measure, as in Duncombe and Yinger (2005). The primary drawback to the level measure is that it may bias the coefficients on student characteristics (see Meyer, 1996, for a discussion of value-added versus level student output measures); on the other hand, it may be more straightforward for policymakers who are interested in

the total cost of achieving some target level of student performance. Studies also vary in whether they include other measures of student outcomes such as dropout or graduation rates (Duncombe *et al.*, 1996) or the number of advanced courses offered (Reschovsky and Imazeki, 1998).

All cost-function studies include measures of district and student characteristics, typically district size, the percentage of students in poverty, limited English proficiency, or disabled, and teacher salaries. However, there are differences in how these variables are measured. For example, Reschovsky and Imazeki (1998, 2003) typically measure district size with a quadratic term (thus allowing for economies and diseconomies of scale) while Duncombe and Yinger (2005) have included indicator variables for various enrolment categories (e.g., below 1000, 1000–2000, 2000–5000, etc.). Duncombe and Yinger (2005) also compare different measures of poverty, using both the proportion of students in the free and reduced-price lunch program (the more common measure in other studies) and the child poverty rate from the census.

Most cost-function studies have assumed a log-linear functional form (e.g., Imazeki and Reschovsky, 2006; Duncombe and Yinger, 2005). With this function, the coefficients can be interpreted directly as the marginal effect of a one-unit change in the variable. In contrast, Gronberg *et al.* (2004) estimate a translog cost function for Texas. The translog is highly flexible, including interactions among all the variables and quadratic terms for all the variables; the trade-off is that the resulting coefficients are more difficult to interpret as the marginal effects of individual variables will depend on the values of all the variables in the model.

Efficiency

Although cost functions are built from a theoretical model that assumes schools allocate resources in order to minimize cost, in reality, some schools may operate inefficiently. These potential inefficiencies are not directly observed and, if not addressed, may bias the cost-function estimates. However, the measurement of efficiency in the context of elementary and secondary education is exceedingly complex; in order to accurately measure school district efficiency, it is necessary to accurately identify and quantify both the educational goals of each school district and the factors that contribute to the achievement of these goals and to school district expenditures.

One approach is to use statistical techniques such as stochastic frontiers or data envelopment analysis to attempt to identify spending that is high, relative to spending in districts with similar performance and costs; see, for example, Duncombe *et al.* (1996), McCarty and Yaisawarng (1993), and Deller and Rudnicki (1993). However, the measurement of school district efficiency using these statistical methods is highly sensitive to the way that

school district goals are measured. For example, in school districts that emphasize vocational education, or arts and music – subjects not directly measured by standardized tests – money spent on these alternative educational objectives will be counted as inefficient spending.

An alternative approach to addressing district inefficiencies is to include control variables that are likely to be correlated with efficiency; for example, Imazeki and Reschovsky (2004, 2006) use a measure of district competition while Duncombe *et al.* (2003) use district characteristics associated with tighter or looser budget constraints (such as property values and state aid). Although this does not require as strict a set of assumptions as the statistical approach, there is also a greater potential that inefficiency will be underestimated and resulting estimates will still contain bias.

Estimation Methods

When school districts strive to achieve higher levels of student performance, such goals presumably will require additional spending. At the same time, decisions by local school boards about per-pupil spending are likely to have an impact on student performance goals. That is, school districts often make decisions about spending levels and student outcome levels simultaneously. If not addressed, this simultaneity can lead to bias in the estimated cost-function coefficients. However, statistical tests can be used to assess whether this bias is, indeed, present. For example, Gronberg *et al.* (2004) and Imazeki (2007) rule out the need to adjust for simultaneity in their data.

When needed, the most common approach to the issue of simultaneity is estimation with two-stage least squares (i.e., instrumental variables). The challenge is to find instruments that are correlated with student outcomes but not correlated with school district spending. Imazeki and Reschovsky (2004) follow the literature on demand for education and use variables such as median income and tax price. Duncombe and Yinger (2005) rely on geographic proximity, using measures of fiscal capacity, student need, physical conditions, and student performance in adjacent districts.

Data Requirements

Although not under the control of the analyst, another issue for estimation of educational cost functions is that such estimation requires data on quantifiable outcome measures and student and district characteristics from a large number of districts, ideally over multiple years. The cost-function model also assumes districts allocate resources in order to maximize outcomes/minimize cost. When good data are not available, or districts are particularly constrained in their ability to allocate resources

efficiently, other methods for assessing the costs of adequacy are likely to be more appropriate. (See Imazeki, 2007, for a discussion of the biases that can arise in cost functions when districts face such constraints.)

Cost-Function Results

Although cost-function studies vary in how they handle these estimation issues, all of the studies are consistent in at least a few ways. Costs are consistently found to be higher for students in poverty, for English learners, for special education, and for very small districts, although there is variation in the magnitude of the cost differentials. For example, **Table 1** shows the base and marginal costs from four recent cost-function studies. Base costs refer to the costs for a low-need district to achieve the state standard; that is, a district with relatively low levels of poverty, few English Learners, etc. It is important to keep in mind that base costs may vary across time or across states because of differences in standards (e.g., if states raise their performance standards, the base cost will increase) or differences in regional price levels (e.g., southern states may have lower base costs than northeastern states); thus, comparisons across states must be viewed with much caution. But in a given year and state, the base cost represents the minimum bar for per-pupil spending within that state.

Marginal costs refer to the additional costs associated with specific student or district characteristics (such as poverty, English learners, and special education), above and beyond the base cost in a district with none of these special needs. For example, suppose the marginal cost of a student in poverty is determined to be 10%. If the base cost for a student with no special needs is US\$8000 per pupil, then the cost for a poor student is US\$8800, or 10% more. Many state-aid formulas try to account for marginal costs by assigning extra weight, and thus extra revenue, to students in certain categories. Following the same example, a poor student may be given an extra weight of 0.1 and this generates 10% revenue for that student, relative to the revenue allocated for a non-poor student. One advantage of cost functions is that these marginal costs are straightforward to calculate from the cost function coefficients. (See Imazeki, 2007, for a complete description of how the weights in **Table 1** are calculated, and for an expanded comparison of the estimates.)

The different choices made by the researchers are apparent in **Table 1**, since differences in the cost functions estimated in each state have large implications for the resulting pupil weights. For example, the 2004–05 Texas study and the New York study do not include separate measures of students with severe disabilities; it is thus not possible to calculate a separate weight for these students. (In the New York study, the special education

Table 1 Comparison of base and marginal costs^a

^eNew York pupil weights from Duncombe and Yinger (2005, table 6).

variable does not include minor disabilities and thus captures something in between the two variables used in the California and 2002–03 Texas cost studies.) Overall, the marginal cost estimates from New York are larger than in the other states but all of the studies find that students in poverty and in special education require significantly more resources, and three of the four studies find that English learners also require additional funds. (Imazeki and Reschovsky, 2006 find a negative relationship between English learners and costs. They suggest this may be due to economies of scale, since Texas regulations require districts to provide a certain level of services if there is even one English learner in the district.) It is also worth noting that the cost differentials shown in **Table 1** are all larger than the existing state aid for student needs in each state; for example, in California, the average district receives only about 10% more aid for students in poverty while the California cost function suggests at least 30% more is required.

Although there are multiple ways to identify the costs of an adequate education, economists have tended to focus on statistical methods and the estimation of educational cost functions. Of course, no method is perfect, and even researchers using similar methods may make different choices that influence their results. However, the growing body of adequacy research consistently supports the need for additional resources for students from particular backgrounds and in particular educational settings. School finance systems designed to ensure that all students have equal access to an adequate education must recognize these differential costs.

Economic Approaches to School Efficiency

L L Taylor, Texas A&M University, College Station, TX, USA

Glossary

Allocative efficiency – Allocative efficiency is an aspect of school efficiency. Schools are allocatively efficient when the relative productivity of educational inputs equals the relative price of those inputs. Thus, if administrators are paid twice as much as teachers, then allocative efficiency requires the school to choose a mix of teachers and administrators so that administrators are also twice as productive as teachers.

Data envelopment analysis (DEA) – It is a mathematical (as opposed to statistical) strategy for identifying a best-practice frontier. The best-practice frontier is a series of linear segments connecting the decision-making units – in the education context, the schools, school districts, or universities – that maximize the stated objectives given the stated constraints. For example, the objective could be to maximize a set of school outputs given the observed quantities of school inputs.

Scale efficiency – Scale efficiency is an aspect of school efficiency. Schools are scale efficient when there are no productivity gains from changing the size of the school.

Technical efficiency – Technical efficiency is an aspect of school efficiency. Schools are technically efficient when it is not possible to increase educational outputs without increasing inputs. Equivalently, schools are technically efficient when it is not possible to reduce all inputs proportionately without reducing school output.

efficient when they are using the right mix of inputs, given the relative prices and productivity of those inputs. Thus, allocative efficiency requires that when teachers are twice as expensive as teacher aides, they must also be twice as productive. The third aspect of school efficiency is scale efficiency. Schools are scale efficient when there are no productivity gains from changing the size of the school. Although most of the literature focuses on technical efficiency, researchers have found evidence that schools are inefficient in all three dimensions.

Econometric Approaches

Researchers have used a number of analytic techniques to examine school efficiency. The three most common strategies are data envelopment analysis (DEA), stochastic frontier analysis (SFA), and corrected ordinary least-squares analysis (C-OLS). All three approaches have been used to identify best practices among schools or school districts. Deviations from best practices are then attributed to inefficiency (DEA and cross-sectional C-OLS) or to a combination of technical inefficiency and random error (SFA and panel C-OLS). In all cases, inefficiency is measured relative to current best practice, which may fall short of the theoretical ideal.

Data Envelopment Analysis

DEA uses a mathematical optimization technique called linear programming to identify a best-practice frontier. The best-practice frontier is a series of linear segments connecting the schools, school districts, or universities that maximize output (or minimize costs) given a set of constraints. Typically, the best-practice frontier represents the highest level of school output achievable with a given set of school inputs, although other specifications have been used to measure school efficiency (e.g., Ruggiero and Vitaliano, 1999; Grosskopf *et al.*, 1999). Schools that are on the frontier are deemed technically efficient, while schools that are not on the frontier are inefficient. The closer the school is to the best-practice frontier, the more efficient it is. Although DEA can be used to measure allocative and scale efficiencies (e.g., Grosskopf *et al.*, 1999), it is primarily used to evaluate technical efficiency.

DEA has a number of attractive properties. The methodology can accommodate multiple inputs and outputs, allowing it to reasonably reflect the educational process.

Efficiency in an Education Context

Many researchers have found little or no empirical relationship between school resources and school outcomes. This lack of correlation implies that schools are economically inefficient, and has given rise to a substantial literature examining the nature and causes of such inefficiency.

This literature focuses on three important aspects of school efficiency. The first is technical efficiency. Schools are technically efficient when it is not possible to reduce all inputs proportionally without reducing output. The second is allocative efficiency. Schools are allocatively

In addition, DEA does not require the researcher to specify a functional form for the relationship between inputs and outputs or for the distribution of school efficiency. As such, the method is largely insulated from specification errors (although like all other approaches it can yield biased estimates of efficiency when relevant variables are omitted). Research also suggests that DEA yields more accurate efficiency estimates than C-OLS when an input is endogenous (Bifulco and Bretschneider, 2003; Ruggiero, 2003).

One downside to DEA arises from the method's sensitivity to extreme observations. DEA identifies all schools with a unique mix of inputs or outputs as frontier schools because there are no other schools to use for reference. Any increase in the number of inputs or outputs tends to increase the number of schools that are unique in some dimension, and therefore the number of schools on the DEA frontier. To limit the number of schools that are efficient by default, researchers must use a relatively parsimonious model of school behavior.

The need for parsimony has led many researchers to adopt a two-stage estimation strategy. The first stage uses DEA with a minimal number of inputs and outputs to generate efficiency scores. The second stage uses regression analysis to adjust those efficiency scores for student demographics and other factors that were omitted from the first stage. As discussed in Johnes (2006), this two-stage approach implies that the variables omitted from the first stage of the analysis influence school efficiency, but not the educational production process itself. As such, it is not always obvious which variables belong in which stage of the analysis. Excessive parsimony in the first stage of the analysis can lead to biased estimates of school efficiency, even after the second-stage adjustments. Furthermore, Simar and Wilson (2007) argue that correlations among the DEA efficiency scores invalidate many of the regression techniques commonly used in second-stage analyses.

More problematically, DEA is an approach that presumes all inputs and outputs are measured without error. Measurement error with respect to the schools that make up the best-practice frontier leads to biased estimates of school efficiency, even for schools that are measured without error. If a school is on the frontier because its output is overestimated (or its input is underestimated), then DEA will overstate the inefficiency of all schools that use the mismeasured school as a reference. Research suggests that the inaccuracy can be substantial, even when the measurement error is relatively modest (e.g., Bifulco and Bretschneider, 2003). Exploiting multiple observations for each decision-making unit – either by relying on multiple years of data or by aggregating school data to the school district level – can increase the accuracy of the efficiency estimates if the measurement error is random (Ruggiero, 2006), but not if the measurement error is systematic.

Stochastic Frontier Analysis

SFA is a regression technique that formally incorporates both technical efficiency and random error into the estimation of a best-practice frontier. Estimation error from the regression is presumed to represent two distinct parts. The first is the normal random error that is associated with any regression-based estimation. The second represents inefficiency and is therefore only found on one side of the estimated frontier. The estimated relationship between inputs and outcomes is based on best practice within the data because the composite error is asymmetric.

As with any regression-based analysis, researchers using SFA must designate the functional relationship between inputs and outputs. Many researchers choose highly flexible functional forms to avoid imposing undue structure on the relationship. However, in small samples, such flexibility can bias the estimates of technical efficiency when the underlying relationship between inputs and outputs is more parsimonious (Jensen, 2005).

Researchers also must specify a distribution for the inefficiency term. Most researchers presume that school inefficiency follows a half-normal distribution, but other distributions have also been used. Jensen (2005) finds that specifying a half-normal distribution for the inefficiency term generates more reliable estimates of technical efficiency than other assumptions about the distribution of inefficiency.

Corrected OLS

Corrected OLS is exactly what it sounds like it is. With this approach, researchers use OLS regression to estimate a production, cost, or distance function, and then make a correction to the intercept term to reflect school inefficiency. The predicted values from this adjusted regression represent the C-OLS frontier. As with DEA, all deviations from the C-OLS frontier are interpreted as inefficiency. However, unlike DEA or SFA, the relationship between inputs and outputs along the frontier is determined by the average practice of schools in the data rather than the best practice.

As with SFA, the researcher must designate the functional form of the educational production process. However, the researcher has no discretion over the distribution of school efficiency. The C-OLS methodology imposes a normal distribution on the technical efficiency estimates. While there is seldom any *a priori* reason to believe that efficiency is normally distributed, research suggests that in a great many cases, C-OLS produces more accurate efficiency rankings than does SFA (Jensen, 2005).

Regression analysis using multiple years of data and indicator variables (i.e., fixed effects) for each school or district (as in Schwartz and Zabel, 2005) can be thought of

as a special case of C-OLS. In this case, researchers must assume that school inefficiency is constant over time – a particularly strong assumption in a changing policy environment – but face no other restrictions on the distribution of school efficiency.

Specifications and Measurement

A variety of specifications have been used to estimate school or school district efficiency using DEA, SFA, or C-OLS. Some researchers estimate a production function, wherein a composite (or representative) school output is modeled as a function of school input quantities, environmental factors like student poverty, and technological factors like school size. Other researchers estimate cost functions, wherein school expenditures are a function of one or more school outputs, input prices like teacher wages, environmental factors, and technological factors. Still other researchers use distance functions like the input distance function, which is dual to (i.e., a mathematical translation of) the cost function but requires data on input quantities rather than input prices.

Regardless of the specification or estimation strategy, researchers must struggle with three important measurement issues. First, researchers need reliable measures of school output. Second, researchers need reliable measures of school inputs. Finally, given the significant role that home and family play in student learning, researchers need a credible strategy for incorporating differences in the educational environment.

School Outputs

Most researchers rely on standardized tests to measure school outputs. Test scores are readily available, tractable, and consistently defined measures of student performance in subject areas that have been associated with higher lifetime earnings (e.g., Blau and Kahn, 2005). Many states incorporate test scores into their accountability systems, making test performance a direct objective of school administrators. Research also suggests that differences in test scores are capitalized into housing values, implying that the home-buying public also interprets test scores as an indicator of school quality (Taylor, 2005).

No one believes that test scores measure all of the important differences in school outcomes, however. Many of the things schools do, such as arts, music, and other enrichment activities, are not directly measured by the minimum competency tests available to researchers. Taylor (2005) finds that test scores and student demographics can explain less than one-third of the premiums buyers pay for homes in specific school-attendance zones, suggesting that the school outcomes not captured by test scores are far from negligible.

Test scores are also a questionable indicator of school outcomes because they do not reflect exclusively the performance of schools. Education researchers have long recognized that students from advantaged backgrounds can score well on standardized tests despite ineffective schools, while students from disadvantaged backgrounds can score poorly even when the schools are highly effective. As discussed in Hanushek and Taylor (1990), unadjusted test scores are biased estimates of the marginal effects of schools.

Unfortunately, reliable estimates of school effects can be hard to come by. A student's performance in the current year is a function not only of current school and family inputs, but also of the student's complete history of school and family inputs, and therefore the data required to estimate school effects can be substantial. Most researchers did not have access to the necessary data on individual student performance, demographics, and history.

Measurement error is clearly a concern, because school effects must be estimated. Kane and Staiger (2001) find that much of the variation in estimated school effects – either performance-level effects or performance-gain effects – may be attributable to nonpersistent factors and noise. Furthermore, the measurement error increases as the size of the group under analysis falls; so, the measurement error is most pronounced for small schools and student subgroups within schools. However, Kane and Staiger (2001) also demonstrate that averaging student performance over time can greatly reduce the measurement error in estimated school effects.

At the university level, there are few measures of student performance from which to estimate marginal effects. Therefore, researchers tend to measure teaching output using quantity measures such as the number of degrees awarded or the number of full-time-equivalent students. Most researchers also include measures of research activity as a second type of school output. The ready availability of research ratings for British universities may explain why analyses of the UK dominate the literature on higher education efficiency.

School Inputs

While researchers generally use some measure of test scores as an output, there is much less consensus in the literature regarding the appropriate measures of school inputs (Worthington, 2001). Some researchers use real input measures such as the number of full-time-equivalent teachers, the number of administrative staff per pupil, the number of books in the school library, or the pupil-teacher ratio. Others use expenditure measures, such as instructional expenditure, teaching expenditure per pupil, or current operating expenditure.

Researchers who use real measures of personnel inputs seldom deal explicitly with the heterogeneity of the teacher corps. A teacher is a teacher whether she is a rookie with a newly minted bachelor's degree or a classroom veteran with 20 years experience and two advanced degrees under her belt. Arguably, observable characteristics like experience and educational attainment have little power to differentiate effective teachers from ineffective ones, so greater precision may not be possible. However, even unavoidable imprecision introduces measurement error and has a detrimental effect on estimates of school efficiency.

Researchers who use expenditure as a proxy for real inputs implicitly assume that the prices of such inputs are constant across the schools under analysis. While such an assumption is plausible for school supplies, it is much less plausible for labor inputs. Wages vary dramatically from one labor market to another, even within a single state (Taylor and Fowler, 2006). Any variation in prices introduces noise into expenditure-based measures of school inputs.

Variation in input prices is a key element of cost function analysis, and reliable measures of input prices are essential to any analysis of allocative inefficiency. It is particularly important to measure educator wages accurately because education is such a labor-intensive industry. Average wages are a poor proxy for the price of educator labor because differences in average wages reflect differences in staff composition from one school to the next. Instead, theory favors a wage index that indicates the price schools must pay to hire an educator with specified characteristics (such as a teacher with 5 years experience and a bachelor's degree). Average wages for beginning teachers are a common proxy for such an index, although this approach can be problematic if some schools do not have beginning teachers, or if variations in beginning teacher wages reflect endogenous variations in teacher quality.

Environmental Factors

The influence of student and family characteristics on educational outcomes is well known. Therefore, virtually all researchers incorporate some measure of the educational environment into their analyses. The most common measures of environmental conditions are indicators of parental education and socioeconomic status (Worthington, 2001).

These environmental factors can be thought of as indirect measures of the student and family inputs to the educational production process, or as shift factors that capture differences in the education technology. When outputs are measured with test scores rather than school effects, these factors (at least in a stochastic setting) also serve to partially control for measurement error in the outputs.

Whatever role the common environmental indicators play in the analysis, it is unlikely that they are sufficient to perform the task. A single summary statistic like family income cannot possibly reflect the array of abilities and motivations that students bring to the classroom. The richness of the literature on peer effects makes the treatment of this issue in the school efficiency literature seem rather paltry. Student-selection issues are largely ignored, which is particularly problematic for analyses that compare efficiencies across magnet, charter, private, and post-secondary schools. A careful analysis of the appropriate role for student characteristics in school efficiency measurement is long overdue.

Findings Regarding School Efficiency

Much of the empirical literature on school efficiency has focused on estimating and comparing technical efficiency scores. These studies find that there is significant inefficiency in the education process in the United States, the United Kingdom, and most other countries for which such studies have been conducted. Researchers typically find average technical inefficiencies in the education sector that are between 5% and 20%. As such, the evidence suggests that the average technical inefficiency of the education sector is similar in magnitude to the average technical inefficiency outside of education (Ruggiero and Vitaliano, 1999; Johnes, 2006).

Occasionally, researchers have estimated technical inefficiency scores using multiple econometric techniques. Generally, these researchers find that efficiency scores are sensitive to differences in specification and methodology, and that there is more correlation among efficiency rankings than efficiency scores.

Researchers have also found evidence of significant allocative inefficiency. The DEA has been the most common tool for analyses of allocative inefficiency because it can yield direct estimates of the optimal resource allocation (e.g., Grosskopf *et al.*, 1999). However, stochastic approaches can also support estimates of allocative inefficiency (e.g., Grosskopf *et al.*, 2001). Intriguingly, despite popular rhetoric about excessive administration in education, schools appear only slightly more likely to overuse administrators and administrative staff (given their relative wages) than to overuse teachers and other instructional staff (e.g., Grosskopf *et al.*, 1999, 2001).

The literature on scale efficiency in education has developed separately from the literature on technical and allocative efficiency. Most researchers interested in economies of scale have estimated cost and production functions using variants of OLS estimation rather than frontier methodologies. However, their decision not to recover the C-OLS efficiency scores from such analyses

does not affect the applicability of their findings on scale efficiency. As discussed by Andrews *et al.* (2002) researchers have generally found that there are economies of scale in elementary and secondary education, but that schools with more than 600–1000 students (depending on grade level) and school districts with more than 6000 students are inefficiently large. Analyses of higher education also tend to indicate economies of scale.

The Determinants of School Inefficiency

There are many possible explanations for the demonstrated inefficiency of the education sector. One of the most frequently explored is the perceived lack of competition at the elementary and secondary school levels. A number of researchers have found evidence that inefficiency is greater in less-competitive markets. For example, Grosskopf *et al.* (2001) find that allocative inefficiency rises with market concentration, and that schools in concentrated education markets are at least 16% more allocatively inefficient than schools in competitive markets.

Another possible reason for school inefficiency arises from the principal-agent problems common to public institutions. School administrators may have some objectives – such as increasing their bureaucratic power or maximizing their budgets – that are inconsistent with efficient operation of schools. Administrators are more likely to pursue their own objectives when it is difficult for the public to monitor them effectively. Researchers have found that common proxies for monitoring activity (such as home-ownership rates, tax rates, and the educational attainment of the adult population) are significantly correlated with school efficiency, and that schools are less efficient where monitoring is less likely (e.g., Grosskopf *et al.*, 2001).

Regulation may also partially explain school inefficiency. Many of the parameters of the educational production process are set by state agencies or statutes. State policies determine maximum class sizes and minimum teacher salaries; require schools to hire full-time nurses and counselors; specify the length of the school year; and dictate the minimum square footage per pupil in each classroom. The restrictions imposed on schools, districts, and universities may make it impossible for them to behave efficiently. Comparative analyses of charter schools (which are a largely unregulated form of traditional public schools), private schools, and private universities may be the key to more fully understanding the impact of regulation on public school efficiency.

Union activity is another possible explanation. Union contracts typically limit school flexibility with respect to the allocation and compensation of labor. Work rules and seniority protections can make it very difficult to fire ineffective teachers, or close dysfunctional schools.

To the extent that unions lead schools to diverge from best practice, they contribute to measured inefficiency.

A lack of population density can explain some types of inefficiency. It is not possible to operate a scale-efficient school when there are only a handful of sixth graders within a 100-mile radius. In turn, inefficiently small schools find it very difficult to avoid allocative inefficiencies, particularly with respect to labor.

Finally, measured inefficiency may reflect nothing more than the general inadequacies of available data. All of the efficiency estimation strategies are vulnerable to omitted variables bias and measurement error. In the education sector, omitted variables are common, and measurement errors are pervasive. As a result, apparently efficient schools may simply be schools that rely heavily on an unmeasured input or that operate in a favorable environment. Similarly, some apparently inefficient schools may actually be best practitioners that are either focusing their attention and resources on an unmeasured output, or operating in a very unfavorable educational environment.

Conclusions

An extensive literature has developed to explore the efficiency of the education sector. Much of that literature has focused on applying existing tools for efficiency measurement to schools, school districts, and universities. An array of researchers report finding significant technical, allocative, or scale inefficiencies in the education sector.

The literature on the determinants of inefficiency is less well developed, but potentially more influential. Researchers have identified a number of institutional structures that appear to foster inefficiency. Changes to those structures could lead to significant improvements in the efficiency of the education sector. Given the tight fiscal situation facing most governments, improvements in efficiency may be a necessary precondition for any improvements in public support for education. Therefore, research into the determinants of school inefficiency may be particularly useful going forward.

The primary challenge facing researchers, however, rests with the measurement of school characteristics, not with the analysis of school efficiency *per se*. No measure of school efficiency can be more reliable than the underlying data, and the data underlying many efficiency analyses are questionable. Fortunately, the school accountability movement is generating a flood of data that will allow researchers to improve their measures of school characteristics. In addition, wider adoption of analytic strategies designed to reduce the influence of measurement error, such as panel-data analyses or the estimation of confidence intervals for efficiency scores, will greatly enhance the credibility of any future analyses of school efficiency.

By refining their measures of school inputs, outputs, and environmental characteristics, researchers should be able to greatly improve our understanding of the nature and determinants of school efficiency.

School Finance Reform

T Downes, Tufts University, Medford, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Capitalization – Change in the price of a house (or any other asset) as a result of differences between communities with respect to taxes or the provision of public services.

Tax price – The cost to local taxpayers in additional property taxes, of an additional dollar of spending.

Introduction

During the past several decades, federal and state governments have pursued a variety of redistributive policies aimed at fostering equality of economic opportunity – the idea being that although people's incomes may vary, this variance should be primarily due to factors such as individual ability and effort, not due to differences in circumstance. Many in the policy arena have suggested that opportunities could be further equalized via the implementation of changes in the way elementary and secondary education is financed. The article provides a brief review of the multifarious effects of large-scale modifications, typically stimulated by court challenges to financing systems, to the formulas states use to determine aid to local school districts.

For many years, those concerned with the persistence of income inequality in the US have argued for reforms in the method of financing public elementary and secondary schools that would make education spending more equal. These arguments, which have been buttressed by substantial evidence that pre-market factors play a significant role in determining subsequent labor-market outcomes, have been cited by those who have argued in the courts for fundamental reforms of the way in which public schools are financed. These court challenges have experienced a resurgence in the last decade, with state supreme court decisions mandating equalization in states such as Arkansas, Kansas, New York, Texas, Montana, and New Hampshire further altering a school finance landscape that has changed dramatically since 1970 (Yinger, 2004). The end result of these court challenges is that, in almost every state in the nation, the system of financing the public schools has been fundamentally altered, with state governments becoming an ever-more important part of the educational financing landscape.

Because court decisions have been the antecedent of many of the school finance reforms that have occurred over the last four decades, one common strategy in empirical studies has been to classify reforms on the basis of whether they were a direct response to a court decision. This method of classifying reforms represents but one of many attempts to develop a simple rubric to reduce to one or two dimensions what are very heterogeneous policy changes. And while this classification method is as imperfect as any other, the focus on court-ordered reforms does highlight one aspect of the policy environment that may explain why some reforms seem to have large effects, while others do not. The combination of the possibility of free-riding on the policy innovations of others and the down-side risk associated with failed policy innovations will tend to result in less policy innovation than is socially optimal. In the case of school finance, this may mean that, unless they are pushed by outside forces, policymakers are likely to make modifications to aid formulas that are less ambitious than may be necessary. Court decisions, threats of a court decision, or a politician's dare (as in the case of Michigan), can provide politicians with the cover to make reforms that may be risky but necessary. Thus, finance reforms that result from intervention outside the traditional political arena would be expected to have larger effects than reforms that do not result from such intervention. And such reforms can reasonably be thought of as exogenous, since the placement of outside interventions in place and time is effectively random. Much of the empirical literature on the impact of finance reforms has taken advantage of this fact to quantify the effects of reforms.

The remainder of this article documents the results of this empirical literature, starting with a review of the evidence on the impact of finance reforms on the level and distribution of spending. Next the effects of finance reforms on student performance are discussed. The article concludes by providing a brief overview of the growing literature documenting some of the other effects of finance reforms.

Effects of School Finance Reforms on Spending

Impact of Reforms on the Distribution and Level of Spending

Starting with the decisions of the California Supreme Court in the Serrano versus Priest case, the earliest

court rulings on the constitutionality of state school finance systems focused on the cross-district equity of education spending. Even more recent decisions that have focused on whether the finance system makes it possible for all districts to provide an adequate education have been described by researchers as effectively being equity decisions. Thus, quantifying the equity implications is a natural starting point for evaluating any finance reform.

Uniformly, analyses of court-ordered finance reforms find that these reforms result in more equal spending. The literature has not, however, reached consensus on whether this greater equality is attributable to raising up the spending of districts at the bottom of the spending distribution or of leveling down the spending of districts at the top of the spending distribution. Research that has quantified the effect of finance reforms on mean per-pupil spending in a state has established that there is significant cross-state variation in the impact of court-ordered finance reforms on mean spending. That cross-state variation depends on characteristics of the state's population that affect the political landscape of the state.

National-level studies that have used district-level (as opposed to state-level) data have tended to confirm the conclusions drawn from state-specific analyses. Reforms that followed court mandates have equalized per-pupil spending, though reforms that followed court decisions based on adequacy grounds have resulted in less equalization (Corcoran and Evans, 2007). The district-level data used in these studies have made possible relatively nuanced examinations of the leveling-up/leveling-down question. Analyses that treat court-mandated reforms as discrete, exogenous events have generally concluded that equalization happened through leveling-up, with spending increasing everywhere in the spending distribution (Murray *et al.*, 1998). On the other hand, analyses that attempt to account for the political nature of spending decisions tend to echo the conclusion of cross-state variability reached in some of the studies that used state-level data. Research has begun to establish that one critical determinant of the impact of a reform on spending in a district is the impact of that reform on the district's tax price (Hoxby, 2001).

How Are Additional Dollars Spent?

Recent research also has begun to move beyond the more traditional focus on the level and distribution of spending to analyze how districts use any additional dollars that they get. Districts that receive relatively more dollars after a finance reform use a substantial fraction of those additional dollars to increase current expenditure. The increased spending in these districts has been allocated primarily to instructional expenditure and expenditure on student support services.

Impact of School Finance Reform on Student Performance

The earliest work on the impact of school finance reforms on student performance focused on the extensive school finance reforms in California in the late 1970s (Downes, 1992). Those reforms generated greater equality across school districts in per-pupil spending but not greater equality in measured student performance. The problem with using the California case as a benchmark is that it has proven to be the exception, not the rule. First, the limits imposed on local control over spending have not been duplicated in any other state. Even in Michigan and Vermont, the states in which the most extensive post-Serrano reforms have been implemented, some degree of local control over taxes and spending is permitted. Further, the population of students served by California schools changed more dramatically than the population of students in any other state in the nation. These demographic changes make it difficult to quantify the impact of the finance reforms in California on the cross-district inequality in student achievement.

In response to the realization that lessons from California may not be generalizable and in an effort to examine the impact of finance reforms on mean student performance in reform states, a number of researchers attempted to use national-level data to determine how the level and distribution of student performance in a state was affected by a finance reform. These studies have varied in how they measured student performance, how they classified the nature of finance reforms, and how they characterized the distribution of student performance. Further, because the national-level nature of these analyses made cross-state comparisons possible, these studies tended to focus much of their attention on the impact of reforms on mean performance. These studies have not, however, produced a consistent vision of the impact of finance reforms on student performance. Several national-level studies indicate that relative performance may have declined and the extent of variation in performance may have increased in states in which finance reforms have been implemented. Other research using national-level data offer a more sanguine picture of the effects of such finance reforms. Test scores of those students who were most likely to benefit from finance reforms show evidence of relative improvement, and dropout rates appear to have declined in those school districts that benefited most from the finance reforms.

The fundamental reason for the absence of a consistent picture of the impact of school finance reforms is the tremendous diversity of these reforms. Even though there is general consensus that the key elements of a finance reform are the effects of the reform on local discretion, the effects of the reform on local incentives, and the

change in state-level responsibilities in the aftermath of reform, in national-level studies, different authors have taken different approaches to account for the heterogeneity of the reforms. The result is variation in conclusions reached in studies that are asking the same fundamental question.

For that reason, a number of authors have chosen to analyze carefully the impact of reforms in individual states. Analyses of individual states also allow for examination of the effects of reforms in those districts likely to benefit most from the changes in the financing system. While the contexts and the methods of analysis vary, most of these studies document relatively small reductions in variation in student performance in the aftermath of finance reforms.

Strikingly, the results of the state-specific analyses of finance reforms do not appear to depend on the method used for quantifying the impact of the reforms. A number of authors use an education production function-style analysis that relates spending to performance, other authors use an event analysis that compares performance before and after the reform for different types of districts, and still other authors use both methods. The estimated effects of the reforms appear to depend far more on the context than the method, a conclusion that is particularly strongly supported by the results of those studies that use both methods to evaluate the same reform.

Other Effects of School Finance Reforms

While much of the focus of the empirical work on school finance reforms has been on the impact of these reforms on education spending and on student performance, a significant body of research has developed that documents the variety of responses of states, localities, and private citizens to school finance reforms and that show that these responses vary in type and magnitude. Among the effects that have been examined are those on spending on other public services, community composition, housing prices, private school enrolment, and private contributions to public schools. The remainder of this article briefly summarizes the current state of knowledge on the nature of each of these effects.

Spending on Other Public Services after Finance Reforms

Analysis of the impact of school finance reforms on local spending shows that, while state aid for K-12 education increases after a court-mandated school finance reform, state aid for other public services declines. Spending on K-12 education appears to be different from every other spending category, with state resources being shifted away from other spending toward education in the aftermath of

a finance reform. On average, however, the composition of spending at the local level appears to be unaffected. In particular, in counties located in states in which there had been a court-mandated school finance reform, per capita expenditures on education, on police and criminal justice, on public welfare, health, and hospitals, and on other services (such as parks and recreation and libraries) appear to be unaffected. Highway expenditures might decline, but that decline appears to be small quantitatively.

The effects of reforms are not, however, uniform. There is evidence of heterogeneity in the extent to which spending on other services may change in the aftermath of finance reforms. This cross-locality variation may result because counties in which median family income is higher tend to benefit less from the increases in state education aid and tend to experience larger reductions in state aid for other services.

These results confirm a conclusion hinted at by other research: increases in spending on services that might substitute for education spending would not be expected in the aftermath of court-mandated school finance reforms. No substitution would be expected both because finance reforms impose, at most, minimal constraints and because state governments limit the impact of reforms on high-income communities by reducing state-level expenditure in other areas of spending.

Finance Reforms and Community Composition

Empirical research on the impact of finance reforms on community composition built off of a body of theoretical work that extended the classic Tiebout (1956) model to develop predictions concerning the impact of school finance reforms on community composition, housing prices, and private school enrolment. These theoretical papers indicate that restrictions on the ability of individuals to consume their desired level of education services in the public sector will tend to break down the tendency of individuals to sort on the basis of income or parental education. Further, many of the high-income individuals who move from previously high-spending to previously low-spending school districts will, at the same time, be choosing to opt out of the public schools.

This tendency of finance reforms to induce significant changes in community composition depends, however, on the extent to which the ability of schools to produce outcomes depends on the quality of peers in the schools. While the existence of peer effects need not accentuate the tendency to sort, the degree of sorting will depend critically on the benefits that high-income or high-ability individuals get from mixing with lower-income or lower-ability individuals. If the benefits of mixing are perceived to be low or if the benefits of having high-ability peers are sufficiently strong, individuals will either opt out of the

public sector or, by extension, will only choose the public sector if they are able to reside in homogeneous communities. Pursuing the logical implication of this reasoning, if parents feel high-ability peers are sufficiently important, school finance reforms could accentuate the tendency of individuals to sort both across communities and across schools.

Empirical research on the impacts of finance reforms on the degree of homogeneity of affected districts has shown that these reforms have relatively modest effects on community composition. The earliest work indicated that only in states where the constitutionality of a finance system was upheld, was there any consistent evidence of changes in community composition (Aaronson, 1999). More recent work, that has focused more directly on the composition effects of finance reforms in those districts, where reforms have had the largest impact and have considered measures of community composition other than income, has documented evidence of substantive changes in the extent of homogeneity of school districts. The evidence on the nature of these composition effects is equivocal, with national-level analysis indicating that court-mandated finance reforms may have led to a higher number of minority, lower-income, less-educated, and non-English-speaking students in previously low-spending districts, while state-level analysis indicates that the extent of sorting by education and income may have been reduced. These studies do, however, consistently show that these composition effects appear to be concentrated in those public school districts that were low-spending prior to the reforms. They produce no consistent evidence of composition changes in school districts that had been high-spending.

Housing Prices and Finance Reforms

The capitalization of the spending changes associated with court-mandated finance reforms into housing prices and rents may offer an explanation for the absence of consistent evidence of composition effects in the aftermath of finance reforms. Changes in the gap in housing costs between high-spending and low-spending school districts will influence the relative attractiveness of districts that were, before the finance reform, low-spending or high-spending. Theoretical models have established that changes in equalizing intergovernmental aid will be capitalized into property values. These capitalization effects can have dramatic effects on the impact of the changes in the aid program on consumer well-being. The potential impact of capitalization on community composition would be one such effect.

Research using national-level data on property values drawn from the decennial census has shown that the effects of court-mandated finance reforms are capitalized into property values (Dee, 2000). State-level analyses

have tended to confirm these findings. Further, the state-level analyses indicate that the capitalization effect is isolated in high-wealth communities. This loss in value in high-wealth communities could ultimately affect the sustainability of the finance reform, both because it affects revenue available to finance the schools and popular support for the system of finance.

Do Finance Reforms Lead to Shifts of Enrollment to Private Schools?

Finance reforms may not only result in movement from one school district to another; they may also result in movement to and from private education. While early work on the impact of finance reforms on private school enrolment suggested that families making schooling choices did not appear to have been sensitive to reforms in public school finance, more recent research has indicated that finance reforms can result in students shifting from public to private schools in significant numbers. For example, about 45% of the increase from 1970 to 1980 in the private school share in unified (K-12) districts in California could be attributable to the combined effect of Proposition 13, a tax limitation measure, and Serrano (Downes and Schoeman, 1998). While the long run shift to private schools in California is less than the shift that occurred in the immediate aftermath of the constraints, there was a permanent increase in the private school share.

A growing body of work has suggested that the growth in private school enrolment that occurred in California was not unique to that state. Constraints on spending imposed on some districts after a finance reform can lead some students to leave the public sector for the private sector. And those who depart may potentially be the highest-ability students.

Finance Reforms and Private Contributions to Public Schools

The other private response that has been studied extensively is the growth in private contributions to public schools that follows the imposition of constraints. This research has established that, while private contributions are a substantial portion of district revenues in a small number of school districts, these contributions typically have little impact on the post-finance reform distribution of education expenditures. For example, in California, the state in which private contributions have been most studied, 81.75% of students attended schools for which the combined contributions to the school and the district were less than US\$50 per pupil. Further, only 1.2% of students attended schools for which combined contributions were at or above US\$500 per pupil. Overall, contributions per pupil in California were only US\$39 in 2001 (Brunner and Imazeki, 2005).

Only in Vermont is there any evidence that private contributions were of sufficient magnitude to have muted the effect of finance reforms. In the state of Vermont, the court-mandated finance reform enacted in 1997, provided particularly strong incentives in some districts for private contributions to be a major source of local revenue. As a result, for a small subset of districts, contributions went from being inconsequential to comprising almost a fifth of revenues. Nevertheless, while contributions may have muted the impact of constraints slightly, the overall effect of contributions on the distribution of spending in Vermont was limited. Further, once sharp incentives to contribute were removed by changes in the finance system that took effect in 2004, private contributions went back to being inconsequential in all districts in Vermont.

Summary

Over the past four decades, school finance reforms, stimulated primarily by state supreme court decisions invalidating existing financing systems, have dramatically changed the educational landscape. These finance reforms have succeeded in reducing within-state variation in spending. And, while a fraction of the additional dollars that have flowed to previously low-spending districts have been used to provide property tax relief, the majority of these new dollars have been used to increase instructional expenditures. The effect these reforms have had on mean per-pupil spending has been less uniform, with the impact of the reforms in any state depending both on the context in which they have been implemented and the changes in incentives that have resulted from the reforms.

Analyses of the impact of finance reforms on student achievement indicate that the reforms tend to result in small, but significant, reductions in within-state variation in student achievement. Less clear is the effect of a finance reform on the mean level of achievement in a state. Undoubtedly, this lack of clarity is attributable to the heterogeneity of reforms and the dependence of the impact of a reform on the individual state context.

The changes in incentives that are a by-product of finance reforms have resulted in a number of effects of reforms both inside and outside the education sector. In general, the reforms have not resulted in significant substitution of other public expenditure for education expenditure or growth in private giving to public schools that is sufficient to undo the equalization that is the intent of the new financing system. The share of students attending private schools has, however, grown in the aftermath of court-ordered finance reforms, and property values have declined in those districts which had high levels of spending and property wealth prior to these reforms.

Finally, while the number of papers examining these other effects of finance reforms has grown dramatically in

recent years, much still remains to be learned about these other effects. Improved data and the abundance of recent finance reforms will make it possible for researchers to continue to deepen our knowledge of the full range of effects of finance reforms.

Glossary

School finance – The process of raising, distributing, and utilizing money for the purpose of providing educational services.

Introduction

School finance is a broad and evolving field encompassing three resource-related functions – raising revenue, allocating resources, and using resources – all aimed at providing educational opportunities and producing educational outcomes. All of these activities occur in a broader context of educational goals and societal values that shape how finance systems are structured and executed. In this article, we provide an overview of school finance, emphasizing the enduring challenges and highlighting new ways of thinking about them. We begin by exploring contextual factors that influence school-finance decisions; this includes a discussion of the goals and purposes of public education and the broader societal values that frame public finance. The next section describes traditional and contemporary mechanisms for raising revenue to support education systems, and examines the role of different levels of government in supporting public education. The section that follows discusses how resources are allocated across education systems, and emphasizes the evolution of equity and efficiency considerations in our allocation decisions. We conclude with a set of critical resource-utilization issues that are at the center of current school-finance-policy deliberations.

Throughout the article, our goal is to provide a sense of how this field has evolved, and we emphasize longstanding challenges and new ways of thinking about enduring issues. With the goal of offering an overview of the field, we prioritize breadth over depth and refer readers to other sources for additional information on the complexities and nuances of the topics covered. In addition, many of the ideas touched on in this article are given more in-depth attention elsewhere in this encyclopedia. Our focus here is on K-12 public-education systems in the United States. Issues related to financing higher education, nonpublic education, and education in international contexts are addressed in other articles elsewhere in this encyclopedia.

School Finance in Context

The goals and purposes of public education are to meet both individual and societal demands for schooling. In general, purposes of education are to produce individuals who can contribute to the economic, political, civic, social, and cultural institutions in our society. As such, we expect high school graduates to have acquired a wide range of competencies, skills, and personal qualities. These ideas are consistent with those of early proponents of public education including Horace Mann and Thomas Jefferson. Further, they reflect the work of international efforts to identify the array of “key competencies that contribute to a successful life and a well-functioning society” (Rychen and Salganik, 2003).

While many of the benefits of formal education are enjoyed by individuals in the form of better employment opportunities, higher wages, better health, expanded options for leisure time, and a better life for themselves and their children, it is the social benefits of education that justify a publicly financed system of schools. These social or collective benefits include all of the benefits enjoyed by individuals in the society, plus additional benefits that are uniquely collective in nature (Cohn and Geske, 2004). For instance, from a societal perspective, investments in public education pay returns in the form of national economic productivity and growth, good citizenship and a working democracy, a more peaceful society, and lower costs associated with prisons and social services. Analysts typically classify educational benefits into a four-cell matrix, as shown in **Table 1**.

Calculating the returns on investments in education has been the focus on research, and estimates depend on a number of contextual factors including the developmental status of the nation, and the level and type of education (Psacharopoulos, 2006). Taken together, studies show that education is a good investment for individuals and for society, with a rate of return typically exceeding 10% (Becker, 1993). Estimating the full returns to education has long been a challenge due to the difficulties of quantifying many of the nonmarket benefits, though some progress has been made capturing the value of benefits like lower crime rates, better child education, and household health resulting from investments in education (e.g., Baum and Payea, 2005; Barnett and Masse, 2007).

Table 1 Classification of the benefits of education

<i>Benefit type</i>	<i>Private</i>	<i>Social</i>
Market	Employability Higher earnings Labor-market flexibility	Higher productivity Higher net tax revenue Less reliance on government financial support
Nonmarket	Greater mobility Greater consumer efficiency Better household health Nonwage remuneration (fringe benefits and working conditions) Future opportunities for children	Lower crime rates Less spread of infectious diseases Better social cohesion Civic participation (Voter participation, volunteerism, charity; service in public agencies) Technological change

From Wolfe, B. and Zuvekas, S. (1997). Non-market effects of education. *International Journal of Education Research* 27(6), 491–502; Psacharopoulos, G. (2006). The value of investment in education: Theory, evidence, and policy. *Journal of Education Finance* 32(2), 113–136.

The estimated benefits of education, particularly education at the elementary level that gives rise to basic literacy skills, make a compelling case for a public investment in education. Each year, hundreds of billions dollars in federal, state, and local revenues are dedicated to public K-12 education (NCES, 2006). From 1982 to 2003, total revenues allocated to public K-12 education in the United States steadily rose from around US\$117 billion to US\$462 billion. Decisions about how best to raise and allocate these resources are influenced by three broad and sometimes competing goals: efficiency, equity, and liberty (Garms *et al.*, 1978). While the ideas presented here are relatively straightforward, each of these goals is multifaceted and complex. For instance, our definition of efficiency deals with production efficiency, but efficiency in exchange is also an important consideration (see Monk, 1990). The goal of efficiency holds that resources should be used to pursue the best set of outcomes in ways that minimize the use of resources. The goal of equity emphasizes the fairness in the distribution of a good, service, or burden. The goal of liberty holds that revenue generation and resource allocation should be conducted in a way that properly balances individual in contrast to collective interests. While each of these goals is important in its own right, they are often in tension with one another requiring policymakers to strike a reasonable balance among them as they consider options for raising, distributing, and utilizing resources to realize the goals of public education.

Raising Revenue: Multiple and Evolving Roles

Historically, school finance in the United States has largely been a local function. For a history of education finance, see Guthrie *et al.* (2007). Families and communities raised resources to provide local schools so that children would learn the knowledge, skills, and values needed to be competent and productive adult members of the community. As the broader civic, social, and economic benefits of public education became more apparent, state laws requiring children to attend school were adopted. Compulsory-education laws, first enacted in the mid-1600s, obligated states to establish school systems to finance and administer public education. By the mid-1800s, systems of universal, tax-support education involving multiple levels of government spread throughout the country. Most often, these systems were organized around school districts that were responsible for raising revenue, typically through the use of the local property tax, and providing educational services for students. This local system of education finance coupled with the uneven distribution of wealth across districts, however, resulted in large disparities across communities in education spending, services, and outcomes. Despite the efficiencies expected to result from this decentralized system of school finance (i.e., the potential for local systems to better meet the preferences of their constituencies), the inherent inequities associated with such a heavy reliance on the local property tax for revenue generation led to court cases challenging the legality of state systems of school finance. For a detailed review of school-finance litigation, see Minorini and Sugarman, 1999. One outcome of these court cases was a gradual shift to more state involvement in revenue generation for public education. Over the period from 1919 to 2003, the state share of revenue for public education increased from 17% to 49%, while the local share decreased from 83% to 43% (NCES, 2006). This shift in the share of revenue provided by states and districts reflects a normative shift in school finance from the traditional emphasis on liberty to a greater emphasis on equity that could only be ensured through an increase in state involvement.

Since education is fundamentally a state responsibility, the federal role has always been relatively modest, typically accounting for about 7% of total government revenues for K-12 public education (NCES, 2006). In general, federal funding for education has been motivated by three key concerns: ensuring opportunity for all students, countering underinvestment that might result in national labor shortages, and realizing scale economies through national research and development efforts (Guthrie *et al.*, 2007). Federal expenditures to promote equity include programs like Head Start that provides early educational opportunities for disadvantaged students, the Elementary and Secondary Education Act that supports education for

low-income students, and Public Law 94–142 that funds education for handicapped students. Federal policies to promote efficiency include vocational-education initiatives, the National Assessment of Educational Progress (NAEP) and other efforts to monitor the achievements of schools, and data collection and research efforts to guide decision making. Finally, the federal government has promoted the goal of liberty through policies that enhance freedom and choice. Arguably, the No Child Left Behind Act of 2001 (NCLB) advances all three goals by making federal funds for low-income students contingent on demonstrated performance (adequate yearly progress) for all subgroups of students served, and providing alternatives for students in chronically failing schools. However, more than 5 years since its adoption, NCLB has fallen short on a number of counts and the level of federal investment in public education has become a matter of contentious debate (Sunderman and Orfield, in press).

In addition to local, state, and federal revenue sources, many schools benefit from funding and resources from nongovernment sources. Since states vary in their reporting requirements, available information about the types, amounts, and distributions of nongovernmental resources is limited and uneven. Existing evidence shows that private contributions to public schools can be substantial, giving rise to related questions about the implications these resources have for efficiency, equity, and liberty (Schwartz, *et al.*, 2002).

The different levels of government tend to rely on different types of revenue-raising instruments, and these instruments have been studied in terms of their effects on equity and efficiency. As noted above, local districts tend to rely most heavily on the property tax, states have typically used a combination of sales and income taxes, and the federal government relies primarily on income taxes. Evaluations of these taxes tend to focus on five criteria: tax base, yield, equity, economic effects, and administrative and compliance costs (Odden and Picus, 2004). The most desirable taxes are progressive approaches that have a broad base and a low rate, a stable yield, minimal economic effects, and low administrative costs. Education-finance systems typically incorporate a combination of taxes across levels of the education system, balancing the strengths and weakness of each instrument. Further, as is discussed in the next section, intergovernmental grants are often used by federal and state agencies to encourage local districts to assume their share of the tax burden for public education.

In addition to the more traditional taxes used to raise funds for education, lotteries have been considered by many state legislatures as a potential revenue source for public education. Lotteries provide fungible revenues that are often earmarked for public education (Novarro, 2005). Lotteries are popular alternatives in the face of constrained resources, and earmarking lottery profits for K-12

education tends to increase spending (Evans and Zhang, 2007). However, revenue from lotteries tends to be unstable and regressive, qualities that make this strategy less attractive – on both practical and normative grounds – as a sustainable means to generate revenue for public education.

Distributing Resources: Multiple and Competing Goals

As described above, states assumed a more active role in school finance following court cases that challenged the equity of heavy reliance on the local property tax to fund education. In this section, we describe the dominant approaches used by states over the years to allocate funds for public education. Next, we review school finance litigation to highlight the key equity considerations in the distribution of resources for public education. Finally, we discuss issues related to the efficient use of educational resources.

Mechanisms for Distributing Revenue Across School Districts

Several state equalization formulas have become common tools to redistribute funds in more equitable ways. Four approaches have dominated the landscape. A more detailed treatment of these formulas is provided by Odden and Picus (2004) and Monk (1990). Flat grants have been used to ensure that all schools are funded to provide a basic education for students. These programs provide all schools a grant of equal size (either by school or by enrolment) to help support elementary education programs. However, by treating all schools the same, flat grants fail to recognize the varying fiscal capacity of different districts that gives rise to inequities in the first place.

Foundation programs were introduced in the early 1900s in direct response to the shortcomings of flat grants. The foundation program is rooted in the philosophy that states have an obligation to provide a minimum level of education. The state sets a foundation, the per-pupil expenditure needed to provide a minimum quality education, and requires a minimum tax rate to ensure local effort as a condition for state aid. States fund the difference between the per-pupil expenditure that districts are able to generate at the minimum tax rate and the state-established foundation per-pupil expenditure. In this way, states distribute funds inverse to local wealth with the goal of helping all school districts to provide a minimum foundation of education. Districts are free to tax themselves above the minimum required rate to supplement this foundation level of spending, but the revenues generated beyond the required tax rate are a function of local wealth alone. So long as the foundation level and

the minimum tax rates are set at relatively low levels, inequities stemming from differences in the fiscal capacity of school districts remain a problem.

Guaranteed tax base (GTB) programs were introduced in the 1970s in response to school-finance litigation based on unequal local fiscal-capacity arguments. A GTB program guarantees, through the allocation of state aid, that each school district in a state can function as if it had an equal tax base. Essentially, the state establishes the tax base that will be guaranteed for all school districts and provides aid such that any district with an actual tax base less than the GTB will generate revenue as if they had the GTB. This program grants school districts the liberty to determine their own tax rate, and equalizes fiscal capacity up to the level of the GTB. State aid is awarded inversely to local wealth, thereby improving equity without limiting liberty. However, the cost to the state can be excessive.

The fourth formula that states have used to allocate funds to support education is a combination of the foundation program and GTB program. This combination approach overcomes the problems of each of the formulas; the foundation program requires that districts provide at least a basic level of education, and the GTB ensures equity if districts choose to spend beyond the foundation level.

Beyond these four basic formulas, states have employed a variety of strategies to promote greater equity. For instance, state-determined-spending programs prescribe the per-pupil expenditure across districts in the state. This per-pupil expenditure may be funded by the state (e.g., Hawaii) or some combination of state and local revenues (e.g., Vermont). States have also placed revenue limits on local school districts to restrict the difference in spending across jurisdictions (e.g., California). While these sorts of programs are intended to promote greater equity, they can have serious implications for liberty.

Regardless of the state formula used to distribute funds to districts, additional adjustments are commonly made to account for student needs and geographic cost differences across school districts. Adjustments for special-needs students tend to take the form of weights that recognize the higher-than-average costs associated with educating low-income, limited-English-proficient, and special-education students. If these students were evenly distributed across schools and districts, such weights would not be necessary. However, some districts have higher concentrations of such students and require additional funding to provide education programs. States provide this additional funding through weighted student adjustments, but some research indicates that states tend to underestimate the influence of poverty and limited-English-proficiency status on cost (Baker and Duncombe, 2004). Determining student eligibility and the magnitude of the weights to be assigned to various types of students is a process that varies across

states and involves a number of assumptions about the costs of providing education services to students with special needs. For additional discussion, see Chambers *et al.* (2002) and Duncombe and Yinger (2005).

A second type of adjustment recognizes differences in what a dollar can purchase across different jurisdictions. There is broad consensus that the cost of educational inputs varies geographically due to differences in local labor markets, house prices, transportation costs, energy prices, and the like. Despite the intuitive appeal, measuring cost differentials is difficult due to the scarcity of geographically detailed data on the prices and quality of inputs purchased. Nonetheless, some headway has been made and various estimates of geographic cost differentials in education, mostly focused on teachers, now exist. A prime example is the geographic cost of education index (GCEI) developed by Chambers (1997) which adjusts teacher salary to account for differences in workplace characteristics. More recently, Taylor and Fowler (2006) developed a comparable wage index (CWI) to adjust for differences in the cost of education that are beyond the control of school districts. The CWI is constructed on salary differentials of noneducators and reflects the systematic, regional labor-cost variation due to differences in both the cost of living and local-community characteristics (such as crime rate).

Equity and Adequacy

The distribution formulas and weighting mechanisms that states use to allocate resources across school districts are a direct response to demands for greater equity in education finance. But defining what specifically, constitutes equity has been an evolving process, one driven largely by the courts. School-finance litigation has been categorized into three waves (Guthrie *et al.*, 2007). During the first wave, which spanned the 1960s through 1973, plaintiffs challenged school-finance systems through the federal Constitution's equal protection clause. The second wave, from 1973 through 1989, was characterized by challenges based on state-education clauses, equal-protection clauses, or a combination of the two. The third wave, from 1989 to the present, includes cases based on claims that school-finance formulas prevent poor school districts from providing an adequate education as defined by state-education clauses. Research suggests that litigation, and the public and judicial pressure resulting from litigation, has improved equity. In most cases, this is a result of leveling up, or increasing overall state funding such that the additional funds are allocated to lower-wealth districts (Evans *et al.*, 1999).

The school-finance adequacy litigation expands the traditional equity paradigm to consider what is needed to achieve a "high-minimum quality education for all"

(Minorini and Sugarman, 1999: 188). Several methodologies have been developed to determine an adequate expenditure level, including the professional-judgment approach (Guthrie and Rothstein, 1999), the successful-district approach (Augenblick, 1997), and the cost-function approach (Reschovsky and Imazeki, 2003). Despite the efforts to estimate the cost of an adequate education, no consensus exists as to how much money is needed to reach the adequate level. Some researchers suggest that the evidence is converging (Odden *et al.*, 2004).

Efficiency

Earlier we noted that the goal of efficiency is served to the degree that the best outcomes are being produced in ways that minimize the use of resources. Efficiency is always a matter of degree and policymakers at all levels of educational systems have an ongoing responsibility to improve efficiency within their areas of responsibility.

While the efficiency concept is seemingly straightforward, it is actually riddled with complexities. Notice, for example, the stipulation about the selection of the best outcomes. A system could be minimizing the use of resources in pursuit of useless outcomes and fall far short of the efficiency goal. Similarly, a system could be pursuing the right outcomes, but by doing so in ways that are wasteful, thereby again fail to achieve efficiency. Moreover, in the real world, it can be difficult to reach consensus about what counts as best. Measurement problems also abound and it can be devilishly difficult to disentangle available fiscal data so that a good map can be made showing what resources are actually being expended in pursuit of what goals.

There has been great interest recently in measuring the value added by educational resources, particularly teacher resources (Sanders and Rivers, 1996). The logic is that teachers vary in how much value they add to their students' performance. If these value-added contributions can be measured accurately, then policymakers could take steps to increase the efficiency of the system. Shifts could be made in personnel policies to increase the incidence of teachers with high value-added scores. But these high value-added teachers may not be available at prevailing wages. If it becomes necessary to pay higher salaries in order to attract and retain the high value-added talent, the efficiency gains associated with having the more productive teachers in place could be undermined.

Attempts are also being made to use accountability systems to stimulate efficiency, although typically, the focus is more on achieving performance targets rather than on minimizing costs. Efficiency will be enhanced to the degree that the accountability system stimulates performance, regardless of the means, without adding to costs.

Utilization of Resources: Current Policy Issues for School Finance

Education expenditures are of interest to the extent that they are used to purchase resources that translate into meaningful learning experiences for students, and, ultimately, desired outcomes like economic productivity, social responsibility, and civic participation. In this section, we address three current policy issues that have implications for education-finance systems and, specifically, how educational resources are utilized.

Teacher Compensation

A first set of policy issues relates to teachers and teacher compensation. Teacher compensation consumes more than half of K-12 public-education operating expenditures. This substantial investment in teachers is justified on the grounds that teachers are the most important school resource provided to students (e.g., Sanders and Rivers, 1996). Concern about the supply and quality of teachers, particularly in geographic and subject-shortage areas, has induced policymakers and researchers to consider how compensation can be used to attract and retain quality teachers into the profession and to the schools that need them the most.

While most school districts rely on traditional single-salary schedules, some districts have begun to experiment with alternative compensation structures that may be more efficient and equitable for teachers, students, and taxpayers (see Podgursky and Springer, 2007). In addition, districts have used a variety of economic incentives – for example, signing bonuses, tuition remission for university credits, and housing assistance – to attract teachers to geographic and subject-shortage areas, but we have little evidence on the impact of these investments (Guarino *et al.*, 2004). Clearly, more work is needed to understand how to structure teacher compensation in ways that advance the overarching goals of public education.

Special Education

A second highly contested area in the utilization of resources is special-education finance. Almost six-million children receive federally funded special-education services with total expenditure estimated around US\$50 billion (Chambers *et al.*, 2004). States and districts support special education with a variety of funding sources and distribution formula, and studies show that the proportion of total education expenditure spent on special education has increased over time (Kolbe and O'Reilly, 2005).

The level of funding needed for special education is a function of the number of students in need of services, and the cost of those services. Both identifying eligible students and determining the appropriate funding levels

for those students have presented challenges to policy-makers. The rising number of students in less-severe, high-incidence special-education categories accounts for the majority of growth in special-education enrolments and spending (Parrish and Esra, 2006). Researchers have considered the extent to which state policies provide fiscal incentives and disincentives that might affect the identification of special-education students (Mahitivanichcha and Parrish, 2005), giving rise to debates about how state-funding structures might lead to overidentification.

In addition, policymakers struggle with challenges related to the most effective and efficient delivery of special-education services. This includes designing and implementing more effective alternatives to provide special education in the general-education setting, particularly for students with mild-to-moderate learning disabilities. More research is needed on the relative cost-effectiveness of different program and service options (Kolbe and O'Reilly, 2005). Establishing reasonable special-education service standards could help control costs, narrow the variation in per-pupil expenditures across systems, and guide determinations about special-education funding adequacy. For a detailed discussion of special education adequacy, see Harr *et al.* (2006). This requires a better system of periodic, reliable data on what is spent on special education and the student outcomes that result.

Expanding the Scope of Education

A final example of resource utilization in school finance relates to expanding the scope of educational services. Initiatives like investing in early-childhood education and linking education with other social services are typically advanced as efforts to improve the education opportunities for students from economically disadvantaged families. Research suggests that these kinds of initiatives may also have important implications for efficiency.

While policies aimed at narrowing the achievement gap typically target school-age children, research shows that a substantial gap exists at the outset of formal schooling (Lee and Burkham, 2002). Proponents of early-education programs recognize that investments in the young have relatively high returns (Carneiro and Heckman, 2003). Cost-benefit analyses of preschool programs for disadvantaged children have shown that the long-term effects of early education are associated with monetary benefits that exceed the costs of the programs (see Belfield *et al.*, 2006; Temple and Reynolds, 2007; Ludwig and Phillips, 2007). While the price tag associated with these programs may be high, the investment may be wise on both equity and efficiency grounds.

The conventional bounds of public education finance are also challenged by proposals to expand the role of schools. The idea is that efforts to narrow the achievement

gap must recognize the wide range of social and economic factors – including healthcare quality, nutrition, housing quality and stability, parental occupation and aspirations – that affect student achievement (Rothstein, 2004). Proposals to address these multiple influences may involve greater collaboration between schools and other social service fields, or they might require providing a broader set of services (e.g., health and dental care) to low-income students within the school setting. Either approach has implications for fiscal policy and the potential to advance goals of efficiency, equity, and liberty.

The Economics of Tuition and Fees in Higher Education

R G Ehrenberg, Cornell University, Ithaca, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Net tuition – Tuition paid by students minus the average amount of institutional and other grant aid they receive.

Tuition discount rate – Percentage of undergraduate tuition revenue that goes back to undergraduate students in the form of institutional grant aid.

Introduction

Tuition and fee policies in higher education vary widely across countries and, in some countries, widely across academic institutions within the country. This article focuses on one country, the United States. Readers interested in policies in other nations can consult the website of the Center for International Higher Education at Boston College, which provides a comprehensive listing of international higher education journals and has numerous working papers dealing with the subject.

The American higher education system is a highly decentralized one. There are over 4200 degree-granting institutions in the United States. While the majority of institutions are private, not for profits, about two-thirds of all undergraduate students enrolled in four-year colleges attend public institutions; this share rises to about four-fifths when one takes into account the students enrolled in 2-year colleges, which are predominately public institutions. A small but growing share of students are enrolled in private for-profit degree-granting institutions.

For a number of years, the College Board has been collecting data on tuition and fees and publishing it in annual volume *Trends in College Pricing*. In 2007–08, the average tuition and fees at 2-year public institutions, 4-year publics, and 4-year privates were US\$2361, US\$6185, and US\$23 712, respectively (College Board, 2007). The figures for public institutions are for students who reside in the same state as the institution is located; students from out of the state and foreign countries are charged higher levels of tuition at the publics. The average public 4-year out-of-state tuition and fees was US\$16 640 during that period.

These averages mask considerable variation in the tuition and fees that students pay to attend both public

and private institutions. For example, in 2007–08 about 19% of the students attending private 4-year institutions faced tuition and fees that were over US\$33 000, while almost 18% faced tuition and fees that were less than US\$15 000. Similarly, while 45% of the in-state and out-of-state students attending public 4-year institutions faced tuition and fee levels that were less than US\$6000, 13% faced tuition and fee levels that were more than US\$12 000.

It is important to stress that an institution's tuition and fee level does not reflect the full cost that the institution incurs in educating undergraduate students. Gordon Winston from Williams College has very carefully documented that no undergraduate student at a public or private non-profit college or university (including those who receive no financial aid) pays the full cost of his or her education because of subsidies that are provided to them (Winston, 1999). In private higher education, these subsidies come from the income that the endowments of the university provide, from annual-giving streams to the institutions provided by alumni, foundations, corporations, and other donors, and from the value of the services of the buildings on campus that were constructed using funds from external donors. In public higher education, these subsidies come from all of the previous sources, as well as from current state appropriations and previous state appropriations for buildings and capital equipment. For future reference, it is important to note that Winston has also documented that the subsidies students receive are largest in absolute value at the nation's most selective (in terms of admission standards) and wealthiest private colleges and universities.

An institution's tuition and fee level also overstates the costs that many students incur to attend the institution because of financial aid provided to students by the federal government, state governments, the institutions themselves, and private donors. At the federal level, aid currently takes the form of grant aid for students from lower and lower-middle income families, subsidized loans for students from lower and middle income families, and tax credits. A number of states have grant-aid programs for students who reside in their state and attend colleges within the state. Sometimes, these grant programs are restricted to students attending public colleges in the state. Depending upon the state, these grant programs may be either need-based or merit-based; an example of the latter is the Georgia HOPE scholarship program. HOPE provides grant aid to Georgia students who attain a B average in high school and attend either a public or private academic

institution in the state. Continuation of the aid after a student's first year of college is contingent on the student's maintaining a B average in college. A number of states also have special scholarship programs or loan-forgiveness programs for students who are employed in the state after graduation in relatively low-paying occupations that are deemed to be of critical importance to the state.

Researchers and policymakers have long worried whether academic institutions will try to capture some of the grant aid that governments provide to help students afford college by raising their tuition levels. To date, the empirical evidence on whether this has occurred is ambiguous (Long, 2004).

Institutions also provide grant aid to students. Grant aid may be based upon financial need (as at the nation's most selective private colleges and universities) or it may be based upon merit. Merit is broadly defined here to include efforts by institutions to attract students with strong academic or strong athletic backgrounds. For a number of years, the National Association of College and University Business Officers (NACUBO) conducted an annual tuition-discounting survey to estimate how undergraduate grant aid provided by an institution compared to the tuition revenue that the institution was receiving; recently, this survey has been taken over by the College Board. These surveys suggest that the typical private American college or university has a discount rate in the range of 33%, in the sense that it returns roughly this share of the tuition revenue that it receives back to undergraduate students in the form of grant aid (Baum and Lapovsky, 2006). Of course, at the richest private institutions, much of these grant funds come from endowment income. Increasingly, public colleges and universities also provide grant aid to students; in recent years, the average tuition discount rate at public 4-year institutions was in the range of 15% of tuition revenues.

Tuition Keeps Rising in Private Higher Education

In 1967, William Bowen published an important book that examined what had happened to tuition and fee levels at a set of selective private colleges and universities in the United States during the first two-thirds of the twentieth century (Bowen, 1967). He found that, on average, the institutions increased their tuition and fee levels by 2–3% more than the rate of inflation (as measured by the increase in the consumer price index (CPI)) each year. He attributed this partially to the growth of new knowledge and graduate programs, which added costs to the academic institutions. But first and foremost, he attributed this to the fact that higher education institutions were not sharing in the productivity gains that were occurring in the rest of the economy.

To understand Bowen's argument, consider a very simple model in which tuition is the only source of revenue for an academic institution and faculty salaries are the only cost for the university. Suppose also that the institution believes that a high-quality undergraduate education is dependent upon maintaining a fixed student/faculty ratio. In such a world, faculty members' productivity does not increase over time; each year they educate the same number of students. However, in the rest of the economy, productivity is increasing because of investments in new capital equipment and changes in technology and since real wages (wages adjusted for inflation) depend upon productivity growth, they too are increasing.

In such a world, the administrators at the academic institutions face a dilemma. If they restrict tuition increases to the rate of inflation, salaries of faculty would remain constant (in inflation-adjusted terms) and would fall behind the earnings of people in other professional occupations. This would make it difficult to retain existing faculty members and to attract new people into graduate study and then faculty positions in academia. Inevitably then, the quality of higher education would decline. Alternatively, the administrators could bite the bullet, raise tuition by more than inflation, and try to keep the salaries of faculty members competitive with salaries in the rest of the economy. The pattern of tuition increases during the first two-thirds of the twentieth century suggests that they chose the second option.

As documented in *Tuition Rising* (Ehrenberg, 2000), throughout this period of time, tuition and fees at selective private higher education in the United States did not increase as a share of median family income, because median family income also increased more rapidly than inflation because of the growth in labor productivity and the growth in the number of two-income-earner families in the United States. However, the decade of the 1980s was one of virtually no real income growth in the United States, yet tuition kept increasing throughout this decade at rates greater than the rate of inflation. As a result, while tuition and fees at the typical selective private college and university in the United States was in the range of 30% of median family income in 1975, today it is over 50% of median family income. While the growth in financial aid has caused net tuition to rise by a smaller amount, it too is still much higher today as a share of median family income than it was 30 years ago.

In *Tuition Rising* there has been a detailed description of the forces that have allowed the selective private colleges and universities to keep increasing their tuition and fees at rates that substantially exceed the rate of increase in the CPI. A few of the more important ones have been highlighted in this article.

First, the selective private colleges and universities have but one objective; they want to be the very best that they can in every dimension of their activities. They

want to have the best instructional and research facilities, attract the best students and faculty, provide the highest quality education and support services, and the like. To do all these things takes money. While they try to diversify their revenue streams (by attracting more annual giving to support current operations, to build the endowment and to finance new construction, and by trying to commercialize their faculty members' research findings), in the absence of any market forces that limit tuition increases, increasing tuition is an easy way to generate increased revenues. After all, the institutions can always price discriminate (and they do); they can use a share of the increased revenue that they generate from a tuition increase to provide more grant aid to students who otherwise would not be able to afford to attend the institution to ensure that the tuition increase does not restrict access.

Each year, the number of students who apply to attend these institutions keeps getting larger, while the number of positions in their first-year students has increased only slightly. These institutions have focused primarily on maintaining or increasing their quality rather than increasing their size (although several are now marginally doing so) and despite their increased tuition and fees, students increasingly flock to them. This has occurred in large part because, as the distribution of earnings becomes more disperse in the United States, students and their parents instinctively understand that where one goes to college may matter as much as whether one goes to college. In what has become an increasingly winner-take-all society, there is increased pressure on students and their families, in the words of my colleague Robert Frank "to buy the best" (Frank and Cook, 1995). And empirically, with one exception, all empirical research on the topic suggests that students who attend selective private colleges and universities in the United States, which Winston's research indicates, provide the greatest subsidy to their students, are making a rational economic choice; they receive benefits in the form of higher post-college earnings and increased probability of being admitted to high-quality professional and graduate programs than would otherwise be the case. Put simply, as long as long lines of students keep knocking on the doors of these selective private institutions clamoring to gain admission to them, there are no market forces to hold the rate of increase in tuition down at these institutions.

Of course, these institutions could try to be socially responsible, improve the efficiency of their operations, and get better by substitution rather than by increasing expenditures. Often they do try to do this, especially in the nonacademic sphere of their operations. However, there are a number of forces that prevent them from doing this in the academic sphere of their operations. One is the system of shared governance that prevails within them that gives faculty members an extraordinary amount of influence over academic decisions. Faculty

members are crucial to the reputation of these institutions because they are the creators of new knowledge and the ones who educate undergraduate and graduate students. Administrators strive to keep the faculty happy because the labor market for faculty at these top institutions is very competitive and top faculty are mobile; often, this requires the administrators to make greater expenditures than they otherwise would prefer to do.

Another factor is the important role that alumni and other external constituents play. Alumni are vital to these institutions because they help recruit new students, provide internship opportunities and summer employment opportunities for existing students, provide job opportunities for graduates, and provide financial support in the form of donations for current operations, endowment, and new buildings. However, alumni often have very strong preferences for specific programs (often ones that they were involved with when they were students) and any attempt to cut back the scale of, or eliminate a program, may lead to a threat to withhold contributions or other sources of support for the institution if the action is undertaken. This makes it difficult for administrators to cut any program that an external constituent really cares about.

A third factor is the role that the annual *U.S. News & World Report* (*USNWR*) rankings, which in many respects is now the gold standard in rankings, now plays in American higher education. Empirical research shows that when an institution improves in the rankings, other factors held constant, it attracts more applicants, can be more selective and admit a smaller fraction of these applicants, a greater fraction of the students it admits will enroll at the institution, these enrolled students will have higher test scores, and the institution will be able to spend less on grant aid to attract the students (Monks and Ehrenberg, 1999). Conversely, when an institution falls in the rankings, just the reverse occurs. Administrators passionately care about these outcomes and while administrators often claim that they pay no attention to the *USNWR* rankings and that the rankings do not influence anything that goes on at the university, such statements are simply false.

The formula that *USNWR* uses to compute its rankings gives positive weight to the educational expenditures per student that an academic institution makes. Hence, any academic institution that unilaterally reduced its expenditures per student, or even the rate of growth of its expenditures per student relative to its competitors' rate of growth, would find that it would fall in the rankings. Hence, the *USNWR* ranking methodology does not reward academic institutions for holding their costs down; it puts pressure on the institutions to spend more.

Of course, to say that the selective private colleges and universities continue to have long lines of applicants clamoring to gain admission is not to say that most private colleges in the United States face this situation. In fact,

many private colleges and universities admit large fractions, if not virtually all, of the individuals that apply to them. Yet, these other private colleges and universities, for the most part, have increased their tuitions at roughly the same rates over time as the most selective privates.

They have been able to do this in part because of the belief that in the higher education market, posted price (tuition and fees) is taken by many to be an indicator of quality; if an institution lets its tuition fall relative to its competitors, it runs the risk of being perceived as an inferior institution. In part, they have been able to do this because students and their families do not seem to respond in a symmetric fashion to tuition increases and grant aid increases; Christopher Avery and Caroline Hoxby have found that in awarding accepted students a merit-based grant has a larger effect on their enrolment probabilities than reducing tuition by an equal amount (Avery and Hoxby, 2004).

Not surprisingly, tuition discount rates tend to be higher at smaller less-selective private liberal art colleges than they do at the more-selective private liberal art colleges and the private research universities. The more selective an institution is, the less it needs to use grant aid to try to attract students to it.

Tuition Keeps Rising at Public Institutions

During the last 30 years, rates of tuition and fee increase at 4-year public higher education institutions in the United States have been equal to or greater than the rates of tuition increases at the 4-year privates. However, while tuition increases at the privates have always been associated with increases in expenditures per student, tuition increases at the publics have often been associated with decreases in expenditures per student. This occurs because in addition to the factors described above that influence tuition growth in private higher education, tuition growth in public higher education is influenced by changes in the state appropriations that public higher education institutions receive. As described in *The Perfect Storm* (Ehrenberg, 2006), tight budgets faced by the states during the period due to several recessions, limitations on the willingness of the public to increase state tax rates, competing demands on state budgets from elementary and secondary education, Medicaid, and the criminal justice system, and large increases in college-age populations, have limited the ability of states to increase their support for their higher education institutions. On a real per-student basis, state appropriations per student today are only slightly greater than they were at the start of the period. As a result, tuition has risen and state appropriations have fallen as a share of public college and university budgets in the United States.

Although tuition has risen at roughly the same rate (in recent years roughly 3% more than the rate of increase in the CPI) at public and private higher education institutions in the United States, because state appropriations have failed to grow at a similar rate, expenditures per student have fallen in public higher education relative to that in private higher education. As a result, faculty salaries in public higher education have fallen relative to faculty salaries in private higher education, which makes it more difficult for the public institutions to attract and retain high-quality faculty. Student–faculty ratios have also risen in public higher education relative to those in private higher education. Great concern has been expressed that these changes are causing a decline in the relative quality of public higher education in the United States.

To try to reduce these financial pressures, public higher education institutions are pursuing a number of strategies. Public colleges and universities have always charged higher tuition and fee levels to students enrolling in their institutions who are not residents of the state in which the institution is located. Many public institutions have substantially increased the dollar gap between what in-state and out-of-state students are charged and, when possible, have sought to increase the share of their students they enroll from out-of-state as a way of generating additional revenues.

A number of them have moved toward charging differential tuition and fee rates for undergraduate students depending upon the program in which the student is enrolled. Historically, colleges and universities charged the same rate for all students; the notion being that students should be able to choose what to study based upon their intellectual interest, not based on costs. However, financial pressures have led public institutions to begin to charge higher tuition and fees for high-cost majors (due to small class sizes or the need for expensive equipment) and/or for majors that promise to lead to jobs with high economic returns. The intellectual justification for such strategies was articulated long ago by Stephen Hoenack and William Weiler (Hoenack and Weiler, 1975).

Graduate and Professional Program Tuition and Fees

The discussion above all deals with undergraduate education. American colleges and universities also enrol graduate students in professional degree programs in law (JD), medicine (MD), business and management (MBA), and a host of other fields. They also enrol students in research masters (MA or MS) and PhD programs. Tuition and fees for professional degree programs are often market determined and are often higher than the tuition charged to undergraduate students at the same institution. The

higher tuition levels are justified by the high earnings that entry into these professional fields promises to potential students. Students bear the cost of tuition and fees in most professional degree programs, although increasingly professional programs award both need- and merit-based aid to attract a diverse student body and to improve its academic profile.

In 2007–08, annual tuition and fees at many top private law, graduate business, and medical schools were in the US\$40 000–US\$45 000 range. With tuition levels this high, many students have extremely large loan burdens upon graduation. To encourage law students to enter low-paying public service law careers, many of the selective private law schools have funded their own programs that provide for loan forgiveness if graduates are employed in public service positions for a specified number of years. A recent study by Erica Field looked at an interesting quasi-experiment that the NYU law school conducted (Field, 2006). Applicants who expressed interest in entering public law careers were offered either a loan-forgiveness program or free tuition, with the understanding that the tuition would have to be paid back if they did not enter public interest law careers upon graduation. The two options were developed to have identical present value to participants. Field's striking finding was that providing tuition remission upfront was much more effective in inducing students to enter public interest law careers.

Tuition levels for students enrolled in most PhD programs are much more similar to undergraduate tuition levels. However, at the best private and public universities, very few students actually pay tuition on their own. Doctoral programs must provide financial support to doctoral students to induce them to enrol in their programs because the economic return upon graduating from a PhD program in many fields is relatively low. This support often comes in the form of a multi-year guarantee, with the support being either a fellowship (no work expectation), a teaching assistantship, or a research assistantship; students often have a variety of these forms of support during the time as doctoral students. Tuition remission and increasingly the provision of health insurance are part of these packages.

Concluding Remarks

Looking to the future, the most pressing issue relating to tuition and fees at American colleges and university is whether undergraduate tuition and fees can continue to increase in the years ahead at rates that exceed the rate of inflation. America no longer leads the world in the fraction of its recent cohorts of young people who attain college degrees. The major growth in its populations is coming from groups that traditionally have been under-represented in higher education, who are least able to

afford higher education. Congressional debate over the rate of increase in college tuitions has intensified and recent legislation winding its way through Congress, if enacted, would begin to publicize those institutions whose tuition increases are above average. A decade from now, an article in the next edition of this encyclopedia on tuition might look very different.

Education and Civic Engagement

T S Dee, Swarthmore College, Swarthmore, PA, USA

One of the most fundamental and recurring questions in economics involves how we should understand the proper division of human activity across the public and the private sectors. The field of education is certainly no exception. Public-sector involvement in virtually all forms of formal educational activity is both diverse and extensive. Correspondingly, the intellectual justifications for education-related public policies and institutions reflect a broad variety of distinct normative concerns. However, a conjecture that is central to claims about the importance of government involvement in education is the substantive role that educational investments are thought to play in the formation of an engaged and enlightened citizenry. For example, the claim that widespread education is critical for a stable, functioning democracy was a key motivation for the dramatic growth in access to formal schooling in the United States during the nineteenth century. More recently, the putative civic benefits of investments in education have motivated arguments for private-school vouchers as well as for the Great Society investments in higher education.

From an economic perspective, the basic argument is that individual investments in education may generate a positive externality through improvements in civic engagement that effectively benefit the entire society. This article provides a critical overview of the available evidence that has examined the effects of schooling on subsequent measures of civic engagement. The available evidence is largely, although not exclusively, based on data from the United States. However, it is also important to note that, while the existence of a civic externality from schooling can motivate government intervention in education, it does not have unambiguously clear implications for the exact form of that intervention. The existence of

civic externalities from schooling also does not speak directly to the important question of how public and private schools compare with regard to promoting subsequent civic engagement. This article also discusses the more limited and recent evidence that touches on these issues and concludes with some promising directions for future research.

The Civic Returns to Educational Attainment

Civic engagement refers to a diverse set of behaviors, attitudes, and knowledge that constitute effective citizenship. For example, one particularly prominent dimension of civic engagement involves the allocation of time: participation in voting, volunteering, membership in civic organizations, and engagement with elected representatives. A second key component of civic engagement is a belief in the validity and desirability of democratic, pluralistic institutions, and related values such as tolerance and respect. A third dimension involves having both the requisite cognitive skills and an awareness of current events that make an informed deliberation on complex social and technological issues possible.

Investments in education are widely thought to be a critical determinant of all dimensions of civic engagement, and, by implication, of maintaining a stable, well-functioning democracy. In particular, increases in educational attainment are thought to promote civic engagement both by inculcating students with a sense of civic responsibility and by providing them with the skills and knowledge that allow them to make informed decisions. However, basic economic theory suggests a number of other, potentially contrary

ways in which additional schooling may shape civic engagement. For example, the well-documented effect of schooling on wages implies that educational attainment increases the opportunity cost of time. This increase should reduce the willingness to invest time in civic activities such as voting and volunteering. This effect may be particularly relevant for volunteering, which, relative to voting, implies a more intensive and sustained commitment of time. Additional schooling could also reduce voter participation if it makes voters more aware of the paradox of voting. More specifically, additional school could encourage voters to view voting as a largely expressive and meaningless act rather than an instrumental one with a nontrivial likelihood of directly influencing an election's outcome. Finally, it should be noted that the effects of additional schooling on civic responsibility may work through the changes in peer-groups and social norms rather than through the effects of schooling *per se*.

A large number of older, empirical studies, mostly from the field of political science, have examined the effects of educational attainment on dimensions of civic engagement in the United States (Converse, 1972; Wolfinger and Rosenstone, 1980; Nie *et al.*, 1996; Putnam, 2001). These studies generally find that, conditional on several observable traits, higher levels of educational attainment are associated with substantial increases in multiple dimensions of adult civic engagement. In fact, several authors have stressed the central role that education seems to have among all determinants of civic engagement (Converse, 1972; Putnam, 2001). The apparent gains from increases in educational attainment appear to exist at both the secondary and the postsecondary levels. Furthermore, the strong partial correlations between educational attainment and civic engagement also appear to exist internationally (e.g., Franklin, 1996).

However, several recent studies on this topic have been motivated by the concern that the partial correlations between levels of schooling and civic engagement may be misleading. The basic concern is these correlations could, quite plausibly and to an unknown degree, reflect inherently unobservable individual, family, and community traits that influence both educational attainment and subsequent civic engagement. For example, families and communities that foster and encourage educational success may also be more likely to promote the development of civic virtue. One recent study addressed this potential source of bias by conducting comparisons within 85 pairs of monozygotic twins from New Zealand and found that an additional year of schooling appeared to lower the likelihood of volunteering by roughly 12.5% (Gibson, 2001). This contrarian finding is consistent with the effects of schooling on the opportunity cost of time.

Two other recent studies have examined the causal effects of additional schooling on more diverse measures

of civic engagement by exploiting the credibly independent variation in educational attainment generated by teen exposure to child labor and compulsory schooling laws (Dee, 2004; Milligan *et al.*, 2004). Using different data sets of respondents from the United States, these studies find that increases in educational attainment do appear to generate substantial increases in the likelihood of voting. Furthermore, these studies present evidence that additional schooling increases the quality of civic participation both in the United States and in the United Kingdom as measured by awareness of public affairs and support for free speech (Dee, 2004; Milligan *et al.*, 2004).

Additional evidence has focused on the civic returns from additional schooling at the postsecondary margin in the United States, using geographic access to 2-year and community colleges as a natural experiment (Dee, 2004). The evidence from this approach indicates that college attendance leads to substantial increases in rates of subsequent voter participation. However, the estimated effects of college attendance on volunteering in adulthood were negative and statistically imprecise. Furthermore, this study did not address the effects of college attendance on other dimensions of civic engagement (e.g., civic knowledge and values) because of the apparent lack of a data set that simultaneously accommodates the use of a credible natural experiment and includes the requisite outcome variables.

Comparisons of Public and Private Schools

The available empirical evidence indicates that increases in educational attainment lead to substantial increases in several measures of civic engagement in adulthood, with the possible and notable exception of volunteering. In other words, the widely held view that investments in schooling generate some meaningful and positive civic externalities appears to be valid. These results imply that schools and classrooms are an important and highly effective setting for the development of civic engagement. However, the effects of additional schooling on civic engagement are often used to motivate continued or additional financial support for publicly managed elementary and secondary schools. From an economic standpoint, this policy interpretation is not clearly justified. Narrowly interpreted, the existence of these civic externalities argues only for the existence of corrective financial subsidies that encourage individuals to acquire additional schooling. More specifically, a subsidy equal to the value society places on the civic engagement created by additional schooling could encourage individuals to choose the socially optimal level of schooling (i.e., a level that reflects both the internal and external benefits of schooling). In fact, the seminal argument for private-school

vouchers appealed to the existence of civic externalities as an important justification (Friedman, 1955).

A more compelling economic argument for an extensive and publicly managed system of elementary and secondary schools, similar to that observed in the United States, would turn on evidence that the public sector is more effective than the private sector at promoting the development of civic engagement. There are a number of reasons to suspect that, even with regulation, private schools will not promote a socially desirable level of civic engagement. For example, because private schools are largely accountable only to the parents of their students, they may place more emphasis on skills and knowledge with clear individual benefits and less emphasis on outcomes with larger external benefits. Furthermore, the sectarian and, sometimes, segregated nature of many private schools may also harm key dimensions of civic engagement. However, there are at least two ways in which private schools could be more effective at promoting the development of civic engagement. First, private schools may be more successful at developing civically relevant cognitive skills. Second, private schools may be more effective at increasing student exposure to social capital (i.e., shared norms and trust), which, in turn, promotes the development of civic engagement.

Despite the importance of these issues, the comparative effects of public and private schools in promoting civic engagement have been the subject of surprisingly little empirical study. However, the limited evidence that is available uniformly suggests that private schools are actually more effective than public schools. For example, two recent studies based on nationally representative survey data found that attending a Catholic high school instead of a public high school was associated with improvements in civic participation, knowledge, and attitudes (Greene, 1998; Campbell, 2001). Another study based on data from college students in Texas also found a correlation between measures of political tolerance and private-school attendance (Wolf *et al.*, 2001). However, as with the strong correlations between increased schooling and civic engagement, this evidence could merely reflect selection biases. In other words, the students who attend private, instead of public, schools may experience unobserved family and community environmental traits that promote higher civic engagement in adulthood.

A recent study based on detailed data from the High School and Beyond longitudinal study examined the effects of attending a Catholic high school on several forms of civic participation, using specifications that addressed the potential influence of selection bias (Dee, 2005). In particular, this study used residence in a county with a Catholic high school as a kind of natural experiment (i.e., an instrumental variable) for attending a Catholic high school. The results of this approach suggested that attending a Catholic high school significantly increased the likelihood of voting in

adulthood. However, the estimated effects of Catholic school attendance on volunteering were smaller and statistically insignificant.

A critical assumption implicit in this analysis was that the geographic distribution of Catholic schools is unrelated to the unobserved propensities for civic engagement in adulthood. The fact that the presence of Catholic high schools was driven in large part by patterns of immigration in the late nineteenth and early twentieth centuries is consistent with this approach. Furthermore, a confounding bias would occur if communities with Catholic high schools also tended to have higher levels of civic engagement. However, Dee (2005) found that counties with Catholic high schools actually have lower voter-turnout rates. Nonetheless, Dee (2005) also estimated the degree of potential bias directly by assessing how the instrumental variable influenced the adult civic outcomes among students for whom the presence of Catholic high schools was largely irrelevant (e.g., those attending public school for eighth grade). The results provided no evidence of statistically significant bias from this approach. However, at least two other caveats with regard to this study are relevant. First, due to data constraints, this study did not provide any evidence on how Catholic schools influenced other key civic outcomes, such as tolerance and support for democratic values. Second, it is not clear whether the apparent civic advantage of Catholic high schools generalizes to other types of private schools.

Nonetheless, this evidence indicates that public schools are not as effective as they could be with regard to fostering voter participation in adulthood. Interestingly, the relative ineffectiveness of public schools does not appear to be due solely to being less effective at promoting educational attainment. More specifically, the estimated effectiveness of Catholic schools in promoting high school completion combined with the estimated effects of completing high school on civic outcomes explains less than half of the apparent Catholic school advantage (Dee, 2005). These effect-size comparisons imply that other factors, such as social capital within school communities and instructional practices, play an important role in the relative success of Catholic schools in increasing subsequent voter turnout.

This discussion has focused on how public and private schools promote the civic development of the students they serve. However, it should also be noted that a provocative recent study has argued that public schools play a critical role in sustaining and promoting civic engagement among adults in their communities (Fischel, 2006). More specifically, this study argues that local public schools provide an important complement to local social capital by facilitating connections among parents that, in turn, lower the transaction costs involved in a variety of civic activities. Some descriptive empirical evidence, such as the correlation between the levels of social capital and the presence of smaller school districts, is consistent with this

claim (Fischel, 2006). This study also suggests that the extensive use of private-school vouchers would harm the production of social capital and civic engagement by dispersing students from their communities and increasing the social isolation of neighboring parents.

Summary and Future Directions

Investments in schooling appear to lead to substantial increases in voter participation and civic awareness, although not necessarily in volunteering. As it is not clear how to monetize improvements in civic engagement, the exact implications of these results for the social rate of return to education are not clear. Nonetheless, these results confirm the conventional wisdom that what occurs within schools and classrooms plays a vitally important role in the civic development of students. Furthermore, the existence of some civic externalities provides an important motivation for policies designed to promote high school completion and to expand access to higher education.

However, the limited evidence that is available also suggests that public schools are inferior to Catholic schools with respect to promoting adult voter participation and, possibly, other dimensions of civic engagement. These comparative results imply that public schools are, on average, underperforming with regard to one of their core goals. Therefore, the identification of educational policies and practices that are effective at promoting civic engagement will undoubtedly address an important policy need. One prominent way in which schools have been increasingly embracing their civic missions is through the encouragement of volunteer activity among students. A key argument made in support of promoting or requiring community service among students is that early engagement with volunteering may create lifelong volunteers. However, there is little in the way of credible evidence that these efforts have actually been effective in promoting sustained civic engagement. In particular, the evidence on college-level initiatives to promote volunteering and service learning is largely descriptive (Dee, 2008). Furthermore, a recent study examined the effect of Maryland's mandatory community-service requirement for high school graduates and found that it influenced only the timing, and not the overall level, of volunteering (Helms, 2007).

Glossary

Externality – An effect on others not considered by the individual decisionmaker.

General educational development (GED) – A test that may be taken in the U.S. by high-school dropouts that is meant to serve as an equivalent to high-school completion.

Human capital – An individual's skills or productivity as acquired through schooling, training, prior work, or other types of investment activities.

Social benefits – Benefits to society as a whole, including the individual decisionmaker and others.

Introduction

This article analyzes the relationship between education and crime. The article describes a number of important factors that may drive this correlation, and reviews the current empirical literature on the interrelationship between education and crime. The article concludes with a discussion of the social savings from crime reduction associated with increasing high-school graduation rates.

The Economics of Education and Crime

This section discusses a number of factors that may contribute to a correlation between education and crime. Many of these points are more formally analyzed in Lochner (2004), who takes a human capital approach to analyzing the relationship between education and crime. (Lochner also argues that the age–crime profile may be partially explained by the accumulation of human capital over the lifecycle.) This framework assumes that education (as well as job training) develops formal labor-market skills, which raises the opportunity costs of crime commission. Education may also develop criminal skills, although this is only likely to be important for certain white-collar crimes. Alternatively, education may socialize individuals such that they prefer not to engage in crime.

The Effects of Education on Subsequent Crime Among Adults

There is a relatively large literature linking wages and unemployment rates to criminal behavior. Recent studies

conclude that crime is increasing in local unemployment rates and decreasing in wage rates (e.g., Raphael and Winter-Ebmer, 2001; Gould *et al.*, 2002; Machin and Meghir, 2004). To the extent that education increases wage rates (and reduces the likelihood of unemployment), it increases the opportunity costs of crime and will tend to reduce postschool criminal activity. Higher wages raise the opportunity costs of crime in two distinct ways. First, since crime may require time to commit, that time cannot be used for other productive purposes like work. Here, it is useful to think of all of the time involved in planning a crime, locating a target, and, potentially, evading detection and arrest. Second, each crime committed entails an expected period of incarceration, which is more costly for individuals with better labor-market opportunities and wages.

On the one hand, property crimes such as burglary, auto theft, and drug dealing can involve significant planning or time spent on the actual activity itself. On the other hand, violent crimes such as assault would appear to require less time for planning and execution but are associated with higher expected probabilities of arrest, conviction, and incarceration as well as longer sentence lengths conditional on incarceration. For example, Lochner (2004) calculates that for each assault, the perpetrator can expect to spend 63 days incarcerated; however, the expected incarceration period for a burglary is only 13 days. These time costs would appear to exceed the direct time costs associated with committing most crimes. Thus, changes in wages or unemployment rates could have greater effects on violent crimes than on property crimes. (The estimated effects of low skill wages on violent crime are larger than on property crime for some specifications in Gould *et al.* (2002).)

Education may also affect the rewards from crime. This is most likely to be true for white-collar crimes such as fraud, forgery, and embezzlement. Education may actually increase these types of crime if it increases the rewards from crime more than it increases legitimate wages. Lochner (2004) finds some evidence that white-collar crime rates are increasing in average education levels as discussed below. To the extent that schools socialize students to become better citizens and to treat others better, education may also reduce the psychic returns to crime causing individuals to forego lucrative criminal opportunities.

Education may also teach individuals to be more patient. This will discourage crime, since forward-looking individuals place greater weight on any expected punishment associated with their criminal activities. Education may also affect preferences toward risk. To the extent that

schooling makes individuals more risk averse, it will tend to discourage crime.

Contemporaneous Crime and Education Decisions Among Youth

Youth crime will tend to be decreasing in both contemporaneous and future wage rates. Higher contemporaneous wages increase the direct opportunity cost of committing crime, while higher future wages increase the costs associated with potential incarceration. As education increases future wage rates, youth who are enrolled in school will be less likely to engage in crime than otherwise similar youth who are not in school. (Prison is costly for those who stand to earn a lot in the future — either legitimately or illegitimately. The extent to which education increases post-school criminal returns also tends to discourage youth crime. The potential to earn high rewards from white-collar crime after school may discourage youth criminal activity to avoid imprisonment.)

Schooling is not exogenously determined. Youth will choose to enrol in school if they receive a net benefit from doing so; otherwise, they will not. Not only does an increase in wages for high-school graduates or college attendees reduce crime for all youth who would have attained these schooling levels in the first place, but it also causes more youth to finish high school and attend college, lowering their lifetime criminal activity as well.

Since the benefits from schooling through higher lifetime earnings are delayed, youth who are more patient are more likely to attend school. More patient youth are also less likely to engage in crime, since the punishments tend to be delayed. Thus, differences in patience across the population will tend to lead to a negative relationship between education and crime. Population heterogeneity in preferences toward risk may also lead to a correlation between education and crime. If the rewards to school are risky as some economists suggest, more risk-averse youth will tend to quit school at earlier ages. Risk-averse youth are also more likely to engage in crime regardless of their schooling, generating a negative correlation between crime and education.

Youth who plan to commit more crime as adults will tend to benefit less from each year of school for two reasons. First, those who allocate more time to crime and less to work will benefit less from the increased wages associated with schooling (assuming schooling raises legitimate wages more than the returns from crime). Second, those who commit more crime can expect to spend more time in prison, a place which offers little reward to additional schooling. As a result, education decisions may depend on factors that affect the returns to or costs of crime. For example, a higher return to crime or more favorable treatment to prisoners will encourage criminal activity and, therefore, lower the returns from schooling.

The effects of a reduction in arrest or incarceration rates on schooling are less clear. On the one hand, a reduction in the probability of incarceration directly increases the value of schooling holding criminal activity constant. On the other hand, a lower incarceration probability encourages crime, which reduces the value of education. In general, criminal abilities/opportunities and law enforcement policies should affect the schooling decisions of marginal youth.

The role of peers or social networks may also be important determinants of crime and educational attainment. Youth who drop out of school may be influenced by a more negative set of peers, which may exacerbate any tendencies to engage in crime. Similarly, youth who join gangs or who otherwise engage in crime may be encouraged to leave school by their peers. Crime, or arrest and incarceration, may also come with a stigma which makes school more difficult, an issue we discuss briefly in the following section.

All of these factors suggest that youth will tend to make an early choice between little education and a life of street crime or a good education and a largely crime-free life. Education does not pay if one intends to participate in gang life, selling drugs, and engaging in other criminal activity. The fact that such a lifestyle is also likely to come with substantial periods of incarceration further reduces any potential benefits from schooling. At the same time, youth in neighborhoods with poor schools or that offer few jobs even to those who do finish high school are likely to find the street life relatively attractive. Social networks and peers are likely to strengthen these forces.

Empirical Evidence on Crime and Education

The empirical literature on education and crime has focused almost exclusively on the effects of educational attainment on postschool criminal activity; however, a few studies have attempted to estimate the effects of school enrolment on contemporaneous crime. Given the simultaneity of enrolment and crime choices (do youth drop out of school because they want to sell drugs all day or do they sell drugs because they dropped out of school?), this is a particularly daunting task and one that is often ill-defined. Recently, a few studies have attempted to estimate the effects of youth arrest and incarceration on educational outcomes. Studies that attempt to estimate the effects of law enforcement policies or criminal opportunities on educational decisions are virtually nonexistent. We briefly summarize the current state of empirical evidence on these issues.

The Effects of Education on Crime

We have discussed four primary reasons schooling might affect crime: (1) education raises wage rates, which raises

the opportunity costs of crime; (2) education may directly affect the financial or psychic rewards from crime; (3) education may alter preferences for risk taking or patience; and (4) schooling may affect the social networks or peers of individuals. For most crimes (except, possibly, white-collar crimes), one would expect these forces to induce a negative effect of schooling on crime.

Empirically, there is a strong negative correlation between educational attainment and various measures of crime. Freeman (1996) points out that more than two-thirds of all incarcerated men in 1993 had not graduated from high school. In the 1980 wave of the National Longitudinal Survey of Youth (NLSY), 34% of all men aged 20–23 with 10 or 11 years of completed schooling self-reported earning some income from crime, compared with 24% of those with a high-school degree, and only 17% of those with more than 12 years of school (Lochner, 2004). Similar differences are evident for other self-reported measures of both violent and property crime.

Early studies of the relationship between education and crime focused on their correlation conditional on measured individual and family characteristics using multivariate regression methods. For example, Witte and Tauchen (1994) find no significant relationship between educational attainment and crime after controlling for a number of individual characteristics. Grogger (1998) estimates a significant negative effect of wages on crime, but he finds no relationship between years of completed schooling and crime after controlling for individual wage rates. Of course, increased wages and earnings are important consequences of schooling. Thus, this study suggests that education may indirectly reduce crime through increased wage rates. (Gottfredson (1985), Farrington *et al.* (1986), and Witte and Tauchen (1994) explore the link between time spent in school and contemporaneous crime, concluding that time spent in school significantly reduces criminal activity. This type of analysis is particularly difficult to interpret given the simultaneous nature of the crime and schooling choices.)

These earlier studies must be interpreted with caution. A negative correlation between education and crime, even after controlling for measured family background and neighborhood characteristics, does not necessarily imply that education reduces crime. Standard regression studies are unlikely to estimate the causal effect of education on crime (i.e., the effect increasing someone's schooling on his criminal activity) for a number of reasons. First, unobserved individual characteristics such as patience or risk aversion are likely to directly affect both schooling and criminal decisions. Individuals who choose more schooling (even after conditioning on observable characteristics) might also choose less crime regardless of their education level, in which case regression-based estimates do not identify the causal effect of schooling on crime. Second, using variation in crime and education across states or

local communities may also produce biased estimates. Governments may face a choice between funding law enforcement and good public schools, which would tend to produce a spurious positive correlation between education and crime. Alternatively, unobserved characteristics about communities or their residents may directly affect the costs or benefits of both education and crime. For example, communities with few job opportunities that reward schooling may also be faced with severe gang problems. While it is often possible to account for permanent unobserved differences across communities by examining the relationship between changes in schooling and crime over time, such an approach cannot account for the effects of changing unobserved community characteristics. Third, reverse causality is another important concern, in which case traditional regression estimates may be confounded by the effect of criminal activity on schooling. Individuals who plan to heavily engage in crime (e.g., because they are particularly good at it, enjoy it, or live in areas with plenty of illicit opportunities) are likely to choose to leave school at a young age. Arrests or incarceration associated with juvenile crime may also cause some youth to drop out of school early. Finally, it is difficult to measure crime itself; instead, researchers are often forced to use measures of arrest or incarceration rather than actual crimes committed. It is possible that education reduces the probability of arrest and incarceration or the sentence lengths administered by judges. Estimates based on measures of arrest or incarceration will incorporate these effects in addition to any effects of education on actual crime.

Recently, economists have attempted to address these difficult issues through the use of instrumental variable (IV) estimation methods. In the context of estimating the effect of educational attainment on crime, an instrument is valid if it induces variation in schooling but is uncorrelated with other factors that directly affect criminal behavior (e.g., individual preferences or abilities). Intuitively, this approach exploits differences in educational attainment across individuals that arise in response to factors that have no direct effect on criminal decisions. An ideal instrument would randomly assign some youth to drop out of high school and others to finish high-school. Then, comparing the differences in crime rates across these groups would identify the causal effect of high-school completion on crime. In practice, we typically do not observe such perfect experiments, but researchers can sometimes come close.

Lochner and Moretti (2004) use changes in state-specific compulsory schooling laws over time as an IV for completed schooling to estimate the effects of education on arrest rates and the probability of incarceration among adult men. Intuitively, they measure the extent to which an increase in a state's compulsory schooling age leads to an immediate increase in educational attainment and reduction in subsequent crime rates for affected cohorts. This identifies the causal effect of schooling on

crime as long as the changes in compulsory schooling laws are not related to changes in the underlying propensity to commit crime. Lochner and Moretti's (2004) analysis suggests that changes in compulsory schooling laws are exogenous and not related to prior trends in schooling or state expenditures on law enforcement; so it appears to be a valid instrument.

Lochner and Moretti (2004) first use individual-level data on incarceration and schooling from the 1960, 1970, and 1980 US censuses to estimate the effects of educational attainment on the probability of imprisonment separately for black and white men. Their estimates control for age of the respondent (3 year age categories), state of birth, state of residence, cohort of birth, and state-specific year effects. Most importantly, controlling for state-specific year effects allows for the possibility that different states may have different time trends for law enforcement policies or may simply exhibit different trends in aggregate criminal activity. Identification comes from the fact that in any given state and year, different age cohorts will have faced different compulsory schooling laws during their high-school years, causing them to acquire different levels of schooling and to commit crime at different rates. Interestingly, both ordinary least squares (OLS) and IV estimates are very similar and suggest that, on average, an extra year of school reduces the probability of imprisonment by slightly more than 0.1 percentage point for whites and by about 0.4 percentage points for blacks. Given the probability of incarceration for male whites without a high-school degree averaged 0.83% across all three censuses and the incarceration rate for male black dropouts was 3.6%, these effects are sizable. OLS results suggest that completion of the 12th grade causes the greatest drop in incarceration, while their is little effect of schooling beyond high school.

In their analysis of male arrest rates, Lochner and Moretti (2004) use state-level arrest rates by criminal offense and age (5 year age categories beginning at ages 20–24 through 55–59) from the Federal Bureau of Investigation (FBI)'s Uniform Crime Reports (UCR) for 1960, 1970, 1980, and 1990. These data are linked to 1960–1990 US Census data on educational attainment and race to estimate regressions of the form:

$$\ln(A_{cast}) = \beta E_{ast} + \gamma B_{ast} + d_{st} + d_{sc} + d_{sa} + d_{ct} + d_{at} + d_{ac} + \varepsilon_{cast} \quad [1]$$

where $\ln(A_{cast})$ is the logarithm of the male arrest rate for crime c , age group a , in state s in year t (from UCR); E_{ast} is either average education or the high-school graduation rate for males in age group a in state s at time t (from Census); B_{ast} is the percent of males that are black in age group a in state s at time t (from Census). They analyze arrest rates for the following crimes: murder, rape, assault, robbery, burglary, larceny, auto theft, and arson. In using log arrest rates, the effect of education on arrest rates is assumed to be the same in percentage terms for all types of crime.

The d 's in eqn [1] represent indicator variables that account for unobserved differences across states, years, cohorts, and criminal offense types. The term d_{st} allows for state-specific time effects, which is more general than including time-varying observable state-level variables reflecting differences in public spending, economic conditions, or law enforcement. The inclusion of d_{sc} allows the distribution of crimes or arrests across states to differ. Some states may focus arrests more heavily on one type of crime, while others focus on other types. Furthermore, the age distribution of arrestees need not be the same across states – some age groups may be more prone to commit crimes in some states or the arrest policy with respect to age may differ across states. The term d_{sa} absorbs long-run differences in age–arrest patterns across states. Crime-specific and age-specific trends in arrest common to all states are accounted for by d_{ct} and d_{at} , respectively. Finally, d_{ac} accounts for long-term differences in age–crime profiles across different types of criminal offenses.

Using OLS, Lochner and Moretti (2004) estimate that a 1-year increase in average education levels in a state reduces state-level arrest rates by 11%. IV estimates suggest slightly larger effects, although they are not statistically different. These estimated effects are very similar to the predicted effects derived from multiplying the estimated increase in wages associated with an additional year of school by the estimated effects of higher wage rates on crime (Gould *et al.*, 2002). This suggests that much of the effect of schooling on crime may come through increased wage rates and opportunity costs. Using OLS, Lochner and Moretti (2004) also estimate separate effects of education for different types of crime. These results suggest similar effects across the broad categories of violent (murder, rape, robbery, and assault) and property (burglary, larceny, motor vehicle theft, and arson) crime — a 1-year increase in average years of schooling reduces both property and violent crime by about 11–12%. However, the effects vary considerably within these categories. A 1-year increase in average years of schooling reduces murder and assault by almost 30%, motor vehicle theft by 20%, arson by 13%, and burglary and larceny by about 6%. Estimated effects on robbery are negligible, while those for rape are significantly positive. This final result is surprising and not easily explained by standard economic models of crime. (However, it is consistent with evidence in Gould *et al.* (2002), which suggests that local wage rates are positively correlated with local rape crime rates.)

Lochner (2004) follows a similar approach to estimate the effects of average schooling levels on arrest rates for white-collar crime (forgery and counterfeiting, fraud, and embezzlement) using UCR and Census data from 1960, 1970, and 1980. In contrast to the results for violent and property crimes, he estimates a positive, though statistically insignificant, effect of schooling on white-collar arrest rates.

One obvious concern with these studies is their use of arrest and incarceration as measures of crime. It is possible that education improves the chances that someone evades arrest or conviction or that judges tend to give more educated defendants lighter prison sentences. While there is little direct evidence on these issues, Mustard (2001) finds negligible effects of defendant education levels on the sentence lengths they receive. Furthermore, results using self-reported measures of criminal activity in the National Longitudinal Survey of Youth (NLSY) support the case that education reduces actual violent and property crime and not just the probability of arrest or incarceration conditional on crime (Lochner, 2004, Lochner and Moretti, 2004).

A growing body of evidence suggests that early childhood interventions can also substantially reduce adult crime rates. Most famously, the High/Scope Perry Preschool Program for disadvantaged minority children measured lifetime arrests for randomly assigned participants and nonparticipants. While 55% of all nonparticipants were arrested five or more times through age 40, only 36% of the preschool participants had been arrested that often (Schweinhart *et al.*, 2005). The Syracuse Family Development Program also produced large reductions in delinquency (Lally *et al.*, 1988). These findings lead Donohue and Siegelman (1998) to conclude that small, rigorous early intervention programs may pay for themselves through reduced crime rates alone, if they can be targeted to high-crime groups.

A provocative recent study by Jacob and Lefgren (2003) explores the contemporaneous effects of school attendance on juvenile crime rates. To identify these effects, the study uses exogenous variation in teacher in-service days across jurisdictions over time, essentially comparing local juvenile crime rates on days when school is not in session to those when it is in session. Their findings suggest that school attendance reduces contemporaneous juvenile property crime while increasing juvenile violent crime. These results are consistent with an incapacitation effect of school that limits participation in property crime. However, the increased level of interaction among adolescents facilitated through schools may raise the likelihood of violent conflicts after school. It is important to distinguish between the contemporaneous effects of school attendance and crime estimated in this study from the effects of educational attainment on subsequent crime estimated by Lochner and Moretti (2004) or Lochner (2004). There is no logical inconsistency between the findings of these studies.

The Effects of Arrest and Incarceration on Education

Hjalmarsson (2006) empirically examines the effects of juvenile arrests and incarceration (through age 16) on

high-school completion by age 19. Her main specifications control for youth cognitive achievement, juvenile criminal activity, and family background. She also considers additional models that account for state or family fixed effects to account for differences in state-level juvenile law enforcement and education policies as well as differences in family (and, therefore, neighborhood) environments. Her regression-based estimates suggest substantial effects of both arrest and incarceration on subsequent schooling attainment; however, she finds that her estimated effects for arrest may be largely due to unobserved heterogeneity across youth. Her findings for juvenile incarceration are more robust and suggest that youth who become incarcerated, holding their juvenile criminal activity and arrest rates constant, are roughly 25 percentage points less likely to complete high school by age 19 than similar youth who are not arrested.

Hjalmarsson (2006) next explores a number of mechanisms that may generate an effect of incarceration on schooling. First, she finds that the effects are substantially larger for parochial school students than public school students. Second, she finds that incarceration has its greatest effects on high-school graduation when the sentence overlaps with the school year; however, the length of the sentence does not affect the probability of graduation. Finally, she finds that incarceration has substantially larger effects on high-school completion in states that require the justice system to notify schools of an arrest when compared with other states that do not require notification. All of this evidence suggests that teachers and/or administrators may treat students differently if they are known to have been incarcerated. Thus, juvenile incarceration may carry a negative stigma in schools, just as it appears to in the labor market.

Education and Training in Prison

Vast majority of US correctional facilities offer some form of education and training for prisoners, with General Educational Development (GED) preparation courses being the most common. To the extent that prison education programs help build valuable market skills (in the same way traditional schools do), we would expect them to increase postrelease earnings and reduce recidivism. Unfortunately, convincing empirical studies on this topic are scarce, primarily because prisoners who choose to enrol in prison education programs likely differ from those choosing not to enrol. Tyler and Kling (2006) attempt to account for these differences through a rich set of prisoner characteristics (e.g., sentence length, marital status and number of dependents, employment status prior to arrest, offense type, and a measure of cognitive ability), comparing the postrelease earnings of prisoners who received a GED in prison with similar high-school dropout prisoners who did not. They further account for prisoner differences by

controlling for preprison earnings. Their findings suggest that a GED earned in prison offers no postrelease earnings benefit for white offenders, but it does increase the earnings of minority offenders for the first 2 years after release (by about \$800 per year). The earnings benefits for minorities fade quickly after the second year and are no longer statistically significant.

Conclusions

To the extent that education reduces crime, schooling may have important externalities and social benefits that are not taken into account by individuals. When making their schooling decisions, youth may not consider the important negative costs they impose on society if they choose to drop out of high school in favor of a life of crime. Thus, policies to promote schooling may benefit society through reduced crime, in addition to the more obvious gains from increased productivity. Lochner and Moretti (2004) estimate that a 1% increase in high-school graduation rates would save the US economy nearly \$2 billion from reduced costs associated with criminal activity. (All social savings figures are reported in year 2006 dollars.) The social savings per additional male graduate from crime reduction alone amounts to \$1600–2900, or 14–26% of the private return to individuals from increased earnings.

Education and Economic Growth

E A Hanushek, Stanford University, Stanford, CA, USA

L Wößmann, University of Munich, Munich, Germany

© 2010 Elsevier Ltd. All rights reserved.

Education has long been viewed as an important determinant of economic well-being. The theoretical growth literature emphasizes at least three mechanisms through which education may affect economic growth. First, education can increase the human capital inherent in the labor force, which increases labor productivity and thus transitional growth toward a higher equilibrium level of output (as in augmented neoclassical growth theories, cf. Mankiw *et al.* (1992)). Second, education can increase the innovative capacity of the economy, and the new knowledge on new technologies, products, and processes promotes growth (as in theories of endogenous growth, cf., e.g., Lucas (1988), Romer (1990), Aghion and Howitt (1998)). Third, education can facilitate the diffusion and transmission of knowledge needed to understand and process new information and to successfully implement new technologies devised by others, which again promotes economic growth (cf., e.g., Nelson and Phelps, 1966; Benhabib and Spiegel, 1994).

Despite these theoretical predictions, the empirical evidence on the impact of education on economic growth has long been mixed. In large part, this seems to reflect measurement problems. Most people would acknowledge that a year of schooling does not produce the same cognitive skills everywhere. They would also agree that families and peers contribute to education. Health and nutrition further impact cognitive skills. Yet, until recently, research on the economic impact of education – largely due to expedience – has almost uniformly ignored these aspects. Recent research shows that ignoring differences in the quality of education significantly distorts the picture of how educational and economic outcomes are related.

Early Studies of Schooling Quantity and Economic Growth

The majority of the macroeconomic literature on economic returns to education employs measures of the quantity of schooling. The most common measure is years of schooling, averaged across the working-age population. (Woessmann (2003) surveys issues of measuring and specifying human capital from early growth accounting to current cross-country growth regressions.) The standard method of estimating the effect of education on economic growth is to estimate cross-country growth regressions where average annual growth in gross domestic product

(GDP) per capita over several decades is expressed as a function of measures of schooling and a set of other variables deemed important for economic growth.

Following the classical contributions by Barro (1991, 1997) and Mankiw *et al.* (1992), a vast early literature of cross-country growth regressions tended to find a significant positive association between quantitative measures of schooling and economic growth. Extensive reviews of the literature are found in Topel (1999), Temple (2001), Krueger and Lindahl (2001), and Sianesi and Van Reenen (2003). To provide an idea of the robustness of the basic association, primary schooling turns out to be the most robust influence factor (after an East Asian dummy) on growth in GDP per capita in 1960–1996 in the extensive robustness analysis of 67 explanatory variables in growth regressions on a sample of 88 countries by Sala-i-Martin *et al.* (2004).

Figure 1 provides a basic representation of the association between years of schooling and economic growth on the most recent version of available data. This research suggests that each year of schooling is associated with long-run growth that is 0.58 percentage points higher.

Yet, questions persist about the interpretation of such relationships. A substantial controversy addresses whether it is the level of years of schooling (as would be predicted by several models of endogenous growth) or the change in years of schooling (as would be predicted by basic neoclassical models) that is the more important driver of economic growth (e.g., Krueger and Lindahl, 2001). It seems beyond the scope of current data to draw strong conclusions about the relative importance of different mechanisms for schooling quantity to affect economic growth. Even so, several recent studies suggest that education is important both as an investment in human capital and in facilitating research and development and the diffusion of technologies, with initial phases of education more important for imitation and higher education for innovation (Vandenbussche *et al.*, 2006).

Two more skeptical studies raise caveats. Bills and Klenow (2000) raise the issue of causality, suggesting that reverse causation running from higher economic growth to additional education may be at least as important as the causal effect of education on growth in the cross-country association. Pritchett (2001, 2006) raises questions about the plausibility of simple growth models with years of schooling and stresses that it is important for economic growth to get other things right as well,

Figure 1 Association between years of schooling and long-run economic growth. Added-variable plot of a regression of the average annual rate of growth (in percent) of real GDP per capita in 1960–2000 on average years of schooling in 1960 and the initial level of real GDP per capita in 1960.

in particular the institutional framework of the economy. Both issues are discussed further below.

However, most importantly, using average years of schooling as an education measure implicitly assumes that a year of schooling delivers the same increase in knowledge and skills regardless of the education system. This measure also assumes that formal schooling is the primary source of education and that variations in the quality of nonschool factors affecting learning have a negligible effect on education outcomes. This neglect of cross-country differences in the quality of education is the major drawback of such a quantitative measure.

Initial Evidence on the Quality of Education and Economic Growth

Quite clearly, the average student in Ghana or Peru does not gain the same amount of knowledge in any year of schooling as the average student in Finland or Korea; however, using measures of years of schooling assumes that they are equivalent. In addition, using years of schooling implicitly assumes that all skills and human capital come from formal schooling. Yet, extensive evidence on knowledge development and cognitive skills indicates that a variety of factors outside of school – family, peers, and others – have a direct and powerful influence. Ignoring these nonschool factors introduces another element of measurement error into the growth analyses.

Since the mid-1960s, international agencies, such as the International Association for the Evaluation of Educational Achievement (IEA) and the Organization for Economic Co-operation and Development (OECD), have conducted many international tests – such as the Trends in International Mathematics and Science Study (TIMSS), the Programme for International Student Assessment (PISA), and their predecessors – of student performance in cognitive skills mathematics, involving science, and other subjects. In order to make performance on a total of 36 international tests from 12 testing occasions comparable, Hanushek and Woessmann (2009) develop a common metric to adjust both the level of test performance and its variation through two data transformations. First, each of the separate international tests is benchmarked to a comparable level by calibrating the US international performance over time to the external standard of the available US longitudinal test (the National Assessment of Educational Progress, NAEP). Second, the dispersion of the tests is standardized by holding the score variance constant within a group of 13 OECD countries with relatively stable secondary school attendance rates over time.

Figure 2 reports average performance at the standardized tests, which serves as a proxy for the quality of education. The variation in the quality of education that exists among OECD countries is already substantial, but the difference from developing countries in the average amount of learning acquired after a given amount of

schooling dwarfs any within-OECD difference. Outside of East Asia, nearly every developing country that participated in one of the tests performed dramatically lower than any OECD country (except Mexico).

Over the past 10 years, growth research demonstrates that considering the quality of education, measured by the cognitive skills learned, dramatically alters the assessment of the role of education in economic development. Using

the data from the international student achievement tests through 1991 to build a measure of educational quality, Hanushek and Kimko (2000) find a statistically and economically significant positive effect of the quality of education on economic growth in 1960–1990 that is far larger than the association between the quantity of schooling and growth. Ignoring quality differences very significantly misses the true importance of education for economic

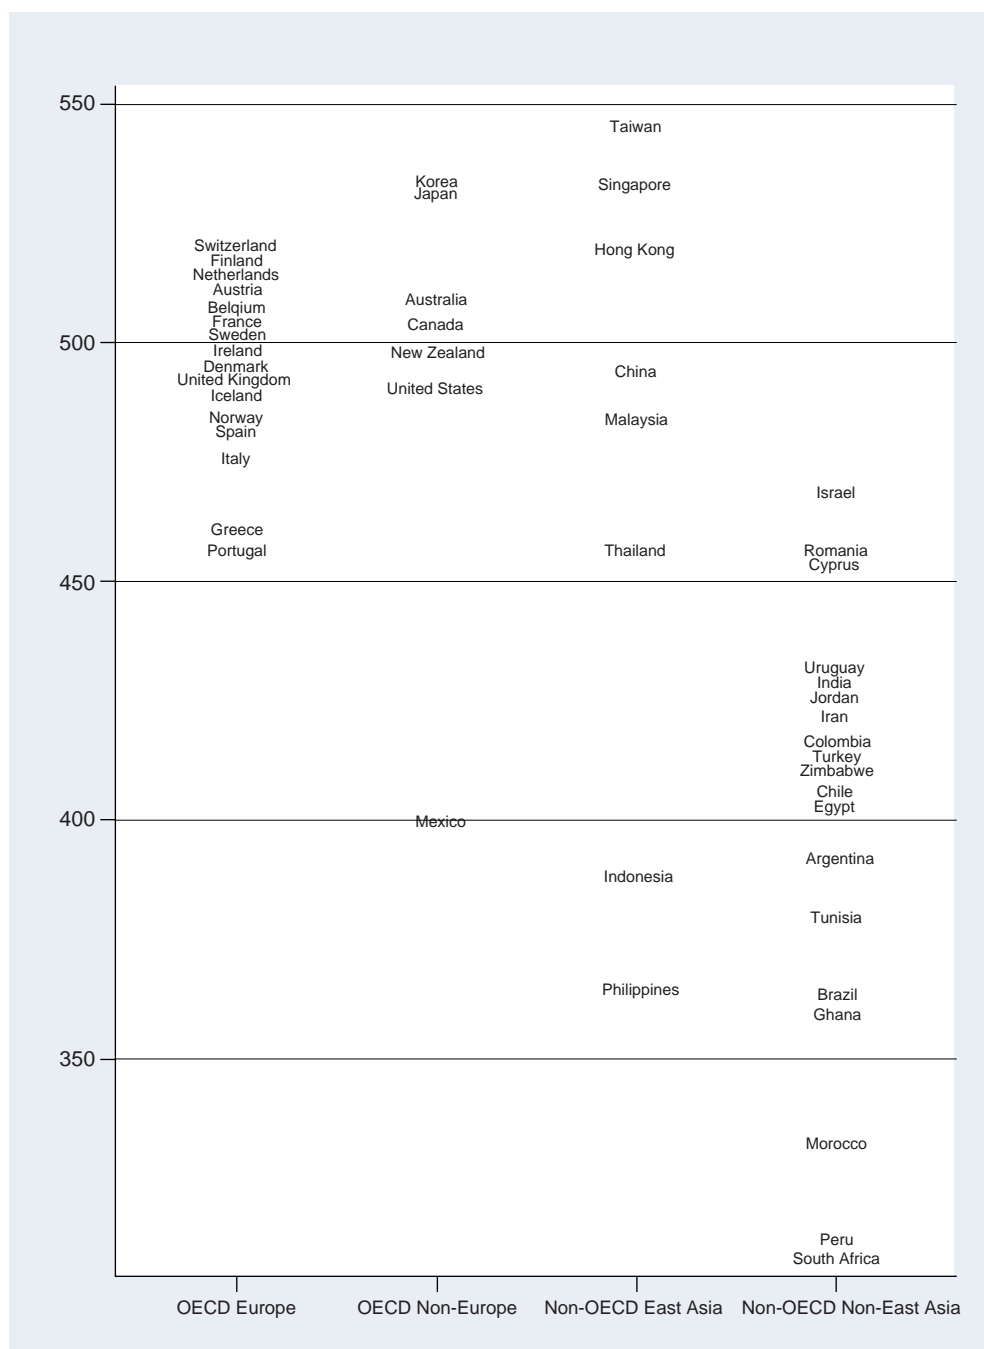

Figure 2 Performance on international student achievement tests. Simple average of the mathematics and science scores over all available international tests, using the rescaled data by Hanushek and Woessmann (2009) that puts performance at different international tests on a common scale.

growth. Their estimate suggest that one country-level standard deviation higher test performance (equivalent to 47-test-score points on the scale used in (Figure 2) would yield about one percentage point higher annual growth.

This estimate stems from a statistical model that relates annual growth rates of real GDP per capita to the measure of educational quality, years of schooling, the initial level of income, and several other control variables (including, in different specifications, the population growth rates, political measures, openness of the economies, and the like). Adding educational quality to a base specification including only initial income and educational quantity boosts the variance in GDP per capita among the 31 countries in Hanushek and Kimko's sample that can be explained by the model from 33% to 73%. The effect of years of schooling is greatly reduced by including quality, leaving it mostly insignificant. At the same time, adding the other factors leaves the effects of cognitive skills basically unchanged.

Several studies have since found very similar results, including Barro (2001), Woessmann (2002, 2003), Bosworth and Collins (2003), Coulombe and Tremblay (2006), and Jamison *et al.* (2007). In sum, the evidence suggests that the quality of education, measured by the knowledge that students gain as depicted in tests of cognitive skills, is substantially more important for economic growth than the mere quantity of schooling.

Recent Evidence on the Importance of Cognitive Skills for Economic Growth

The most recent evidence by Hanushek and Woessmann (2008, 2009) adds international student achievement tests not previously available and uses the most recent data on economic growth to analyze an even longer period (1960–2000). It extends the sample of countries with available test-score and growth information to 50 countries. These data are also used to analyze effects of the distribution of educational quality at the bottom and at the top on economic growth, as well as interactions between educational quality and the institutional infrastructure of an economy.

The measure of the quality of education is a simple average of the mathematics and science scores over international tests, interpreted as a proxy for the average educational performance of the whole labor force. This measure encompasses overall cognitive skills, not just those developed in schools. Thus, whether skills are developed at home, in schools, or elsewhere, they are included in the growth analyses.

After controlling for the initial level of GDP per capita and for years of schooling, the test-score measure features a statistically significant effect on the growth of real GDP per capita in 1960–2000 (Figure 3). According to this simple specification, test scores that are larger by 1 SD

(measured at the student level across all OECD countries in PISA) are associated with an average annual growth rate in GDP per capita that is two percentage points higher over the whole 40-year period which is almost identical to the prior estimates in Hanushek and Kimko (2000).

Adding educational quality to a model that just includes initial income and years of schooling increases the share of variation in economic growth explained from 25% to 73%. As reported above, the quantity of schooling is statistically significantly related to economic growth in a specification that neglects educational quality, but the association between years of schooling and growth turns insignificant and is reduced to close to zero once the quality of education is included in the model (Figure 4). In addition, considering the variation just within each of five world regions, educational quality is significantly related to economic growth, indicating that it does not simply reflect economic differences across regions.

Recent literature on the determinants of economic growth emphasizes the importance of the institutional framework of the economy (e.g., Acemoglu *et al.*, 2001, 2002). The most common and powerful measures of the institutional framework used in empirical work are the openness of the economy to international trade and the security of property rights. These two institutional variables are jointly highly significant when added to the model. However, the positive effect of educational quality on economic growth is very robust to the inclusion of these controls, albeit slightly reduced in magnitude to 1.26 percentage points annual growth per standard deviation of cognitive skills.

Other possible determinants of economic growth often discussed in the literature are fertility and geography. However, when the total fertility rate and common geographical proxies, such as latitude or the fraction of the land area located within the geographic tropics, are added to the model, neither is statistically significantly associated with economic growth.

The results are remarkably similar when comparing the sample of OECD countries to the sample of non-OECD countries, with the point estimate of the effect of educational quality slightly larger in non-OECD countries. When the sample is separated based on whether a country was below or above the median of GDP per capita in 1960, the effect of educational quality is statistically significantly larger in low-income countries than in high-income countries (cf. Hanushek and Woessmann, 2009).

Among the developing countries, the conclusion is that once there is a high-quality school system, it pays to keep children in school longer – but it does not pay if the school system does not produce skills.

The results are very robust to alternative specifications of the growth relationships. For example, the impact of

Figure 3 Test scores and long-run economic growth. Added-variable plots of a regression of the average annual rate of growth (in percent) of real GDP per capita in 1960–2000 on the initial level of real GDP per capita in 1960, average test scores on international student achievement tests, and average years of schooling in 1960. Calculations from Hanushek, E. A. and Woessmann, L. (2008).

Figure 4 Years of schooling and economic growth after controlling for test scores. Added-variable plots of a regression of the average annual rate of growth (in percent) of real GDP per capita in 1960–2000 on the initial level of real GDP per capita in 1960, average test scores on international student achievement tests, and average years of schooling in 1960. Calculations from Hanushek, E. A. and Woessmann, L. (2008).

cognitive skills remains qualitatively the same when measured just by the tests performed at the level of lower secondary education, which seems the most readily comparable level. The results are also robust to performing the analyses in two subperiods, 1960–1980 and 1980–2000, and to dropping East Asian countries (which have both high levels of cognitive skill and rapidly growing economies).

All in all, the results do not appear to be an artifact of the specific time period, set of countries, or achievement measurement decisions.

Results are also confirmed when looking at whether a country's estimated cognitive skills affect the earnings of immigrants working in the United States. Higher home-country cognitive skills translate into higher earnings

if the immigrants were educated in their homeland, but not if educated in the United States (cf. Hanushek and Woessmann, 2009, for details). By looking at workers on the same labor market, this analysis addresses several issues of endogeneity, excluding the possibility that the results might be driven by other attributes of the countries that affect growth, such as efficient market organizations, which may also be associated with efficient and productive schools.

The Interaction of Educational Quality with Economic Institutions

Economic institutions appear to interact with the effect of educational quality on economic growth. The institutional framework of a country affects the relative profitability of piracy and productive activity. If the available knowledge and skills are used in the former activity rather than the latter, the effect on economic growth may be very different, perhaps even turning negative (North, 1990). The allocation of talent between rent-seeking and entrepreneurship matters for growth: countries with more engineering students grow faster and countries with more law students grow more slowly (Murphy *et al.*, 1991). Education may not have much impact in less-developed countries that lack other facilitating factors such as functioning institutions for markets and legal systems (Easterly, 2001). Besides, due to deficiencies in the institutional environment, cognitive skills might be applied to socially unproductive activities in many developing countries (Pritchett, 2001).

Adding the interaction of educational quality and one institutional measure – openness to international trade – to the growth specification indicates not only that both have significant individual effects on economic growth but also that there is a significant positive interaction. The effect of educational quality on economic growth is indeed significantly higher in countries that have been fully open to international trade than in countries that have been fully closed. The effect of educational quality on economic growth is significantly positive, albeit relatively low at 0.9 per SD in closed economies but increases to 2.5 per SD in open economies. When using protection against expropriation rather than openness to trade as the measure of institutional quality, there is similarly a positive interaction term with educational quality, although it lacks statistical significance.

In sum, both the quality of the institutional environment and the quality of education seem important for economic development. Furthermore, the effect of educational quality on growth seems significantly larger in countries with a productive institutional framework, so that good institutional quality and good educational quality can reinforce each other. Thus, the macroeconomic

effect of education depends on other complementary growth-enhancing policies and institutions. However, cognitive skills have a significant positive growth effect even in countries with a poor institutional environment.

Finally one issue related to institutions remains unresolved, Glaeser *et al.* (2004) suggests that human capital may itself lead to better institutions: as, such, the estimates of cognitive skills without consideration of economic institutions would be appropriate.

Simulating the Impact of Educational Reform on Economic Growth

It is important to understand the implications of policies designed to improve educational outcomes. The previous estimates provide information about the long-run economic implications of improvements in educational quality. For a better understanding of the impact of improved achievement, it is useful to relate policy reforms directly to the pattern of economic outcomes consistent with feasible improvements.

As a benchmark, consider a reform that yields a 0.5 standard deviation (SD) improvement in average achievement of school completers. We can put this metric in the context of the previous estimates. Consider, for example, a developing country – such as Brazil, Indonesia, Mexico, or Thailand in PISA 2003 – with average performance at roughly 400 test-score points, approximately minimal literacy. An aggressive reform plan would be to close half the gap with the average OECD student, an improvement of one half SD. Alternatively, consider what it would mean if a country currently performing near the mean of OECD countries in PISA at 500 test-score points (e.g., Norway or the United States in PISA 2000, or Germany in PISA 2003) managed to increase its educational quality to the level of top performers in PISA at roughly 540 test-score points (e.g., Finland or Korea). Such an increase amounts to 0.4 SD.

The timing of the reform is also important in two ways. First, such movement of student performance cannot be achieved instantaneously but requires changes in schools that will be accomplished over time (say, through systematic replacement of teachers through retirement and subsequent hiring). The time frame of any reform is difficult to specify, but achieving the change of 0.5 standard deviation (SD) described above for an entire nation may take 20–30 years. Second, if the reforms succeed, their impact on the economy will not be immediate – initially the new graduates will be a small part of the labor force. It will be some time after the reform of the schools before the impact on the economy is realized. In other words, the prior estimates are best thought of as the long-run, or equilibrium, outcomes of a labor force with a given educational quality.

Faster reforms will have larger impacts on the economy, simply because the better workers become a dominant part of the workforce sooner (**Figure 5**). However, even a 20- or 30-year reform plan begun in 2005 has a powerful impact. For example, a 20-year plan would yield a GDP 5% greater in 2037 (compared with an economy with no increase in educational quality). The figure also plots 3.5% of GDP, an aggressive spending level for education in many countries of the world. A growth dividend of 5% of GDP would more than cover all primary and secondary school spending. But even a 30-year reform program (not fully accomplished until 2035) would still yield more than 5% higher real GDP by 2041.

Projecting these net gains from improved educational quality further past the reform period vividly shows the long-run impacts of reform. Over a 75-year horizon, a 20-year reform yields a real GDP 36% higher than without a change in educational quality.

It must nonetheless be clear that these effects represent the result from actual gains in educational outcomes. There have been many attempts around the world to improve student outcomes, and many of these have failed to yield gains in student performance. Bad reforms – those without impacts on students – will not have these growth effects.

This simulation shows that the previous estimates of the effects of educational quality on growth have large impacts on national economies. At the same time, while the rewards are large, they also imply that policies must be considered across long periods, requiring patience – patience that is not always clear in national policymaking. These reforms must also be put in a broader perspective

because other kinds of institutional changes and investments will also take time. Changing basic economic institutions, for example, seldom happens overnight, and the economy needs time to adjust.

Summary

The accumulated evidence from analyses of economic outcomes is that the quality of education – measured on an outcome basis of cognitive skills – has powerful economic effects. Economic growth is strongly affected by the skills of workers. What people know matters.

This message is important in developed and developing countries alike. In the latter, much of the discussion of development policy today simplifies and distorts this message. It recognizes that education matters, but focuses most attention on ensuring that everybody is in school – regardless of the learning that goes on. As a recent report by the World Bank Independent Evaluation Group (2006) documents, high priority was accorded to increasing primary school enrolment in developing countries over the past 15 years. Whether children were learning garnered much less attention. International testing indicates that, even among those attaining lower secondary schooling, literacy rates (by international standards) are very low in many developing countries. By reasonable calculations, many countries have fewer than 10% of their youth currently reaching minimal literacy and numeracy levels, even when school attainment data look considerably better (cf. Hanushek and Woessmann (2008) for details).

Figure 5 Simulation of the impact on GDP of moderately strong knowledge improvement. Simulation of the impact on the economy of reform policies beginning in 2005 and taking 20 or 30 years for a 0.5 SD improvement in student outcomes at the end of upper secondary schooling. The figure indicates how much larger the level of GDP is at any point after the reform policy is begun as compared to that with no reform; that is, the estimates suggest the increase in GDP expected over and above any growth from other factors. The figure also plots 3.5% of GDP, an aggressive spending level for education in many countries of the world. Even a 30-year reform program would yield a growth dividend covering the whole of this spending level by 2036. See Hanushek and Woessmann (2007) for details. From Hanushek, E. A. and Woessmann, L. (2007). The role of school improvement for economic development. *NBER Working Paper 12832*. Cambridge, MA: National Bureau of Economic Research.

Because of the reported findings – that knowledge rather than just time in school is what counts for economic growth – policies must pay more attention to the quality of schools.

Glossary

Fetal origins hypothesis – A biological theory suggesting that the environment an individual is exposed to as a fetus can have long-term effects on his or her health.

Grossman health model – A theoretical model describing how an individual's health relates to his or her previous health and choices of medical inputs, such as medical care, food, and housing.

Sibling fixed effects – A regression analysis technique that compares siblings to each other in order to remove the statistical bias due to family background.

Introduction

Investments in education pay off in the form of higher future earnings, and differences in educational attainments explain a significant fraction of the adult variation in wages, incomes, and other outcomes. But what determines a child's educational success? Most studies point to family background as the primary factor. But why does background matter? While many aspects are no doubt important, research increasingly implicates health as a potentially major factor. The importance of health for education and earnings suggests that if family background affects child health, then poor child health may in turn affect education and future economic status.

What evidence exists about the effect of parental socioeconomic status (SES) on child health? What evidence exists about the effect of child health on future outcomes, such as education? A great deal of evidence shows that low SES in childhood is related to poorer future adult health (Smith *et al.*, 1998). The specific question at the heart of this article is whether low parental SES affects future outcomes through its effects on child health. In most of the studies cited, SES is defined by parental income or poverty status, although some measure SES through residential neighborhood or parental schooling attainment. The article focuses primarily on children from developed countries because it is more obvious why the common and severe health problems of children

in many developing countries might impede human capital development.

Does Parental Socioeconomic Status Affect Child Health?

External Benefits of Parental SES

Parental SES may impact both parents' own health and the health of their children. Schooling attainment, in particular, has a stronger correlation with a parent's own good health than does income or other measures of SES (Grossman, 2007). The association between education and parents' own health is only partially explained by better health knowledge and may be better explained by the fact that more highly educated parents tend to exhibit better health behaviors. Even after controlling for income, parents with more schooling smoke less, drink less alcohol, exercise more, and work less often in dangerous occupations. They also adhere more carefully to prescribed medical therapies and are more likely to use newer medical technologies to address health problems. These tendencies may be caused by education, or they may indicate that people who plan for the future better tend both to pursue more schooling and to behave in healthier ways.

This article focuses, however, not on the internal benefits of parental SES (i.e., for parents' own health) but on the external benefits of parental SES for children's health. Through what channels might these benefits flow? In the health model presented by Grossman (2000), a health production function Q_t describes how a child's current health depends on health inputs such as medical care, food, and housing, as well as previous health levels Q_{t-1} , Q_{t-2} , etc. This is similar to an education production function that models how a child's test score depends on inputs such as teachers and textbooks as well as previous test scores. Grossman's health model yields several insights into how parental SES might affect child health. First, and perhaps most obviously, budget constraints bind more in poorer families, preventing them from buying more or better material health inputs such as better-quality medical care and food, as well as safer housing and neighborhoods.

Second, SES affects what parents choose to do with the health inputs they can afford, as parents of lower SES may have different past experiences with the healthcare system, or different health preferences, or different health beliefs (e.g., whether it is normal for a child to wheeze).

Parental education may play a particularly important role in this regard. Maternal schooling is strongly correlated with neonatal mortality rates and children's overall health, which may indicate the importance of health knowledge but is more likely explained by the association between schooling and various health behaviors (Grossman, 2007). More highly educated mothers smoke less, drink less, take more vitamins, and receive more prenatal medical care. In other words, they treat health inputs that impact their children, like cigarettes and alcohol, differently than do less-educated mothers. Once these inputs are controlled for, maternal schooling has little additional association with child health, suggesting that parental education may affect child health largely through the use of such health inputs.

Finally, children of lower SES families are likely to have lower health status at birth. This is not necessarily due to a worse genetic endowment but may stem from differing environmental triggers that activate certain genes (Rutter, 2006). Thus, a low SES child may have poor health at birth because of the circumstances surrounding gestation and birth, rather than because of worse genetic endowments. All of the above may be mechanisms through which SES affects child health.

Evidence

Correlation

Differences in the health of high and low SES children are apparent at birth. Data from Britain and California show that low SES children are more likely to have low birth weight than high SES children. Maternal reports of overall child health from the US, Britain, and Canada all show that the health gap between high and low SES children continues through early childhood and beyond (Currie *et al.*, 2007). The health gaps are smaller in Britain and Canada than in the US, perhaps due to universal health insurance coverage, but are still present.

Variations in the incidence of health insults (such as hospitalizations or new diagnoses of chronic conditions) may be of particular importance in explaining the gap in health status between rich and poor. Evidence from the US, Britain, and Canada suggests that poor children are more likely to receive health insults and suffer from chronic conditions than rich children (Currie and Lin, 2007). More than twice as many poor children than nonpoor children are reported by their mothers to be in less than very good health, a gap that increases as children age. Further, 32.4% of poor children suffer from a chronic condition, compared to 26.5% of nonpoor children, a gap that would likely be even larger if differences in diagnosis probabilities were accounted for. Such chronic conditions also limit poor children more than nonpoor children. The percentage of poor children report being limited by their chronic conditions is 11.4% as compared to 7.0% of nonpoor children. The fraction of children with a limitation

due to a chronic condition rises with age, and rises more sharply for poor children than for others. By their teenage years, poor children have almost double the probability of being limited by their chronic condition: 14.1% compared to 7.8% of nonpoor children.

Theoretical models suggest that persistent poverty is likely to have worse effects on health than transitory poverty. Although more research is needed, evidence from several studies suggests that persistent poverty affects child mental health, particularly aggressive behavior, more than current poverty (Strohschein, 2005).

Causation

The fact that children of low SES parents are less healthy on average than other children does not necessarily imply that low SES causes poor child health. A third factor such as poor parental health may, for example, cause both poverty and poor child health. Alternatively, poor child health may cause low SES by reducing parental earnings. Identifying causal effects matters very much because interventions to improve parental SES will not necessarily improve child health if parental SES does not directly affect child health. Unfortunately, relatively little literature attempts to identify causal impacts of parental SES on child health in a developed country context, perhaps because of the difficulty of finding interventions that affect parental SES but that do not also directly affect children's health. Research in this area uses one of two approaches. The first approach is to ask whether the correlation between SES and child health remains once other variables are controlled for. The second is to examine the effect of natural experiments that randomly change some parents' SES relative to a control group.

Mother's education, one measure of SES, seems to have a positive impact on child health. In the US, the great expansion of higher education in the 1960s and 1970s raised women's education levels, which in turn improved infant health as measured by birth weight and gestational age (Currie and Moretti, 2003). The effect may have occurred through increased rates of marriage and prenatal care, as well as through substantial reductions in smoking.

Income itself, as a measure of SES, seems to have relatively little effect on child health. Welfare-to-work experiments, for example, have had little impact on child health, either positive or negative. Income may, however, matter more in a developing country context. For example, black South African girls increased their height-for-age when their grandmothers started receiving old-age pensions, suggesting increased investment in nutrition (Duflo, 2000). Finally, the state of the economy may impact child health. Dutch citizens born during recessions have higher mortality rates at all ages compared to those born just prior to the recession, though the precise pathway for this effect is unclear (Van den Berg *et al.*, 2006).

Studies of American and British families find that the apparent effect of income on child mental health is considerably lessened once other factors, such as parenting skills and physical home environment, are controlled for (Berger *et al.*, 2006). Estimates from the American study suggest that even cash subsidies to bring every family up to the poverty line would not eliminate the observed gaps in child outcomes.

Neighborhoods are often said to be an important pathway for SES to affect outcomes. Some evidence on this point comes from a US social experiment that randomly assisted some public housing residents to move to low-poverty neighborhoods. This moving-to-opportunities experiment improved the mental health of girls through reductions in generalized anxiety disorders and psychological distress (Orr *et al.*, 2003). Curiously, there was no such positive effect for boys.

Some recent research has attempted to control for unobserved family background characteristics by examining children born to the same mother (i.e., estimating models with sibling fixed effects). Some studies of American mothers suggest that on average, maternal income during pregnancy does not affect the probability of having a child with low birth weight, but that it does matter if the mother herself had a low birth weight. Evidence from California birth records suggests that, even among women with the same mother, being born in a poor area increased the probability of being low birth weight and of later delivering a baby with low birth weight (Currie and Moretti, 2007). One final piece of evidence that maternal SES affects infant health comes from examination of the health improvements black women experienced as a result of the US Civil Rights movement. Infants of black women who themselves had healthier infancies as a result of the Civil Rights movement (which improved hospital access for blacks in southern states) show large gains in birth weight relative to the infants of black women born just a few years earlier (Almond *et al.*, forthcoming).

In summary, it is difficult to prove that the strong and exceedingly robust correlation between parental SES and child health is a causal relationship. The literature attempting to do so is underdeveloped. There is, however, evidence that maternal SES early in the child's life matters, and that child mental health may be particularly susceptible to the effects of early deprivation.

Does Child Health Affect Future Outcomes?

Possible Channels

Poor child health may impact adult labor supply and productivity through two channels. First, it may damage adult health. Cohorts that suffer high death rates in childhood

may also show high death rates in adulthood, in part because of the direct effects of childhood health conditions on future morbidity. In rich countries, cohorts that suffer a higher disease burden in childhood have higher adult death rates, though in poor countries the relation is reversed because only relatively healthy people survive to adulthood (Bozzoli *et al.*, 2007). In the US, adults' reports about their overall childhood health are highly correlated with current adult outcomes, a pattern that continues to hold even once family background is controlled for by comparing siblings to each other. Thus, adult siblings who had better health in childhood have 24% higher incomes, higher wealth, more weeks worked per year, and a higher growth rate of income (Smith, 2007). Comparing siblings to each other reduces the apparent effect of childhood health on future education, suggesting that childhood health may affect future income through mechanisms other than educational attainment. Sickly children may, for example, be less able to work hard as adults.

Second, poor child health may impair children's educational attainment and thus skill acquisition. Among older children, school absences may be a mechanism for health to affect education, although overall absenteeism is quite small for both poor and nonpoor children. It is more likely that poor health impacts skill acquisition by impairing children's ability to learn while they are in school. Conditions such as anemia and lead poisoning have this effect, though today they are relatively rare in developed countries. Conditions such as tooth decay and ear infections are much more common and might therefore have a greater overall impact. Mental health conditions may be a particularly important mechanism because they are common and have worse effects on schooling attainment than most physical chronic conditions.

Evidence

In developing countries, children in poor health tend to have lower educational attainments, but surprisingly little examination of this relationship has occurred in developed countries. Data on older Americans show that the apparent effect of a retrospective measure of childhood SES on future health, education, and income shrinks when child health measures are included (Luo and Waite, 2005). This result implies that child health may explain some of the impact of low childhood SES on future outcomes.

The primary deficiency of this literature is that correlations between child health and future outcomes, including those mentioned above, may be due to other characteristics of households that are associated both with poor child health and worse outcomes. Until the last decade, most studies claiming a causal connection between child health and future educational attainment suffered from methodological weaknesses, but in the past decade an outpouring of research on this topic has paid careful attention to the

causal question. The remainder of this section examines specific child health problems that may work through the two channels described above, starting with conditions *in utero* and low birth weight, for which there is much causal evidence, and continuing with nutrition, mental health, asthma, acute conditions, and environmental toxins, for which there are fewer causal studies.

Conditions in utero

Increasing numbers of studies have focused on the hypothesis that fetal conditions are related to adult risk of disease, an idea that has become known as the fetal origins or the Barker hypothesis (Barker, 1998; Gluckman and Hanson, 2005). This literature strongly suggests that conditions *in utero* affect not only birth weight but features such as basic metabolism, which in turn affect future health outcomes. Fetuses starved *in utero* may develop more efficient metabolisms that raise the risk of future obesity, heart disease, and diabetes. As adult health is strongly linked to adult economic well-being, this suggests a relationship between health *in utero* and future outcomes.

The most compelling tests of the hypothesis look for sharp exogenous shocks in fetal health caused by conditions outside the mother's control. Dutch adults who were *in utero* during the 1944–1945 famine caused by Nazi occupation were more likely to suffer various health impairments including nervous disorders, heart disease, and antisocial personality disorders. Swedes who were *in utero* when the 1986 Chernobyl disaster exposed their mothers to low-dose fallout were less likely to qualify for high school and had lower grades (Almond *et al.*, 2007). Americans who were *in utero* during the 1918 influenza epidemic were much less likely to graduate from high school, had lower wages, were more likely to be poor and receiving transfer payments, and as adults suffered more from schizophrenia, diabetes, and stroke (Almond, 2006). In general, health shocks in early life due to wars, famines, and other crises can have large, lasting effects on health.

Cognitive functioning can also be directly affected by conditions *in utero* and in infancy. For example, maternal alcohol consumption can lead to permanent brain damage, as can trauma during the birth itself. Extreme deprivation in early childhood, such as that experienced by some Romanian orphans in state-run nurseries, demonstrably impairs cognitive functioning (O'Connor *et al.*, 2000). Severe health insults *in utero* or in early childhood clearly can cause permanent cognitive impairments, but questions remain about how sensitive these sensitive periods are and whether damage due to less-extreme deprivation is noteworthy or widespread.

Birth weight

More direct evidence is provided by recent literature linking low birth weight to negative future outcomes. In the US, low-birth-weight babies have a much higher

infant mortality rate than their heavier counterparts (Conley *et al.*, 2003). They also have lower average scores on a variety of tests of intellectual and social development. British children with low birth weight have lower test scores, educational attainments, wages, and probabilities of being employed as adults, even conditional on many measures of family background (Case *et al.*, 2005).

Many of the studies exploring the effect of birth weight on future outcomes compare siblings or twins in an attempt to control for unobserved family characteristics that might otherwise bias the results. Some small-sample studies that do this in an American context conclude that siblings with lower birth weight tend to attain less education. More recently, several studies have employed individual-level national vital statistics (birth certificate) data in Canada, Norway, and Scotland to examine this question. All of these studies show a link between low birth weight and lower educational attainment, and some show a negative effect on height and intelligence, even among siblings or twins (Black *et al.*, 2007). Similar findings occur in the US, where a number of studies confirm that siblings (or twins) with lower birth weight attain less education than their higher birth-weight counterparts (Currie and Moretti, 2007). Data from the US also suggests that lower birth weight is associated with a higher probability of living in a poor area, a lower probability of being married, lower earnings, worse health, and worse cognitive abilities.

Nutrition

Nutrition may play a significant role in the child's cognitive development. Randomized trials in developing countries such as Guatemala, for example, indicate that poor nutrition can harm cognition (Maluccio *et al.*, 2006). It is less obvious that nutritional supplementation should have a large effect on the cognitive achievement of children in richer countries. Several US studies have, however, found positive effects of prenatal participation in the special supplemental nutrition program for women, infants, and children (WIC), which provides coupons that can be redeemed for specific foods to women, infants, and children who are deemed to be nutritionally at risk (Kowaleski-Jones and Duncan, 2002). Children of mothers participating in WIC had better outcomes on cognitive tests even when compared to a control group of higher income, better-educated women also receiving prenatal care in clinic settings. Children born while their mothers participated in WIC show better temperament, although not better motor or social skills, than their siblings born while their mothers were not participating. These studies underline the importance of the prenatal period.

Further evidence on the importance of nutrition comes from the fact that height is a good measure of a population's average health. Interestingly, the well-established relationship between adult height and earnings disappears when early childhood cognitive test scores are controlled for

(Case and Paxson, 2006). Since much of the variation in adult height is due to childhood nutrition, this suggests that poor childhood nutrition likely affects both cognitive performance and adult height, leading to the observed correlation between height and earnings.

Mental health

The prevalence and importance of child mental health problems have been increasingly recognized. Approximately one in five children and adolescents in the US exhibit some impairment from a mental or behavioral disorder, 11% have significant functional impairments, and 5% suffer extreme functional impairment. Moreover, mental health problems are one of the leading causes of days lost in the workplace because they strike many people of working age. Retrospective questions asked to US adults suggest that those with early-onset psychiatric problems were less likely to have graduated from high school or attended college. Children's mental health problems are usually grouped into four categories: anxiety, depression, hyperactivity, and conduct disorders (aggressive or antisocial behavior). The evidence to date suggests that these last two externalizing problems have the greatest impact on outcomes.

Children with behavioral problems in Britain and New Zealand have poorer schooling, earnings, and employment outcomes as young adults than their counterparts without such problems. Hyperactivity and conduct disorders seem to cause these negative outcomes, while anxiety and depression have little effect. US data also suggest that children with behavior problems at young ages are less likely to graduate from high school or to attend college, even after conditioning on maternal characteristics (McLeod and Kaiser, 2004). American children with attention-deficit hyperactivity disorder (ADHD) complete less schooling and are more likely to have continuing mental health problems than a group of control children consisting either of children from the same school or nonpsychiatric patients in the same medical center (Mannuzza and Klein, 2000).

Beyond adding available controls to regression models, many of these studies do not address the possibility that the negative outcomes might be caused by other factors related to a diagnosis of mental health problems, such as poverty or the presence of other learning disabilities. Recent studies address these challenges by comparing siblings, thus eliminating any family background characteristics as a source of bias (Currie and Stabile, 2006). In both the US and Canada, siblings with high scores on an ADHD screener had lower math and reading scores and higher probabilities of being in special education or having repeated a grade than their siblings with low scores on the ADHD screener. ADHD appears to have larger effects on academic outcomes than childhood depression, conduct disorders, or other mental

problems, and the effects of ADHD are large relative to those of physical chronic conditions.

Asthma

Poor children are more likely to suffer from and be limited by asthma, the most prevalent childhood chronic condition, than are nonpoor children. Though siblings with controlled asthma show no difference in achievement scores than siblings without asthma, several studies indicate that asthmatic children are more likely than similar but nonasthmatic children to have behavior problems, even when the asthma is well controlled (Calam *et al.*, 2003). Asthmatic children are absent more frequently from school, have higher incidence of learning disabilities, and repeat grades more often. They also have lower scores on a test of school readiness skills and their parents were three times more likely to report that they needed extra help with learning, particularly if children reported that their asthma caused activity limitations. These studies suffer from the deficiency that the apparent connection between asthma and outcomes could reflect omitted third factors because asthma is more prevalent among poor and minority children. The fact that several of the studies do, however, use very homogeneous groups of children and still find behavioral differences suggests that uncontrolled asthma probably does have a causal effect on behavior.

Acute illnesses

Poor children are more likely to suffer from acute illnesses such as tooth decay and ear infections than their richer peers. Ear infections affect most young children at one time or another and are the most common reason children visit a doctor. Roughly 5% of 2–4-year-old children have hearing loss because of middle-ear effusion lasting 3 months or longer. Hearing loss can delay language development, but little research has been done to determine how important these effects might be in explaining disparities in cognitive or academic outcomes.

Environmental toxins

One final category of health problems that may explain disparities in outcomes between poor and nonpoor children is exposure to environmental toxins. The most obvious of these toxins is lead, as lead poisoning has been shown to significantly decrease IQ, and majority of affected children are from low-income families. Lead may also worsen children's mental health, making them more prone to antisocial behavior. Adoption of public health measures such as banning lead in paint and gasoline have, however, caused the number of US children with unsafe lead levels to decline from 13.5 million in 1988 to less than half a million in 2000. Relatively little research examines the health effects of exposure to other environmental toxins at the level now generally occurring

in the population. Data on possible human health effects generally come from either animal studies, or disastrous releases. Residents of areas near hazardous waste sites are more likely to be poor and have lower levels of education than people in the remainder of the country and therefore their children's health outcomes are likely to differ even in the absence of negative health effects from exposure. Some studies try to control for observable confounding factors, but unobservable characteristics of people who live near hazardous waste sites may tend to cause bad outcomes.

One approach that avoids this omitted variable problem uses variation in pollution levels stemming from implementation of the 1970 and 1977 Clean Air acts, which caused exogenous changes in air-pollution levels across counties. Countries that experienced larger air-pollution reduction also experienced decreased rates of infant mortality (Chay and Greenstone, 2003). The Clean Air acts also reduced prenatal exposure to lead, which in turn decreased infant mortality and the proportion of low-birth-weight babies (Reyes, 2005). Other papers account for omitted characteristics such as ground-water pollution and SES by examining changes in pollution over time within single zip-code areas. These studies reveal that reducing pollutants such as carbon monoxide lowers infant mortality rates, as well as hospitalization rates for childhood asthma (Currie and Neidell, 2005). These studies show that pollution can have causal effects on child health, but there has been little investigation of whether these effects have long-term consequences for children's outcomes. The National Children's Study attempts to remedy this by examining the effects of environmental exposures on 100,000 children from birth to age 21 years.

Can Health Account for Gaps in Children's Educational Outcomes?

In order for a given health problem to lead to a disparity in educational outcomes, the health problem must either be more prevalent among the poor or have a larger negative effect on the poor, and must also be associated with lower educational attainments. Few of the specific health problems mentioned above fit both these criteria. Mental health problems are much more prevalent among the poor and have large negative effects, but are still too rare to explain observed human capital disparities. Similarly, the long-term effects of low birth weight are statistically significant but relatively small. The same is true for many of the other specific conditions, while for some of the other large categories, such as injuries and exposure to environmental toxins, too little evidence currently exists to determine the likely long-term effects or the extent of the disparity in exposures. One exception to this generalization is the fetal injuries mentioned above, which have

very large effects on future outcomes. Children of US mothers infected during the flu epidemic were 15% less likely to graduate from high school, and Swedish children exposed to low-level radiation after Chernobyl were 5.6% less likely to qualify for high school. These results raise the provocative idea that one of the best ways to safeguard children's health and educational attainments may be to start with their pregnant (or prepregnant) mothers.

To summarize, this article surveys literature focusing on two questions: Do parental circumstances affect child health at early ages? Does child health matter for future educational attainments? The answer to both questions appears to be yes. It is too early to tell how important these feedbacks between health and more conventional measures of human capital may be. We know too little about the cumulative and interactive effects of health insults. The available evidence suggests that fetal health may be particularly important. We need to understand more about the reasons why poor children suffer a higher incidence of negative health events, even *in utero*, so that we can do more to prevent them. Much of the literature reviewed here is extremely recent, suggesting that this topic will continue to be a fruitful area of research.
