What are stakeholders' values, criteria, and standards for judging evaluands as they operate in particular contexts? Given the variety of e-learning stakeholders and their definitions of evaluands they want to evaluate, there are many criteria to consider in evaluating e-learning (see **Table 3** for examples). Most criteria may be organized as learning quality (knowledge, skills, and dispositions as measured through direct and indirect performance indicators or learning outcomes), efficiency (lower costs for equal or higher performance), and improved access to learning opportunities (Graham, 2006) – or in terms of inputs, processes, and outcomes for each of five pillars of

e-learning (Lorenzo and Moore, 2002): cost effectiveness and institutional commitment, learner access, learning effectiveness, student satisfaction, and instructor satisfaction.

In addition, industry standards for judging subsets of a learning experience might be considered important by some stakeholders and could be taken into account. For example, there are standards for web-based e-learning called Sharable Content Object Reference Model or SCORM (Advanced Distributive Learning, 2004) and for content areas such as math (National Council of Teachers of Mathematics, 2000) and reading (International Reading Association, 2004).

Questions

Exploring the four components of the evaluation framework yields what should be or criteria and standards that evaluators translate into questions stakeholders want answered so they can evaluate what is against those criteria. For example, in a university economics department, faculty and students as key stakeholders might agree to ask if the computer programs they anticipate buying to train students in economic statistics meet standards such as minimal cost, easy Internet access to minimize lab use, large data-set capacity, reduced need for faculty mentoring, and high student-performance scores when using them, while also meeting SCORM and other technical standards. Once criteria are identified, articulated evaluation questions focus on assessing how well competing computer programs meet these standards.

Clarifying What Is

Once what should be and associated questions are established, e-learning evaluators select methods, and gather and interpret data to answer the question of what is.

Selecting methods to fit questions

Funding pressure has grown to evaluate with randomized control group trial studies. However, professional evaluators (AEA, 2003) and other experts (AERA, 2003) agree that answering questions about what is compared to what should be involves quantitative, qualitative, or mixed data, collected through many designs including experiments, quasi-experiments, surveys, and case studies.

Likewise, a review of methods and results for evaluating e-learning for K–12 children (WestEd, 2008) suggests that the most useful evaluation studies triangulate multiple stages and methods to replicate and confirm findings. In this review of seven online learning-program evaluations, the US Department of Education guide identifies challenges and recommends methods for meeting needs of multiple stakeholders, building on existing literature, recognizing evaluands as multifaceted, doing comparison studies whenever possible, gathering valid data, and

moving stakeholders to action with evaluation results. Many resources for facilitating K–12 and higher education e-learning evaluations are noted.

Data gathering and analysis

Depending on the questions asked, data gathering may involve observing, interviewing, artifact reviewing, testing, surveying, and measuring unobtrusively (e.g., web analytics). Analyses include statistical description and hypotheses testing to make inferences about the power of findings as well as thick qualitative descriptions and identification of patterns and themes to facilitate interpretation of results.

The seven studies mentioned earlier (WestEd, 2008) illustrate these multimethods. The evaluators used comparison studies when possible but remained flexible in order to address emerging interests of multiple stakeholders through multistage studies that addressed formative and summative questions. They used surveys, observations, interviews, tests, and computer-usage data to examine the implementation and impact of distance-education programs, teacher-training programs, self-paced online classes, blended courses, online mentors, digital libraries, online learning activities and diagnostics, video-conferences, podcasts, blogs, games, and other digital tools to enhance e-learning.

Completing the Evaluation

Evaluation: Comparing what is to what should be

The heart of evaluation involves comparing the current activities and/or outcomes associated with an evaluand to the criteria that stakeholders care about and deciding how worthy or meritorious that evaluand is. E-learner could make this comparison regarding their own personal-learning environment and their learning process and outcome goals, asking if they are learning what they want and need from sources they select. Parents could compare what their child is learning while participating in a computer lab to what they want them to learn or what the lab sponsors claim they should be learning. A business could compare how efficiently they are able to train their employees using an Internet-based simulation and how well employees can perform before and after training. In each case, evaluation compares described reality to the stakeholders' ideals and invites them to make formative or summative decisions about the evaluand.

Carliner and Shank (2008) combine many evaluations made by experts in e-learning based on their experiences and evaluations of efforts to use innovative technologies to enhance learning. They conclude that e-learning has been over-sold and efforts to evaluate and enhance e-learning should be more critical and rigorous. Several authors in their edited book note that e-learning has not grown as fast as projected and some stakeholders treat e-learning as another educational fad – demanding the latest new developments without demanding evidence that the results

are effective or available cost efficiently. A few meta-analyses have been done of e-learning (see several in the section titled 'Further reading') but conclusive evidence regarding the effects of technology, pedagogy, teacher content knowledge, and the many other variables discussed in this article continues to elude researchers. Ongoing evaluation of e-learning over time may estimate how well educators using technology to enhance learning are succeeding and how e-learners judge the quality of their experiences in those programs as well as their own personal-learning environments.

Reporting and recommendations

Reports may be automatically generated and shared efficiently by posting user ratings, as exemplified on Amazon.com and other websites. Khribi *et al.* (2008) encourage such web-usage mining to generate recommendations from internal consumers' perspectives. Usually, findings are presented in written and/or oral reports, for review by stakeholders, with encouragement to collaborate with evaluators to generate and implement recommendations.

Recommendations may urge stakeholders to buy an e-learning tool after comparing it to standards, to revise an e-learning curriculum to better meet standards, or to reject an e-learning data-management system from further consideration. Stakeholders who will need to implement them are in the best position to decide how realistic and sensible recommendations are, even though they usually benefit from collaboration with external third-party evaluators who are less invested in the outcomes.

Metaevaluation

Professional evaluators have collaborated with stakeholder groups to create standards for judging evaluations (Sanders, 1994) and principles to guide sound and ethical evaluation practice (AEA, 2004). Stakeholders of e-learning evaluations can use these resources to ensure that the evaluations proposed and implemented are trustworthy, valuable, and useful. However, very few examples of e-learning stakeholders using evaluation standards and principles are found in the literature (Williams and Campbell, 2001).

Extended Case Vignette

To holistically illustrate principles and practices identified above and demonstrate how e-learning can be evaluated, a sample study is analyzed below. In this case, an online e-learning activity was integrated into a face-to-face university class. Such blended learning has been called the single greatest unrecognized trend in higher education (Young, 2002: A33) and was also identified by the American Society for Training and Development as one of the top ten trends in the knowledge-delivery industry (Rooney, 2003). Examples from informal social network-based

learning, K–12 schooling, adult education, and corporate training could also be used to illustrate the use of e-learning evaluation.

Clarifying What Should Be

The framework activities presented in **Figure 1** for clarifying what should be are illustrated in this example.

Context

A university instructor decided to create a class wiki to encourage class members to build a learning community. She invited students to join her in contributing weekly to the wiki by summarizing readings, issues, and accomplishments associated with their own research projects, questions they wanted to answer, and responses to others' entries. Throughout this innovative experimentation, the instructor invited the students to internally evaluate the experience with her.

The scope of the evaluation study was focused on the wiki activity within a blended setting. The instructor wanted to formatively refine use of wikis or some form of virtual collaboration for use throughout the semester and beyond. Many of the students were summatively judging whether they would ever participate in a class using wikis in the future. The instructor and the students together were internally evaluating their own use of the wiki and associated learning. Although this process was initiated by the instructor as a way to enhance the students' learning through an institutional-management system, the students were free to interpret the use of the wiki in various ways and could make it part of their own personal-learning environments to whatever degree they preferred.

This evaluation was formal in that the instructor planned to gather data systematically from the students by observing their use of the wiki and by interviewing them. The evaluation continued through all stages of the wiki's development as the instructor interviewed students about her plan and invited them to join her in evaluating their use of and learning from it during and after implementation of the wiki. The wiki was evaluable because the instructor introduced and monitored it in a stable way, provided sufficient evaluation resources by making evaluation of the wiki a part of the course, and built upon literature she had reviewed regarding the use of class wikis. The instructor and students, as co-stakeholders, were willing to participate in making the experience evaluable.

Stakeholders' evaluands, criteria, and questions

The stakeholders were the instructor and students using a class wiki. The instructor was tempted several times to dominate the study because the wiki was her idea and she would be teaching this class after the students finished as well. However, she wanted to understand the students' experiences and judgments of the wiki activity too. So, she invited them to not only evaluate it but to tell her at

the earliest stages possible what their expectations and worries were concerning use of the wiki. They had the opportunity to collaborate with her in creating the wiki and in evaluating this learning activity and their own learning while using it.

The most apparent evaluand was the class wiki. That was what the instructor explicitly invited the students to jointly evaluate. But she also invited them to help create it. So, the wiki emerged during its evaluation and changed throughout the semester by accretion from the entries participants made. Each student chose to contribute to the wiki in slightly different ways, and thereby made it their own to different degrees. Some students gravitated to some parts of the wiki more than others and their views of the value of the wiki modulated, as did their learning associated with what they put into and took from the wiki activity. Thus, the evaluand became a combination of the Internet and computers which made creation and use of the wiki possible, the pedagogical purposes guiding the instructor's identification of this learning community-building activity, the wiki product the collaborators generated together, the differential energy and interest given to this activity by the students, and the related learning activities and outcomes in which they participated.

The instructor's main criteria for the wiki activity were that the students would participate in using it to record their experiences and understandings associated with their readings and projects and they would learn better by participating in a collaborative learning community. The students' criteria varied from being able to earn a good grade by meeting the instructor's expectations sufficiently, to learning from the wiki activity, to expanding their personal-learning environments. They wanted to meet not only their class-learning goals but also their own personal-learning goals.

Based on the context, stakeholders, evaluands, and criteria, the main evaluation questions for this emerging evaluation became:

1. Do the students participate to the instructor's satisfaction in using the wiki?
2. Do the students learn better by participating in the wiki activity than they would have without participating?
3. Do the students meet additional personal goals to their satisfaction?

Clarifying What Is

The instructor selected formal methods for gathering and interpreting data regarding the e-learning associated with the students' use of the wiki. However, the students played key roles in that data collection and analysis and therefore modified it from the instructor's original plan.

Selecting methods to fit questions, data gathering, and analysis

As this was a class-level study, the instructor could have randomly assigned half the students to participate with the wiki and the other half to form a control group. However, she knew they would be referring to the students' use of the wiki during class discussions; so she decided she would compare the students' behaviors, performance, and attitudes to data she had collected from students in previous semesters and to the students' own judgments of their experiences and views before, during, and after the class.

In addition to her analysis of the wiki itself and the students' participation in writing entries in it, the instructor assessed students' performance on the course-learning outcomes and interviewed them about their learning experiences, opinions regarding their growth, and how well they achieved their personal goals associated with the wiki activity, if they had any. She also invited the students to interview one another about their experiences and individual goals they had set for themselves. The analyses were both quantitative and qualitative. The instructor counted the number of entries per student and the length of their entries as estimates of their level of participation. But she focused mainly on the quality of the students' entries, descriptions of their experiences and opinions about their growth, and understanding what their personal goals had been, how they evolved, and how well they were achieved.

Completing the Evaluation

The teacher invited the students to collaborate with her in comparing their experiences to their goals and to identify recommendations for continually evaluating and improving the use of technology to enhance learning in future semesters.

Comparing, reporting, recommending, and metaevaluating

In response to the evaluation questions, which reflected the instructor's and students' criteria, they found that 85% of the students participated very actively (with more than 50 words per entry and made entries in the wiki at least 90% of the 30 times they could have contributed). This was more than satisfactory to the instructor. In addition, the instructor judged that the students learned better by participating in the wiki activity than they would have without it, based on her experiences with prior classes and the students' ratings of their learning before, during, and after the semester. Finally, the majority of the students noted that they had developed and accomplished several additional personal goals to their satisfaction.

As this evaluation was completely internal and formative, the instructor did not write up a report but shared the

results with the students and with her rank-advancement committee to certify that she was seeking feedback on her teaching initiatives and would continue using the wiki as an e-learning tool because most students said it was helpful. She noted that a few students did not participate in using the wiki and they did not learn as well or have as positive views of the content as did those who participated. She visited with them about their experiences and decided she should explore ways to engage future students who do not participate in the wiki activity. The students who participated were so positive about their additional learning and achieving of personal goals that she decided to continue the wiki activity the coming semester with just a few modifications.

Students who participated most in the wiki activity also reported they expanded their personal-learning environments to include blogs, wikis associated with other classes, and tools associated with other social media they believe will enhance their formal education, personal, and informal learning experiences.

The instructor did not metaevaluate her evaluation of the wiki activity before or during its implementation, which she learned later is the recommended process. But she was able to go to a website where a checklist (Stufflebeam, 1999) guided her through several key questions regarding the evaluation in terms of metaevaluation standards. She plans to use what she learned from this self-evaluation to conduct better studies of her teaching and her students' e-learning in subsequent semesters.

Challenges and Opportunities

Challenges

Major challenges with evaluating e-learning include understanding how to engage stakeholders in clarifying their evaluands of interest and criteria for judging them, and helping stakeholders systematically gather and analyze data to compare against those ideals. Metaevaluations are needed to raise the quality of e-learning evaluations.

Why do these challenges persist? There is a tendency to champion new learning technologies without collecting associated evidence. There are also difficulties evaluating phenomena that are constantly changing and as complicated as those found in e-learning situations. As the WestEd (2008) studies show, evaluators of e-learning must anticipate difficulties and adjust designs to skillfully complete helpful studies. Multiple sources of information and replications of studies are needed to reach dependable conclusions.

Opportunities

In spite of challenges, there are hopeful opportunities associated with evaluation of e-learning. Government efforts to encourage evaluation of various forms of e-learning

instruction are growing. Many stakeholders in the private sector also acknowledge that data-based decisions can make their efforts more profitable, ethical, effective, and efficient. There have been significant advances in evaluation theory and methodology, which can enhance e-learning evaluations.

Perhaps most hopeful is the growth in social networks and other forms of communication that encourage learners to take responsibility for their own learning, whether in formal education settings or on their own. Development of personal-learning environments implies development of personal-evaluation skills through which learners decide what resources to use to meet their learning goals, test themselves through reality-based performance opportunities, and share their findings and self-evaluations with others through various peer-based reviews.

Research into e-learning itself will continue but inquiry into the evaluation of e-learning must also proceed. This field is dynamic and involves people of all ages and in all walks of life who are shaping their criteria and definitions of what constitutes e-learning success faster than evaluation can evolve by itself.

Evaluating Schools as Learning Communities

S M Thomas, University of Bristol, Bristol, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

CPD – Continuing Professional Development.
DCSF – UK's Department for Children, Schools and Families.
DFES – UK's Department for Education and Science (replaced by DCSF in 2007).
GCSE – General Certificate of Secondary Education.
GNVQ – General National Vocational Qualifications.
GTC – UK's General Teaching Council.
KS2 – National Curriculum Key Stage Two (England).
KS4 – National Curriculum Key Stage Four (England).
NCSL – UK's National College for School Leadership.
PLC – Professional Learning Community.
PLCs – Professional Learning Communities.
VA – Value-Added measure.

Introduction

Recent emphasis on the fundamental – but not particularly new – idea that teachers working and learning together can enhance the quality of learning and teaching in schools has led to renewed interest in the potential of professional learning and professional learning communities (PLCs) to advance school improvement. Indeed, it is now central to England's National College for School Leadership's (NCSL's) revised National Standards for Head teachers and the Department for Children, Schools and Families (DCSF) Core Principles for raising standards in teaching and learning. Research studies in a range of international contexts, particularly in the USA, have similarly emphasized the value and role of professional learning communities to enhance professional practice (Stoll and Louise, 2007, Hipp *et al.*, 2008). Effective PLCs are seen as more likely to generate and support sustainable improvements in student and other outcomes because they build the necessary professional skill, capacity, and shared good practice. However, can the effectiveness and quality of a PLC be measured and does it have a quantifiable positive impact on pupil outcomes? Although relatively few research studies address these specific questions, this article reviews the available evidence and reports in detail select findings from a large-scale research project funded by the UK's Department for Education and Science (DFES),

General Teaching Council (GTC), and National College for School Leadership (NCSL) 'Creating and Sustaining Effective Professional Learning Communities' (Bolam *et al.*, 2005). In particular, this article illustrates the quantitative research tools used to define and measure specific aspects of PLCs and examines the relationship between these measures and pupils' academic outcomes. At this point, it is important to point out that the term professional learning community, used in this article, overlaps with – but is, nevertheless, more focused on – professional staff learning, than the term school learning community which is, generally, seen as broader and refers to all learners in the school community.

Approaches to Evaluate Schools as Learning Communities

One common approach to evaluating schools as learning communities is to examine the school characteristics and processes that have been identified as key features of a PLC. International research suggests that PLCs are characterized by five aspects: shared values and vision; collective responsibility for pupils' learning; reflective professional inquiry; collaboration; and the promotion of group, as well as individual learning (Stoll *et al.*, 2003, 2006a). However, more recent research has identified three new characteristics and four processes relevant to the creation and effective functioning of PLCs (Bolam *et al.*, 2005). Therefore, although PLCs do not look exactly the same in all schools, the research has found that they seem to display eight characteristics which – irrespective of the educational phase or context – they exhibit to a greater or lesser degree:

1. shared values and vision;
2. collective responsibility for pupils' learning;
3. collaboration focused on learning;
4. individual, group, and collective professional learning;
5. reflective professional enquiry;
6. openness, networks, and partnerships;
7. inclusive membership; and
8. mutual trust, respect, and support.

In addition, four processes are required to create and sustain a PLC:

1. optimizing resources and structures to promote the PLC;

2. promoting individual and collective professional learning;
3. evaluating and sustaining the PLC over time; and
4. leading and managing to promote the PLC.

These findings are illustrated in greater detail below by presenting select results from a questionnaire survey used to test out the relevance of different characteristics and processes of PLCs in different kinds of schools in England (Bolam *et al.*, 2005).

A second approach to evaluating schools as learning communities is to use statistical techniques to identify and examine a finite set of key indicators or factors related to the processes of continuing professional development (CDP) and, more broadly, to the development of PLCs. This approach has been used in a study in the Netherlands by Visscher and Witziers (2004) who identified six PLC concepts (policy and evaluation; consultation and cooperation; consensus; decision-making, school leadership; and departmental leadership) and measured these via a teacher questionnaire administered to mathematics teachers in 39 schools. Pedder *et al.* (2005) have also explored the nature of professional learning via a factor analysis of teachers' responses to a questionnaire and identified four factors related to teacher learning. The factors were:

1. *Inquiry*. Using and responding to different sources of evidence; carrying out joint research and evaluation with colleagues.
2. *Building social capital*. Learning, working, supporting, and talking with each other.
3. *Critical and responsive learning*. Through reflection, self-evaluation, experimentation, and by responding to feedback.
4. *Valuing learning*.

One purpose of this kind of approach is to establish the existence of one or more factors that could be useful as indicators to measure and evaluate particular aspects of schools' capacity and success in developing as a PLC. Moreover, indicators of this type could provide a helpful feedback to inform school self-evaluation and improvement processes (see, e.g., Scheerens *et al.*, 2003).

A third – and, arguably, the most crucial – approach to evaluating schools as learning communities is to examine the relationship between the indicators of PLCs and a range of pupil outcome data in order to establish whether or not the extent of school characteristics and processes that are associated with PLCs are also linked to improved student outcomes. There is very limited evidence with regard to the impact of continuing professional development – and, more generally, of PLCs – on student outcomes and progress (see, e.g., Lee and Smith, 1996; Louis and Marks, 1998; Wiley, 2001). However, findings in this area are extended by a more recent study (Bolam *et al.*, 2005), which provides a rare

opportunity – via the collection of school-questionnaire-survey data alongside access to the national pupil-assessment databases – to produce some relatively hard data. The nature of this data is, of course, correlational – not causal – but, nevertheless, this evidence is arguably more robust than previous studies and is employed in this context to illustrate, in detail, the findings and methods used to evaluate the effectiveness of PLCs in terms of promoting student outcomes.

The three approaches mentioned above are discussed, in detail, in the following sections by drawing on findings mainly from Bolam *et al.* (2005) work.

Characteristics and Processes of Schools as PLCs

As noted above, previous research has identified eight key characteristics and four processes relevant to the creation and sustainability of schools as PLCs. The study conducted by Bolam and colleagues employed both case-study and questionnaire-survey methods to draw its final conclusions. However, the detailed findings from the questionnaire administered to almost 400 English schools provide a useful example of the most and least common PLC features reported by schools.

The questionnaire was developed from a review of the literature on PLCs and was designed to be completed by the headteacher or CDP coordinator of each school participating in the study – in consultation with other staff. The questionnaire comprises three parts:

- *Part 1*. Items designed to gather opinions regarding aspects of PLC in the school; these questions are framed in terms of the proportion of staff in the school engaged in particular activities or having particular views. These items reflect different aspects of CDP and teachers, professional life: teacher support for pupil learning; professional learning; support for professional learning; collaboration and culture; research and professional enquiry; external links and networking; and participation of teaching assistants and nonteaching support staff in PLC.
- *Part 2*. Items exploring the perceptions of a definition of a PLC and the factors that the respondent felt facilitated, or were barriers, to the school becoming a PLC.
- *Part 3*. Items related to factual information with regard to the range and extent of professional development and school self-evaluation activities in the school.

The questionnaire findings indicated which PLC characteristics and processes the respondents were most and least likely to report, on average – in terms of the proportion of staff engaged in particular PLC activities, as well as which activities were the most and least variable across schools – thereby suggesting agreement among schools on the importance of some key PLC features (see **Table 1**).

Table 1 Perceived aspects of PLC by primary schools and secondary schools: three items (indicated with the original questionnaire numbers) with the highest/lowest means and standard deviations

	<i>Mean</i>	<i>Standard deviation</i>	<i>n</i>
<i>Highest mean – primary schools</i>			
Q1: collective responsibility for pupil learning	3.77	0.56	224
Q3: create conditions for pupils to feel the confidence to learn	3.74	0.52	225
Q4: learn together with colleagues	3.73	0.51	223
<i>Highest mean – secondary schools</i>			
Q1: collective responsibility for pupil learning	3.64	0.54	164
Q3: create conditions for pupils to feel the confidence to learn	3.40	0.61	164
Q24: are members of at least one professional team	3.80	0.55	160
<i>Lowest mean – primary schools</i>			
Q9: carry out classroom-based research	1.81	1.00	209
Q36: experience job rotation	1.83	1.07	214
Q38: have opportunities for work shadowing	1.75	1.03	215
<i>Lowest mean – secondary schools</i>			
Q36: experience job rotation	1.13	0.34	160
Q38: have opportunities for work shadowing	1.36	0.71	157
Q44: receive financial support from the school for award-bearing courses	1.42	0.85	153
	<i>Mean</i>	<i>Standard Deviation</i>	<i>n</i>
<i>Highest standard deviation – primary schools</i>			
Q13: have dedicated time for classroom observation	2.48	1.25	222
Q44: receive financial support from the school for award-bearing courses	1.95	1.26	207
Q45: have some protected time for joint planning and development	2.57	1.37	218
<i>Highest standard deviation – secondary schools</i>			
Q13: have dedicated time for classroom observation	2.28	1.13	162
Q43: use professional development profiles/portfolios	2.41	1.14	158
Q45: have some protected time for joint planning and development	2.36	1.18	163
<i>Lowest standard deviation – primary schools</i>			
Q1: collective responsibility for pupil learning	3.77	0.56	224
Q4: learn together with colleagues	3.73	0.51	223
Q18: share a common core of educational values	3.71	0.55	225
<i>Lowest standard deviation – secondary schools</i>			
Q1: collective responsibility for pupil learning	3.64	0.54	164
Q24: are members of at least one professional team	3.80	0.55	160
Q36: experience job rotation	1.13	0.34	160

Only includes items from the PLC survey part 1.

The four-item response categories are treated as a numerical scale from one to four as follows: nearly all staff (>80%) = 4, most staff (50–80%) = 3, some staff (20–49%) = 2, a few staff (<20%) = 1.

Highest/lowest mean in bold; highest lowest standard deviation in bold (3).

Adapted from Bolam, *et al.* (2005). Creating and sustaining effective professional learning communities. *DfES Research Report RR637*. University of Bristol.

The findings show that two question items, in particular, are crucial in terms of primary and secondary schools reporting the highest mean level of teacher involvement. These are: collective responsibility for pupil learning and creating conditions for pupils to feel the confidence to learn. Responses to these two items also demonstrate a high level of consensus among schools, given the low item-score variability in comparison to other items. These findings suggest, not surprisingly, that pupil learning is the foremost concern of teachers and that this is a PLC characteristic that is very common in all schools.

In contrast, the results for two different items (experience job rotation and have opportunities for work shadowing) indicate that both primary and secondary schools,

typically, reported a low level of teacher involvement in these activities. The finding suggests that these particular aspects of CDP related to learning and developing staff roles, were not a common characteristic in most schools.

Finally, the results for two further items (have dedicated time for classroom observation and have some protected time for joint planning and development) suggest that, although a medium level of staff involvement is reported by primary and secondary schools, there is a notable lack of consensus (i.e., high item-score variability) concerning these two activities across schools. This finding suggests that some aspects of CDP – concerned with improving classroom practice – are very variable across schools, with some schools reporting a high level of

Table 2 Percentage of schools reporting different stages of PLC development

Stage	Nursery and primary schools (n = 227)	Secondary schools (n = 166)
Mature/ established	25	16
Developer	57	67
Starter	14	15
Working to reestablish PLC	2	1
No response	2	1

The primary and the secondary school samples included special schools, respectively.

staff involvement and others reporting a low level of staff involvement. The issues of teachers' time management and professional culture may have an impact here.

Schools in the sample were found to be adequately representative of the national picture in terms of context factors, such as the percentage of pupils in the school entitled to free school meals. However, it is important to note that schools were asked specifically, in part 2 of the survey, to assess their current stage of development as a PLC. The provisional working definition of a PLC quoted in the survey was as follows: "An effective professional learning community has the capacity to promote and sustain the learning of all professionals and other staff in the school community with the collective purpose of enhancing pupil learning." A majority of respondents – 57% from nursery and primary schools and 67% from secondary schools – reported that their school was a developing PLC (see **Table 2**). Therefore, the survey findings reported above reflect the features of this self-reported group of schools more than any other. Moreover, it is important to note that the survey findings are a summary of data collected at one point in time from one respondent – either the head or CDP coordinator – in each school responding to the survey. Of course, the situation may have changed since the data were collected and, in addition, other members of the school may have different opinions concerning the questions. Clearly, these issues should be considered when interpreting the survey findings, although interviews in case-study schools – also conducted as part of the study – generally confirmed survey respondents' perceptions of their school's current stage of PLC development.

Summary Indicators of PLCs

In addition to the questionnaire-item results outlined above, the study also provides a useful example of findings

Table 3 Questionnaire items included on the factor of professional and pupil learning ethos

Factor 1	Professional and pupil learning ethos
1:	Collective responsibility for pupil learning
2:	Base their approach to change on the use of good evidence
3:	Create conditions for pupils to feel the confidence to learn
4:	Learn together with colleagues
5:	Ensure pupils receive constructive feedback about their work
6:	Set learning targets for individual pupils
7:	Routinely collect, analyze, and use data and evidence to inform their practice
8:	Have low expectations of children
9:	Actively seek and use feedback from pupils
10:	Regularly monitor the learning and progress of individual pupils
11:	Share a common core of educational values
12:	Use the staff room at break times for professional links
13:	Are involved in seeking solutions to problems facing the school
14:	Regularly discuss teaching methods
15:	Share their professional experiences and successes
16:	Experiment and innovate in their work
17:	See the school as stimulating and professionally challenging
18:	Routinely share information with parents and the community
19:	Learn from each other
20:	Take responsibility for their own professional learning
21:	Give priority to learning more about pupils learning

that employ quantitative factor-analysis techniques to establish the existence of one or more summary indicators or factors that could be used to measure and evaluate schools as professional learning communities. Four independent factors were identified from the questionnaire results which relate to:

1. professional and pupil learning ethos;
2. within-school policy, management, and support for professional learning;
3. enquiry orientation (external and internal); and
4. participation of nonteaching support staff in PLC.

As an illustration of the results, the questionnaire items loading on factor 1 (professional and pupil learning ethos) are shown in **Table 3** (for further details, see Atkins and Thomas, 2004). Correlations between the factor scores showed that, although there is some overlap between factors (i.e., all correlations are positive), there are, nevertheless, observable differences between these PLC summary indicators. Therefore, the evidence indicates that at least four dimensions reflecting different aspects of PLCs exist and individual schools can have a very different profile of results across the four factors. The findings related to professional and pupil learning and enquiry orientation are also reflected in a comparable questionnaire study which focused specifically on professional learning and was conducted on the basis of a teacher survey – over 1000 individual teacher responses from 32 schools (Pedder *et al.*, 2005). As previously noted, in

the study carried out by Pedder and his colleagues, four factors were identified using standard factor-analysis techniques which comprised aspects of inquiry and using different sources of evidence, building social capital, critical and responsive learning, and valuing learning. Broad similarities could also be found with the PLC concept factors identified by Visscher and Witziers (2004).

The validity of the PLC concept at the primary and secondary phases of education was also examined by Bolam and colleagues in terms of whether schools from different educational phases report similar levels of staff involvement as measured by the PLC factors. **Table 4** depicts the mean and standard deviation of the factor scores from primary and secondary schools. Overall, the findings indicate that primary schools, generally, report higher levels of staff involvement in PLC processes than secondary schools. Interestingly, the highest level of primary-phase staff involvement suggested by the factor scores is in terms of pupil and professional learning ethos (factor 1). In contrast, for the secondary phase, the highest level of staff involvement is in terms of enquiry orientation (external and internal; factor 3).

In the survey, respondents were also asked to assess their current stage of development as a PLC in three developmental stages: mature/established, developing, and starting the journey to become a PLC. The validity of conceptualizing PLCs in three stages was examined by looking at the relationship between schools' four-factor scores and their self-reported stage as a mature, developer, or starter. In some cases, the findings suggest an overlap between mature and developer PLCs – with starter PLCs falling behind on some factors. In addition – not surprisingly – in all cases, the primary mean factor score for a particular PLC stage is higher than the equivalent secondary mean factor score, again reflecting the overall tendency for primary schools to have reported higher teacher PLC involvement than secondary schools. Given these findings, it is not clear whether it should necessarily be expected that primary and secondary phases would report a similar level of staff involvement

in the PLC. This is because secondary schools are, usually, much larger and it is possible that smaller PLCs exist within the schools surveyed but were not identified because the focus was at the whole-school level. For example, one or more secondary school subject departments may operate as a PLC and display the characteristics and features of a mature PLC, but the proportion of total school staff involved may be low.

Nevertheless, overall – from these findings – it appears that whole-school PLCs within secondary schools may be less developed than those within primary and nursery schools, because the results indicate that a smaller percentage of staff are perceived to be engaging in the measured PLC behaviors. Of course, such a response pattern is not uncommon in questionnaires of this type (e.g., McCall *et al.*, 2001), and achieving secondary school improvement is notoriously more difficult than that in primary schools (Louis and Miles, 1990).

Overall, the results from the PLC factors do appear to be broadly in line with schools' self-reported stage of development – in all cases, schools reported as mature PLCs have higher average factor scores than starter PLCs. Despite this, it is also important to point out that by combining the results from different questionnaire items into summary indicators (i.e., factor scores), a greater degree of differentiation can be employed in measuring each factor than the three crude PLC developmental stages of mature, developers, and starter. This evidence does seem to suggest that the conceptualization of a PLC needs to shift from the idea of a single dimension in three developmental stages to multiple dimensions – each being on a continuum – although the two approaches could also be seen as broadly complementary.

Relationship Between Pupil Outcomes and PLC Processes and Contexts

The research conducted by Bolam and colleagues also provides evidence of the relationship between the

Table 4 Means and standard deviations of the four PLC factor scores by educational phase

	<i>Educational phase</i>			
	<i>Nursery and primary schools n = 227</i>		<i>Secondary schools n = 165</i>	
	<i>Mean</i>	<i>Standard deviation</i>	<i>Mean</i>	<i>Standard deviation</i>
<i>Learning ethos (factor 1)</i>	0.29	0.94	–0.41	0.95
<i>Support for professional development (factor 2)</i>	0.28	1.03	–0.38	0.82
<i>Enquiry orientation (factor 3)</i>	0.22	1.06	–0.32	0.81
<i>Participation of nonteaching staff (factor 4)</i>	0.26	0.82	–0.36	1.12

Factor scores were standardized across the whole sample with mean = 0 and standard deviation = 1.

The primary and the secondary school samples included special schools, respectively.

Adapted from Bolam, *et al.* (2005). Creating and sustaining effective professional learning communities. *DfES Research Report RR637*. University of Bristol.

characteristics of PLCs and pupil outcomes and these findings address the crucial question of whether there is a statistically significant relationship between school PLC indicators (e.g., factor scores) and school academic performance measures. As outlined in greater detail below, only tentative evidence of a positive relationship has been found. Nevertheless, the findings support previous research by several researchers. Lee and Smith (1996: 103) found that “Achievement gains are significantly higher in schools where teachers take collective responsibility for students’ academic success or failure rather than blaming students for their own failure. Achievement gains were also higher in schools with more cooperation among staff.” Louis and Marks (1998) also found that the promotion of a professional community for teachers has a positive relationship with the organization of classrooms for learning and the academic performance of students. Similarly, Wiley (2001) found a positive effect for professional community on student achievement – but only in situations where teachers’ experience of (transformational) leadership was also positive.

Relatively sophisticated analyzes (multilevel modeling) have also been conducted to establish whether or not there is a statistically significant link between schools’ value added in terms of pupils’ relative progress and their capacity as a PLC. Crucially, sophisticated value-added (VA) measures of relative pupil progress provide a more valid measure of educational and school effectiveness than the raw results (Thomas and Mortimore, 1996). However, for comparison purposes, raw (unadjusted) assessment and examination results have also been employed – as published in the annual league tables in the UK.

Calculating VA and raw school performance

A variety of different multilevel models were tested prior to deciding on the final ones to use for calculating VA school performance (see Thomas (2001) for a similar approach). This approach was seen as preferable to assess the long-term impact of a school on a pupil’s progress in learning and attainment as the models utilize outcome and baseline data that span, by and large, the period spent in that school phase by pupils. However, both the VA and raw (unadjusted) models have been used to analyze the end of phase-schooling outcomes. The Outcomes for primary schools comprise the mean National Curriculum Key Stage 2 (KS2) assessment score across the core subjects of English, mathematics, and science for 11-year-olds. Outcomes for secondary schools comprise the Total National Curriculum Key Stage 4 (KS4) assessment score, including grade scores for all subjects taken by 16-year-olds in the General Certificate for Secondary Education and in General National Vocational Qualifications (GCSE/GNVQ).

The final multilevel VA models take account of the variability in pupil outcomes due to the characteristics of the

pupil intake for a school. Thus, pupils’ prior attainment, gender, socioeconomic background, and other variables are controlled for in the statistical analysis (see Smith and Thomas, 2004). The VA score (or residual) for each school is determined from the model results and used to make more robust (reliable) comparisons about how pupils in a school perform compared with pupils in other schools. The raw model is used to calculate school performance in terms of raw pupil outcomes when no adjustment for intake and other factors has been made.

Correlations between school performance and PLC indicators

The four PLC factors were correlated with primary and secondary schools’ VA and raw performance. However, only a minority of these comparisons were found to be statistically significant at the 0.05 level and the findings are summarized below (see Bolam *et al.*, 2005, for further details of statistical results). At the primary level, positive and statistically significant correlations were found between schools’ factor 1 score professional and pupil learning ethos and their 2002 KS2 performance – both raw and VA. At the secondary level, positive and statistically significant correlations were also found for both factor 1 professional and pupil learning ethos and factor 2 support for professional learning – but only in terms of schools’ VA GCSE/GNVQ performance. Of course, it should be noted that the relationships are fairly weak (no correlations reported are greater than 0.3). However, it could be argued that this would be expected, given that any statistical relationship is likely to be tenuous between process measures collected as a snapshot at one point in time and pupil performance and progress over a relatively long time period (4–5 years).

The relationship between pupil outcomes and the individual items from part 1 of the survey, were also examined. As expected, the findings support those from the PLC factor results reported above. Several positive and statistically significant correlations (at 0.05 level) were found, but only two were fairly strong ($r \geq 0.3$) and these relate only to the primary phase (teachers have low expectations of pupils and teachers share a common core of educational values – note that both of these items are included on factor 1).

There are only three items that are statistically significant (at 0.05 level) across both the primary and secondary phases and the evidence tentatively indicates that these aspects of a PLC are key in terms of enhancing pupil progress. Positive relationships were found between schools’ VA residual outcomes and their responses to the following items teachers create the conditions for pupils to feel the confidence to learn, teachers share a common core of educational values, and teachers see the school as stimulating and professionally challenging. A positive

relationship (at the 0.05 level) was also found between primary VA residuals and teachers' experiments and innovation in their work.

Correlations between school performance and PLC factual characteristics

The relationship between pupil outcomes and the PLC factual characteristics, from part 3 of the survey, were also examined. Both positive and negative statistically significant correlations (at 0.05 level) were found – six indicating a fairly strong relationship ($r \geq 0.3$). These six strongest correlations were found between pupil outcomes and items related to the status of the school – that is, being in an Education Action Zone or part of an Excellence in Cities initiative (negative relationships) or being a Beacon School, having other working links or Specialist status (positive relationships). Clearly, a school's involvement in these kinds of initiatives is often related to school performance and effectiveness. (A school being in an Education Action Zone or Excellence in Cities initiative indicates that it receives additional funding and support due to being located in a particularly economically disadvantaged area. Beacon School or specialist status indicates that a school has met the criteria for excellence and/or additional resources in particular aspects of the curriculum.)

In addition, interestingly at the primary level, weak but nevertheless statistically significant positive associations were found between school VA outcomes and the degree to which staff were monitoring pupil progress. This finding supports previous research that underlines the need for systematic monitoring of pupil progress in schools to improve school effectiveness (Thomas *et al.*, 2007). At the primary level, the total number of supply teaching days for 2001/02 was significantly negatively correlated with raw pupil outcomes suggesting that frequent teacher absences have a detrimental effect on pupil outcomes.

Finally, in addition to the correlational analyzes described above, further more sophisticated multilevel analyzes were also carried out to determine whether the previously identified PLC factors and other school characteristics have a combined (as well as individual) impact on pupil progress in the VA models (i.e., given pupil intake factors have already been accounted for in the analysis) and whether they further reduced the remaining unexplained school and total variance. In line with the correlational analyzes, it was found that, in the primary school analyzes, the addition of factor 1 professional and pupil learning ethos to the VA model was statistically significant (at the 0.05 level); however, this resulted in a very small reduction in school and total variability in KS2 mean score outcomes. Similarly, in the secondary school analyzes, the addition of both factor 1 professional and pupil learning ethos and factor 2 internal support for professional

learning individually into the VA model, was statistically significant. However, overall, the findings indicated that any positive link between school PLC factors and pupil outcomes is fairly weak and may be difficult to distinguish when other (possibly confounding) school factors and context – such as percentage of pupils entitled to free school meals – is taken into account.

In summary, these findings are interesting as they do suggest that a weak, but positive, link exists between individual PLC factors and pupil outcomes – particularly, VA performance, which measures the relative progress of pupils in a school in comparison to pupils in other schools (arguably one of the most valid measures of school effectiveness). Findings of this kind are important because it may be argued that particular features of PLCs can only be validly evaluated as effective if a positive impact on student outcomes can be demonstrated. Of course, it may be that quantitative measures used in the research conducted so far are not sufficiently sensitive to fully reflect the complex relationship among PLCs and pupil performance and progress. Therefore, clearly, further research is necessary to contribute stronger evidence on this issue which has only rarely been addressed using sophisticated quantitative techniques.

Conclusion

In conclusion, a limited number of relevant studies have been reviewed and the findings indicate that some key PLC characteristics are more (or less) commonly reported in schools (e.g., opportunities for work shadowing and experience job rotation were, generally, less common). In addition, some key PLC characteristics are more-or-less variable among some schools than others (e.g., dedicated time for classroom observation and protected time for joint planning and development were more variable). These findings reveal an important message for policymakers – that there are some key areas of teachers' professional development that either happen very infrequently in schools or are highly variable across schools.

The Bolam *et al.* (2005) and other similar studies found that the summary indicators of different aspects of a PLC can be identified using quantitative factor-analysis techniques. However, it is important to recognize that the different factors identified are not, necessarily, comprehensive for the purpose of evaluating the nature and quality of PLCs. The qualitative case-study data, also reported by Bolam *et al.* (2005), tapped into considerable detail and depth concerning the nature of PLCs and, subsequently, revealed important new aspects of PLC processes and characteristics such as trust and distributed leadership, which were not directly included on their questionnaire survey.

Moreover, in Bolam and colleague's final conclusions, it was suggested that PLCs should be evaluated not only in terms of pupil outcomes – indeed, overall, the quantitative evidence linking student outcomes and PLC functioning, seems to be fairly weak – but also via impact on staff morale and practice, and potential for developing leadership capacity, as well as by establishing that PLC characteristics are in place and processes are operating smoothly. Further research is, of course, needed to explore these issues in more detail, given that future theory building will require stronger evidence of this kind to clearly differentiate between the effects of the wide varieties of learning, development, and improvement activities that teachers, schools, and PLCs engage in.

In conclusion, this article indicates fairly strongly that a school, as a PLC, is multidimensional and complex in nature. Evidence also, tentatively, suggests that some PLC characteristics and processes may be enhanced or hindered by the advantages or disadvantages of particular contexts (e.g., smaller size may allow greater opportunities for collaboration, higher percentage of student disadvantage indicated by their eligibility for free school meals may indicate higher funding levels for professional development activities). The idea of three developmental stages (mature, developer, and starter) may be helpful as a starting point in understanding the PLC concept but, in the end, may be too crude to measure the complexity of PLC characteristics and processes. This article demonstrates that a more detailed approach is needed to help teachers and other professionals working in schools to understand the conditions and contexts that underpin systematic and effective professional learning as well as to enhance PLC development in schools. Further evidence is also needed to better understand the links between professional learning and the learning of other members of the school community – such as students and parents – in order to explore whether the processes and outcomes of a PLC mirror those of the school learning community as a whole.

Overall, the review findings indicate that quantitative and qualitative methods can be used to evaluate different aspects of the effectiveness and quality of a PLC and demonstrates the potential for creating valid measures of professional learning within schools. These kinds of measures could provide a useful method of enhancing information available to schools and, if used alongside other types of evidence, could meaningfully inform school improvement and self-evaluation activities (see Stoll *et al.* (2006b) for examples of PLC evaluation materials produced for use in schools).

Evaluation of Adult Education and Training Programs

G McNamara, P Joyce, and J O'Hara, Dublin City University, Dublin, Republic of Ireland

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Competences – The integration of knowledge, skills, and attitudes concerned primarily with developing the ability to acquire further knowledge, rather than simply the possession of a particular amount of current knowledge.

Evaluation – The systemic assessment of an object's worth, probity, feasibility, safety, significance, and/or equity.

Formative evaluation – Evaluation conducted during the development of a program.

Program evaluation – The use of social research procedures to systematically investigate the effectiveness of social intervention programs such as education and training.

Quality – The ongoing and continuous analysis of the provision and outcomes of programs.

Summative evaluation – Retrospective assessments of completed or established programs.

Introduction

Evaluation occupies an increasingly major place in public and private decision-making processes, serving many political functions such as analysis of spending, allocation of funds, and provision of accountability. On the other hand evaluation is also increasingly concerned with learning, with empowering program participants and enabling social transformation.

Program evaluation is the use of social research procedures to systematically investigate the effectiveness of social intervention programs such as education and training (Stufflebeam and Shinkfield, 2007). At one level the demand for an appropriately skilled workforce in an evolving global economy has made the evaluation of adult education and training programs a high priority but one which seemed relatively straightforward. However ideological, curricular, and political rethinking has fundamentally undermined this seeming simplicity. The conceptual framework underpinning theories of adult education and training has become deeply contested. In terms of curricular structure the traditional focus on behavioral outcomes has been replaced by the broader concept of competences.

Equally, increased demands for value for money in public services have resulted in concerns about accountability and quality moving to the fore. Evaluation has also progressed dramatically and is now no longer simply concerned primarily with measurable outcomes but with process, stakeholder roles, values, and quality.

In this article, the contextual issues to be considered in the evaluation of adult education and training programs are outlined. Key questions which need to be answered whichever approach is undertaken are presented. Evaluation models and approaches are summarized and two particular models are highlighted as popular but contrasting approaches to evaluating adult education and training programs. Finally a greater emphasis on self-evaluation is suggested as an approach worth considering for the twenty-first century in the field of adult education and training.

The Changing Face of Evaluation in Adult Education and Training

Evaluation theory and practice in adult education and training has, in recent times, undergone significant development. This development reflects not only evolving concepts of evaluation but equally dramatic changes in the philosophy and curriculum of adult education and training. For example, education and training in nursing and medicine have undergone significant reform in the past 10–15 years. Continuing with a strong practice-based focus it now also has an explicit focus on problem-based learning, change management, and policy development. The focus has also changed from one of instruction, for example, an apprenticeship model, to a learning paradigm, where the emphasis is on student-centered learning. The role of the adult learner is one of active participant who sees a relevance to learning which can be applied to practice.

The purposes and ideology of much adult education and training have become deeply contested. Traditionally, adult education and training had been seen as primarily concerned with issues such as skills, labor market productivity, and economic development. More recently, post-modernist thinking has moved the focus to issues of social transformation concerned primarily with personal and societal development as key purposes in adult education. Particularly influential have been constructivist theories

reminding us that knowledge, while individually constructed, requires collective and collaborative interaction as a key element of learning. Thus, while for certain purposes objectives-based training in the form of skills development may well be defensible and appropriate, the concept of adult education and training has expanded significantly in line with postmodernist views of epistemology and ontology.

In the light of this changing conceptual focus, the nature and structure of the curriculum in adult education and training has also been reformed. In response to changes in society, and in particular the emergence of the knowledge economy, adult education and training is increasingly concerned with the development of broad competences. Competences integrate knowledge, skills, and attitudes and are concerned primarily with developing the ability to acquire further knowledge rather than being simply about the possession of a particular amount of current knowledge. In consequence, the structure of adult education and training programs has undergone radical change, with an ever greater emphasis on issues of process and less concern with the acquisition of a particular skill set.

Somewhat paradoxically, in tandem with this change in the philosophy and curriculum structure of adult education and training programs, there has been also a parallel increase in policies designed to ensure quality and value for money in the provision of such programs. This is in line with the international neoliberal movement often referred to as new public management which has resulted in greater oversight of programs and initiatives in the public sector and determination to introduce the alleged efficiencies of the free market. Quality is understood to be concerned with the ongoing and continuous analysis of the provision and outcomes of programs (Kells, 1992). It is a broad concept which includes both external requirements for accountability and accreditation such as national standards and benchmarks and internal control of quality within educational institutions and programs.

Evaluation has become dramatically altered as a result of these developments. From its traditional role as a once-off measurement of program outcomes, evaluation is now perceived as an integral part of a continuous cycle of quality assurance which includes program philosophy, curriculum development, definition of quality standards, assessment, strategic planning, and internal and external evaluation. Moreover, since in most cases evaluation, as now constituted, encompasses both accountability and improvement focuses it must be multilevel, capable of responding to different needs and expectations from a variety of audiences.

The above trends have paralleled and are closely linked with changing concepts and practices in the evaluation of adult education and training. Consistent with

developments in other fields there is an increased focus in evaluation on methods which include community or stakeholder input from the beginning of program definition and design. Such methods are designed to help program participants to evaluate themselves and their programs, still with the goal of improving outcomes but also of fostering autonomy and decentralized decision making.

Before the days of competences and quality assurance, the evaluation of adult education and training was primarily concerned with the measurement of traditional behavioral objectives. More recently, evaluation theory and practice has become increasingly defined by a more sophisticated analysis of programs involving the inclusion of stakeholder perceptions and multiple forms of evidence, data, and indicators. There has been a tendency to break away from the classical, objectivist, outcome-based, and performance-orientated concept of evaluation toward a multiplicity of new models. Among these models are responsive evaluation as illumination, ethnographic evaluation, naturalistic evaluation, utilization-focused evaluation, the integrated information development and evaluation model, fourth-generation evaluation, empowerment evaluation, participative evaluation, self-evaluation, and others. In the more recent past, there has been a move from debates between positivists and post-positivists to a dialog between the paradigms leading to a greater emphasis on multimethod approaches.

Therefore, the design of evaluation of adult education and training programs is now more complex than in the past. It has to take into account the changing priorities of the curriculum in such programs, emphasizing key competences at many levels. Evaluation must also be reconceptualized to fit within structures designed not as once-off appraisals but rather continuous cyclical quests for improvement. In design it must reflect these imperatives, and in consequences, educational evaluation theory and practice has moved from simplistic notions of measuring outcomes to more complex concerns with stakeholders' roles and the process of learning.

Designing Evaluation for Adult Education and Training

From the aforementioned discussion it should be clear that the design and conduct of evaluation in the field of adult education and training presents difficulties peculiar to that field. For example, a curriculum based on the complex notions of competences requires standards, indicators, criteria, and appropriate assessment procedures if it is to be coherent. All these features must be evaluated. Since by their nature many competences are in the expressive domain and resistant to traditional notions of measurement, a variety of largely qualitative methodologies will be

applied alongside more traditional modes of testing. If, as likely in the bulk of cases, the evaluation is concerned with both accountability and improvement, and internal and external audiences, the evaluation design must be able to meet all these needs. This may be achievable in theory but recent work in the field by McNamara and O'Hara (2004) suggests that evaluation for accountability and for improvement are not complementary but competing, and that formative goals focused on learning can easily be derailed by the demands for summative judgment. Finally, in the modern discourse of evaluation, the emphasis on negotiation and collaboration and on iterative research processes and methods are often at odds with contractual requirements and realistic resources and timescales.

The increasing complexity of educational evaluation design is illustrated by the definition by Stufflebeam and Shinkfield (2007), which describes evaluation as the systematic assessment of an object's merit, worth, probity, feasibility, safety, significance, and/or equity. This more values-oriented definition is an extension of that put forward by the Joint Committee on Standards for Educational Evaluation (1994) in the USA which defined evaluation as the systematic assessment of the worth or merit of an object. The merit of a program can be judged by examining if it does well what it is supposed to do. Worth refers to a program's combination of excellence and service in an area of clear need within a specified context. In evaluating probity, assessments are made of the program's honesty, integrity, and ethical behavior (Stufflebeam and Shinkfield, 2007). A good evaluation should provide direction for efficient use of time and resources and be politically viable. Many programs require evaluations that examine safety of facilities, influence, importance, and visibility. Evaluators need to consider the possibility that a program can have far-reaching implications outside the local arena and evaluate its significance over time and in other settings. The criterion of equity argues for equal opportunities for all people and emphasizes freedom for all. It is also concerned with the roles and rights of all legitimate stakeholders including politics, ideology, and imbalances in power relationships. Taking this array of concerns into account in evaluation design is clearly a formidable task.

In the following section we look at two contrasting models of adult education and training evaluation. Kirkpatrick's four-level model is very much in the Tylerian behavioral objectives measurement tradition and is still widely utilized in the evaluation of skills-training programs (Thackwray, 1998). In contrast Jacobs' (2000) approach is representative of models concerned with stakeholder empowerment, constructivist concepts of knowledge, and social transformation. We begin by explaining the categorization of evaluation into formative and summative and propose key questions which need to be answered whichever approach is undertaken. Finally, the increasing emphasis on self-evaluation is mentioned and it is suggested

that for both conceptual and practical reasons it will become increasingly influential in the field of adult education and training.

Evaluation Models

Designing an evaluation of adult education and training programs involves a number of key steps. Such a structure is important so as not to omit any vital parts of the process. In addition the timing of evaluation is very important and this should be decided in advance of setting up any adult education and training programs.

Formative and Summative Evaluations

The timing of evaluations has been generally differentiated into summative evaluations (retrospective assessments of completed or established programs) and formative evaluations (conducted during the development of a program). Formative evaluations are used to modify and improve a program and this is frequently used to provide feedback to staff while the program is in operation. These evaluations assess and assist with the formation of goals and priorities, provide direction for planning, and guide program management. Information from formative evaluations is directed to improving operations and serves quality assurance purposes. In contrast, summative evaluations are used to prove something, satisfy accountability, or make a judgment about the overall quality of the program. They draw together previously collected information, for example, from formative evaluations. Both formative and summative evaluations are needed in the development of a program (Rossi *et al.*, 1999). In general, formative evaluation will be dominant in the early stages of a program and summative will take over as the program concludes.

Key Questions

Regardless of model or approach chosen, a number of key questions need to be answered when organizing a program evaluation (Thackwray, 1998):

- How is evaluation defined?
- What are the functions of the evaluation?
- What are the objects of the evaluation?
- What kinds of information should be collected regarding each object?
- What criteria should be used to judge the merit of an evaluation object?
- Whose interests should be served by the evaluation?
- What methods of enquiry should be used?
- Who should do the evaluation?
- By what standards should the evaluation be judged?
- How and when should the results be presented?

The process of considering these issues and integrating them into evaluative research design is very well exemplified in two evaluation models which have become hugely influential, namely case study evaluation as developed by Robert Stake and utilization-focused evaluation created by Michael Quinn Patton. An interesting range of examples of evaluation practice in complex learning organizations which respond to the above questions is provided in a recent publication of the American Evaluation Association (Braverman *et al.*, 2008).

Kirkpatrick's Model

Introduced over four decades ago, this model is still used by many for evaluating training and development programs and can be categorized as a results or goal-based evaluation (Figure 1). Initially a four-level model, it was later adapted to include a fifth level to measure return on investment. Each level measures different but complementary aspects of training and development. In essence, Kirkpatrick sought to stimulate those with responsibility for the management of training and development to increase their efforts in evaluating training and development actions. Critics of Kirkpatrick assert that his evaluation process may not always produce genuinely meaningful, long-term results. This model implies that evaluation is a standardized, prepackaged process, which is clearly not always the case.

Reaction or level one is easy to measure and quantify and is interpreted as determining how people feel about the program. Criticisms of this level state that it does not measure any learning which takes place so that moving to level two is important. Recommendations for level two include the use of a before-and-after approach so that learning can be related to the program. Evaluation of behavior or level three of this model is more difficult. It may be possible to appraise performance before and after the program or to have a posttraining appraisal 3 months or more after the program so that participants have an opportunity to put into practice what they learned. The fourth or results level is the most difficult area to evaluate effectively. This level defines results to include an institution's capacity to learn, change, and develop in line

with its stated agreed objectives. MacDonald *et al.* (2000) used Kirkpatrick's model to examine the impact of applying adult education principles to training in advanced technology companies. The evaluation explored levels one to four and data was collected by observation notes, post module surveys, post assignment surveys, and the participants' summative evaluation of the program. The authors suggest that the assignment data and summative evaluations confirm a level four on Kirkpatrick's model was reached on this evaluation.

Jacobs' Model

However, for many evaluators today, the process as well as the outcomes of modern evaluation has to be meaningful and compelling for the stakeholders if they are to have any useful impact on daily activities in organizations (Figure 2). The epistemic changes in both adult education and training and evaluation theory and practice outlined earlier in this article demand an operational model that permits built-in evaluations with continuous streams of information for both descriptive and evaluative uses. These changes also demand a methodology of evaluation that covers both the technical and social aspects and is comprehensive enough to include the historical, the political, the analytical, and the naturalistic aspects. Such an evaluation will be supported by statistics and stories, quantities and qualities, careful description, and impressions and anecdotes. The current literature on evaluation has many examples of such models. The following based on the work of Jacobs is representative.

Jacobs outlines a ten-stage evaluation model. The opening three stages are concerned with collaborative and negotiated understandings around the context and policy framework of the intervention, the goals of the evaluation, and the identification of and consultation with the principal stakeholders and relevant constituencies. Stages four through seven again involve iterative negotiated agreement on evaluation purposes and criteria, the interests to be served by the evaluation, the aspects of the program to be evaluated, the sources of information to be used, and the evaluation methods most appropriate. Stage eight involves the collection of data from the agreed sources and stage nine involves the analysis and interpretation of the data in the context of the agreed, negotiated criteria. Stage ten involves the dissemination of findings to the stakeholders and constituencies identified at the beginning of the process.

Jacobs stresses that evaluators should employ this negotiated and iterative process, regardless of where the call and resources for the evaluation have come from. She argues that it is central to the appropriate role of the evaluator to recognize the interests and rights of all legitimate stakeholders and to take into account power differentials between groups. Jacobs also advises that

Level 1 Reaction:	What the participants felt about the project or program – the happy sheet?
Level 2 Learning:	Internal validation – where the objectives met?
Level 3 Behavior:	External validation – has training transfer taken place?
Level 4 Results:	Has the project/program made a difference? That is, what has been the impact on the institution?

Figure 1 Kirkpatrick's four-level model of evaluation.

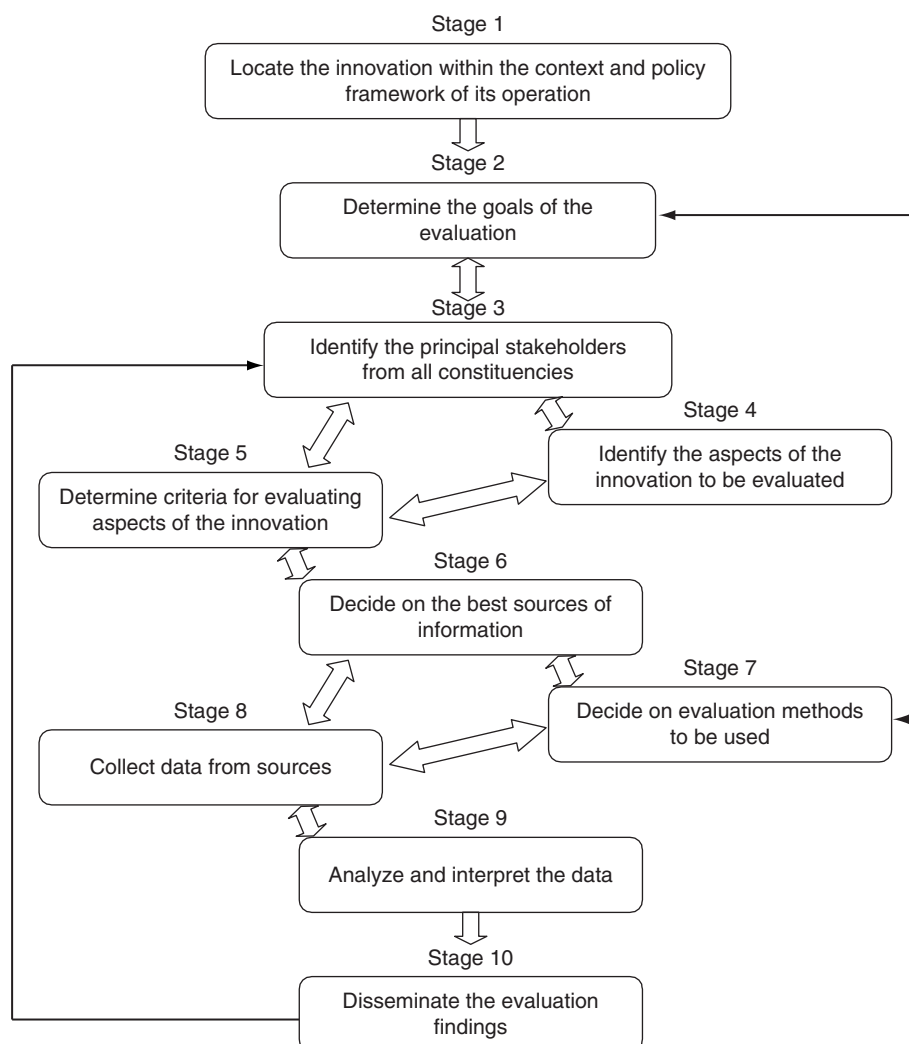

Figure 2 Stages in the process of evaluating educational innovation. Adapted from Jacobs, C. (2000). The evaluation of educational innovation. *Evaluation* 6(3), 261–280, with permission from Sage.

evaluators should give due weight to formative, summative, and illuminative goals and draw from the widest possible range of evidence.

Process-centered models of evaluation such as Jacobs' are widely used in areas of adult and vocational education where the emphasis is on personal and professional development rather than skills acquisition. A good example of collaborative and iterative evaluation in this vein can be found in the work of Bhola (1998).

Self-Evaluation

Despite the developments in evaluation theory and practice outlined so far, many of these models, including more progressive recent ones such as Jacobs', represent a form of evaluation which involves judgments made through the eyes of the external evaluator and the connotation persists of evaluation as an external monitoring of professional practice. The professionalization of evaluation,

the dominance of the contract and terms of reference, and the increasing use of consultants with little knowledge of the field in which they are trying to apply generic research methods are all likely to contribute to the legitimization of market-driven innovations which deskill and disenfranchise practitioners. Educational evaluation is not therefore an objective, external, value-free process, but rather is deeply influential in shaping educational philosophy and policy. The conceptual and ethical stance it adopts is influencing the educational debates to a significant degree.

One particular approach the present authors suggest is to move the focus away from external evaluation to one focused on empowering practitioners to self-evaluate. In the case of adult education and training programs the focus of judgment can move from the evaluators to the practitioners and the former can find a new role in supporting the professional development of the latter. Inviting educators to become the key evaluators of educational innovation as opposed to measuring the outcomes in

some external or objective way is of course controversial. For example, it can be argued that educators cannot be objective evaluators as at one level it is their work and effectiveness that is being evaluated. On this account evaluation must be primarily external. However, herein lies the dilemma not just of evaluation but also of perceptions of teaching and learning. On the one hand, there is increasing pressure to reduce teaching to merely implementing a proven or tested program of instruction. On the other hand, the literature of educational improvement has come increasingly to emphasize that the quality of student learning has to be seen in relation to the quality of teachers' learning.

This view of educators' professional learning emphasizes that the quality of teaching is closely bound up with the capacity of teachers to make professional research-based judgments on their own practice and on the programs and methodologies they are being required to implement. This approach is coming to fruition in initiatives such as peer review and peer observation of teaching, best-practice research scholarships, action research, reflective practice, practitioner-led research, and institution-wide development planning. However, for this to truly happen, the values and methodologies of self-evaluation must be inculcated into specific education and training programs.

Conclusion

Learning from and about evaluation often requires us to change our mental models – to rethink our assumptions and beliefs and to develop new understandings about our programs and evaluation processes. This logically should lead on to an organizational learning approach to evaluation. Such an approach to evaluation would be context-sensitive, ongoing, support dialog, reflection, and decision making at department and organization-wide levels, and contain strong commitments to self-evaluation and practitioner empowerment.

Effective evaluation is a significant contributor to quality but does not necessarily guarantee that those in authority will heed the outcomes of evaluation and take necessary corrective action. According to Kells (1992) institutions and programs can be strengthened substantially through effective evaluation and the basis for choices about the future can be soundly established by a combination of internal self-assessment and unbiased, informed peer review. If adult education and training programs are to gain from evaluation procedures and processes then the proper conditions for securing these improvements must be established. A vision of evaluation for the twenty-first century may be one which is made honest, accurate, and useful by engaging in a partnership with practitioners, people, and programs. Evaluators will be held to a higher standard and will be expected to do good through evaluation. In fact evaluation

must move from just generating findings about specific programs to generating knowledge.

To an increasing extent the evaluation model chosen is influenced by the evaluators' own philosophy about evaluation, although other factors such as time, resources, expertise, and availability of staff also strongly influence procedures used. Most program evaluation experts agree that there is no one best model. It is necessary, therefore, for the program evaluator to select a model which matches the requirements of a situation to produce evaluation findings which are most likely to accurately appraise a program's merits, worth, probity, feasibility, safety, significance, and equity.

Evaluation of Integrated Health Programs in School

T M Franke, University of California at Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

School-based health clinics provide an essential resource for children and families around the world. From a historical perspective they have clearly evolved in form and function over the past 100 years. One needs, only looking at the current outbreak of swine flu in the United States and throughout the world, to see an example of the role that school-based health clinics can play in identification, referral, and the dissemination of current information. This article focuses primarily on the development of school-based health clinics in the United States and the role evaluation has played in demonstrating the efficacy of integrated health programs in schools. In examining the literature around the evaluation of school-based health centers, several prominent themes appear. These themes include the evaluation of school-based health centers from the standpoint of utilization, mental health access/services, reproductive health, and clinic effectiveness/costs.

The History of School-Based Health Clinics in the United States

The beginnings of the American school-based health system can be traced back to the Progressive Era. From the mid-1850s through the early 1900s, industrialization, urbanization, and immigration were permanently changing city living. As more people moved to the cities, living and working conditions became increasingly worse, creating perfect conditions for the spread of disease and epidemics. These conditions were instrumental in bringing some level of healthcare to schools, where epidemics could easily be spread. Funding was provided to prevent such an occurrence. As was evident in the 1872 smallpox epidemic in Elmira, New York, which began the vaccination of the school children still practiced today (Dryfoos, 1994; Lear, 1996).

Disease would continue to open doors for school healthcare. For the next 20 years, epidemics swept through Boston and its schools. Boston's response was to start city-wide inspections, especially screening children at schools, for disease that spread quickly to other cities. By 1911, 300 cities required medical inspection; nine states had mandatory school health inspection laws while ten states permitted local agencies to hire school health inspectors (Kort 1984; Dryfoos, 1994).

The end of the Progressive Era (1890s–1920s) brought critical changes for school-based healthcare. The first was

a distinction between the medical treatment and preventive health services. Preventive health services would offer screening and health education, while medical treatment is the actual practice, diagnosis, and treatment of the disease. Free medical treatment in schools was perceived as taking away from the private practice of medicine. Some labeled it as a form of socialism and saw it as infringing on the rights of the family and home. One of the leading voices against healthcare in schools came from the American Medical Association that used its political power to discourage the medical community and society from supporting any service that could threaten the private fee-for-service medicine (Dryfoos, 1994; Lear, 1996). This effectively put a stop to the fledgling movement of school-based healthcare for many years.

School health policy would make drastic shifts between the 1920s and 1970s. By the end of the 1920s, the idea that the school was not meant to maintain health but rather just educate had emerged. Schools simply became referral points for private practice physicians. By the 1930s, educational psychology began to take over school healthcare. The focus in school-based healthcare shifted from treatment, case finding, and medical care to prevention, universal intervention, and health education (Dryfoos, 1994) and remained the primary focus of school-based health centers until the 1960s. With President's Johnson's War on Poverty, policy began to shift the emphasis back to case finding, and medical treatment as a result of new services such as (1) Medicaid, (2) Medicare, (3) Head Start, (4) Early Periodic Screening, Diagnosis, and Treatment (EPSDT), and (5) the Elementary and Secondary Education Act (ESEA). These led to later policies such as (6) the Education for the Handicapped Children Act of 1975 (subsequently renamed the Individuals with Disabilities Education Act).

1. *Medicaid* – Title XIX of the Social Security Act is a Federal/State entitlement program that pays for medical assistance for certain individuals and families with low incomes and resources. This program became law in 1965 as a cooperative venture jointly funded by the Federal and State governments to assist States in furnishing medical assistance to eligible needy persons.
2. *Medicare* – health insurance program administered by the United States government, providing health insurance coverage to people aged 65 or older, people under age 65 with certain disabilities, and people of all ages with End-Stage Renal Disease (permanent kidney failure requiring dialysis or a kidney transplant).

3. *Head Start* – a national program that promotes school readiness by enhancing the social and cognitive development of children through the provision of educational, health, nutritional, social and other services to enrolled children and families.
4. *Early Periodic Screening, Diagnosis, and Treatment (EPSDT)* – EPSDT is the child health component of Medicaid. It is required in every state and is designed to improve the health of low-income children, by financing appropriate and necessary pediatric services.
5. The Elementary and Secondary School Act (ESEA) – It is a United States federal statute enacted on 11 April 1965, which funds primary and secondary education such as professional development, instructional materials, resources to support educational programs and parental involvement programs. Recent reauthorizations of the Act include: Education Consolidation and Improvement Act of 1981, Improving America's Schools Act of 1994, No Child Left Behind Act of 2001.
6. The Education for All Handicapped Children Act (sometimes referred to using the acronyms EAHCA or EHA, or Public Law (PL) 94-142) was enacted by the United States Congress in 1975. This act required that all public schools accepting federal funds to provide equal access to education for children with physical and mental disabilities. Public schools were required to evaluate handicapped students and create an educational plan with parent input that would emulate as closely as possible the educational experience of non-disabled students.

Shortly after, new models for school-based clinics and services began to emerge. These school-based health clinics (SBHCs) were programs created under medical supervision that typically operated out of a health department hospital or community health center. The first three models were prototypes for the school-based health clinics to come. In Cambridge, Massachusetts, the Cambridge program featured primary care medical clinics within elementary schools staffed by pediatric nurse practitioners. The Hartford project made dental and primary care services available to all students in one urban and one suburban school in Hartford, Connecticut. In Galveston, Texas, pediatrician Philip Nader linked Galveston School District health services to those offered at University of Texas Medical Branch (Lear, 1996). The Posen-Robbins program pioneered setting up medical clinics in the very disadvantaged neighborhood of Cook County, Illinois with a team of two full-time school nurse practitioners, four health aides, a lab technician, and outreach workers along with medical backup offered by two neighboring hospital physicians. SBHCs would learn from these first schools and start to proliferate quickly (Dryfoos, 1994).

As many new SBHCs appeared, research was needed to evaluate the efforts; however, this proved to be a difficult

endeavor. The main problem was that the children and families who benefited from the programs were moving targets. A significant proportion of children and families did not stay in the same schools for very long – a challenge that still exists. (The United States has the highest rate of residential mobility among industrialized countries. According to the US Census Bureau (2000), every year nearly 1 in 6 persons (17%) in the US relocate or change their place of residence.)

Although school mobility has the potential to affect school performance, social and emotional performance, and peer relationships (Mehana and Reynolds, 2004; Nelson *et al.*, 1996), it is especially problematic when attempting to perform evaluation of school-based health services. The cost of evaluation could end up equaling or exceeding the cost the service provided (Dryfoos, 1994). Despite this, by the early 1990s, many programs had appeared throughout the USA and substantial evaluation of school-based health clinics was being conducted.

Finances have emerged as another core issue for SBHCs. Government healthcare programs operate through managed care delivery systems, which makes receiving reimbursements for out-of-network service very difficult. Nevertheless, school-based health clinics have adapted and evolved. The 2004–05 National Assembly on School-Based Health Care census identified 1235 school-based health centers, 805 offering mental health services and 153 offering dental health services (NASBHC, 2005).

Evaluations of School-Based Health Centers

Overall, more discourse exists on the positive findings associated with SBHCs. The focus of the evaluations ranges from utilization to program and cost effectiveness and typically addresses health broadly. The following sections will examine several prominent themes in the evaluation of school-based health centers.

Utilization

Numerous evaluations have been implemented to compare students' use of medical, mental health, and substance abuse services located in school-based centers with traditional locations. The School Health Demonstration Program (SHDP) in New York provided low-income families with children in preschool through 12th grade with primary care. This program was created with the help of the New York State Department of Health, Education, and Social Services and comprised a team consisting of a nurse practitioner, health aide, and a pediatrician or family practice physician acting as supervisor and was linked to a local health facility that provided medical, dental, and mental health counseling services.

It allowed parents to choose level of care on the enrolment forms and provided health education curricula, which focused on family life education, dental health, summer safety, etc.

The evaluation examined data from nine states in which the SHDP was first implemented. Approximately 36 000 children from 55 public, parochial, and private schools were invited to participate in the program; with 22 689 finally enrolled. The evaluation found that parents chose levels of care greater than the regular school health services, with 53% selecting comprehensive physicals for complete care (NYSDoH, 1983). Overall, the SHDP had 83 602 encounters with children during the school term, including 38 514 screenings, 22 373 primary care services, 15 055 first aid visits and responses to minor complaints, 9121 follow-up visits, 7212 comprehensive physical exams, and 2119 immunizations. In addition to an increase in healthcare utilization, the NYSDoH (1983) evaluation found that principals and teachers reported support for the program, appreciated having it as a quick-response resource for disease and unintentional injuries and felt the program had positive impacts on attendance and learning.

Another study by Anglin *et al.* (1996) focused on 3818 adolescents and three high school-based student health centers using 4 years of archived data to find the frequencies of student use of the SBHC. Adolescents who used the SBHC had higher rates of visit frequency than those that used traditional medical care. The evaluation found that 94% of the students used the clinic for medical providers; 25% for mental counseling; and 8% for substance abuse counseling. The visit frequency increased significantly for students who used two and three categories of service; going up from four to five visits for a single service type to 13–15 for two categories of providers and 32 total visits if all three services were used. Overall, SBHCs increased adolescents' access to medical, mental health, and substance abuse services.

Kaplan *et al.* (1999) looked at the effects of SBHC access and utilization of physical and mental health services by children between 4 and 13 years old. The study compared a school with an SBHC and a comparison school in Denver, CO both having 93% Hispanic students with over 85% being on free-lunch programs. The study was a retrospective cohort analysis of parent surveys from both schools with return rates being 570/728 at the intervention school and 440/571 at the comparison school (Kaplan *et al.*, 1999). The results showed that families utilizing the SBHC reported less difficulty receiving physical healthcare for their children compared to the comparison group; access to the SBHC was independently and significantly related to lower emergency department use and greater likelihood of a yearly physician's visit and annual dental examination. Respondents using the SBHC as their primary health service reported significantly more

satisfaction with the services offered than respondents who mainly used hospital and community clinics. Traditionally underserved minority children, with access to SBHCs, receive significantly better healthcare than those without SBHC access, independent of insurance status and confounding variables (Kaplan *et al.*, 1999).

Mental Health Access/Services

By the mid-1990s, there was mounting evidence that traditional mental health services were not available and not adequate to meet the needs of school age children (Weist *et al.*, 1996). Pastore *et al.* (1998) examined students with mental health problems who had access to SBHCs. A questionnaire was administered on health center use and mental health concerns in an urban high school with a 2-year-old SBHC in New York, NY; 630 responses were received from both users and nonusers of the SBHC (Pastore *et al.*, 1998). Three significant findings emerged. First, average users, frequent users, and nonusers did not differ in mental health problems measured. Second, students who used the SBHC's mental health services were strongly satisfied with the care they received (92%). Third, the study found that respondents had a variety of reasons for nonuse: 60% already had a physician, 50% said they did not need it, and 45% preferred continuing previous healthcare. While the study has some limitations, it demonstrated satisfaction and utilization of mental health services available through an SBHC.

Research continued to look at mental health programs and the ability to bridge the gap between service need and service utilization at the school level. Armbruster *et al.* (1997) looked at the central clinic collaboration with the New Haven Public Schools to establish health services for thirteen inner city schools in 1992. The purpose was to compare the characteristics, both clinical and socio-demographic, of the children in the school-based clinics to those in the central clinic. A similar follow-up study by Armbruster and Lichtman (1999) looked at efforts to bridge the gap between service need and service utilization at 36 inner city schools with a sample of 220 clinic cases and 256 school cases of children and adolescents 5–18 years olds. The study found that children from both groups had similar Children's Global Assessment Scale (C-GAS) and Global Assessment of Functioning Scale (GAF) improvements even though the school case children were seen for a shorter period of time (5 months vs. 8 months for the clinic case children), with both samples having an equally frequent level of service of three sessions per month in each setting. The study also notes that the school-based mental health program was also more cost-effective for three reasons: (1) no attrition as children were seen in school; (2) due to program effectiveness, grant funding from public and private sources has increased; (3) school-based services

were part of the child's psychiatric outpatient clinic and were easier to reimburse.

Reproductive Health

One of the very early programs was the Health Start program; a nonprofit organization based in St. Paul, Minnesota, which beginning in 1973 offered comprehensive, multidisciplinary healthcare to adolescents, which included laboratory tests, including pregnancy tests, onsite. The main purpose of the program was to prevent unwanted pregnancies and provide prenatal care to female students in seventh through twelfth grades (Edwards *et al.*, 1980). From its inception through the 1978–79 school year, the clinic serviced 403 students, 85 of which were given prenatal care and subsequently delivered at the St. Paul-Ramsey Medical Center.

Data on all 403 students who received family planning services and/or prenatal care at the three Health Start school clinics were reviewed. The researchers also calculated contraceptive usage and the fertility rates for the female population for each year the clinic was open. The evaluation had limited findings; however, it did show that by the 1977–78 school year, 25% of the schools' female students were receiving family planning services through the Health Start clinics, and 87% of those receiving family planning services were still using contraception three years later (Edwards *et al.*, 1980). The Health Start clinics later evolved into general adolescent health clinics in five St. Paul high schools.

Another early program, the Self Center Program, was a project that dealt with pregnancy and associated issues for seventh through 12th grade students. It tried to raise students' knowledge on issues such as reproductive biology, pregnancy, and sexual activity. The goals were to postpone the onset of intercourse, increase clinic attendance and contraception use, while lowering the risk of pregnancy. The program was a collaboration between The John Hopkins University School of Medicine and the Baltimore City Departments of Education and Health and included both mental health services and clinical services along with the health education. The program provided classroom presentations, education and counseling services within the school, and education, counseling and medical services provided after school in a storefront clinic. The staff consisted of a registrar, nurse's aide or licensed practical nurse, a physician (on some days) and two teams of a social worker and a pediatric nurse practitioner or nurse-midwife.

Extensive evaluation conducted from 1981 to 1984 as part of a study was focusing on African-American students in both junior and senior high schools living in public housing in inner-city Baltimore (Zabin *et al.*, 1986). The program groups consisted of 667 males and 1033 females from one junior and one senior high school, and the control

group included 944 male and 1002 female students from two other junior and senior high schools. The program and control groups completed pre- and post-program questionnaires. The program groups completed follow-up questionnaires for three subsequent years. The researchers found that after 16 months of exposure to the program, the pregnancies rose by 13% among program females, while rising 50% among controls; after 20 months, pregnancy rates fell 22.5% among program females, while rising 39.5 among controls. The trend continued in the same direction, as after 30 months, pregnancy rates fell 30.1% among program females, while increasing 57.6% among controls. The post-program analyses revealed that less than 20% of the program females had participated in unprotected intercourse versus the 44–49% of the control group.

Kirby *et al.* (1991) focused on the reproductive health programs of six school-based clinics that were only part of a comprehensive health program and differed in emphases on reproductive health, sexuality education, and family planning. However, each clinic employed at least one physician and nurse practitioner within the school. The main purpose of the program was to influence sexual behavior and contraceptive usage among ninth through twelfth graders. The schools represented various socioeconomic populations, both rural and urban; however, the majority of the students were low-income families with large proportions of African Americans and other minorities with limited access to healthcare.

The Kirby *et al.* (1991) study had somewhat limited findings overall. In one of the three sites that provided contraceptives in the clinic, students were significantly more likely than comparison school students to use birth control during last intercourse. At the same time, Kirby *et al.* (1991) found that one clinic school with a strong AIDS education program observed a sharp increase in condom use; one clinic school with a strong pregnancy prevention component observed a higher use of condoms and birth control pills relative to its comparison school. However, the study could not show a difference in pregnancy rates between schools with clinics and schools without clinics. The study also found that students in schools with clinics did not engage in sexual activity earlier than students at schools without clinics.

Research throughout the 1990s and 2000s continued to look at SBHCs impact on fertility rates. Ricketts and Guernsey (2006) examined the decline in fertility rates among African-American adolescents in Denver between 1991 and 1997 and its possible association with the Denver SBHCs. The team compared the changing fertility rates among areas with and without SBHCs by using geocoded birth certificates and school enrollment data. The African-American fertility rate declined significantly in areas with SBHCs, enough to suggest that SBHCs were effective in meeting the needs of students at risk of pregnancy (Ricketts and Guernsey, 2006). The African-American fertility rate

in SBHC areas dropped from 165/1000 in 1992 to 38/1000 in 1997. The team found that the rate of decline in areas with SBHCs was significantly greater than areas without SBHCs, 77% and 56%, respectively. The decline is credited to SBHCs being able to properly identify, intervene, and follow-up on high-risk students (Ricketts and Guernsey, 2006).

Clinic Effectiveness/Costs

One of the central concerns with school-based health clinics in the United States is whether or not there is a real benefit to the children, and at what financial cost. Research has shown that SBHCs offer both educational benefit and medical benefit. The Gillespie Student Health Project in Greensboro, North Carolina, is an example of a program that showed educational benefits to students from its evaluation. The program involved the Guilford County Department of Public Health, the Moses Cone Hospital, Greensboro Public Schools and the Robert Wood Johnson Foundation in providing an Alternative Education Program (AEP) which taught health education, health promotion, and screening. The clinic served low-income, at-risk students, over half living in single-parent female-headed households (Klein and McCord, 1992).

The researchers sought to determine associations between clinic use and positive scholastic outcomes, lowered rates of absences, suspensions, dropping out and increased rates of promotion and graduation; data were taken from archival student records, school attendance records, and clinic use records on all AEP students ($n = 322$) during the 1990–91 school year. Students who used the clinic had a lower rate of absence than students who registered but never used the clinic and those who did not register. They also found that students who were registered for the clinic were more likely to stay in school as opposed to the students who did not register (44% vs. 29%), and that registered students were also more likely to graduate and/or more likely to be promoted than the nonregistered students (Klein and McCord, 1992).

The School-Based Adolescent Health Care Program (one of the bigger programs) offered evidence of medical benefits to the students in the SBHCs. Started in 1986 by the Robert Wood Johnson Foundation, the program awarded grants of up to \$600 000 to public and private institutions to set up adolescent health centers (Brodeur, 2000). Twenty-four sites were established across the nation with the goal to deliver primary healthcare services to high school adolescents (Lear *et al.*, 1991). The program offered clinical, health education, counseling and mental health services as well as community coordination.

The evaluation focused mainly on students from 23 clinics in ethnically diverse high schools in 14 cities and 11 states (Lear *et al.*, 1991). The grantees sent quarterly

reports to the Robert Wood Johnson Foundation for analysis, which looked for trends, characteristics, and other important findings over the 3 years of reports. Lear *et al.* (1991) found that of the 34 106 students that had been enrolled in the 23 clinic schools, 46% of the students were clinic users; each of the clinics had, on average, 685 users. Acute illness or injury made up 26% of the total visits; it was the leading service provided by the clinic. Mental health-related care was second in frequency, making up 21% of the clinics visits while reproductive health made up only 12% of the total visits. A trend was also found in terms of parental consent to school-based healthcare, with a steady rise from 34% in 1987 to 71% in 1989–90.

Kisker and Brown (1996) independently evaluated the School-Based Adolescent Health Care Program for whether or not SBHCs offered improvements in access to health care, health status, and risk-taking behavior. The study compared a cohort of students attending 19 participating schools with a national sample of urban youths, using logit models to control for observed differences in the groups. The team compared health center utilization, use of other healthcare providers, knowledge of key health facts, substance use, contraceptive use, sexual activity, pregnancy and birth rates, and health status. They found small, nonstatistically significant impacts on health status and risky behavior although health centers did increase students' access to healthcare and improved their knowledge about health. The team recommended more intensive or completely different services in order to produce significant reduction in risk-taking behaviors.

Other programs, such as the Middletown Adolescent Health Project (MAHP), demonstrate that SBHCs have financial outcomes that are, in fact, cost effective. The project was launched with the cooperation of the local school district, with clinic staff from the Delaware Division of Public Health and intended for ninth through twelfth grade students in rural Middletown, Delaware. A regular school nurse served as a liaison, referring students to the clinic. The main purpose was to provide school-based, comprehensive health services such as treatment of minor and acute illnesses, sports and routine physical examination, laboratory tests, screenings, medical social services, and a number of other services.

The evaluation of MAHP was conducted from 1985 to 1986, was rather simple, consisting of assessing and comparing project cost of the program with the costs of private health available and surveying users' feelings about the project (Siegel and Kriebel, 1987). All the students in the project received the survey, which was distributed and collected over a 3-month period by the evaluation team. Evaluation concluded that the school clinic was able to provide services to many students by being geographically accessible, whereas 68% of the students had a regular doctor outside of their rural community (Siegel and Kriebel, 1987). The clinic was also able to help those who

were economically disadvantaged, from families with one or no wage earners (58% of enrollees). In addition, the clinic also had fewer than 6% of scheduled appointments cancelled due to student no shows. The clinic also proved to be cost-effective to the parents; the treatment costs of MAHP were lower than the costs of the same treatment or services from private physicians. By the end of the first school year of operation, half of the 658 students had used the services.

The effectiveness of SBHCs has also been studied with regard to sexually-transmitted disease (STD) screening and treatment. A study performed by Cohen *et al.* (1999) attempted to determine whether SBHCs' repeated screenings and treatment for gonorrhea and chlamydia would have effects on the infection rate. The team used three high schools with SBHCs and offered over 2000 students at each school an opportunity to get tested for three consecutive years. The team's comparison group was 5063 students at five comparable schools that were used as wait-list controls. Annually, 52–65% of all enrolled students participated, while those who had been in the school for at least 2 years had participation rates of 83.4% for at least one test (Cohen *et al.*, 1999). Intervention and treatment included education, counseling, and treatment with oral single-dose antibiotic therapy.

Research has shown that SBHC may end up saving the states' Medicaid program money. Adams and Johnson (2000) assessed the effects of the Whiteford Elementary School-Based Health Clinic (WESBHC) in Atlanta, Georgia for the years of 1994 through 1996. Their target population of children 4–12 on Medicaid compared to those from another district with no SBHC. Adams and Johnson (2000) identified the sporadic users as well as the frequent users of the WESBHC and analyzed Medicaid claims and expenses per each child enrolled for both the SBHC group and the control group. In 1994, no change in expense was found; in 1995, WESBHC students had significantly lower emergency department expenses; in 1996, WESBHC had lower inpatient, emergency department, nonemergency department transportation and drug Medicaid expenses (Adams and Johnson, 2000). Multivariable analysis confirmed the effect of the WESBHC on lowering the Medicaid emergency department expenses.

To justify SBHCs, some studies looked at the impact those centers made on students, specifically with medical conditions. The Guo *et al.* (2005) study looked at the SBHC impact on children with asthma in terms of hospitalization and emergency department visits. The team conducted a longitudinal quasi-experimental time-series repeated measures design from 1997 to 2003 at four SBHC intervention school districts and two comparable non-SBHC districts in Cincinnati, Ohio. Only children with at least 2 years of continuous enrolment for asthma claims and medications were selected for the sample of 273 children, 196 in SBHC schools, and 77 in non-SBHC schools. The team used student enrolment data and Ohio

Medicaid claims data as well as generalized estimating equation and covariance analysis.

The SBHC programs saw a lowered risk of hospitalization and emergency department visits for children with asthma (Guo *et al.*, 2005). After the SBHC opened, the relative risks of hospitalization decreased 2.4-fold, while emergency department visits decreased by 33.5%. The emergency department visit costs for children in the SBHC were significantly lower than children in non-SBHC schools, and the cost of hospitalization was significantly decreased for children in the SBHC with potential cost-savings estimated at \$970 per child.

One of the more recent evaluations was the Newark Case Study (Silberberg and Cantor, 2008), which looked at three elementary and two high schools with a low-income, largely minority, high-needs population that had SBHCs in Newark, New Jersey. These clinics were created through a partnership with a local hospital and the public school system and had a full-time pediatric nurse practitioner, a social worker, and an administrative assistant working there. They offered referrals for dental, primary and preventive care services, health education and held health fairs.

The study to establish whether or not new models of care were needed in Newark, assess whether clinics already in place were having an effect on health, and shed light on the extent to which student care might be covered by Medicaid and the State Children's Health Insurance Program. A total of 478, predominantly African American, parents were interviewed, 323 from clinic schools, and 155 from nonclinic schools (Silberberg and Cantor, 2008). The findings demonstrated that SBHCs made a difference in health service utilization; however, after the first visit, the study found no association between clinic availability and health-services utilization, which led to a high level of unmet health needs. However, parents rated clinic care significantly and substantially higher than HMO care and gave clinics significantly higher marks for cleanliness, physical condition and translation services when needed (*ibid*). Silberberg and Cantor (2008) found insufficient support for the integration of clinics into public insurance programs. Specifically they found: (1) no general impact on emergency-department use and hospitalization; (2) magnitude of the difference of using healthcare only eight percent with medical, dental, and mental health; (3) after the first-visit effect, there was no impact on health-service utilization (visits to clinics substituted for visits to the community-based provider); (4) no difference between clinics and nonclinic schools on common measures of access to care or health status.

Lessons Learned and Next Steps

Driven by a variety of mechanisms including statutes, policy, and principles, those committed to supporting and enhancing the efforts of SBHC continue to strive to

identify and implement effective models of practice, service provision, and appropriate research/evaluation designs. Despite these efforts, the body of evidence remains somewhat limited and rigorous research/evaluation efforts are needed to continue to build the current evidence base. Over the past 15–20 years, the performance expectations placed on SBHC receiving funds has steadily increased, as it has in most other health, education, and social service settings (e.g., Government Performance and Results Act). The Government Performance and Results Act (GPRA) is a United States law enacted in 1993. It is one of a series of laws designed to improve government project management. The GPRA requires agencies to engage in project management tasks such as setting goals, measuring results, and reporting their progress. In order to comply with GPRA, agencies produce strategic plans, performance plans, and conduct gap analysis of projects). The complexity of the problems, settings, issues, and populations being addressed by school-based health centers presents a number of challenges to randomized designs (e.g., RCT) similar to a few of those discussed previously. Other distinct and equally rigorous frameworks and methods exist that may present distinct advantages in the situations typically found in investigating school-based health centers and the services they provide. These include the use of regression discontinuity designs or propensity score matching procedures. Regression discontinuity (RD) designs are used for evaluating the causal effects of intervention when random assignment is not possible. Assignment to treatment is determined by a cut-off value on the pre-treatment measure. Methodologically, inferences that are drawn from a well-implemented RD design are comparable in addressing threats to internal validity to conclusions from randomized experiments (see Shadish *et al.*, 2002). Another way of addressing the issue of selection bias in nonrandomized experiments is the use of propensity score matching. In its most straightforward form, propensity score matching employs a predicted probability of group membership (e.g., treatment versus control) based on observed predictors, usually obtained from logistic regression to create a counterfactual group (see Luellen *et al.*, 2005).

Trends toward the use of evidence-based practice (e.g., What Works Clearinghouse) are likely to be strong and enduring. There are guidelines and benchmarks being developed both in the United States and internationally across numerous disciplines. Researchers involved in SBHC evaluation need to be involved in their development and application. The increased attention on program outcomes also leads to a challenge that, so far, evaluations of school-based health centers have often navigated successfully – linking program measures to program objectives.

One of the primary challenges in measurement is identifying outcome measures that accurately capture

the objectives of the program. This will become increasingly more important, both in the USA and internationally, as the pressure to be evidenced based is combined with the scarcity of funds and an increase in the number of entities competing for those funds. These combined pressures have a tendency to influence programs into drifting away from actual program objectives and aligned measures, what it was designed to accomplish (e.g., reduce absence), toward a more global level, yet on the surface equally important objectives (e.g., improvement in grades). The idea of drift or distance from the core program objectives can be thought of as a continuum ranging from more proximal to more distal outcomes; outcomes closer to program objectives are referred to as being more proximal while those that are more removed are referred to as distal. For example, measuring the effect of service provision alone, assuming it is effective, will be increasingly more difficult as one uses measures that are further from the actual program objectives, more distal along the continuum (e.g., reducing school-wide absence to increasing school-wide academic performance). To put it more simply, the measurable impact of service provision decreases as the distance between real program objectives and measured program outcomes increases. Evaluators need to be constantly aware of this potential drift. School-based health centers work and the body of evidence supporting this is growing.

Formative Assessment in Teacher Education and Teacher Professional Development

H Tillema, Leiden University, Leiden, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In teacher education and the professional development of teachers, assessment is increasingly being recognized as a valuable tool to promote development and growth in the profession, that is, not only as a means to certification and qualification (Cochran-Smith, 2005) but also as a tool for learning. First, the nature of formative assessment is circumscribed; it essentially means providing informative feedback to the learner and its prime function is to deliver insight into improvements in performance. Second, formative assessment in teaching is delineated as a process of compiling performance evidence, appraising the collected information, and, subsequently, providing feedback in such a way that teaching practice(s) can be improved. It is this (in)formative nature of assessment that makes it valuable to professional growth. Third, it is clarified how different assessment tools or interventions may help the (student)teachers as learners to benefit from assessment which depends to a large extent on the (1) nature of feedback given and (2) the assessment arrangement (i.e., tools and approaches). Finally, reviewing the research on effective formative assessment arrangements, it is shown in what ways feedback can concentrate on (bridging the discrepancies between) where the learner is and wants to go, that is, develop (Sadler, 1998). This implies that formative assessment needs to be integrated and aligned with instruction (Segers *et al.*, 2003) and occurs alongside with mentoring for development (Wang and Odell, 2004).

The Nature of Formative Assessment

Formative assessment is about feedback. In teacher formative evaluation, assessment instruments are means to provide feedback on action, and it is through this informative feedback that one learns (Hattie and Timperley, 2007). Supporting teachers as learners requires moving beyond providing mere knowledge of results to a type of functional (i.e., performance-related) feedback that can articulate developments in practice, anticipate professional learning needs, and monitor the learner's progress during a course of teacher action. Assessment instruments, thus viewed as learning tools, are to enhance insight into both current and aspired levels of performance and, based on this, are to provide possible or alternative learning routes (Zeichner

and Wray, 2003). We need to distinguish this learning-oriented, (in)formative assessment from a summative, often externally initiated or mandated, assessment that documents and appraises work performance in relation to mandate evaluation requirements (De Landshere and Arens, 2003). Assessment in this latter sense is interested in the certification of marked achievements which are being appraised and judged against a set of external standards (often labeled as standard testing or competence testing; Sachs, 2003). Summative assessment for achievement evaluation usually occurs after learning has taken place; and as such, it has its own legitimized function in teacher education (i.e., serving an accountability warrant). Formative assessment, however, occurs in alignment with instruction and learning (i.e., to inform the learner about redirecting and regulating development in competence growth) and adds value to recognition, interpretation, and utilization of teaching experiences in line with the (often personal) goals for achievement (Zimmermann, 2000). Collecting such targeted feedback information by assessors, often together with their assesseees, is meant to scaffold a meaningful appraisal and subsequent decision making on the (alternative) routes to be taken for further professional action (Loughran, 2003). Typically, formative assessment tools document and elucidate a cyclical or recurrent process of professional activity in order to provide a better understanding of one's practice experiences in teaching (Smith and Tillema, 2003). This is accomplished through a continuous monitoring of performance over extended periods of time. As such, it is usually a highly authored process of personal data collection (Wang and Odell, 2003). The formative assessment process, therefore, evolves alongside professional practice to scaffold and integrates professional development goals and learning needs (Havner and McDowell, 2007).

Providing Informative Feedback

Reviews on the impact of formative assessment (OECD, 2005; Lievens, 2001; Darling-Hammond and Bransford, 2004) show that learners neither value feedback *per se* nor accept its deliverance wholeheartedly. Indeed, they are sometimes reluctant to use feedback information that is provided to them. Therefore, simply providing corrective feedback can be counterproductive and may elicit resistance,

Collection	(Reflection)	Appraisal	Recommendation	(Further learning plans)
Compilation and documentation phase	Conceptualization and elucidation of collected data	Provision of feedback and dialog phase	Acceptance of feedback and following recommendations	Intended actions in practice contributing to further professional development

Figure 1 Stages in the deployment of formative assessment for teaching. The steps in brackets refer to an extended interpretation of the formative assessment process, with special relevance to teacher development.

especially when issued too frequently (Falchikov, 2005). Furthermore, studies show clearly that acceptance of feedback is related to the way it is provided, that is, tool dependent (Hattie and Timperley, 2007), which essentially means that particular assessment tools may serve specific learning goals. Moreover, it needs to be noted that beliefs on personal efficacy filter the feedback information (Waldman and Atwater, 1998). In sum, it has been found that factors in feedback delivery (i.e., the assessment tools used) result in divergent acceptance of feedback (Shute, 2008). Formative assessment, therefore, is a complex process, involving distinct steps or stages in its deployment. **Figure 1** depicts the interplay between them with special reference to teacher learning and development.

The collected and to-be-appraised assessment information must fulfill certain requirements to be followed for action, that is, be of relevance to the improvement of teacher practice. Above all, it must be cognitively acceptable in that it correlates with a learner's prevalent goals or perceptions about aspired performance levels (i.e., both in expectations and actual goal setting – Zimmerman, 2000). Crucial to acceptance of feedback is the learners' resolution whether following recommendations is of any advantage to their future action (Topping, 1998). Positive recommendations tend to be accepted and followed more easily than negative or corrective feedback (Waldman and Atwater, 1998). Recommendations, however, given along different performance dimensions (Thornow, 1993) are not found to contribute to a targeted learning. Clear and univocal recommendations that may guide future action are to be preferred over breadth and completeness of advice. Typically, assessment, in which information is collected and appraised in reference to personal standards and aspirations, proves to be a helpful feedback instrument (McDowell, 1995). Furthermore, studies indicate that the amount of feedback information given during appraisal may influence its acceptance (Wade and Yarbrough, 1996); a focused provision and delivery helps to integrate feedback information and subsequent action. In overview, several features in the arrangement of formative assessment have impact on following recommendations. Particularly, assessment as an intervention is considered positively when it is characterized by the features listed in **Table 1**.

Table 1 Principles for providing feedback in assessment for learning

- Being task and goal oriented
- Consistent with pre defined criteria
- Give positive praise and constructive comments
- Focused on particular qualities of the person involved
- Identification of strength and weaknesses in performance
- Guidance about what to improve in performance
- Held in climate of trust
- Occurs strategically throughout learning
- Has a shared understanding between assessor and assessee about purpose of feedback

These principles of assessment interventions and feedback delivery are extracted from proposals of the Assessment Reform Group in Great Britain: *Assessment for learning: 10 principles* (2002) www.assessment-reform-group.org.uk and the OECD report on *Formative Assessment: Improving Learning in Secondary Schools* (2005).

Assessment as Intervention

The way formative assessments are being arranged (i.e., as a deliberate intervention in support of learning) strongly influences what will be learned (i.e., what will be followed as recommendations for action). The strength of an assessment intervention (which is more than the tool itself) is essentially determined by the way it exhibits, appraises and interprets the collected evidence on performance. An assessment arrangement starts with the collected record of performance evidence and ends with the modification of that performance (see **Figure 1**). Typically, in assessment for teacher development, it is the collector, that is, (student) teacher, who compiles instances of practice-related, authentic (Wiggins, 1998) performance and in fact determines what is offered for appraisal. The assessor (i.e., teacher educator, or mentor), in turn, typically is put in the role of feedback provider (Loughran, 2003); and both, that is, (student) teacher and assessor/mentor, are involved in valuing the gathered information (Delandshere and Arens, 2003). Although this process of assessment as intervention in teaching may seem straightforward, it requires a set of framing factors that leads to different assessment arrangements. The arrangement of an assessment is at least governed by the following framing or design factors:

1. the way information is collected, that is, how the collected information is gathered as evidence;
2. the content to be provided in the assessment (the domains and topics in the collected information), that is, what is being collected;
3. the nature of evidence collected (the type of information that will be regarded as relevant), that is, what counts as evidence;
4. the involvement of different types of raters to appraise the collected materials, that is, who is being rated by whom;
5. the purpose of further development (degree of autonomy in support and mentoring), that is, at what stage in development is the information utilized;
6. that is, the criteria for appraisal (i.e., the selection of levels in achievement), which means by what standards it is reviewed;
7. the (time and contextual) frame in which information is collected (setting and duration of the collected information), that is, when and where it is applied.

Table 2 explicates the design decisions that are possible in the arrangement of a formative assessment intervention.

How an assessment for teacher development actually is arranged (i.e., as highly structured with strict standards and pre-specified conditions or not) will determine the nature and impact of feedback. That is, the assessment as an intervention articulates the functionality of feedback.

Different Tools of Assessment for Learning in Teaching

There are several assessment tools in use in teacher education and teacher development to support professional competence development.

The Portfolio

The portfolio (or its digital version: the e-portfolio) is one of the most widely used formative assessment tools in teacher preparation and development; in essence, it is a purposeful collection of work over a period of time. The core elements of the portfolio as a product are:

- *An index.* An indication of what performance evidence is to be included in the portfolio; often in reference to

the teacher-education program's intended learning outcomes.

- *The description of the portfolio entry.* For each entry, clarifying information indicates what actually has led to or would scaffold, and helps to interpret the collected evidence.
- *The evidence.* The core of the portfolio compilation consists of several folders in which the learner has gathered materials that demonstrate certain performance outcomes for each identified goal. This may take several forms, such as analysis of pupil observation, critical incidents in classroom management, work/timetables, notes from project meetings, mentor evaluations, or other suitable materials.

The following elements of the portfolio can be optional:

- *Learning experiences.* An indication of the learning experiences encountered with respect to each particular learning goal/entry.
- *Proposed further actions.* A self-determined indication of the future steps needed to be taken for further development.

The information provided in the portfolio product constitutes the input for the subsequent feedback meeting with the assigned teacher mentor or professional development coach as the feedback provider. The utilization of framing factors in the design of the portfolio (see **Table 2**) leads to different types of teaching portfolios:

1. *Dossier portfolio.* This type of portfolio specifies products of work-related performance included by the learner as best evidence of accomplishments in teaching. This dossier portfolio is a vehicle to collect practice materials to be evaluated in appraisal meetings with the (student) teacher's mentor, coach, or critical friend (Day, 1999). The provided feedback results in concrete assignments and redirections of future work.
2. *The (professional) development portfolio.* During a course (in teacher education or in a professional development program), a detailed description of evidence is compiled to show the attainment of program objectives by the learner. This type of portfolio highlights accomplishments regarding specific targets and favors a display of successive steps in the attainment of goals. The following additional steps to the portfolio's core elements are included (see **Table 2**):

Table 2 Design features of an assessment arrangement

Collection of information	Content to be provided	Nature of evidence	Involvement of raters	Purpose of support	Criteria in use	Context of assessment
Guided	Bounded, restricted	Best evidence	Single assessors – single assessee	Reflective oriented	Prespecified	Constrained
Open	Unspecified	Sampled collection	Multiple assessors – multiple assessees	Performance oriented	Negotiable	Open

- a. *Defined competences/targets to be attained.* Often in the form of a contract, the learner together with the teacher educator/coach specifies which competences are to be given attention during a certain period of time.
 - b. *Self-assessment.* As the contract represents the personal learning goals for the learner, the goals themselves are often framed as discrepancies between self-perceptions about competence levels and the external standards set by the program.
 - c. *Portfolio compilation.* For each specific learning goal, performance evidence is collected, showing visible and tangible proof of competence attainments in the actual work environment, relating it to the standards of competences stipulated in the contract.
 - d. *Presentation of the portfolio.* At agreed-upon moments during the course/training/development program, the learner offers his or her portfolio for identifying the accomplishments that merit further effort in development.
3. *Reflective or personal portfolio.* This type of portfolio is best described as a learner report or account on the professional growth of being a teacher, attained over an extended period of time. The reflective portfolio records notable achievements in daily professional practice (not only best evidence as is the case in the dossier). The choice of records is defined, and selected beforehand by the learner in the introductory, reflective part of the portfolio-index. The learner is the prime owner of both the portfolio construction process as well as the subsequent appraisal process. The reflective portfolio adds the following elements to the core portfolio:
- a. *Focus and scope.* The learner makes a deliberate choice regarding the relevant professional targets to pursue during the period of time and selects various learning goals to be worked out at greater depth.
 - b. *Evidence.* The nature of evidence can be highly diverse and may consist of narrative, comment, or biographical notes for each selected entry/goal, thus helping the learner to embark on a reflective learning dialog to be shared with a critical friend as an assessor.
 - c. *Reflections.* The learners examine their own learning, their efforts, and their achievements as a means of monitoring and critiquing their own work.
 - d. *Future action.* The appraisal is used to initiate either a process of collecting new evidence or establishing new professional learning goals.

Peer Assessment

Peer assessment is a process by which learners rate their peers, and is, as such, of great relevance to teacher development. It signifies the joint collaboration by those

involved in the learning process in the appraisal of their own learning. In a peer-assessment arrangement, the learners consider “the amount, level, value, worth, quality or success of learning of peers of similar status” (Topping, 1998). Peer assessment is not only a direct appraisal of what has been learned (outcomes) but also of the how of learning (process). The supposed beneficial effects of peer assessment are not only diverse, but also inconclusive (Falchikov, 2005). Peer assessment (and its related format: co-assessment, that is, mentor/assessee) is said to help learners develop meta-cognitive skills, for example, communication skills, self-evaluation skills, observation skills, and self-criticism (Havner and McDowell, 2007); and this may lead more readily to acceptance of feedback. However, supposed effects of peer assessment for learning vary considerably. The findings range from better attendance, learning gains, impact on the ability to self-assess, developing critical thinking, to no effects at all (Topping, 1998). Peer assessment in essence is a social appraisal process where feedback is given to and received by others, aimed at enhancing the performance of the learner. Therefore, interpersonal and interactional processes play an important role, such as psychological safety, value diversity between peers, interdependence in social relations, and trust in the other as an assessor. Framing features in the arrangement of peer assessment might condition how peers step into the process of appraising each others’ learning results. A first set of framing features has to do with specifying the contextual arrangement of the assessment, that is:

1. the why, that is, reasons for utilizing peer assessment;
2. the what, that is, objectives, teaching areas, and products/outcomes;
3. when, that is, time;
4. where, that is, place; and
5. how, that is, is it supplementary to grading or required; compulsory or voluntary?

A second set of framing features considers the interaction among peers in the appraisal; because of the interpersonal factors mentioned, the assessment might vary with respect to who assesses whom. This directionality in peer assessment can be one way (from assessor to assessed), reciprocal (peers assess each other, e.g., in pairs), and mutual (all peers assess all peers). In addition, peer assessment may differ in level of privacy (anonymous, confidential, and public) and nature of contact between assessor and assessee (at a distance or face to face).

A third set of framing features refers to the composition of the peer group that provides feedback – it can differ in ability or not; its constellation can vary or not.

In teacher education, student teachers often work and practice together during practice teaching/mentoring. Also in professional development programs, teachers work together as colleagues and share learning experiences.

This setting provides a platform for peer assessment in which the 'learners' appraise each other as critical friends (Edwards *et al.*, 2002).

Self-Assessment

Self-assessment is the relatively autonomous and deliberate engagement in reviewing and critiquing one's work in an appraisal of progress made over a period of time. Often self-assessment is closely aligned with (self)-monitoring and reflection (on action). It is meant to increase the learner's self-responsibility and self-regulation in learning (Zimmermann, 2000). In this sense, self-study, action research, or inquiry and analysis of one's work are the main vehicles of self assessment. Learners engaged in self-assessment are found to be more interested in their work and more able to interpret why and what they are doing. Also by analyzing one's own work self-assessment builds ownership and high expectations on the improvement of one's work, mainly through the internalization of criteria and standards of performance. Deployment of self-assessment therefore gains insights that can be used for further learning. As an arrangement, self-assessment involves procedures as to making judgments about accuracy, worth, and appropriateness within a learning context. In essence, self-assessment is a reflective activity and develops reflective as well as meta-cognitive skills. There are three major formats of self-assessment, mainly differing in whether agreed upon judgments are made on the level of performance or whether monitoring progress in work is involved, thus varying in the level of control by the learner:

- Self-evaluation is a process of critical evaluation of one's performance, in which explicit criteria are being used to scrutinize and appraise work against a set of agreed upon standards. Self-collected performance results are offered for deliberate evaluation in conferencing or supervision meeting with an assessor. This appraisal builds on the application of explicit criteria to the improvement of performance.
- Self-monitoring is a way of continuously looking at practice and meant to scaffold a better understanding of one's task performance to gain insight in its strength and weaknesses. This is often considered a more informal self-evaluation due to its openness and fluidity of goals and criteria. It merges often with activity scheduled within a formal course or curriculum.
- Self-reflection exceeds almost its assessment function as a generic vehicle to scrutinize one's accomplishments. As reflection on action it has found a strong foundation in teacher education and, scaffolded by self-regulation, is meant to direct action and clarify performance.

However it needs to be noted that self-assessment in any context needs to be conducted with a clear reference to

explicit (i.e., shared) standards and deliberate judgments by (external) assessors, who may be operating as either a critical friend or a supervisor.

Research-Based Principles of Assessment for Learning

Strongest benefit of assessment for learning is the insight it provides in performance and the subsequent support it gives for its improvement. Formative assessment's outstanding meaning is to spell out acquired competence in a concrete, visible, and tangible way (Smith and Tillema, 1998). Assessment formats may differ, however. Self-assessment preferably should be carried out in light of (1) feedback from significant others, (2) with a clear focus on content or performance, and (3) in comparison with external sources of evidence. Peer assessment requires favorable conditions regarding interpersonal exchange, fairness, and trust, while openness and reflexivity to look at one's accomplishments appear to be crucial in the portfolio. The manner in which different formative assessment arrangements orchestrate feedback ultimately must correspond, that is, needs to be aligned, with performance goals (i.e., what is actually intended to be achieved). In determining such a precise match between assessment/feedback, it is important to look at how feedback (as a method) can provide for acceptance and following recommendations of the assessment information. Nonetheless, no single feature of feedback delivery serves each type of assessment best. However, what seems to be essential in all of them is a performance-based focus in the delivery of feedback. In reference to teacher development, the link with practical action and work assignments seems to be an additional crucial feature in all of the assessment methods mentioned. Looking at differences between assessment tools will indicate that reflection is a differential but highly effective element (**Figure 1**) in bringing about performance change. Reflection enables a cognizant and meta-cognitive focus on one's self-determined levels of performance, both in the collection of evidence phase as well as later on, in the appraisal and action phase.

The results from studies on assessment interventions in teacher education support a view of formative assessment as a process in which feedback is closely associated with the expressed intentions of both the assessee and the assessor and connected to explicated criteria that are considered relevant by both in the appraisal of the compiled information. A valuable attribute of formative assessment, then, would be the increase of learner control over the content to be assessed as well as over the criteria by which the teaching performance will be scrutinized. In this way, deployment of tools can become both continuous and nonthreatening; or put otherwise, assessment can become a bridging tool between learning needs and actual

Table 3 Principles of formative assessment for teaching, teacher education, and quality assurance

<i>Formative assessment of teachers: guiding principles for assessment practices</i>	<i>Principles for educating teachers in formative assessment</i>	<i>Quality measures to develop formative assessment</i>
Assessments should:	(Student) teachers, practicing teachers and teacher educators, at all levels of teacher education (pre-service, in-service, professional development activities for teachers and teacher educators), need to be given ample opportunity, time and guidance in order to:	Assessment quality, at the local school, or institutional level, entails:
1. Focus on how (student) teachers learn	1. Master the principles of formative assessment and learn how to integrate formative assessment in the learning/teaching process	1. A vision of the relevance and the power of formative assessment for improving learning
2. Be included in the planning of teaching and learning	2. Experience the power of formative assessment as learners in teacher education programs	2. Develop legislation recognizing the role of teachers' professional judgement in the practice of formative assessment
3. Be an integral part of classroom practice	3. Implement various forms of formative assessment and develop personal conceptions of assessment practices that can empower learning	3. Links between formative and summative assessments (e.g., use of formative assessment to prepare summative assessment; use of data from summative assessment for formative purposes at the formative and school levels)
4. Be aimed at significant developmental goals and objectives	4. Undertake diversified activities that allow critical reflection about formative assessment (analysis of examples of (student) teachers' work, self-observation through video-recording, reciprocal observation with peers and colleagues)	4. Guidelines regarding the integration formative assessment practices in curriculum and other teaching materials
5. Recognize the full range of all (student) teachers' achievements	5. Discuss beliefs and attempts to implement formative assessment, with the support of experienced and knowledgeable mentors	5. Tools and teaching resources to support formative assessment and share experiences with formative assessment
6. Promote shared understanding of learning goals and assessment criteria	6. Carry out informed, evidence-based professional decisions about formative assessment having lasting positive effects on (student) teachers learning and achievements	6. Further research and pilot projects to develop strategies and techniques for effective formative assessment
7. Be constructive and sensitive to (student) teachers' feelings	7. Foster the common goal of improving learning for each and every learner across the different levels of the educational system (preschool, primary, secondary, vocational)	7. Schools and districts to be responsible for continuous monitoring of the learning progress of their (student) teachers
8. Take into account (student) teacher diversity	8. Explain the power of formative assessment to stakeholders in the educational system	8. Measures to inform all stakeholders (school management, professional association, teachers, parents, (student) teachers) about the benefits of formative assessment to improve learning

9. Foster (student) teacher motivation for learning
 10. Encourage positive relations and productive exchanges among (student) teachers and between teachers and (student) teachers
 11. Entail forms of regulation (appropriate feedback, differentiated guidance, adaptive instructional activities) that promote (student) teachers learning
 12. Encourage active (student) teachers involvement in assessment (self-assessment, peer and teacher and (student) teachers co-assessment)
 13. Be based on varied sources of information (written/oral, individual/group, quantitative/qualitative)
 14. Situate (student) teachers learning outcomes with respect to educational objectives
 15. Be communicated in a transparent and coherent way to concerned parties ((student) teachers, other teachers)
 16. Enhance (student) teachers' capacity to undertake both independent learning and shared learning in group settings
9. Conditions of professional development that allow teachers to feel confident that their job, status and professional recognition is strengthened when implementing formative assessment to promote learning
 10. Conditions of external assessment (for accountability and quality control) that allow formative assessment to develop fully its role in supporting learning

The principles presented here evolved out of exchanges at the International Conference on Classroom Assessment, held in Portland, Oregon, in September 2005. This conference examined classroom assessment experiences in Australia, Canada, Great Britain, New Zealand, United States, as well as in several countries on the European continent. This overview is authored by: *Linda Allal (University of Geneva), Janet Looney (OECD, Paris), Kari Smith (University of Bergen), Harm Tillema (Leiden University), and Joke Voogt (University of Twente)* and was modified for the purpose of this publication. A copy of the original leaflet can be downloaded from www.uib.no/iuh/forskning/pca.pdf.

competence levels. Admittedly, student teachers and their teacher educators often have great difficulty with such a self-reliant approach to assessment (i.e., being more accustomed to viewing assessments as summative, externally controlled, and with objective procedures) (Wiggins, 1993). Actively collecting and negotiating assessment information, however, lies at the heart of teacher development. Therefore, mastering a self-directed and reflective use of assessment instruments is an effective way of performance monitoring and a valuable tool for redirecting one's learning.

Still, it needs to be recognized that no single intervention produces all relevant feedback. The feedback process is complex (Darling-Hammond and Snyder, 2000). Functional feedback essentially means setting the goals for learning and reflection first (Sadler, 1998) and then focusing on the tools that offer and scaffold careful diagnosis and monitoring of performance (Redman, 1994). A formative assessment process undoubtedly offers self-initiated opportunities for reflection in which the individual learner appraises set goals. However, on the other hand, this self-initiated process may fall short of scaffolding an illuminative evaluation that can promote clear vision and better conceptual understanding of advancements in learning. Without any form of mentoring or supervision, the feedback intervention may leave the learners stuck within their own realm of thinking (Zeichner and Wray, 2000). A collaborative or joint approach in feedback delivery is more conducive to the pursuit of goals in teacher development. Formative assessment, irrespective of who initiates the evaluation, needs to be framed and structured in a way that enables appraisal of collected experiences for the purpose of further development. Principles that may guide this process are listed and summarized in **Table 3** to put formative assessment into perspective for teacher development.

Informal Education and Evaluation

In Disraeli's novel *Sybil*, published in 1845, the life course of the hero Egremont is changed by an accidental conversation with a stranger whom our hero never encounters again or learns the identity of. During the course of that conversation Egremont for the first time reflects on the nature of community and the two nations that comprised Victorian England – the rich and the poor. Over time he revisits that conversation in ways that lead him to reassess both his political beliefs and the direction of his life until eventually he feels obligated to devote himself to seeking ways to remove the social and political chasm separating rich and poor. This example is no mere literary device. Biographies and conversations with older people are replete with similar examples of men and women who at formative moments in their lives experienced similar encounters or experiences: unplanned, unintended encounters that, for good or ill, altered the direction of their lives by demanding that they question and reflect upon who they are, what they believe in, and what they are doing – exchanges that made the familiar unfamiliar, that cultivated learning through reflection and analysis.

Informal educators seek to play a role similar to that stranger in relation to the lives of those they work with. Through the medium of conversation and dialog, they attempt to encourage others to reflect upon what they believe and what they do. They deliberately seek out opportunities to promote educational encounters that foster learning through creative dialog. In doing so they rarely operate randomly, rather they specifically aim to work with and alongside individuals and groups in particular settings. Historically informal educators, paid and unpaid, have predominately, but not exclusively, worked with two groups. One has been young people as they undergo the transition for childhood to adulthood. The intention being to help them clarify their hopes and aspirations; to assess where they are and what they wish to become; and help them negotiate the tensions of adolescence. The second has been those living in troubled and disadvantaged communities.

Ordinarily informal education takes place beyond the classroom – on the street, in youth clubs and settlement houses, in residential facilities and faith settings, as well as in schools and colleges (Jeffs and Smith, 1990). Essentially, it can occur wherever individuals and groups congregate. With regard to schools and colleges, this will be in corridors, dining halls, playgrounds, and public spaces during breaks and before and after formal lessons. Although times and venues are not fixed, this should not be taken to imply that informal education happens purely

by chance. Rather, as Hazler (1998) explains, it usually happens because practitioners behave in ways that encourage others to engage with them and because they pay careful attention to the timbre of the environment in order to maximize the opportunities for conversation. In other words, informal educators make themselves accessible to others and act in ways that foster trust and engagement. Although some practitioners do refer to themselves as informal educators, many do not. They might call themselves, for example, youth workers or youth ministers, community or settlement workers, and adult or outreach educators. In addition, they may at other times be designated, for example, a counselor, school teacher, social worker, or minister of religion. Irrespective of the title what they have in common is that they adopt for at least part of their working day a form of educational practice that consciously seeks to promote learning and impart skills via the medium of conversation and dialog. Also, whatever the setting the relationship is invariably a voluntary one, because those who work alongside retain the freedom to refuse to engage in conversation with the informal educator or to curtail it, and the connection, whenever they choose. Given the basis for the relationship, and the mode of teaching, the content of the conversation and trajectory of the dialog will always be open to negotiation. As Gadamer explains, it is “a characteristic of every true conversation that each opens himself to the other person, truly accepts his point of view as worthy of consideration and gets inside the other to such an extent that he understands not a particular individual, but what he says. The thing that has to be grasped is the objective rightness or otherwise of his opinion, so that they can agree with each other on a subject” (Gadamer, 1979: 347). As a consequence of informal education being based on dialog and conversation, those who engage upon it must teach without recourse to a syllabus or a curriculum.

Nevertheless, although conversation may be unpredictable, informal educators must operate in methodical and professional ways. This entails paying careful attention to:

- the presentation of self to ensure they are both approachable and accessible;
- the sustenance of relationships;
- their knowledge base to enable them to respond in an informed way when required to do so;
- their understanding of the social and cultural norms prevalent within the community in which they work so as to ensure that they behave in appropriate ways;

- the development of a repertoire of techniques relating in particular to the arts of conversation and group work so that opportunities for learning are maximized;
- their behavior and public persona. Besides teaching via conversation and dialog, informal educators do so through the modeling of behavior. Those around them are likely to scrutinize their demeanor for informal educators are engaged in a moral craft that demands constant examination of their motives and conduct.

With respect to all the above, and more besides, informal educators must interrogate and reflect upon their practice to ensure that they help others learn and flourish. They must seek to become at all times what Schon (1983) terms a reflective practitioner some one who accumulates a catalog of examples, images, insights, understandings, and procedures – a repertoire that helps them to make sense of their practice and the situations they encounter and evaluate their actions *in situ* and strengthen their practice via reflection.

Emergence of an Evaluation Culture

Josephine Macalister Brew's (1946) *Informal Education: Adventures and Reflections* (see also Smith, 2001) was the first text to explicitly discuss this genre and employ the term. Although the label may be of recent origin, this educational format, characterized by spontaneity and built upon the interplay inherent in dialog and conversation, has an unbroken history that can be traced back to Athenian society and the ideal of the Socratic dialogue (Jeffs, 2001). Neither Brew nor any of the subsequent literature to emerge during the next quarter of a century broached the topic of evaluation. However, they consistently argued that it was essential for practitioners to reflect upon their work and continually engage in what amounted to a form of evaluation-in-practice, in other words undertake formative evaluation – usually via formal supervision (Tash, 2000) or the interrogation of practice with colleagues in time set aside, often after the completion of a session or piece of work. A helpful example of the incorporation of this approach is to be found in Marie Paneth's *Branch Street* (1944) an account of an action-research project undertaken with young people in a deprived bomb-damaged neighborhood during wartime. Paneth repeatedly interrogates and reflects upon her work and relationships with colleagues, the community, and the young people involved in the project. Evaluation, though she does not use the term, takes the form of dialog and reflective discussion with those involved and is directed toward moving the project forward and discovering, and then responding to, the needs of the young people.

Historically, informal educators conveyed a relaxed stance with regard to the importance of measureable or

identifiable outcomes. According to Brew they “must try not to be too concerned about results, and at all costs not to be over-anxious. It is always difficult to measure any good influence in the total lives of human beings” (Brew, 1957: 183). However sporadic attempts were made during this early period to evaluate effectiveness via the measurement of outcomes. For example, the study undertaken by Brown (1956) of the Red Shield Boys' Club in Louisville claimed to demonstrate that it achieved a 52% decrease in juvenile delinquency in the 11 years it operated from 1944 to 1955. In comparison, delinquency rates tripled in one comparable neighborhood and increased 33% in another. Such empirical evaluative research was uncommon for a number of reasons. First, because informal education, in the guise of youth work, adult education, and community work, was viewed as being of self-evident value. An essential component of civil society sustained by an army of volunteers who by undertaking this work contributed to the vibrancy of democratic structures and the accumulation of what Putman (2000) subsequently labeled social capital. Therefore, for key writers on community work such as Follett (1929), adult education (Lindeman, 1926), and youth work (Brew, 1957), the value resided not only in the measurable outcomes of daily practice but also in the ways informal education enriched the social networks that fostered a sense of community and a democratic way of life. Citizenship, equity, and service lay at the heart of informal educational practice both as guiding principles and outcomes. As Paneth (1944: 46) explained “my goal in educational work was to make good, independent citizens in a good community.” Second, because evaluation was not imposed on practitioners or required by those who helped support the work via charitable donations. In part, this was because the work was overwhelmingly undertaken by volunteers who saw a transparent value in what they freely chose to do and fund. Third, both young people and community groups who engaged with the informal educators in clubs and settlements were not, at least in theory, viewed as clients or users, but as members or, especially the young people, as citizens-in-the-making. Therefore, democracy and self-government must be given practical expression which meant informal educators sought ways to make themselves answerable to the members and management committees elected in part or whole by those same members. Consequently evaluation, as we might understand the term, was not a priority for members who had direct control or at least an influence over issues relating to priorities, outcomes, and where applicable, the performance of professional staff. The quality of the program and the worth of the project was continuously monitored by members who were able to seek change through democratic mechanisms or could withdraw their financial support by not paying membership subscriptions. The staff, salaried or not, were unremittingly evaluated by

those they served. Judgments regarding the quality and value of their contribution were inevitably incorporated into the daily round of relationships for they were the servants of those they served.

Changing Focus of Evaluation

State involvement in the funding of informal education was, prior to the early 1960s, minimal, or in many localities, nonexistent. In the United States, the type of agencies currently employing informal educators rarely secured significant federal and state funding until the late 1960s and 1970s and it was from that period onward that evaluation gradually became an integral part of service delivery. Although local government funding was more common in the United Kingdom and Europe from an earlier period, formal evaluation again did not begin to play a significant role until approximately the same period when central government started to usurp local government as the main source of subsidies. The growth of state funding reflected, and indeed may have contributed to a decline in the vibrancy of the public domain and the weakening of civil society (Marquand, 2004). For whatever reason, informal socializing, volunteering, and affiliation to membership-based organization has rapidly declined during the last three decades (see Putman, 2000; Smith, 2000). Those organizations that historically generated and sponsored the bulk of informal education waned, and the space they vacated was partially filled by professionals paid directly or indirectly by the state and, to a lesser extent, corporate charity.

At a macro-level, this shift created within all Western industrialized nations what Neave describes as an evaluative state, within which governments employ evaluation as a means of enforcing strategic change and use evaluation techniques to “elicit how far goals have been met, not by setting the prior conditions but by ascertaining the extent to which overall targets have been reached through the evaluation of ‘product’” (Neave, 1988: 9). Within this environment, evaluation *apropos* informal education has shifted from a historic emphasis upon process, the practitioners reflecting on their interaction with learners and the community, toward a focus upon outcomes or product. This has had a profound impact upon practice. In particular, it has meant the informal educator and the citizen are now rarely viewed as partners in dialog. Rather, the latter is perceived as a learner, client, or customer deficient with regard to specific skills or social attributes, while the former is judged in relation to the extent to which the learner and customer acquire new skills and patterns of behavior. As a consequence in recent years, the focus has shifted from formative to summative evaluation.

This change has meant that evaluation in relation to informal education practice has, according to France,

predominately “been imposed, designed and planned by ‘experts’ or ‘managers’” (France, 2001: 277). The function and purpose being:

- to ensure what is being done for, and to, young people, communities, and others has a positive outcome;
- to clarify aims and purposes, set unambiguous objectives concerning the boundaries of the work; and clearly state what the work is, is not, about; and
- to support funding claims and justify external investment.

The result has been that evaluation, which in its original Latin context meant ‘to strengthen,’ has come to mean something else in relation to informal education. It has become a tool of funders rather than being an integral part of educating. The focus has shifted toward counting and comparing rather than an ongoing evaluation that is intrinsic to dialog and conversation.

Three Approaches to Evaluation

Whatever the prime focus, three broad approaches to evaluation are commonly encountered in relation to informal education practice.

Directed Evaluation

In this approach, external agents, usually funders, set criteria. The focus is predominately upon measurable outcomes and outputs. Attention is paid to the number of contacts or conversations, measurable changes in the behavior of those with whom the informal educator works. Comparisons are made between agencies and workers. The format is designed to measure efficiency, effectiveness, and value for money. The result is often the creation of conformity as agencies and workers endeavor to deliver the required outputs and outcomes. In addition, it generates competition, the fabrication of results, and rejection of unprofitable customers in order to sustain funding and maximize income. Some of the most visible signs of the use of this mode of evaluation are the translation of its findings into data for league tables, funding report forms, and inspection reports. Within the last few decades, it has encouraged the imposition of programmatic work directed toward assessed or measured outcomes (Hirsch, 2005) so that those involved in community work, adult education, and youth work have had less space to engage in informal education.

Negotiated Evaluation

Here, the judgments regarding practice are made according to criteria agreed between the different parties involved. Management committees, funders, workers, and participants may all make a contribution toward

deciding what is to be evaluated and why. There is debate and discussion, although not all may be involved in everything. The criteria and the method may be imposed by outside bodies and can also vary from situation to situation. However, they are set out in advance. The methods can also be contiguous to those employed in directed evaluation. Apart from collecting data (about, for example, the numbers using a facility or contacts made on the street), this approach can involve the widespread use of evaluation forms and questionnaires. This model is advocated, for example, by Feuerstein (1988) and Kuriel (1991), both of whom argue that it offers the potential for partnership and engagement with the least powerful members of a group or community.

Dialogical Evaluation

This approach places the prime responsibility for evaluation on educators and participants. Its purpose is to enrich performance and it is integral to practice. Here informal educators seek conversations that focus on issues concerning the value of people's experience and learning. This entails engaging with people to describe experiences, explore meanings, confront issues, and reconstruct practice (Smyth, 1993). As part of the daily round of working, the informal educator encourages people to look at what they have learnt and their experiences of learning. They listen to what others are saying (and not saying) and reflect on their own experiences in order to evaluate what is taking place. The educator will ask questions or make suggestions so that others may develop their capacity to evaluate their own experiences. At the same time, they might invite them to join in making judgments about the work undertaken. For much of the time, this will not be planned and will not make use of formal tools. It will interweave with and develop through conversation and dialog. This means it may take some unraveling – hence the importance of recording on the part of the informal educator and the need for nonmanagerial supervision. More formal activities may be required to stimulate reflection. These can range from the production of annual reports, creation of focus groups, and holding of business meetings. The keynotes are dialog and the exercise of democratic power. This approach involves the making of decisions and an expectation that those who make the evaluative judgments will live with the consequences of the actions that they lead to.

Dialogical evaluation requires not merely clarity regarding how it might be undertaken and the methodology, but also a degree of precision concerning what questions need to be asked. In particular, attention needs to be paid to the following:

- *Interactions.* What are the characteristics of these? What purpose did they serve? What or who initiated them?

To what extent, if any, were they educative? Are they sustained? Did they reflect the sort of values the informal educator is seeking to encourage?

- *Focus.* What issues and topics form the focus for conversation and dialog? Which of these are initiated by the informal educator and which by others? What are the most common subjects or concerns that arise?
- *Setting.* Where is the work being undertaken? What physical settings best stimulate conversation and dialog? What is the impact of setting upon subject matter, the nature of those worked with, and the quality of interaction?
- *Aims.* What was the informal educator aiming to achieve? What were the aims of others involved? What actual or potential conflicts might arise between the two?
- *Strategies.* How did we, as educators, plan to achieve our aims? Who set these, and were they agreed or imposed? How, if at all, were they altered during the course of the interaction and who influenced this? What strategies did others have? How did they change?
- *Outcomes.* Were outcomes set, and if so by whom? What appeared to be the outcomes for different participants? What did we learn from our engagement? Are there questions and issues that now need to be addressed? Who needs to know about these?

By considering these – and how they relate to each other – it becomes possible to begin making judgments relating to the value and experience of informal educational practice interventions, to evaluate the quality and impact of practice and make decisions about future modes of intervention and strategies.

Problems in Evaluating Informal Education

Irrespective of the methodology adopted in relation to the evaluation of informal educational practice, a number of problems emerge. First, the different things that influence the way people behave cannot be easily broken down. For example, an informal educator working with a project to reduce teen crime in two localities might notice that the one with a youth center open every weekday evening has less crime than the area without such provision. But what will this variation, if it even exists, prove given most teen crime remains unreported? It could equally be explained by differences in the ethos of local schools, policing practices, housing quality, unemployment rates or the opportunities that exist for offending in a given neighborhood.

Second those who may be influenced by the work of informal educators are often not easily identified. It may be possible to list those who have been worked with directly

over a period of time. However, much contact is sporadic and may, like Egremont's meeting with the stranger, take the form of a single accidental encounter. The indirect impact is just about impossible to quantify. The efforts of the informal educator may result in significant changes in the lives of people we do not work with. This can happen as those we work with develop. Consider, for example, how we reflect on conversations that others recount to us, or ideas that we acquire second or third hand. Good informal education seeks to achieve a ripple effect to stimulate and contribute to the full and free communication that Dewey (1927: 11) argues is essential for the creation of "the great community." Informal education aspires to encourage learning through conversation, dialog, and example. Indeed, the more successful it is in reaching this goal, the more limited will the awareness of what has been achieved, more irrelevant the attempts to measure that success.

Third, change can rarely be monitored even on an individual basis. For example, informal educators who focus on say alcohol abuse within a particular group can face an insurmountable problem if challenged to provide evidence of success. They will not be able to measure levels of use prior to intervention, during contact, or subsequent to the completion of their work. In the end, all the informal educator will be able to offer, at best, is vague evidence relating to contact and anecdotal material.

Fourth, there is an issue with timescales. Change of the sort with which an informal educator is concerned does not happen overnight. Changes in values and the ways people come to appreciate themselves and others are notoriously hard to identify – especially as they are happening. What may seem ordinary at the time can, with hindsight, be recognized later as special and transformative.

Lastly, we encounter the thorny topic of candor within evaluation. The growth of the audit culture with its concern that everything public servants do must be measured and assessed to ensure value for money has created a cascade of forms and returns the bric-a-brac of a system rooted in a distrust of the professional. These accumulate much information regarding how informal educators spend their time, who they meet, and what they do. It consumes a great deal of time and reduces the proportion of the working day spent on face-to-face work. The result is that much of the data collected is likely to be of dubious value, for it is gathered and collated for others rather than to strengthen the practice of those who provide it and who consequently have no incentive to ensure its authenticity. As Squires and Measor (2005) note, it also frequently fails to offer the level of analysis needed to strengthen practice for such "evaluation does not have the free pursuit of knowledge as its central focus and, by virtue of the fact that it is tied to a particular funder, some of its independence and space to develop criticism is diminished" (2005: 29).

Conclusion

Informal education like all forms of educational practice, is future oriented. It is about stimulating development and growth within individuals and groups. Informal education, like so much education that is relational, is essentially based upon faith and hope (Halpin, 2003). For this reason, those who practice it are as eager as colleagues operating within classrooms and other formal settings to evaluate their practice, to know what forms of intervention are most likely to be effective, and to know what factors are most likely to generate productive and worthwhile educational encounters. Having said that, as Brookfield and Preskill (1999: 170) conclude, it is probably the case that there really are no "standardized protocols or universal measures we can apply to assessing" the competence of those required to foster discussion, debate, and dialog. Informal educators may wish to secure better ways of evaluating their practice but that does not mean that they will be able to secure tools and methods that possess similar accuracy to those available to educators operating in other settings. For Paneth, her prime aim was to offer the young people a "store of happy memories" (Paneth, 1944: 86), something that by definition cannot be effectively measured; likewise Brent (2004), who in an account of working with a group of bereaved young people, identifies one measure of success as being able to see them smile more freely. For Paneth and Brent, like so many informal educators, the more challenging the task, the more pressing the need, the more laudable the aspiration, the more elusive it seems as a mechanism for evaluating success and failure.

Glossary

Formative evaluation – This is conducted during program development to collect information which can be used to improve the program, including the technology, the intervention, and its implementation.

Performance assessment – This requires students to perform a task rather than select a response from a set of provided options. A performance assessment task is designed to be as similar as possible to a task delivered in the intervention, usually including a context and a complex problem to solve. Performance assessments are also known as alternative or authentic assessments.

Portfolios – The alternatives to performance assessments as measures of higher-level knowledge and skills, which include examples of student work, usually with student self-reflections and teacher comments. Scoring is usually done using rubrics.

Qualitative methods – The evaluation methods used to describe and understand the program by contact with the program and participants using observation, interviews, and surveys.

Quantitative methods – The evaluation methods involving measurement of prespecified outcomes or process to show a relationship between program activities and outcomes in order to provide information on program effectiveness.

Quasi-experiments – These have many of the features of experiments except random assignment to experimental and control groups and full control of all variables, for example, the timing of exposure to the experimental treatment.

Random-assignment experiment – This experiment requires random assignment of the unit of treatment application, for example, students, classrooms, or schools, to experimental and control groups in order to achieve equivalent groups in terms of variables not explicitly controlled by the experimenter.

Summative evaluation – This is conducted following implementation to provide information on the program's effectiveness.

Technology evaluation – An evaluation determining the effectiveness of technology for use in a particular context for a particular purpose. Based on systematic collection of information about how a

program operates and/or about the effects it may be having in order to support decisions about the technology application – how to improve it, whether to expand it, or whether to discontinue it.

Theory of change – A description of the causal processes through which change is believed to happen as a result of an intervention's strategies and action.

The goal of technology evaluation is to determine the effectiveness of technology for use in a particular context for a particular purpose. In educational settings, contexts include such things as teacher and student demographics, access to technology resources, local support, and time and budget constraints. Purposes of technology use include instructional applications intended to improve student learning and productivity applications intended to reduce student, teacher, and administrator time and effort. Productivity applications are not unique to education, and there is a large literature on fairly standardized approaches to their evaluation. In this article, we focus on technology evaluations unique to education – evaluation of applications of technology for instructional purposes, which also has an extensive literature but with less agreement on methodologies.

Technology evaluation is important because evaluation results are used to guide or justify decisions that lead to investments of scarce resources on technology-based educational interventions that may have positive effects with varying degrees of cost effectiveness, negative effects, or no effects at all. The results of high-quality evaluations can help make the impacts positive and cost effective. The methods used to evaluate technology are important because they affect the quality of the evaluation. Method selection and design are not easy tasks because technology evaluation is very difficult, for all the reasons educational research is difficult, and there are additional difficulties that come with the use of technology. The effectiveness of an educational intervention is due to a combination of causes, not one, and the causes may interact in complex ways. The instructional experience depends on many variables, including teacher background, teaching philosophy, training, and experience; the support of school management; characteristics of the students; school district; and community context. When technology is part of the experience, there are additional variables, including availability of hardware, software, and technical support;

professional development in technology integration strategies; student prior experience with and expertise in using technology; teacher expertise in technology; home access to technology; technology use in classes other than those in which the intervention is conducted; and teacher skill in implementing the intervention.

This article discusses the current state of technology evaluation methodology. We begin with an overview of three major methodological approaches, the random-assignment experiment, quasi-experiments, and alternatives based on qualitative methods; then we discuss issues which must be addressed by any method. We conclude with a discussion of heuristics for matching methods to situations.

Methodological Approaches

Random-Assignment Experiments

A random-assignment experiment requires random assignment of the unit of treatment application, for example, students, classrooms, or schools, to experimental and control groups. The unit of treatment application is the unit of analysis, and it defines the sample size. Random assignment is required in order to achieve equivalent groups in terms of variables not explicitly controlled by the experimenter. Variables explicitly controlled by the experimenter are the treatment – the introduction of the technology-based intervention – and all measures and procedures that may affect the results. Treatments must be applied within same time period following a written experimental protocol.

The use of random-assignment experiments for educational research has been dominant from as far back as the Thorndike era in the 1920s. More recently, motivated by sponsors of large-scale curriculum-development projects who wanted summative information to guide funding decisions, and by US government policymakers who wanted to ensure accountability, technology evaluations of the 1960s and 1970s emphasized experimental methods using random assignment of students, classrooms, or schools to experimental groups receiving the treatment (technology intervention) and control groups not receiving the treatment. The approach is also specified by the No Child Left Behind Act in the US, which calls for long-term evaluation of the impact of educational technology using scientifically based research and control conditions.

The argument for the use of random-assignment experiments is that they provide better evidence for causal inferences than any other method. This is true, assuming that the conditions required for experiments are met. The difficulty of meeting these conditions has led to strong objections to experiments in education research, including technology evaluations. The key problem is the requirement for random assignment. Schools do not typically assign students to classrooms and teachers randomly, and

students and teachers are not randomly assigned to schools. It is also difficult to meet the requirement for a control group not receiving the treatment. Technology use may not be a legal entitlement, but parents and school boards do not readily accept withholding the use of technology for the sake of an experiment. It may also be the case that technology use in other classes and at home is so widespread that it is difficult or impossible to have a control group with no experience that might be relevant. Many argue that the goal of educational technology is to provide experiences not possible without the technology, which means that it is impossible to have a control group receiving the same experience but without the technology intervention. In addition, the fidelity of the implementation over time is a problem and differential attrition from experimental or control groups can introduce bias.

Another criticism of the experimental approach is that although it provides better evidence for causal inferences, it does not provide information on why the intervention had its effects. The argument is that the experiment is a black box that provides evidence of connections between causes and effects, but does not provide information on the processes inside the box that explain why the intervention caused the effects, many of which are based on the context of the intervention.

Finally, there are the practical problems of cost and time. Experiments are expensive and time consuming. They may require all the funds available for evaluation and take so long to complete that decisions are made before results are available. Whether this is unique to random-assignment experiments is arguable, but it is a common criticism nonetheless.

Quasi-Experiments

Quasi-experiments have many of the features of experiments except random assignment to experimental and control groups and full control of all variables, for example, the timing of exposure to the experimental treatment. One example is the time-series experiment, in which periodic measurements are taken over time and an experimental change is inserted at some point in the time series of measurements. Changes after insertion not only may indicate an effect caused by the experimental change, but may also be caused by other events occurring during the time series because there is no control over events other than the introduction of the experimental change. Another example is the nonequivalent control group design, one of the more common designs in educational research. There are two groups – an experimental group and a control group. Both are given a pretest and a posttest, but only the experimental group receives the experimental treatment between the two tests. This is similar to an experimental design, but students are not randomly assigned to each group. Causation can be inferred if there is an experimental

versus control group difference in the posttest score. As the two groups are naturally assembled, for example, students in two different classrooms, not randomly assigned, they cannot be considered equivalent, and it is possible that some difference affecting the groups other than the experimental treatment could be the cause. Although this may seem unlikely, it is possible. The point is that the evidence from quasi-experiments is not as strong as the evidence from random-assignment experiments, but it is also true that quasi-experiments are usually more feasible and practical in an education setting.

Qualitative Methods

Qualitative methods do not attempt to compare experimental and control groups at all, or to control variables. They investigate the intervention through observation, review of artifacts, and interviews, studying cases in their natural setting to consider variables as they appear in all the complexity of the context. These methods are very popular in education research, including technology evaluation, due in part to the difficulties in doing experimental research in educational settings, and in part to the desire to obtain information on why the intervention had its effects – the processes and mechanisms that lead from specifics of the intervention to effects – and the contextual conditions under which the intervention is more or less effective. The focus is on the context of the technology intervention, for example, local engagement, collaboration, and feedback, and looking at the why of the result. Understanding the why of the result involves developing a theory of change, a description of the processes through which the effects are produced. Qualitative methods are weak on causal inference, but the contextualization makes them very useful to decision makers by providing models (theories of change) describing how and why the intervention works or does not work in the existing system, information needed to decide whether, how, and when to use the technology-based intervention.

Qualitative methods are especially useful for studying a broad range of naturally occurring practices found in many different parts of the education system, not from a particular intervention using a particular technology, which would usually be evaluated with an experiment. Such studies are often descriptive, interested in the frequency of various technology uses and practices, not their effects. Some correlate descriptive data with student outcomes to attempt to identify relationships, if not causes. Concluding anything about causation from correlations is, of course, problematic.

Combined Methods

As is usually the case when there is a debate over the merits of radically different points of view, the practical truth lies somewhere in between. There is no one right

way to do technology evaluation. The approach depends on the purpose of the evaluation, the nature of the intervention, and the context in which it is situated. Some will require quantitative methods, some will require qualitative methods, and usually the evaluation will benefit from a combination providing both quantitative and qualitative data on student learning and attitude outcomes, context, and the implementation of the intervention. A process for deciding when to use what methods and combinations is described in the section titled ‘Matching methods to situations’ at the end of this article.

Issues

There are several important issues which must be addressed by any methodology. These include defining the implementation, maintaining the treatment, and defining the measures.

The Implementation

Designing and developing the technology are only part of the problem. At least as important, if not more important, is the implementation of the technology. Implementing the same technology in a different way is a different intervention. There are two aspects to consider. First, for any intervention, certain conditions must be met for it to be effective. These include things such as the availability of the required technology, teacher and student competency in using the technology, access to the technology, and sufficient time to learn and use the technology. Second, even when conditions for a successful implementation are met, the intervention may not be implemented as planned. How the intervention is implemented depends on the teacher, students, the school facility and technical support, and many other contextual variables. Differences may include how the intervention is introduced, how well it is integrated with the curriculum, how much time is spent on it, and the teacher’s attitude. If implementation differences cannot be avoided, which is usually the case, they should be minimized, and at least recorded to define the actual implementation.

Maintaining the Treatment

For random-assignment experiments and quasi-experiments, the difference between treatment and control groups must be maintained over time. This is difficult due to the problems mentioned earlier, for example, the control group could have access to the technology in other classes or at home, and the school may be reluctant to maintain the treatment-control difference because it could be viewed as depriving some students of equal access. In addition to differences in how the intervention is implemented, there

are typically differences in implementation over time. A teacher may, for example, decide that there is a better way to implement the intervention, eliminating elements that do not work and adding elements that may work better. Teachers want to improve their instruction, but these changes change the intervention.

Defining the Measures

Measures should be considered in five general categories: cost, context, participants, implementation, and outcomes. In addition to information about the effectiveness of a technology-based intervention, decision makers may want information about resources required by the intervention and its cost effectiveness. Cost information includes direct costs of staff time, materials, equipment, and facilities. It may also be useful to measure opportunity cost, the difference between benefits of the evaluated intervention and the benefits that could have been received from an alternative course of action. Context includes variables that may influence the effectiveness of the intervention, such as local support, leadership, communication, and time and budget constraints. Participant characteristics may also influence the effectiveness of the intervention. Characteristics of interest include age, sex, language, background, and school record. As noted above, how the intervention is implemented is extremely important in influencing outcomes because implementation is part of the definition of the intervention.

Outcome measures must be aligned with the intended outcomes of the intervention as implemented. Using an outcome measure not aligned with the intervention will not detect the effects of the intervention. This seems obvious, but many technology evaluations use standardized multiple-choice tests of basic skills as outcome measures for interventions targeting higher-level knowledge and skills such as problem solving. Standardized tests are readily available, are relatively easy to use and inexpensive to administer and score, and are understood and valued by consumers of the evaluation results. They also have known and fairly good technical quality, for example, reliability, which makes them seem a good choice. Without alignment to the intervention, of course, they are not valid, but this is often overlooked when validity is not understood. Outcome measures must tap the entire range of knowledge and skills at the same level of complexity addressed by the intervention, and they must be validated for the purposes and situations to which they are applied. Validity is the key indicator of technical quality, but it is not a general property that applies to all uses for all time. Rather, it depends on the context and inferences to be drawn from the results.

Another popular outcome measure is the opinion survey. If teachers and students like the intervention and think that learning has occurred, then the intervention is a success. Opinion surveys are relatively easy to develop

and administer, and they are understood by information consumers. Again, however, there is a validity problem.

To evaluate technology-based interventions targeting higher-level knowledge and skills, we need measures of the targeted knowledge and skills. For example, if we are interested in conceptual understanding, an essay or knowledge map may be appropriate measures, but for interventions targeting higher-level cognitive processing, measures derived from performance assessments or portfolios may be required. A performance assessment is a task designed to be as similar as possible to a task delivered in the intervention. These tasks usually include a context and a complex problem to solve, for example, designing an experiment to measure the sources of groundwater contamination, and they may be performed in groups, requiring measures of collaboration as well as planning and design. Problem-solving strategies and behaviors in performance assessments can be measured using scoring rubrics.

Another option is using measures embedded in the technology itself. Many technology-based interventions targeting higher-level knowledge and skills are based on simulations. Measures embedded in a simulation enable the unobtrusive measurement of task performance as the task is delivered in the simulation. This can provide valuable information on the problem-solving strategies used by the student as well as measures focused on the outcome of the process, such as a rating of overall success, the number of errors, and time to complete. In tasks performed by manipulating objects on a computer screen, it is possible to record the clickstream – the responses of the examinee in performing the task, usually mouse clicks, with the associated location, time, and task context of the clicks as appropriate. Using the technology to deliver instruction as well as measure the outcomes has a certain elegance, providing both alignment and efficiency of measurement as it does, but there is a danger. Embedded assessments are necessarily specific to the implementation of the intervention, which limits the generality of conclusions and eliminates the possibility of an equivalent control group. A student who has not used the technology-based intervention would probably not have been exposed to the same content, may not have access to the assessments, and if the assessment is accessible, may not know how to use the technology to perform the assessment task.

However they are delivered, because performance assessments are complex and take longer to complete, a limited number can be administered in the time available for collection of data. This may limit the generalizability of the results because, unlike selected response tests that provide equivalent forms, the problem of designing equivalent performance assessment tasks has not been solved. If time is available for only one assessment task, there is uncertainty as to whether performance on a different task thought to require the same knowledge and skills would provide the same results.

Portfolios are alternatives to performance assessments as measures of higher-level knowledge and skills. These include examples of student work, usually with student self-reflections and teacher comments. As with problem-solving strategies and behaviors in performance assessments, scoring rubrics can be used for portfolio measures, but like performance assessments, these measures have typically not had good technical quality. Technical quality is, of course, critical when scores are to be used to make important decisions.

Whatever the measure, studies should try to measure student performance longitudinally, not at a single point in time. There should also be an attempt to define and measure variables that may be alternative causes of the outcomes, and to estimate effects for students with different characteristics and at different levels of the education system, for example, classroom, school, and district.

Matching Methods to Situations

As already noted, there is no one right way to do technology evaluation. What is required is selection from a range of methods, from random-assignment experiments to quasi-experiments to qualitative methods, such as in-depth case studies and ethnographic analysis, the choice depending on the purpose of the evaluation, the nature of the intervention, the context in which it is situated, and practical constraints including site cooperation and available time, finance, equipment, and support resources. The choice need not be limited to a single design. Depending on the purpose, intervention, context, and practical constraints, the appropriate technology evaluation may and usually should consist of a combination of designs.

Figure 1 summarizes a heuristic process for matching evaluation methods to situations and requirements. The major distinction is between investigations of specific projects, evaluations concerned with the impact of a specific technology-based intervention (project-linked), and studies of promising practices, in which the goal is to study existing technology-based practices or access to technology rather than investigate a particular project. Studies of naturally occurring practices obviously require the use of qualitative methods, but when the goal is to identify successful practices, the evaluation should start with a quantitative study to identify successful sites based on some measure, then qualitative methods should be used to understand the differences between successful and unsuccessful sites and the practices related to success.

If the investigation is project-linked, there is a distinction based on the purpose of the evaluation: a formative evaluation to improve the intervention, or a summative evaluation to determine the effectiveness of the intervention. Formative evaluations are used to improve early-stage projects by

collecting information that can be used to guide the development and implementation of the intervention. This requires the use of qualitative methods to provide information on how the technology, the intervention, and the implementation work in the intended setting, used by the intended users. The evaluator will be interested in how features of the environment interact with features of the intervention, and how features of the intervention will influence behavior. To understand the contexts in which the intervention is and is not likely to be effective, the evaluation should look at it in several contexts, for example, classrooms with students from a range of economic backgrounds and students for whom English is not the native language, and schools with minimal resources.

If the purpose of the evaluation is to provide summative information on the intervention's effectiveness, there is another distinction, this one is based on whether causal information is desired. If not, qualitative methods are appropriate. If causal information is desired, quantitative methods are indicated. Random-assignment experiments are best for determining causation and should be considered first, but before selecting an experiment, the evaluator must determine whether the key requirement can be met: it must be possible for students, classrooms, or schools to be randomly assigned to conditions. If the answer is yes, a random-assignment experiment may be possible; if no, a quasi-experiment should be considered.

Before selecting either, however, the feasibility of conducting a random-assignment experiment or quasi-experiment must be determined. Major feasibility criteria are summarized in **Figure 1**. For either experiment type to be feasible, the intervention must be different from standard practice in order to achieve a meaningful comparison, the intervention must be maintainable, participation must not deny students access to an entitlement, human subjects' protection requirements must be met, participants and the site must be willing to cooperate, and funding, equipment, and support resources must be available. These criteria are usually easier to meet when the intervention deals with a relatively small instructional unit and is supported by a particular technology. Feasibility is less likely when the intervention is wide in scope, open ended, and long term, for example, using word processing to support instruction in writing. Different teachers would probably implement such an intervention differently, especially over time. With a long-term intervention, it will be difficult to maintain the composition of experimental and control groups, as students change classes and use the technology for similar purposes in different classes.

If random assignment is possible and feasibility requirements can be met, the evaluator should consider whether there is a requirement for information on conditions of applicability or the process producing the outcomes. If the answer is yes, and this is usually the case, a random-assignment experiment combined

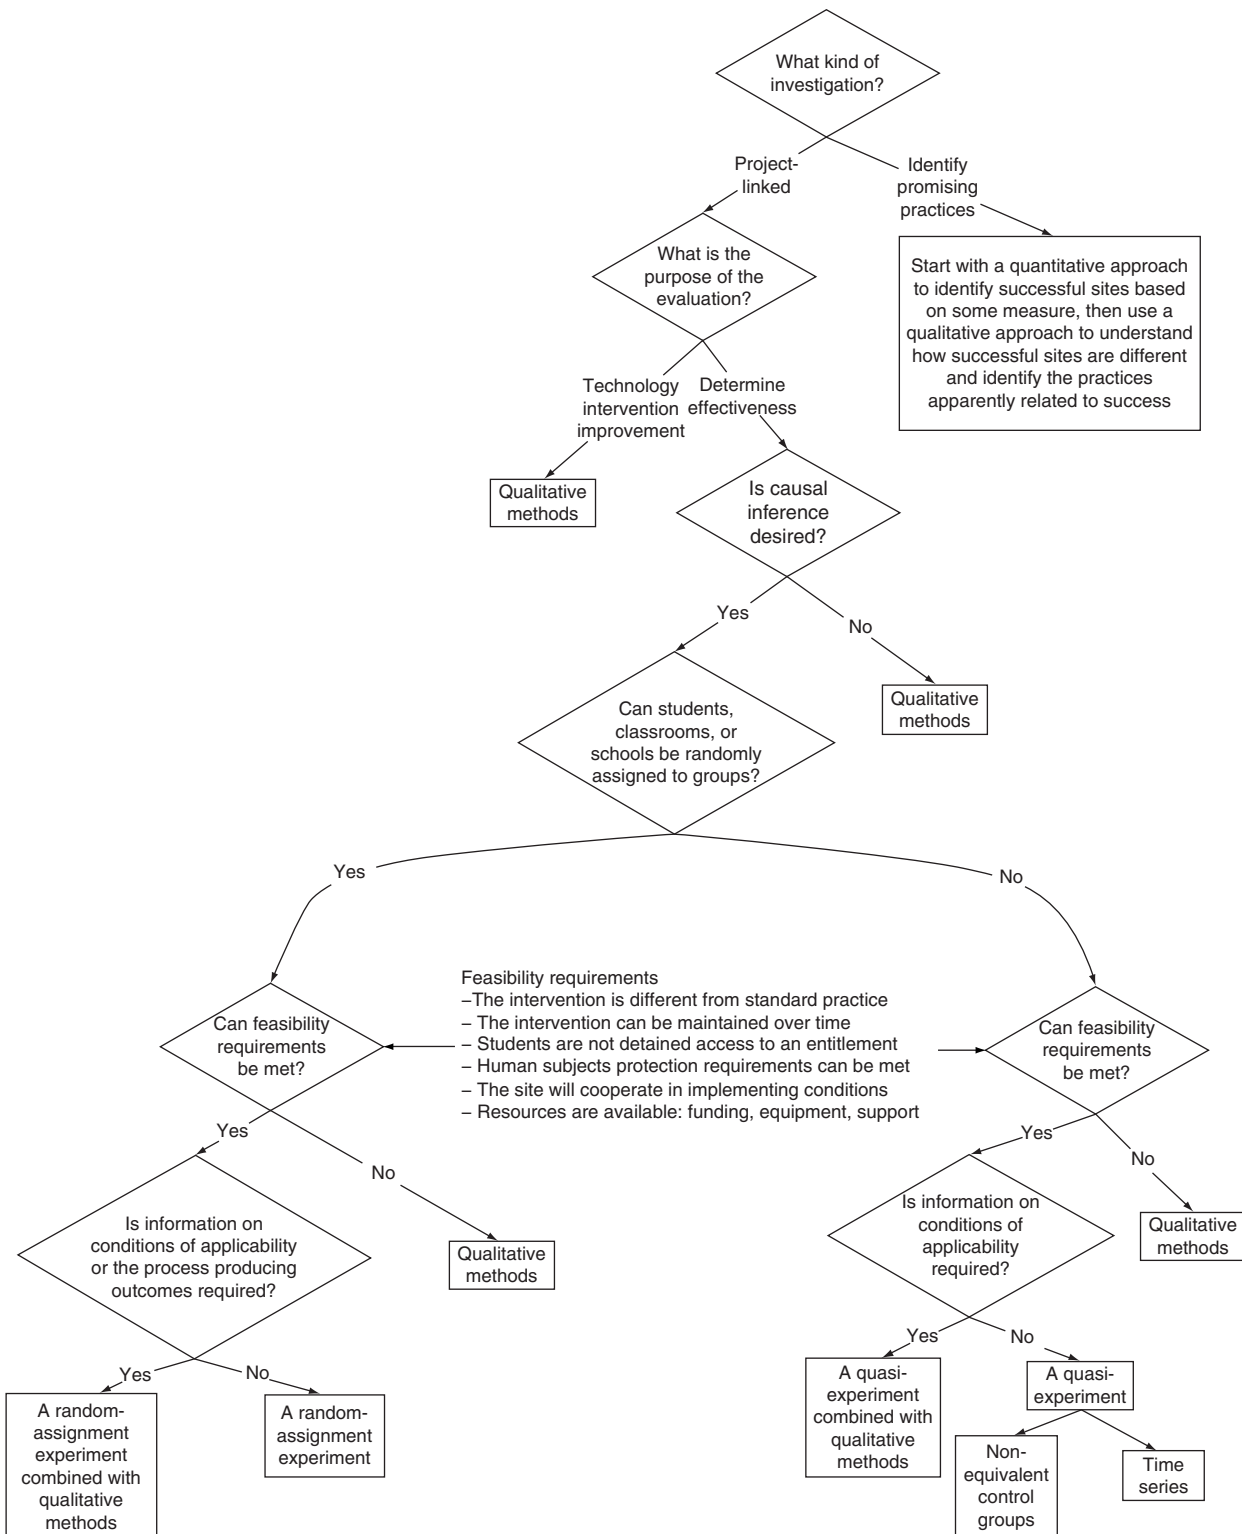

Figure 1 The evaluation method selection process.

with qualitative methods is appropriate. If the answer is no, the random-assignment experiment is sufficient. If feasibility requirements cannot be met, qualitative methods are indicated.

If random assignment is not possible, but feasibility requirements can be met, and there is a requirement for information on conditions of applicability or the process producing the outcomes, a quasi-experiment combined

with qualitative methods would be appropriate. If there is no requirement for conditions of applicability or process, which is not usually the case, a quasi-experiment is appropriate. As with the random-assignment experiment branch of the method-selection process, if the quasi-experiment or quasi-experiment/qualitative method combination is not appropriate, qualitative methods are the choice.

Cost Analysis in Evaluation Studies

J D Fletcher, Institute for Defense Analyses, Alexandria, VA, USA

A core function of evaluation is to inform decisions intended to improve the effectiveness and/or productivity of an enterprise, policy, or program. The hallmark of such decision-making is not just identifying promising opportunities but determining what must be given up to take advantage of them. What must be given up may be defined as cost. Cost may be measured in monetary terms or not, but the most accessible measures of cost are usually monetary (e.g., dollars, pounds, and euros). Monetary cost, therefore, is frequently a key factor in education decision-making, determining whether or not to proceed with some course of action. Cost analysis provides a way to include costs in assessing the net value of a course of action. This article discusses cost analysis as a vital component of education evaluation.

Cost analysis may be called, among other things, efficiency assessment, cost-benefit analysis, return on investment, economic analysis, cost-effectiveness analysis, and cost-utility analysis. There are differences among these analyses, but cost analysis serves as well as anything else as an overarching, inclusive term for them.

The basic idea behind cost analysis is the well-established and straightforward notion that there is no free lunch. The cost analyst looks for opportunities and resources that must be sacrificed to take any course of action. In this way, the cost analyst pursues a marginalist or incrementalist approach. The analyst must determine how much is gained and how much is given up by taking, or continuing to take, some action.

Cost analyses are as subject to controversy as other assessments. Differences in data, data definitions, analysis techniques, models, and assumptions are as likely to be

found among cost analyses as elsewhere. Education decision-makers would be well served by the adoption of generally accepted standard practices for cost-element definitions, data models, and analysis techniques. A variety of commentators have provided a basis for such standards. However, more needs to be done to standardize the practice of cost analysis in education. The best that can be done at present in performing education cost analysis is to be sufficiently explicit to allow decision-makers to determine for themselves and their objectives how well and to what extent any such analysis informs their decisions.

Interest in cost analysis, which began in the manufacturing sector and has now worked its way through the service, healthcare, and public sectors, has arrived as an assessment factor in industrial training (Phillips, 2003) and military training (Orlansky and String, 1983; Fletcher and Chatham, in press); however, it has yet to catch on as an essential component in education evaluation studies (Hummel-Rossi and Ashdown, 2002; Levin, 2001; Rice, 1997; Ross *et al.*, 2007). This need seems particularly urgent, as expenditures for education compete with other public needs that now defend their budgets with cost analyses. Rice described this neglect of cost in education research as a paradox, wondering “why such a seemingly relevant form of analysis has been so underutilized in the field of education” (p. 309). Ross *et al.* (2007) argue convincingly that the neglect continues.

The goals of education, which largely focus on the learning, development, and socialization of young members of society, seem particularly vulnerable in competition with hard-headed analyses of programs in areas such as food safety, transportation, health, and national defense. It is notable that the first myth listed by Thompson (1990)

in his discussion of program evaluation is that many program effects are inherently unmeasurable and unquantifiable. He declares these myths to be false. Both history and more recent practice support his position.

For instance, as early as 1667, public health officials in London defended their expenditures by calculating a benefits-to-cost ratio of 84:1 for investments in combating the plague (Thompson, 1980). More recently, the 1973 Principles and Standards for Planning Water and Related Land Resources, required analyses of trade-offs between national economic development, regional economic development, environmental quality, and social well-being (Sassone and Schaffer, 1978). Accountability for Great Society programs in the 1960s was required by the Planning, Programming, Budgeting System, which was specifically implemented for these programs and now remains a core requirement for defending today's public expenditures in many areas. The continuing emphasis on accountability and on determining quantitative relationships between public investments and their returns suggests the importance of cost assessment in education.

In education, the investment component is more amenable to cost analysis than the return. We can, for instance, determine the costs of lengthening the school day, installing computers and education software, or providing after-school professional tutoring more easily than we can determine the cost value returned to students and their society by improvements in their learning, but it is by no means impossible. For example, an extensive survey by Ross *et al.* (2007) identified 31 cost studies in education that provided an appropriate design for assessing effects, data on costs and benefits, and defensible analyses relating costs and benefits. The studies in their analysis produced credible assessments of the effects of education expenditures on student achievement, private and social educational attainments, the cost-effectiveness of single programs, and the cost-effectiveness of competing program alternatives.

Investment costs generally fall into four major categories: research and development; initial investment; operations and maintenance; and disposal and salvage (Mishan and Quah, 1988). Research and development costs consist of the materials, people, and facilities needed to create, test, and evaluate a capability in which people might invest. Initial investment costs cover the one-time costs of procuring and deploying the resources needed to implement for operational use what research and development has created. Operations and maintenance costs cover those needed to manage, operate, support, and maintain what has been created after it has been implemented. Disposal and salvage costs are the one-time costs of removing what has been implemented from operational use. Cost analyses intended to inform decisions on courses of action usually omit research and development costs, and disposal and salvage costs, leaving as their basis initial investment and operations and maintenance costs.

As difficult as assessment of investment costs may be, returns from improved efficiency and productivity in education seem far more multivariate and difficult to quantify using any metrics, let alone monetary values. Assessments of return from enhanced capacities for innovation, entrepreneurial vigor, a better-informed and more-literate citizenry, economic health, national morale, and so on and so forth turn out to be more difficult, controversial, and resistant to quantifiable measurement than the assessments of investment costs. This difference may account for the preference in education on cost-effectiveness analyses over benefit-cost analyses, which differ in ways discussed below.

Issues in Cost Analysis

Generally, there are two primary issues to consider in cost analysis: the cost model to use and the choice between benefit-cost analysis and cost-effectiveness approaches.

Cost Model

The cost model is the foundation for cost analysis. It identifies, lists, and defines the cost elements that will be included in any analysis that might be performed. As suggested above, specificity and explicitness are critically important for cost analyses. It is, obviously, important for decision-makers and the analysts themselves to both know and be able to articulate what they are talking about. What is not included in a cost element should be as clear as what is included.

Early on, Levin (1983) suggested five classes of elements, or ingredients, to be considered in a cost model. These are: personnel, facilities, equipment and materials, other program inputs, and client inputs. Personnel costs include all the resources required for the human resources needed by the approach. Levin recommended that personnel be classified according to their roles (instructional, administration, clerical, etc.), qualifications (training, experience, specialized skill, etc.), and time commitments (full time, part time, etc.). The costs of facilities include all resources required to provide physical space for the approach. Equipment and materials include furnishings, instructional equipment, and supplies.

Other inputs in Levin's scheme include components that do not fit elsewhere, for instance, instructor training and insurance costs. Client inputs include resources that must be contributed by students and/or their employers. These inputs are especially relevant in military and industrial training where student pay and allowances may be provided by the client, thereby increasing interest in the speed with which students finish the instruction. Much of the rationale for applying technology in industrial and military training is, therefore, keyed to its capacities for self-pacing and the earlier release of students for duty

Implementation					
Evaluation					

Figure 1 A cost-model framework for educational evaluations. Reproduced from Kearsley, G. (1982). *Costs, Benefits and Productivity in Training Systems*. Reading, MA: Addison-Wesley.

(Fletcher, 2004). Both other and client inputs are typically treated together in other costing models as indirect costs, and they are shown that way in **Figure 1**.

About the same time, Kearsley (1982) developed a similar model with one dimension very much like Levin's but with an added dimension keyed to the stages of instruction system development: analysis, design, development, implantation, and evaluation. Although Kearsley's approach is intended for use in training, this second dimension with its instructional elements is readily adapted for education. Its elements should be familiar to most educators. Analysis determines educational objectives – what should be taught to what students so that they attain specified levels of knowledge and skill. Design concerns the selection and application of educational approaches that will most reliably and efficiently accomplish these educational objectives. Development covers the production of the educational materials to design specifications. Evaluation concerns the ability of the materials to produce students who can demonstrate that they have achieved the targeted objectives. Integrated, these two models yield the cost framework shown in **Figure 1**.

The components for each dimension seem appropriate for use as a framework in an educational cost model, but in neither case are the definitions presented here sufficient for the full development of an adequate cost model. Readers are encouraged to turn to Fitzpatrick *et al.* (2003), Kearsley (1982), Levin and McEwan (2007), and/or McDavid and Hawthorn (2005) for a more comprehensive discussion.

Benefit–Cost Analysis

Benefit–cost analysis is used to determine if the benefits returned by some course of action outweigh the costs of investing in it. The calculation of benefit–cost ratios is fairly simple. It reduces all costs of an action to a single unit. It does the same for all benefits. The ratio of benefits to costs is then calculated.

We can calculate a benefits–cost ratio using whatever metrics we choose, but the terms for input and output must be commensurable – both must be assessed using the same

units of measure. Monetary units tend to be those most readily translated from whatever investment resources are required and whatever returns are produced. For that reason, these ratios are almost always expressed in terms such as dollars, pounds, euros, or whatever communicates most easily and usefully to likely decision-makers.

As discussed by Phillips (2003), among others, a benefit–cost ratio is calculated as:

$$\frac{\text{Value of the result}}{\text{Cost of the investment}}$$

It tells us, in quantified terms, how many units of value we get for every unit of cost.

Return on investment is closely related to benefit–cost ratios. It, too, is a ratio, and calculating it is as straightforward as its name suggests. Again as discussed by Phillips (2003) among others, it is:

$$\frac{\text{Value of the result} - \text{Cost of the investment}}{\text{Cost of the investment}}$$

This ratio may be multiplied by 100, so it can be expressed as a percent rather than a proportion. Left as a proportion, any return on investment >1.0 indicates a positive net return. Return on investment must be calculated for some period of time, such as a year. As with monetary units, the length of time covered should be determined by analysts in consultation with decision-makers who are likely to use the results of the analysis.

As mentioned above, both analyses require value and cost to be commensurable. Of the two, return on investment may be preferred because it indicates how many units of net benefits are returned, after investment costs have been subtracted, for each unit invested. There are, of course, spikes, dips, and diminishing returns to be considered with differently timed units of investment, so averaging and curve smoothing may be required.

Neither ratio provides a one-size-fits-all analysis, and neither is likely to satisfy the needs of all decision-makers who turn to it for assistance. Again, what is done for the analysis can, and should, be made as explicit as possible based on a foundation of well-formed and explicated cost models, so that decision-makers receive sufficient

information to determine for themselves the degree to which the analysis is relevant, credible, and able to inform whatever decision they must make.

The issues that arise with the investment side of return on investment analyses usually concern what cost model should be used, what cost elements from it should be included, how specifically to define them, and what values should be assigned to parameters such as discount, interest, depreciation, inflation, and amortization rates. These are not simple issues, but they are easier to resolve and assign costs to than finding data to quantify returns arising from the units of enhanced human performance. For these reasons, we may turn to the cost-effectiveness analysis.

Cost-Effectiveness Analysis

When commensurability is difficult, cost-effectiveness analysis is used. The costs of investment can usually be expressed in monetary units, but the full return, the benefits, of education may be impossible to assess fully in monetary units, despite heroic attempts by economists to do so. Cost-effectiveness analysis allows benefits, such as information retention, job knowledge, and motivation of workers, supervisor ratings, and productivity and effectiveness of the client organization, to be measured in their own units and incorporated in the analysis. It allows the analysis to cover a more complete range of educational outcomes.

Cost-effectiveness is expressed in a way that is directly analogous to benefit-cost ratios. Effectiveness may be measured in units other than those used for cost, so net effectiveness is not measured as it is in assessing the return on investment. Instead, cost-effectiveness is calculated as the ratio of effectiveness divided by the cost of investment – as a direct ratio of benefits to cost. For these reasons, it is common practice in determining cost-effectiveness to hold either costs or effectiveness constant across all the alternatives being considered and observe variations in effectiveness or costs, respectively. Sometimes, either costs or effectiveness is simply assumed to be constant across the alternatives. One could argue that cost is implicitly assumed to be constant by its absence from many educational evaluations. Either assumption may be reasonable, but analysts should present data or information to support it so that decision-makers can decide for themselves if it is warranted.

Cost-effectiveness is a relative term, and relevant decision alternatives must be specified in assessing it. Despite common usage, we cannot properly say that an investment, all by itself, is or is not cost-effective, although there is no harm in calculating a cost-effectiveness ratio for it. An example of cost-effectiveness analysis was provided by Fletcher *et al.* (1990) who calculated the cost-effectiveness of several different education interventions (decreasing class size, lengthening the school day, providing professional tutors, providing peer tutors, and using

computer-assisted instruction) in raising mathematics scores one standard deviation on a standard test of mathematics. Additional examples and more extensive discussions are presented by Ross *et al.* (2007).

The addition of an alternative for achieving the objective(s) after a cost-effectiveness analysis is completed may change its conclusions and recommendations. If a single course of action is to be selected based on cost-effectiveness analysis, the set of alternatives must be as well defined and comprehensive as possible.

One form of cost-effectiveness analysis is cost-utility analysis where the return is assessed in terms of utility or value received by the beneficiaries of the investment. Cost-utility analysis is frequently urged but rarely used in sectors other than health services, where there is significant attention paid to quality-adjusted life years (Drummond and McGuire, 2001). In health services, these analyses are often used to trade-off expected years of additional life for a patient with the quality of his/her life during these years. A measure of expected quality of life is multiplied by the number of additional years of life expected under two or more treatment regimens. Ratios of these measures for different regimens help patients and their medical advisors assess the net benefit or the utility of different regimens for the patient.

Other examples of cost-utility analysis in healthcare are provided by Franke's thorough review of health programs in schools. He cites and discusses many studies, a number of which include costs, that assessed utility-benefits as access to, frequency of, and satisfaction with the mental and physical health services (including substance abuse and sexual activity advice) students received from school-based programs.

An analogous approach might be taken with regard to utility-related benefits of schooling and education. Judgments of quality-of-life improvements obtained from education might be balanced against the opportunity and actual costs of the years of education required to achieve them. Students and their advisors might assess the utility of different programs of education by calculating the ratios of these measures. Levin, starting in 1983, while cautioning against the subject nature of cost-utility analysis, has long advocated it as a component of education evaluation, particularly as a way to assess a wide range of alternatives in a short period of time. Nonetheless, it remains rarely used (Ross *et al.*, 2007).

Considerations in Performing Cost Analysis

A number of discussions suggest steps to use in performing cost analysis (e.g., Barnett, 1993; Fitzpatrick *et al.*, 2003; Hummel-Rossi and Ashdown, 2002; McDavid

and Hawthorn, 2005). Integrating their comments produces the following comments on performing the analysis.

Identifying the Objectives

An analysis must be performed to identify and define what objectives the course or courses of action are supposed to achieve. These objectives may be expressed in terms of what students know or can do once they finish a course of learning, but other objectives and considerations may be in play. Some objectives of significant concern to decision-makers may be implicit. Their inclusion in a cost analysis is a matter for discussion and consultation between analysts and potential decision-makers. Once identified and defined, the objectives then provide the basis for whatever analysis will be performed. As usual, they must be clearly identified and understood by all concerned.

Identifying Requirements for Scale

On a macro level, the education alternative must be able to produce the required number of graduates, given the constraints of time and budget, all of which can affect the outcomes of analysis. Different decision-makers will have different scales of application in mind. The scale of application assumed by the analysis in terms of time, budget, and productivity must be defined and explicated.

Identifying the Cost Model to Be Used

The definition of the cost model and its elements is, as emphasized above, a critical element in any cost analysis. These definitions should be as explicit and unambiguous as possible. Moreover, there may be important differences between planned budget expenditures and the actual costs. The actual costs should be used wherever possible.

For a Cost-Effectiveness Analysis, Identifying the Alternatives

Although a benefit-cost analysis can stand alone, cost-effectiveness analyses must include a realistic and comprehensive set of alternatives. Once the objectives along with the scale of application and the cost model have all been identified for a cost-effectiveness analysis, the alternative approaches that may reasonably be considered for satisfying them should be identified and defined. Generating these alternatives is a critical activity that may require imagination and creativity. It is, of course, unreasonable to include every conceivable alternative in the analysis. As with most cost-analysis issues, the set of alternatives to be considered is a matter for discussion and consultation between analysts and the decision-makers who may consult the findings of the analysis.

Designing the Analysis

Cost analyses may involve an experiment specifically designed to collect data for the assessment (e.g., Barnett, 1985; Fletcher *et al.*, 1990; Kreuger, 2003), or an analysis that takes advantage of already-collected empirical data (e.g., Levin *et al.*, 1985; Borman and Hewes, 2002). Of course, as Hummel-Rossi and Ashdown (2002) advise, the analysis should incorporate “rigorous experimental or quasi-experimental design with attention to . . . hidden and/or qualitative outcomes, and positive as well as negative outcomes” (p. 20).

A test of the adequacy of measures selected in a cost-effectiveness analysis is to determine whether an instructional alternative could excel in most of the measures and still not be best on some intuitive level. This result might occur, for instance, if cost-utility measures are absent. Cost analysis of different approaches to health and sex education might clearly point to programs that would be unacceptable in school districts with religiously conservative parents. In these cases, the assessments may need to be augmented with additional measures.

For a cost-effectiveness analysis, a fixed cost- or fixed-effectiveness approach should be selected. The distinction between education and training may affect the choice. In training, which is a means to an end, the instructional objectives are primarily concerned with producing given and specifiable levels of proficiency, and it may be wiser to choose fixed effectiveness and seek an alternative that achieves that level with minimum cost. In education, which is an end in its own right, decision-makers may be more interested in maximizing achievement. In addition, time and budgets are more likely to be fixed at the beginning of a program of education, so that a fixed-cost approach may be more appropriate for education.

Finally, Kazanowski's (1968) classic list of pitfalls still seems relevant. Four of these, the ratio fallacy, the quantification fallacy, the interrelationship fallacy, and the neglect of spillover effects, are illustrative and seem particularly relevant in education evaluation.

The ratio fallacy involves scaling of the course of action being considered. If the analysis deals with costs that are small in magnitude but the decision-maker is contemplating a sizable implementation, then the magnitude of costs needed to support that implementation must be taken into account. Benefits, effectiveness, and ratios aside, some investments are simply too large to be realistic. The quantification fallacy reminds both the analyst and the decision-maker that it is never safe to assume that everything relevant to the analysis can be quantified. The interrelationship fallacy involves the assumption that the relationship between variables is monotonic and linear. Particularly for educational variables, these relationships may be neither. The spillover effects concern interactions

among systems. A course of action for one system may well, if not inevitably, affect the operation of other systems that are either presently in place or likely to be implemented in the future. Such interactions may be dominant in decision-making and should be included both in designing the analysis and reporting its results.

Performing the Analysis

The analysis should employ data drawn from sufficient sample sizes, designs appropriate for an experimental, quasi-experimental, or analytical approach, and assess both short-term and long-term effects. It should be performed in a manner appropriate for a benefit–cost or cost-effectiveness study. In short, it should be as methodologically correct as time, budget, and circumstances allow.

Performing a Sensitivity Analysis

In any analysis, assumptions must be made about the values assigned to some of its components. Will a piece of equipment last 5 or 10 years? What will the rate of inflation be over the period covered by the analysis? Will 50, 500, or 5000 students use an instructional program or programs under consideration? How frequently will the instructional materials have to be updated? And so on. The outcome of a cost-effectiveness evaluation will be more sensitive to some of the assumptions on which it is based than others. The sensitivity analysis is intended to identify these differences so that decision-makers can see for themselves how robust the analysis is with regard to variations from its underlying assumptions. The analysis may best be designed as a model into which different assumptions or parameters can be substituted. In addition, what components are included in a cost analysis is always an issue. A solution is to assume some base set of elements and then to use sensitivity analysis to help decide what must be added and what may be excluded.

Reporting the Results

When the data are gathered, they should be tabulated in a form suitable for comparison. It is critical for decision-makers to know the strengths and limitations of an analysis. It is not a trivial task to identify the assumptions underlying an analysis, but these assumptions should be identified and described as explicitly as possible. The underlying models of cost and effectiveness should be documented so that decision-makers can see what has been excluded and, therefore, assumed either irrelevant, less important, or treated as equivalent across alternatives in cost-effectiveness analyses. All the cautions concerning clear, unambiguous, and explicit definitions and descriptions of the data model and its elements continue, of course, apply.

If cost data are drawn from different periods of time, they should be adjusted so that they are equivalent. In these cases, cost data reporting should take account of inflation and be reported in year-constant units. If the cost data results are extrapolated into the future, proper discounting should be used so that costs can be reported in whatever year-constant units are selected. Capital equipment (e.g., computers, desks, and texts) should be realistically amortized to account for their different life cycles of use. Fitzpatrick *et al.* (2003), Kearsley (1982), Levin and McEwan (2001), McDavid and Hawthorn (2005), Mishan and Quah (2007), and Phillips (2003), among others, may be consulted for more specific detail and advice about these matters.

Decision-makers may view a tabulated array of findings more as raw data than useful information. As a rule, decision-makers need information first, then the data to support it. Discussion of the findings, the strengths and weaknesses of the data-collection procedures, limitations of the assessment, and presentation of the alternatives in light of the evaluation, should be in order and should be provided.

Conclusion

Phillips (2003) points out that cost analyses allow behavioral scientists to join a transformation begun in the manufacturing sector but that is now arriving at military and industrial training. Education may not be far behind. This progression will transform education evaluation from reactive efforts starting only after some course of action has been taken or some program has been fielded, to a more proactive, integrated activity that begins much earlier in the decision, development, and implementation cycle. Such a transformation will more closely link program effects to specific requirements and objectives, more strongly emphasize not just doing things right but doing the right things, more effectively communicate choices, costs, and effects to decision-makers, help set priorities, and, overall, focus program reporting on the output and results.

Glossary

Activity system – The term drawn from cultural psychology and cultural historical activity theory refers to the organization of human action in everyday settings to accomplish goals associated with the settings. Attention is given in activity system analysis to the ways that participants in activity settings identify the “who,” “where,” “when,” “what,” “how,” and “why” tied to their mutual pursuit and accomplishments of goals.

Critical pedagogy – Critical pedagogy developed from the work of the Brazilian educator Paulo Freire. This approach focuses on the social empowerment of communities that are underserved by society through reliance on the cultural, linguistic, and social assets of community members.

Culture – Culture used in the present article is not a background trait of individuals or a trait inherited from their national or ethnic communities of origin. While drawing on these background influences, culture instead is viewed as a continuously constructed and negotiated way of seeing and acting on the world to in the moment-to-moment pursuit of activity.

Cultural psychology – Sometimes also referred to as ‘cultural-historical activity theory’ by some investigators, addresses the study of human action and its development in specific or local social, institutional, and historical circumstances.

Culturally responsive evaluation – Concerns the importance of making evaluation of educational interventions and strategies (and evaluation more generally) sensitive to the cultural values and practices of community participants from diverse cultural, linguistic, and social backgrounds in the context of everyday life.

Ecological systems theory – Ecological systems theory draws from the work of the developmental psychologist Uri Bronfenbrenner. This theory examines complex ways in which different ecologies surrounding human action such as family, school, community, geographical, policy interact and influence each other and the psychosocial development of humans.

Ecology – A general term which in this article refers to the social, institutional, community, and policy environments or settings surrounding human action.

Generative learning – A theory of human learning introduced by Merlin Wittrock. The theory asserts that humans learn most effectively by actively generating conceptual connections between new knowledge and prior knowledge. Asking learners to communicate new knowledge to others is an effective way to support generative learning.

Kamehameha Early Education Program (KEEP) – The name of an innovative language arts program developed in the 1970s in to serve low income Hawaiian origin children . The program was designed to draw on the home and community cultural, social, and linguistic knowledge of participants as a resource to support reading and comprehension skills development in classroom settings.

Participatory action research – An approach to research on social and educational problems that frames research in terms of questions, issues, evidence, and perspectives of community members most affected by the outcomes of research.

Photovoice – A research technique employed by community members to document and analyze problems in their communities by use of photography, narrative, and expository text for the purpose of undertaking grassroots social action.

Subtractive schooling – A concept introduced by Angela Valenzuela to refer to analyze negative schooling conditions faced by immigrant and US born youths from minority backgrounds who perform poorly in classrooms because of lack of teachers’, school staff’s and community members’ respect for their cultural, linguistic, and social knowledge and lack of understanding of how to apply these resources to improve schooling outcomes.

Youth Empowerment Strategies (YES!) Program – An intervention program implementing the Photovoice technique implemented with inner city youths to undertake identification and solution of local community social, health, and other problems.

Introduction

Educational interventions are often set in the context of a need to solve learning and achievement challenges faced by youths in schools or in informal learning settings relevant to development. The specification of desired educational outcomes that are not being met results from a public policy and educational stakeholder concern that something is not right regarding the educational achievement and progress of students. A prominent pattern of this sort found across nations in the context of formal schooling is that students' achievement test scores are lower than desired for a group of students of identifiable backgrounds. Such backgrounds include, for example, coming from an immigrant background where parents show low schooling attainment and where immigrant families' adaptation to a new host country involves acquiring a new language and new ways of behaving and acting that contrast with an upbringing in a different country with its own privileged languages, customs, and institutional structures related to education and social opportunities. Other student background characteristics often associated with lower-than-desired achievement and attainment also pertain to nonimmigrant students. For example, in many countries around the world there may be failure of certain social groups or ethnic or racial minority groups to attain publicly and policy-specified educational achievement and attainment levels. These patterns can be of a long-standing historical nature associated with differences in the extent to which ethnic-racial subgroups have been integrated into a national society as a whole, and into the wealth-generating and wealth-accumulating institutions that generate economic and social well-being.

Given such contexts, the designers, implementers, and evaluators of educational interventions typically set forth educational remedies intended to change the educational achievement and attainment results of target immigrant and racial-ethnic subgroups, so that these interventions alleviate gaps in achievement and attainment relative to other groups in a nation and setting that show greater educational achievement and attainment on the indicators identified for this purpose by education policymakers. This article explores some of the important challenges faced by educational stakeholders in evaluating the effectiveness of interventions addressing these concerns with attention to the possibilities that achievement and attainment objects and their received indicators themselves may be questioned, given their suitability for members of culturally diverse communities. The matters to be addressed are quite complex in scope and so the intent is to forward important vision elements that should underlie attempts to develop evaluation philosophies and methods attuned to culture as a central issue. Here, vision elements mean deeper conceptual issues that should undergird attempts

to frame the purpose and outcomes of an intervention that has educational aims and the range of evidence that such outcomes have been attained.

Ecology, Culture, Educational Interventions, and Evaluation

There are many ways to approach the development of evaluation philosophies and methods that can lead to educational intervention evaluations sensitive to the cultural lives of members of diverse communities. Here, attention is called to an ecocultural approach building on the work of theorists and researchers such as Bronfenbrenner (1979), Cole (1996), Freire (1974), and van Lier (2004). The basic idea is that the context for educational interventions needs to be broken down into interacting formal and informal institutional systems that compose the realities surrounding the daily lives of community members. An educational intervention such as homework tutoring, mentoring, or specialized reading skill curriculum implementation occurs in a specific setting such as a classroom, community center, or some other location. Any such setting is surrounded and connected to other settings and institutions which can influence what occurs in the actual setting for an intervention.

Classrooms and schools as educational intervention settings are influenced in various direct and indirect ways by governance units for schools, teacher unions, and educational policy setting bodies such as local, regional, and national governance bodies and city school boards, legislatures, and executive bodies of government, such as city councils and state agencies. Business institutions and public policy advocacy groups, such as legal rights organizations, religious organizations, and community organizations, represent other examples of institutions that can influence what is possible and what can occur in an educational intervention setting. Informal organizations influencing what can occur in an educational intervention setting are exemplified by nuclear and extended families, friendship and informal activity peer networks among community members, and information sharing and knowledge dissemination networks implemented on the Internet or through other forms of media. It is important to remember that not all educational interventions occur in schools as part of regular school-day instruction. They may occur after school or on weekends in a variety of community settings such as community youth recreation centers or civic engagement clubs including, but going beyond, the physical setting of schools. The aforementioned formal and informal nonintervention policy setting and governance bodies and other institutions nonetheless may also bear influences – for example, a teacher union might not allow a credentialed teacher to engage in volunteer teaching service after school in a community setting without a

formal contractual arrangement with the institution sponsoring the activity at hand.

Regardless of the setting for an educational intervention, be it in or out of regular school-based instruction, various social organizations may have explicit or implicit stakes regarding the success of different community members and groups being served by an intervention. Different social organizations may show differences in their attentiveness for the success of an intervention based on the social and cultural characteristics of learners served by an intervention. For example, a state educational agency may provide financial support for literacy programs promoting students' acquisition of English-language literacy, but not provide support for maintenance of literacy in a first language. The ways that organizations may become involved in designing, supporting, and sustaining educational interventions is a dynamic outcome subject to local political and participatory motivation regarding ways to improve community well-being. Bronfenbrenner's (1979) formulation of ecological systems theory is helpful in highlighting ways that relationships between and among such organizations and settings evolve and are mutually influential.

Bronfenbrenner's (1979) ecological system formulation can be used by evaluators and educational stakeholders to inform our understanding of ways in which organizations, and, in particular, dynamic relationships among organizations, can affect the implementation and history of educational interventions. According to Bronfenbrenner, microsystem environmental systems include the immediate settings and face-to-face relationships among people in which individual lives occur. Such systems include, for example, community members' family, peer networks, school and neighborhood settings, and the activities that occur within the functioning of these settings. These relationships establish the social identities of individuals and pathways for personal and social development in these worlds or settings. Bronfenbrenner characterizes meso-system environmental systems as those relationships that arise between persons' immediate environmental settings, such as between a family and school setting, because of explicit and expected accountabilities of parents for the care of children, including schooling and schools' expectations of parents. Exo-systems are characterized by Bronfenbrenner as informal relationships that arise between social and institutional settings that affect individuals' performance and development in these settings. For example, parents' experience of racial or ethnic prejudice in the workplace might spill over into home family life, leading parents to express anger to children about social unfairness and reduce the motivation of children to be engaged in schooling activities requiring cooperation across mixed ethnic-racial subgroups. Macro-systems were characterized by Bronfenbrenner to refer to the broader relationships between persons' cultural and social heritage that set the stage for everyday behavior.

For example, immigrant students may have socialized patterns for showing respect for elders and teachers that are appropriate in a native country, but which then contrast with expected or permissible ways to interact with elders and teachers in the social contexts of a new host country. Finally, Bronfenbrenner characterized chronosystems as relationships among other ecological systems that evolve over the life-course of individuals and that thereby influence developmental trajectories over time. Schooling interventions aimed at increasing the educational achievement and attainment of ethnic-racial subgroup members exemplify such systems, albeit they can illustrate both beneficial and disruptive affects on children's lives – for example, see Valenzuela's (1999) work on subtractive schooling which examines how efforts to improve second language and immigrant background schooling achievement might actually have a negative impact on schooling outcomes by disconnecting students from values and knowledge that is part of their natal cultural background.

Bronfenbrenner's notions of ecological systems can prove useful to evaluators by suggesting relationships among different systems that might bear on students' responsiveness to an educational intervention and issues that might arise regarding the appropriateness of an intervention. The field of cultural psychology (Cole, 1996) contributes additional and complementary insights. One key insight is the notion of activity system. Humans in social and institutional settings engage in practices tied to the characteristics and social functions realized in settings. In common sense terms, every setting can be seen to involve persons assuming social roles appropriate to exercising agency in the setting, given its community location and expected functions. Every activity setting involves participants' active and constant negotiation and social interpretation of "who," "where," "when," "what," "why," and "how" – see Wertsch (1998) for an elaboration of these notions and their interdependent nature. An educational intervention when seen as an activity system realized in an ecological setting can be seen as purpose-driven with the end of having the students acquire the learning proficiencies and skills targeted by the intervention. The conduct of the intervention requires that the participants actively negotiate and understand the "wh's" and "how" of the setting and how learners are expected to respond to the guidance of the setting coordinators/instructors.

That stated, there are complications from a cultural perspective. The ways of acting and interacting shown by participants in an intervention setting may not always involve participants interpreting the same meaning for the "wh's" and "how." Classic research studies of classroom interaction involving members of indigenous minority groups in classrooms organized around nonindigenous classroom participation norms have found, for example,

that the failure of students to volunteer answers to teacher questions can arise not because students do not know the answer to questions, but because a student's public display of knowledge conflicts with local community cultural norms regarding polite ways of showing knowledge (Philips, 1993). More generally, students from cultural backgrounds that are different from those of a majority culture may not perceive the nature and demands of academic learning tasks in the same ways as students brought up in majority cultural settings (Adamson, 1993). Ability to communicate in the language used in an intervention setting is particularly crucial. When communicative competence in the language of an intervention is not considered, it is possible that students will not be able to participate as intended in the intervention and thereby not benefit.

From a cultural psychology perspective, the foregoing discussion is undergirded by the point that all humans acquire mediational resources or cultural capital that enable them to participate in everyday activities and settings. These forms of capital apply to every domain of human functioning and knowledge about how to communicate and act in activity settings. When the cultural capital that students possess through their socialization differs from the cultural capital that is valued in schools in a dominant culture intervention setting, there can be problems in that students may not show the responsiveness expected of them in an intervention. This was shown in the previously cited work of Philips (1993). Specifically, she found that American-Indian students from the Warm Springs Reservation showed reluctance to answer a teacher's questions publicly in classroom settings, because such public displays of knowledge violated politeness conventions for display of knowledge learned as part of socialization practices for community members.

Researchers from a critical pedagogy perspective (Cummins, 2001; Freire, 1974; Freire and Macedo, 1987; Valenzuela, 1999; Wink, 2005) carry these ideas further in a way that complements an ecological perspective. They forward the idea that failure of an educational system (and interventions) to build on the cultural assets of immigrant and nondominant ethnic-racial social groups can actually disempower members of these groups from benefiting from education. They also forward the view that when educators and interventions build on the cultural capital or funds of knowledge of ill-served groups, educational outcomes can be raised (González *et al.*, 2004).

Valenzuela's (1999) work on subtractive schooling is illustrative of how such disempowerment occurs. Her ethnographic study of Latino students in Texas classrooms traces how teachers' inability to appreciate the natal cultural values and interaction style of students leads teachers to ascribe low learning motivation and learning ability to Latino students, which in turn leads to a teacher's display of animosity toward students, who then, in turn, display disinterest in classroom

learning and limited evidence of benefiting from instruction. A similar disempowerment was found in the research of Moll *et al.* (1992). These researchers found that when English as a Second Language (ESL) reading teachers believed that elementary school Latino English-language learners were incapable of comprehending the meaning of book stories written in English, they concentrated on teaching only basic English vocabulary skills to children and thereby did not permit children to exercise deeper comprehension and communications skills. In contrast, the researchers found that ESL teachers who required that similar background students write book reports on what they learned from book stories showed evidence of significant understanding of stories.

Van Lier (2004) working from an ecological perspective adds important additional insights. He effectively theorizes the many ways in which members of social and cultural groups construct meaning, social identity, and agency by continuously interpreting their environment and interactions with others. He calls attention to the important phenomena of prolepsis – the capacity of persons individually and collectively to project their identities and agency into the future based on current experiences and the affordances for action and participation in current events.

An example of prolepsis arises when youths describe to others their aspirations of who they will become as adult members of societies. While prolepsis is embodied in projections of future roles in the economy in terms of professions and jobs, it is a much broader notion and includes the ways in which youths see the range of identities as members of society and ways that they will contribute to society – this will be especially evident in the discussion of the out-of-school Youth Empowerment Strategies (YES!) educational intervention program that follows in a later section. From the perspective of prolepsis, if an educational intervention is to work, it must be capable of bridging the existing cultural assets of individual with new tools for thinking, problem solving, and language use that extend the identity and agency of individuals into future circumstances and opportunities for development.

Some Implications of an Ecological Perspective to Evaluation Philosophies and Methods

While there is no singular way to categorize educational evaluation philosophies, one can nonetheless contrast two very different evaluation approaches that illustrate how cultural issues may affect what is learned from an evaluation.

For example, it is possible to distinguish objectivist logic model approaches from transformative participatory evaluation approaches (Mertens, 2009). Objectivist approaches,

in their most simplistic and narrow implementation, for example, might use experimental or quasi-experimental methods to determine whether implementation of an educational treatment intervention is associated with a statistically significant gain by a treatment group over a comparison group on outcome measures such as tests of constructs targeted for improvement as a result of exposure to a treatment, versus nonexposure to the treatment. Such evaluations might take a formative or summative form. If a formative approach is used, the association of changes in outcome measures can be examined as they emerge over time as an intervention is administered, and it is possible that the results of such formative outcomes can be used by educational intervention program staff to improve design and delivery of the intervention with the aim of improving outcomes of a next phase formative assessment. A summative evaluation, in its simplest embodiment, only compares growth in outcome measures at the conclusion of an intervention.

It is common practice for objectivist evaluation approaches to apply an input–output logic model to specify conceptually the hypothesized relationship between exposure versus nonexposure to a treatment and targeted outcome measures. A logic model may also specify measures of ancillary input and process variables that may mediate such relationships. Ancillary input variables may include measures of relevance to the language, and socio-cultural status of participants (e.g., race, ethnicity, immigrant experience gender, and socioeconomic level) in the evaluation, and statistical modeling procedures may be used to assess direct or indirect effects of these variables on process measures and the outcomes produced by exposure to the intervention. In more complex designs, hierarchical linear modeling or structural equation modeling might be used to examine the effects of variables, such as school resources, community location, racial–ethnic school, or community characteristics, as variables independently contributing to changes in outcomes associated with exposure versus nonexposure to an educational intervention treatment.

One of the most basic characteristics of the objectivist approach to evaluation is that the evaluation team is desired to be a separate independent entity from the education program implementing the educational intervention. The reason for this separation is to ensure that the outcome of the evaluation cannot be influenced by inappropriate collection or analytic manipulation of data, leading to invalid specification of education intervention results.

Culturally responsive and transformative participatory evaluation approaches to educational evaluation can take a very different stance, one that is sensitive to an ecological perspective of human action and development. This perspective, in general, would view educational intervention implementers, recipients of an intervention and their families–communities, and evaluators all as mutual stakeholders in the design, development, implementation, and

research evaluation of an intervention. Such approaches can build on an account of how the cultural assets of target community members are the foundation for implementation of a successful intervention. An important quality of this approach is that evaluators can take a more active and accountable role in making educational interventions happen effectively than is the case with an objectivist orientation. The intervention itself can take the features of a clinical design experiment or formative intervention – these going beyond the goals of a traditional objectivist formative intervention to include an active, creative search and exploration for how to go about designing what the intervention is and how it can draw on cultural resources of communities and their formal and informal institutions, given findings collected during implementation of the intervention (Engeström, 2008).

Two educational interventions are mentioned in the following section that illustrate the richness of how cultural issues may affect the design and enactment of evaluations. The Kamehameha Early Education Program (KEEP) interventions and its evaluation illustrate how evidence of the effectiveness of a classroom literacy intervention serving at-risk Hawaiian youths, coupled with a study of Hawaiian community cultural communication practices led to improvements in the delivery of the classroom literacy intervention. The example also led to the discovery that effective delivery of the intervention in another cultural community required understanding the cultural norms for communication in that community and fine-tuning the literacy intervention accordingly.

The second example of an intervention, the YES! after-school program, illustrates how cultural perspectives might inform evaluations concerns, given the goal of having youths from diverse cultural backgrounds learn how to conduct research on how to make their communities better. It is fair to state that the YES! program has yet to evolve a definitive evaluation strategy because of its participatory action–research orientation. This latter orientation has as its goal having youths discover what they want to investigate about their communities and the outcomes of this discovery process and how youths present the outcomes to other community members are unpredictable in advance. The example also illustrates how culture needs to be treated as a continuous construction of meaning of what is going on in everyday life from an ecological perspective in contrast to being considered a background trait of individual community members and groups.

The Evaluation of KEEP as an Example of a Culturally Responsive Evaluation

The implementation and evaluation of the KEEP reading program intervention, serving elementary school youths from low-income Hawaiian backgrounds in the late 1970s

to early 1980s, is illustrative of a culturally responsive evaluation approach (Tharp and Gallimore, 1979, 1988). The KEEP reading comprehension program brought together teachers and teacher trainers, and an interdisciplinary team of researchers, including applied linguists, anthropologists, and educational psychologists. The goal of the program was to improve the reading performance of students as indexed by reading comprehension test scores and other indicators of reading competence. It took over 10 years for the program to arrive at a sustainable, stable configuration that was able to manifest statistically significant growth in reading test scores as compared to reading test scores of children from similar backgrounds not exposed to the curriculum. The early stages of implementation of the program focused on helping teachers acquire proficiency in the delivery of direct reading instruction targeted largely at discrete reading decoding and correct answering of questions about story texts. As the program implementers explored the improvement of reading instruction, the research intervention team developed awareness through studies of classroom videotapes that children showed preferences for how they interacted with each other during instruction that were not part of the direct instruction model. Specifically, they discovered that children working in small groups would sometimes spontaneously look around the classroom for students who appeared to be having problems completing their reading assignments. Students would on occasion then leave their group spontaneously to go and help a student in another group. A second finding was that during direct instruction reading aloud in small groups, students who were not the ones to be reading aloud to other group members had a proclivity to speak up and add vocal commentary regarding the interpretation and meaning of what was being read. It is important to underscore that both of the two behaviors arose spontaneously and not as a result of following the script for intended direct instruction.

The reading implementation and research team came to the discovery that these spontaneous behaviors that manifested students' engagement with learning activity were not accidental, but resulted from cultural practices that were common in the natal community outside of school. Anthropologist team members who were using ethnographic methods to document social and communication practices in the homes of children and in the community found this connection. Their home ethnographies, for example, found that children often helped each other perform chores at home and also that community storytelling practices (known as talk story) involved having story audience members break in to the oral delivery of a story with comments and annotations.

The foregoing discoveries led the KEEP reading intervention team to revise the design of the reading program so as to add in both types of behaviors as encouraged or permissible practices, built into the implementation of the

program. This shift in program implementation coincided with evidence of statistically significant improvement in the reading test scores of students exposed to the curriculum.

The implementers of the KEEP reading intervention went on to attempt to implement the program in the northern Arizona Navajo community of Rough Rock (Vogt *et al.*, 1993) in the elementary grades. The team discovered that the program could not be implemented successfully in this community without adjusting its reliance on small group activity design and the program implementers' expectations that students would naturally be inclined to help each other in the classroom. In particular, they discovered that members of small reading groups would not be engaged in their work unless they were separated by gender. They also discovered that, contrary to their expectations, students were not inclined to help each other spontaneously, as was the case with Hawaiian children. They also discovered that Rough Rock children were best managed by ignoring misconduct during learning activities and reminding the children of honorable behavior compared to the effectiveness of discouraging inappropriate behavior of Hawaiian children with gentle, but stern scolding.

Participatory Action Research and Evaluation: The YES! Program as an Example

The examples of culturally responsive evaluation cited above clearly build on understanding culturally valued ways of acting and communicating as a foundation for implementation of educational interventions, and for use of evaluation, coupled with research, as a way to arrive at effective interventions that can lead to measurable results. A participatory action research and evaluation perspective is a related but more proactive methodology that draws on an ecological account of human action (Fals Borda, 2006; Ulrich and Wenzel, 2009). The YES! Project is an example of such an approach (Wilson *et al.*, 2007, 2008).

The project in question utilizes a critical pedagogy orientation to empower urban, upper-elementary-school-age and adolescent youths to conduct projects they design to enact social action efforts that address local community problems. Youths use a Photovoice technique that employs photography to convey youths' perceptions of problems (Wang and Burris, 1997). Youths author essays that accompany the photos that discuss and analyze the community problem context captured in photos. The fuller curriculum of YES! involves six sequential steps: group formation, photography, Photovoice, community-organizing strategies, engaging the group in social action, and engaging the community in social action. Evaluating the effectiveness of an implementation of the YES! curriculum is a very challenging and creative endeavor. As noted

by the implementers, one of the most important outcomes of an implementation is the unsurfacing of community needs themselves.

The outcomes of YES! are not restricted to outcomes for individual youth participants. They include communications to the surrounding community and appropriate community agencies issues and problems, as seen from the perspectives of youth with the anticipation that both youths and community members can contribute to the resolution of problems.

The community problem identification outcome of the YES! curriculum is an example of a generative learning outcome (Wittrock, 1989) that contrasts with a traditional school curriculum where the target skills and knowledge to be learned by youths is well known and specified by the boundaries and expectations of grade-level learning standards in a subject-matter content area. In contrast, in the YES! curriculum, akin to the critical pedagogy process of problem identification coupled with problem analysis regarding solutions, youth must actively generate their learning regarding what is a significant community problem by exploring their community ecology and analyzing conditions that need to be addressed. The problem identified and partially represented in photographs needs to be explained in an accompanying essay or a creative performance such as a play, and these problem representations and enactments must then be brought to community members for action – proposed solutions, in a convincing manner that could lead to action by community members. Traditional school curricula seldom foster the integrative thinking and civic engagement goals targeted by a curriculum such as YES!, although there are calls by educational leaders for connecting students' school-based experiences with the development of students' capacities as community problem solvers, applying and blending what they learn in classrooms with their knowledge of the ecology of their communities (Association for Curriculum Development, 2009). The implementers of the YES! program describe the proximal outcome goals for YES! for participating youths as increased skill in collaborative decision making, conflict resolution, and increased political participation. Interestingly, these goals resonate well with the twenty-first-century skill priorities for development of a resourceful citizenry (see, e.g., Gardner 2006). However, the implementers of the YES! program do not restrict their vision to proximal goals associated with such skills. They also wish to measure effectiveness and success of the program in terms of youths' learning how to take care of themselves in terms of their broader well-being, as a result of becoming more effective problem solvers regarding community well-being. In this light, long-term outcome goals are described as positive changes in health and wellness awareness (Center for Research on Adolescent Health and Development, 2002–2006).

The breadth of federal, local, and community institutions involved in implementing YES! program illustrates how Bronfenbrenner's ecological perspectives can inform a deeper understanding of educational interventions. The funders of the YES! program include the federal Centers for Disease Control and Prevention via a grant to the Center for Research on Adolescent Health and Development, of the Public Health Institute based in Oakland California, and a local elementary school. The participants in the YES! program are community youths residing in Oakland attending the school in question. The federal–city agency–school–community youth links represent a chain of resources and health education and community improvement capacity building, cutting across very different but interdependent institutions. Other cross-institutional ecologies would also seem worthwhile to investigate as part of an evaluation of the YES! program. For example, youths' investigation of community problems, such as community sanitation needs, would involve their investigating the role of city agencies to supply needed sanitation services. On the whole, a deep evaluation of the outcomes of the YES! program would benefit from addressing how the program's limits and successes build on these relationships to transform the well-being of youths and community members. The YES! program also illustrates the importance of understanding how the everyday sense-making of youth participants coupled with the practices and sense-making of institutions interfacing with the program constitute the construction of culture itself. Culture is made to happen in the practices and meaning-making of community members and institutions as they negotiate their interpretation of reality and the consequences of these interpretations. This is a very different notion of culture, resonating with a cultural psychology and ecological perspective as compared to a perspective that culture is a characteristic or background variable describing intervention participants and stakeholders.

Clearly, much work remains to be done in operationalizing assessment and other forms of evidence of such outcomes. There is very little concrete evidence presented as yet regarding YES! program effects, although the provocative nature and sensitivity of this program in light of cultural and ecological issues augers for such evidence. Thus far the implementers report that youths show some positive qualitative evidence of meeting the ideal goals of the YES! curriculum, although the results also show limitations in youths' capacities to implement the fuller range of analytic thinking skills and explanatory communicative demands required to convey the importance of the problems they identify in a convincing manner (Wilson *et al.*, 2007, 2008). Similarly, a fuller, ecological sensitive evaluation of the YES! program would need to develop methods and lines of evidence to characterize and measure how the implementation and impact of the program is shown by the development of relationships between the program

and other institutions such as the funders, host school and school district, civic agencies, and community groups. It would seem useful to suggest a narrative historical account of how the program developed and the relationships developed as part of such an evaluation strategy.

Conclusion

There are many ways to approach the evaluation of educational interventions that can improve the validity of evaluations in light of cultural and ecological issues. This article has explored only a limited range of such possibilities, although it calls attention to the potential importance of insights drawn from ecological systems theory, cultural psychology, and critical pedagogy that connect well with interventions developed to be responsive to the cultural background and real-world community perceptions of youths targeted by educational interventions. Much work needs to be done to create and strengthen evaluation strategies for such interventions, given the challenges and even impossibilities of adequately capturing and measuring valued outcomes solely by statistical methods.

Evaluation and Accountability

E Sato and S N Rabinowitz, WestEd, San Francisco, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Accountability – The condition or state of being held responsible for one's actions.

Evaluation – The careful appraisal of something in order to judge its significance or quality.

Framework – A guideline that includes criteria for systematically approaching the development and implementation of something.

Qualitative data – Data that cannot be quantified or measured and that are instead represented with words.

Quantitative data – Data that can be quantified or measured.

Stakeholders – The individuals or groups involved in or affected by a course of action or outcome.

Stakes – The level of risk or impact associated with a course of action or outcome.

Triangulation – The analysis and use of information from multiple measures or sources of data in the examination of something. These data may be convergent, inconsistent, or contradictory, but must be rendered sensible by the researcher or evaluator in order to minimize the limitations and intrinsic biases that may be present in a particular measure or data source.

Utility – The degree to which the inferences made on the basis of certain information are clear and easy to understand by key stakeholders, and the facility with which consequent actions can be consistently and accurately implemented as intended.

Validity – The degree to which the inferences made and actions taken on the basis of certain information are trustworthy and appropriate.

Introduction: Evaluation and Accountability

Evaluation is the careful appraisal of something (e.g., product, service, program, and policy) in order to judge its significance or quality (American Evaluation Association, 2006; Madaus and Stufflebeam, 1984; Merriam-Webster, 2003). Accountability is the condition or state of being held responsible for one's actions (American Evaluation

Association, 2006; Linn, 2001; Madaus and Stufflebeam, 1984; Merriam-Webster, 2003). Both evaluation and accountability have applications in many disciplines, and numerous models exist for both. Although a careful discussion of the relative merits of various models of evaluation and accountability across disciplines is of importance, it is not the focus of this article. Instead, the authors describe evaluation and accountability within the educational context and adopt a neutral position and do not endorse or advocate for any particular model. The authors focus on the common function both evaluation and accountability serve of improving learning, teaching, and educational administration, and discuss evaluation and accountability within a framework of validity and utility. Such a framework is important to consider because, although not identical in purpose and methods, both evaluation and accountability require judicious design and implementation to ensure appropriate, meaningful, and practicable outcomes that effectively support educational improvement. For general discussions of the background and models of educational accountability, see, for example, Ananda and Rabinowitz (2001), Baker *et al.*, (2002), Gong (2002), and Linn (2001). For general discussions of the background and models of educational evaluation see, for example, Alkin (2004), Christie (2003), Fuhrman and Elmore (2004), Madaus and Stufflebeam (1984), and Patton (2008).

Framework of Validity and Utility

Overview

The validity and utility framework that this article uses to describe educational evaluation and accountability extends the strong base of relevant research and practice that exists for validity and utility (e.g., Brennan, 2006; Kane, 1992; Messick, 1989). Assuming that the information gathered for evaluation or accountability purposes is accurate and reliable, validity refers to the degree to which the inferences made and actions taken on the basis of the information are trustworthy and appropriate (American Educational Research Association, American Psychological Association, and National Council on Measurement in Education, 1999; Merriam-Webster, 2003; Messick, 1989). Utility refers to the degree to which the inferences made on the basis of the information are clear and easy to understand by a range of key stakeholders, and the facility with which consequent actions can be consistently and accurately implemented as

intended (Assessment and Accountability Comprehensive Center, 2009; Merriam-Webster, 2003).

In general, valid and useful educational evaluation or accountability has:

- a clearly defined purpose and scope,
- appropriate involvement of vital individuals or groups,
- information from multiple measures and data sources,
- context-sensitive outcomes,
- reasonable and defensible interpretations of information that lead to adequate and appropriate actions, and
- reporting that is available and accessible to appropriate stakeholders.

This article elaborates on each of these aspects of the framework and describes implications for educational evaluation and accountability. Additionally, the following sections present critical links between evaluation and accountability that strengthen their contributions to educational improvement, as relevant to each aspect of the framework.

Clearly Defined Purpose and Scope

The purpose – the intended outcomes and uses – of evaluation or accountability efforts should be explicit and clear in order to effectively guide their design and implementation. Additionally, the scope – the scale or extent of the effort, including any limitations or restrictions – should be explicit and clear in order to help determine what resources are needed for evaluation or accountability as well as their design and implementation.

The purposes and scope of evaluation and accountability typically differ. Accountability systems tend to focus on end results relative to an established standard or level of achievement. Evaluation efforts also can produce summative results related to a standard or level of achievement (e.g., whether an educational program or intervention accomplished its stated goals; a program or intervention's level of impact on changing behaviors or practices), but they also can be designed to yield formative information (e.g., specific ways in which or conditions under which an educational program or intervention is successful, or not, as it is being implemented), and data that inform the understanding of relationships among key variables relevant to the target of the evaluation (e.g., product, program, service, and policy).

Common challenges to crafting an effective statement of purpose and scope include having an appropriate focus (not too broad or too narrow), requiring an appropriate level of effort (e.g., relative to time and phases of the effort, level of associated risks or stakes, amount of resources, number and complexity of related tasks), and conforming to requisite limitations or restrictions (e.g., legislation). If these challenges are not addressed, they pose threats to

the validity and utility of evaluation and accountability efforts. Therefore, it is essential that key information for purpose and scope are considered upfront, and that the information appropriately addresses the critical, substantive questions or issues of focus for the evaluation or accountability effort.

More specifically, in the stated purpose and scope, information should be evident to:

- identify who needs to be involved (e.g., students, teachers, administrators, parents/guardians, policymakers, and other members of the community);
- define what the intended outcomes are (e.g., level of achievement, impact or effectiveness of a program, cost/benefit analysis, and quality assurance);
- determine what tasks need to be done (e.g., data collection activities, analyses);
- determine what is needed to accomplish specified tasks (e.g., data, finances, systems, and existing vs. additional resources);
- define how findings are intended to be used (e.g., formative, summative, for rewards and sanctions);
- determine how possible unintended consequences will be identified and minimized (e.g., indicators, procedures); and
- determine what measures will indicate when the intended outcomes have (or have not) been achieved.

Upfront consideration and explicit articulation of key information will more likely lead to the optimization of related design and implementation strategies and will more likely ensure that the outcomes of evaluation or accountability efforts will effectively provide direction and guidance for educational improvement.

Link Between Evaluation and Accountability

Related evaluation and accountability efforts can be conceived concurrently. A critical link that can be established between evaluation and accountability efforts is in the crafting of purposes and scopes that cohere, and such coherence has implications for the validity and utility of the efforts and their outcomes. The focus of accountability can provide information regarding the kind of evaluation that would be most useful in facilitating understanding of accountability findings and their implications, and data from evaluations can provide information regarding the design of accountability systems. That is, given the expected targets (end results) of an accountability system, evaluations can be conceived to provide specific information related to (1) the successes or failures of relevant people, processes, and conditions or contexts, (2) the appropriateness, including the technical adequacy of measures and

information used to determine the degree to which accountability targets are achieved, and (3) the appropriateness of the outcomes and their uses and impact. Therefore, upfront conceptualization of evaluation and accountability efforts that cohere can yield information that is not limited to whether something has achieved a standard or level of expectation (accountability); rather, coherent evaluation and accountability efforts can yield information that informs an understanding of the possible reasons for and the conditions under which something has been achieved (evaluation). Consequently, the information can provide direction for educational improvement.

Appropriate Involvement of Vital Individuals or Groups

The appropriate involvement of vital individuals or groups is essential to ensuring the validity and utility of outcomes. Those who should be involved in evaluation or accountability activities are individuals or groups who:

- have knowledge and experience that will provide information regarding the design of the evaluation or accountability effort;
- are necessary for the successful implementation of the effort;
- are critical to ensure valid interpretation of findings and usefulness of subsequent decisions and actions taken; and
- generally are those whose participation would provide the greatest assurance that the effort ultimately will lead to educational improvement.

The selection of individuals and composition of groups involved during different key phases of an evaluation or aspects of accountability may need to differ, depending on the particular needs or intended outcomes of a phase or aspect of an effort. For example, policymakers may be more heavily involved in early phases of evaluation or accountability efforts determining purposes and scope, while teachers may be better suited to inform implementation phases of evaluation or accountability efforts. No matter who is involved, to best ensure the validity and utility of evaluation or accountability efforts, individuals, at a minimum, should have appropriate expertise and experience, and there should be adequate balance of representation and perspectives across individuals involved and stakeholder groups. Appropriate inclusiveness is essential for effective evaluation, and broad participation and shared responsibility are necessary for successful accountability (American Evaluation Association, 2006; Linn, 2001).

Appropriate involvement, regardless of the phase or aspect of evaluation or accountability, also requires that individuals have:

- adequate training and orientation to the task to which they are attending;

- an understanding of the intended outcomes of the effort and how these outcomes relate to the broader evaluation or accountability objectives; and
- sufficient time for their involvement.

Inadequate individual expertise and experience, imbalanced representation of knowledge and perspectives, inadequate training and orientation, and lack of sufficient time pose threats to the validity and utility of evaluation and accountability efforts. Therefore, it is important that, in the initial stages of planning evaluation or accountability efforts, a general timeline is determined, key phases of the evaluation or aspects of accountability are identified, the particular needs and intended outcomes of each are defined, and the expected level of effort is determined in order to appropriately address such threats. Such upfront planning should provide information regarding the qualifications and range of individuals necessary for an effective evaluation or accountability effort.

Link Between Evaluation and Accountability

A key outcome of accountability is the proper attribution of responsibility for the success or failure of something (Fuhrman and Elmore, 2004; Linn, 2001). Therefore, to the degree that such an attribution could be assigned to an individual or group (e.g., teachers and administrators), those who could be held accountable should be included in accountability and related evaluation activities. Inclusion is not meant to create real or perceived conflicts of interest where those who may be accountable for results hold persuasion over the specific indices and standards for judgment. Rather, proper inclusion is intended to provide information regarding the mechanics of the accountability design and help ensure the meaningfulness of accountability efforts.

Similarly, evaluation efforts should be designed with input from vital individuals or groups in the:

- determination of appropriate indicators for the accountability and evaluation efforts;
- selection of appropriate measures to collect relevant data; and
- implementation of measures in order to ensure they are properly administered and that data are appropriately collected, analyzed, and reported (Alkin, 2004; Patton, 2008).

Additionally, evaluation efforts should gather information from those involved in the efforts about the relative value versus burden of the measures used and the information yielded in order to better understand circumstances related to fidelity of the efforts, interpret findings, and provide information regarding decisions and actions.

Multiple Measures and Data Sources

Multiple measures and data sources (both qualitative and quantitative) are critical to supporting valid and defensible interpretations of information that lead to appropriate actions. There may be limitations to any single measure or data source, and multiplicity provides a means for triangulating information. That is, there may be convergent, inconsistent, or contradictory information across measures or data sources that must be rendered sensible by the researcher or evaluator in order to minimize the limitations and intrinsic biases that may be present in a particular measure or data source (Mathison, 1988). Additionally, using multiple measures and data sources can yield a more robust depiction of the subject being examined, thereby facilitating more valid interpretations of information, minimizing uncertainty, and increasing the utility of the findings. Therefore, whenever possible and appropriate, multiple measures should be used, and both qualitative and quantitative data should be considered.

Common challenges that pose threats to the validity and utility of evaluation or accountability efforts include the quality of measures and data and the possibility of omitting a class of important, relevant information. For example, more standardized instruments (e.g., multiple-choice assessments, highly scripted observation protocols) may have high reliability but less relevance and validity than more open-ended methodologies (e.g., performance assessments, cognitive interviews). An understanding of the technical quality of the measures used, the degree to which something is able to be directly and accurately measured or observed, and possible inherent source(s) of bias of a measure or data source are essential to overcoming such threats. Such understanding will help establish appropriate parameters within which inferences about findings can be made (e.g., limitations, conditions, contingencies), thereby supporting the validity of interpretations and the utility of consequent decisions and actions.

Link Between Evaluation and Accountability

Given the high stakes often associated with accountability outcomes, it is vital that the information used to make accountability judgments is accurate and reliable and supports valid interpretations. Quality information is dependent on the quality of the measures used to gather the information. Therefore, evaluations should be designed to support accountability outcomes by:

- examining the technical quality of the measures used to gather information on which accountability judgments are based (e.g., validity, reliability, freedom from bias and sensitivity issues);

- determining whether the information collected is appropriately central or supplemental to the particular question or issue requiring examination;
- scrutinizing the degree to which and appropriateness with which results of individual indicators generalize to other related indicators;
- appraising the body of information collected and its sufficiency to support various accountability outcomes; and
- examining the efficacy of the indicators of the accountability system's success or failure – in terms of both intended and unintended outcomes.

Coherent evaluation and accountability efforts that include multiple measures and data sources are necessary for gathering a robust body of information, which can lend itself to the validity and utility of outcomes that appropriately guide educational improvements (American Evaluation Association, 2006; Baker *et al.*, 2002).

Context-Sensitive Outcomes

There are a number of contextual influences that can impact the validity and utility of evaluation or accountability outcomes (American Evaluation Association, 2006; Ananda and Rabinowitz, 2001; Linn, 2001; Patton, 2008). Such influences include:

- politics;
- conflicts among interests, values, and priorities;
- existing systems and structures;
- availability of resources;
- the cultural context; and
- the general readiness to act by those who are involved in the evaluation or accountability efforts and by those who will be affected by the outcome(s).

There are obvious ways in which aspects of context can negatively affect evaluation or accountability efforts, including placing restrictions on the focus of the evaluation and the consequences associated with evaluation findings or accountability outcomes, undermining efforts because the efforts are not consistent with or do not necessarily support political or fiscal objectives, manipulating availability or collection of information to serve specific interests, yielding unreliable or invalid information, and yielding biased interpretations that serve a particular agenda or interest group. Understanding the context within which the evaluation or accountability efforts are conducted and their outcomes enacted is essential to avoiding or minimizing threats to validity and utility. Such understanding can be gained through the purposeful inclusion of key stakeholders (e.g., policy-makers, technical experts). Key stakeholders should be identified upfront and opportunities should be planned for appropriate communication and collaboration across these stakeholders. Doing so will best ensure that various (possibly conflicting) perspectives and interests are

appropriately accounted for and balanced upfront, and a shared understanding of the goals and parameters of the evaluation or accountability efforts is established.

Link Between Evaluation and Accountability

Both evaluation and accountability occur within dynamic contexts that typically are laden with politics, practical issues, and values. Evaluation can aid the understanding of aspects of context that may impact the timing and scope of the evaluation itself (e.g., degree to which mid-implementation information and possible revisions are feasible and desirable) and how its findings might inform accountability decisions. Additionally, context-sensitive evaluation can better ensure the accuracy of information gathered, the efficacy of resulting recommendations, and the meaningfulness and appropriateness of the accountability outcomes. Often when accountability models are conceptualized and developed, there can be tension between the broad, overarching goals of policymakers (e.g., the broadly stated objective that all students will achieve at high levels) and the concerns of technicians that the available information is not refined or precise enough for the level of scrutiny and attribution needed to support broad accountability goals. For example, there often are debates in the research and policy arenas about the relative merits of status versus growth goals as the basis to determine school success (e.g., Betebenner, 2008; Goldschmidt *et al.*, 2005). This debate has led to the development and implementation of various value-added methodologies to evaluate teacher success (Sanders *et al.*, 1997). If a growth model is desired with value-added consequences for classroom teachers, it is important to determine the degree to which the available assessments are reliable and will yield data to support valid interpretations related to fine distinctions among different levels of student performance. Evaluation is critical for examining the technical adequacy of the measures used, the accuracy and reliability of the data collected, the validity of the interpretations, and the overall efficacy of the accountability model.

Reasonable and Defensible Interpretations and Adequate and Appropriate Actions

All aspects of the aforementioned validity and utility framework, if appropriately addressed, help to ensure effective evaluation and accountability efforts. The effectiveness of evaluation or accountability efforts in terms of educational improvement is dependent on reasonable and defensible interpretations of information and the adequacy and appropriateness of resultant actions. In order to best ensure the validity of interpretations of information and the utility of outcomes, consideration must be given to the following:

- Diversity of the data – If sources of data are too diverse, with little consistency or connection among the various types of information gathered, then such diversity, when aggregated, may limit the interpretability, generalizability, and utility of the information.
- Weighting of information – Given the critical questions and issues examined by the evaluation or accountability effort, *a priori* consideration must be given to the importance of information gathered from different sources and the influence each source of data and type of data (qualitative, quantitative) should have on interpretations and subsequent decisions and actions.
- Extent and trustworthiness of interpretations and extrapolations made from the data – The degree of inference involved in the interpretation of data, including the degree to which findings can generalize, should be considered.
- Limitations of the data (see related discussion on multiple measures and data sources).
- Amount and type of impact – Both positive and negative consequences should be considered, including the degree to which and manner by which understanding of such consequences can be substantiated with data.

Link Between Evaluation and Accountability

Accountability serves the function of improving learning, teaching, and educational administration, by assigning responsibility for the success or failure of a particular educational endeavor. Accountability efforts can benefit from evaluation because evaluation adds a level and type of scrutiny that can hone understanding of the who, what, and why delineated through accountability efforts:

- Who – To better understand who is responsible, evaluation can focus on group and subgroup characteristics at a greater level of detail than accountability efforts and can provide a richer depiction of the groups and subgroups affected (i.e., determined through the analysis of relevant aggregated and disaggregated quantitative data along with data from qualitative measures, such as surveys and observations).
- What – This aspect of accountability can be better understood through evaluation efforts that closely examine characteristics of the conditions that are affecting groups and subgroups. Such conditions include those aspects of context discussed above. As evaluation often uses group and subgroup characteristics as blocking variables or predictors in complex regression models, the possible differential effects of aspects of context on various subgroups can be better understood.
- Why – Evaluation can be designed to obtain information from representative samples on a number of indicators in a manner that should enable extrapolation of

findings to a broader population and/or context with similar characteristics as the sample. Therefore, evaluation can provide information regarding accountability efforts by providing more robust information related to the positive and negative effects of something – both in terms of what is intended and what may not be intended. Evaluation also can help to appraise the sufficient size and nature of an effect to determine something as a success versus determining something as a failure.

The level and type of detailed information provided by evaluation lends itself to more specific, actionable plans for educational improvement. Thus, evaluation and accountability efforts can be coordinated to increase both the validity and utility of the information.

Available and Accessible Reporting

Transparency of educational evaluation or accountability efforts is important to ensure that the efforts themselves are accountable for the appropriateness of procedures and the adequacy of findings, their interpretation, and subsequent decisions and actions. Transparency can be achieved by making reports available and accessible to stakeholders. Reports should cover key phases or critical findings of an evaluation or accountability effort. In order to make reports appropriately available and accessible, consideration should be given to:

- various audiences or stakeholders, their different information needs about the effort, as well as their need in terms of developing relevant understanding and capacity,
- different formats for communicating and reporting (e.g., paper-based, electronic), and
- establishing a clear way for audiences or stakeholders to ask questions about information presented in a report and to possibly refute the appropriateness and adequacy of procedures or outcomes.

Link Between Evaluation and Accountability

A distinction between evaluation and accountability reports is that evaluation reports typically tend to target professional or technical audiences; that is, individuals who may be charged with revising and implementing the next generation of programs or judging the quality of the evaluation itself. As such, they need to have adequate technical information to demonstrate their levels of internal and external validity. Accountability reports typically are less technical because their primary audiences include many nontechnical groups and others not part of the education establishment. Such constituencies include legislators, parents, business groups, and classroom teachers.

The ways in which information from an evaluation or accountability effort is shared can significantly affect the ways in which audiences perceive, understand, and learn from the outcomes of the efforts. Therefore, upfront consideration of the set of reports that would best serve both the needs of key constituencies and the ultimate goal of educational improvement is critical. Such a set of reports could consist of nontechnical tables with some summary language or a range of reports geared to the interests of the various constituencies. A technical report also could be developed, indicating the reliability and validity of the judgments that are made relative to the findings of the evaluation or accountability effort. An executive summary targeted to policymakers could be developed to provide a summary of findings, conclusions, recommended next steps, and resource needs for the implementation of the next steps. Throughout the set of documents, a description of how results are to improve education (i.e., learning, teaching, and/or educational administration) should be included.

Summary and Conclusion

The value of educational evaluation or accountability is ultimately determined by the degree to which it contributes to the improvement of learning, teaching, and educational administration. For the purpose of this article, discussion focused on this common contribution of both evaluation and accountability and presented relevant information within a framework of validity and utility. As discussed in this article, threats to the validity and utility of educational evaluation or accountability efforts can be minimized through careful attention to a clearly defined purpose and scope, appropriate involvement of vital individuals or groups, consideration of information from multiple measures and data sources, providing context-sensitive outcomes, making reasonable and defensible interpretations of information that lead to adequate and appropriate actions, and providing reports that are available and accessible to appropriate stakeholders to help minimize such threats.

Establishing links between evaluation and accountability efforts can strengthen their relative contributions to educational improvement. The focus of accountability systems can drive determinations of what kinds of evaluations are likely to be particularly useful in enhancing understanding of accountability system findings and their implications for future policy and practice. Data from evaluations can inform the design of accountability systems as well as the understanding of relationships among key components of the systems and possible reasons for and conditions under which the desired standard has been achieved. These linkages suggest that careful communication and coordination among key stakeholders and purposeful coordination of

efforts are essential. Such communication and coordination between those designing and implementing evaluation and accountability systems can better ensure the validity and utility of information to guide improvements. Linking evaluation and accountability in this manner is more likely to increase the overall quality of our education system and the likelihood of achievement and equity for all our students.

Evaluation Governance and Planning

R Picciotto, King's College, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This article outlines the prerequisites for effective evaluation governance and planning in the education sector. Evaluation governance consists of the policies, rules, and practices that initiate and control evaluations, while planning identifies the methods, tasks, and resources needed to carry them out. Together, the two functions contribute to improved performance in the education sector.

The two concepts are complementary and interdependent. First, governance structures shape evaluation planning by setting the rules of the game according to which the evaluation mandate is discharged. Second, evaluation planning influences governance by focusing on the institutional areas that need adjustment in order to achieve improved educational outcomes.

Conditions for Good Evaluation Governance

Good governance aims at legitimacy, accountability, responsibility, fairness, transparency, efficiency, and probity (OECD, 2004). Evaluation contributes to these objectives. It provides external guidance to the supreme authorities of education bodies. In addition, it enhances accountability and probity and makes authority responsible – a role akin to that played by accounting and auditing in the private sector. On the other hand, evaluation only comes into its own within a governance system that is legitimate, guarantees the independence and quality of the function, and reflects intentionality to make use of lessons of experience.

Policy

Evaluation informs not only managerial self-governance (rectors, presidents, deans, etc.) and academic self-governance (e.g., teaching and research staff) but also government ministries, national quality assurance bodies, national-level advisory or consultative bodies, international organizations (e.g., the European Commission), or educational associations (e.g., the Network of Universities from the Capitals of Europe).

Reporting lines are bound to vary since educational structures differ in how they allocate responsibilities and decision-making powers. Hence, evaluation policy must be adapted to the governance architecture in place. However, at the national level, good evaluation practice requires an

official mandate, that is, a policy statement that specifies the basic purposes and features of the evaluation function and its role. International professional associations may also be called upon to draw up relevant evaluation procedures to ensure that they meet commonly agreed standards.

Normally, an explicit evaluation policy is embedded in legislation endorsed by the supreme governing body of the state or region that lays down the rule of operation of the education sector. In the United States, the No Child Left Behind Act has set explicit proficiency goals for all students by 2014 that are tracked at the state level and also at the federal level by an agency that operates under the aegis of the US Department of Education.

Similarly, national standards for evaluation of academic staff may be imposed to induce trust in the quality of education and training. Thus, it is common practice for evaluations of academic staff to form an integral part of compulsory quality assurance procedures while, in order to attest to the overall effectiveness of educational institutions, formal evaluation arrangements may be made by the governing bodies that carry ultimate responsibility for all the affairs of the institution.

Additional safeguards may be provided through independent evaluations contracted by the official bodies that provide educational funding. In Estonia, for example, accreditation requirements established by government state that higher educational institutions need to use criteria and methods that take all fields of activity into account (teaching, students' instruction, research, special tasks, etc). Similarly, evaluation arrangements for the overall effectiveness of education institutions may be prescribed by legislation.

In England and Wales, higher education institutions are legally independent corporate institutions and their councils or board of governors are formally tasked with contracting for quality audits that review the mechanisms and structures designed to monitor and ensure academic quality and standards. In addition, official funding bodies have a statutory duty to ensure the quality of instruction in individual subject areas through quality assessments.

It is a good practice for the legal framework that governs educational institutions to specify evaluation independence, stakeholder involvement, transparency of evaluation processes (including public disclosure of evaluation reports), and the relationships between the independent evaluation functions and the quality-assurance procedures that are the responsibility of the educational establishment.

Rigorous evaluation of academic staff is a characteristic of sound educational governance. In Latvia, evaluation of academic staff occurs before hiring and reevaluation of incumbents of academic posts occurs every 6 years based on the criteria set by the Cabinet of Ministers. In Finland, the performance-based salary scheme is based on the evaluation of two components – evolving job requirements and individual performance. In Romania, the methodological standards for the annual evaluation of higher education staff are set according to performance indicators established by the Ministry of Education and Research.

Independence

The objectivity and professional skepticism that should characterize evaluations cannot be secured unless evaluators are shielded from external threats and influences regarding the collection of information and the assessment process. Sound governance safeguards the independence and impartiality of evaluators. It shields them from the demands and biases of program managers and policy-makers. It provides them with mandatory access to relevant information and full autonomy in carrying out their investigations and reporting their findings. It protects them from intimidation, organizational pressures, financial leverage, and political influence.

Equally, evaluation independence requires distinctive personal characteristics, attitudes, and behaviors among individual evaluators and a frame of mind characterized by curiosity, skepticism, and hunger for evidence. However, evaluators should not be so detached from the activity being evaluated as to shirk interaction with operational managers, staff, or beneficiaries of the activity: independence is not isolation. Good evaluation overcomes information asymmetries, while protecting the integrity and fairness of the process from the influence of vested interests.

Four standards characterize evaluation independence (World Bank, 2007):

1. *Organizational independence.* It ensures that the evaluation unit and its staff are not under the control or influence of decision makers who have the responsibility for the activities being evaluated and that they have full access to the information they need to fulfill their mandate.
2. *Behavioral independence.* It measures the extent to which the evaluation unit is able and willing to set its work program, produce high-quality and uncompromising reports and to disclose its findings to the supreme governance authority without management-imposed restrictions.
3. *Protection from outside interference.* It keeps the evaluation function free to set its priorities, design its processes and products, reach its judgments, and administer its

human and budget resources without intrusion by management.

4. *Conflict of interest safeguards.* They guarantee that current, immediate future, or prior professional and personal relationships and considerations are not allowed to influence evaluators' judgments or create the appearance of a lack of objectivity.

All four criteria are important and none implies trade-offs with operational relevance or influence. In particular, behavioral independence is a privileged dimension of evaluation excellence since it is integrally connected to evaluation quality and can be ascertained not only by assessing governance structures, processes, and practices but also by examining whether, through effective evaluation planning and management, the independent evaluation unit produces quality evaluations.

Quality

Areas typically covered by educational evaluations include the institution's arrangements for designing, approving, and reviewing programs of study, grading protocols and degree classification, as well as internal feedback and monitoring arrangements. To carry out such evaluations, appropriate skills, sound methods, adequate resources, and transparency are required.

Intellectual engagement with the suppliers and beneficiaries of educational services are equally critical to evaluation effectiveness since accurate and fair evaluations combine detachment with empathy and deep understanding. Hence, the importance of a governance system that provides connectivity to stakeholders in order to secure their trust without jeopardizing the integrity and objectivity in the evaluation process.

The implications for organizational design are straightforward. In order to enhance effective use of educational resources, accountability for results, and learning from experience, all stakeholders – parents, teachers, children, school administrators, etc. – as well as political authorities and the general public have an interest in the quality of educational evaluations. In all European countries, the law requires that students be involved in evaluating the quality of teaching staff; in Italy, it is the only method currently used to this end.

With regard to the evaluation of educational programs, whether the emphasis is placed on formative or summative evaluations, stakeholders look to evaluation studies to generate independent and rigorous assessments of educational policies, programs, or projects, their design, their execution, and their outputs, outcomes, and impacts. (Formative evaluation aims at improved program design and performance, whereas summative evaluation helps to determine the extent to which planned outcomes and impacts have been achieved. The former kind of evaluations often takes

place during implementation so as to make use of lessons learned for improved outcomes, whereas the latter types are usually conducted at the end of a program phase to assess performance and assign responsibility for outcomes.) In the United States, evaluations are expected to measure educational impacts in a rigorous way through experimental or quasi-experimental methods.

Compliance with good professional practice means impartiality and absence of bias. Evaluators reach balanced judgments by relying on relevant and accurate evidence about program strengths and weaknesses. To this end, the views of program participants, partners, and beneficiaries should be sought. Where stakeholders wish to challenge the analysis contained in an evaluation, they should be given an opportunity to add dissenting footnotes or statements.

Monitoring

A responsibility of educational managers, monitoring, consists in the continuous assessment of progress made during program implementation and in the design of performance-related salary schemes. Monitoring relies on baseline data and on regular information about the use of inputs for major activities, their outputs, their expected outcomes, and, to the extent practicable, their impact. By providing timely information on program performance and by tracking staff compliance with standards, monitoring provides relevant feedback to education managers, staff, and partners and pinpoints the actions needed to improve performance toward agreed goals.

Thus, monitoring promotes organizational learning in real time. For effective dissemination, reporting is clear, concise, and easily accessible. Good monitoring systems use specific, measurable, attainable, relevant, and time-bound (SMART) indicators that reflect the values and policies embedded in the agreed education program. Toward this end, data collection is carried out professionally and at an appropriate frequency so as to provide timely feedback and facilitate proactive management.

Participation, Transparency, and Ethics

Embedding participation within the evaluation process is a prerequisite of fairness, objectivity, and utilization of evaluation findings. Principled consultation with judiciously selected stakeholders at critical phases of the evaluation process (from initial design to completion follow-up) should be an integral part of the evaluation plan as well as a standard feature of monitoring systems.

Thus, the partners that contribute to the governance, management, and funding of education programs should be consulted, and so should the beneficiaries and communities affected by the education program being evaluated. Special efforts should be made to include organizations

and individuals that represent disadvantaged and neglected groups. Such participation enhances the credibility of monitoring and evaluation arrangements and facilitates buy-in of evaluation lessons.

The reach and impact of evaluation are increased through explicit provision for interaction with stakeholders through advisory bodies, learning events, focus groups, formal surveys, and structured consultations at key stages of the evaluation process. Through such means, stakeholders have an opportunity to comment on the design, methods, findings, and conclusions of the evaluation. It is also desirable for the salient contributions of stakeholders to be transparently displayed in the final report.

Participation is fortified by transparency that enhances ownership of evaluation findings and helps to ensure that lessons drawn from evaluation become lessons learned. Through evaluation transparency, stakeholders and the general public are informed about the evaluation objectives, criteria, and planned use of findings, and information is made available about the confidentiality rules that will govern the evaluation for different categories of stakeholders and at various phases of the process.

The basic presumption should be that stakeholders and the general public have a legitimate claim to accessing evaluation results. Equally, administrators and decision makers should be tasked with informing their constituencies about the decisions taken in light of evaluation findings, for example, with respect to future program design and implementation.

This said, evaluators must strike a balance between the demands placed on them and the rights and sensitivities of those who contribute to the evaluation – or are potentially affected by its results. For evaluative decisions to be made in a way that respects the interests of students, parents, and the public as well as those of educational bodies and their staff, full transparency about the purpose of the evaluation is important.

As in social research, ethical considerations should guide the evaluation process. The rights to privacy of evaluation respondents should be protected and informed consent sought from those who deliver sensitive information about an education program, neither should evaluations contribute to a chilling effect on the openness of educational processes. Confidentiality rules should be ensured, for example, if commercial considerations intervene or access to data is restricted for security reasons, potential retaliation against respondents, or possible embarrassment of participants.

Anonymity of information sources should be respected in the processing of surveys, and evaluators should seek permission before accessing an educational establishment and agreements reached regarding protocols of engagement with pupils, teachers, and administrative staff. Special safeguards are needed in field work that involves children.

Final evaluation reports should be disclosed to the public and a reasoned judgment about the reliability and independence of the evaluation should be included in the final reports.

Such reports should include adequate information about the evaluation commissioning process, the evaluation framework, the financial and human resources employed, their provenance, the data collection arrangements, the assessment methods selected, and their limitations. The responses of the administration to evaluation recommendations should also be made public, and actual implementation of agreed recommendations should be tracked and disclosed.

Beyond the immediate stakeholders, the new knowledge generated by evaluations should be disseminated to the policy community. To this end, documentation resulting from educational evaluations (including abstracts and syntheses of performance data and evaluation lessons) should be clearly presented, be user friendly, and be tailored to diverse audiences. Evaluation accessibility is enhanced by the new information technologies (including websites) as well as the judicious use of workshops, conferences, and media events.

Conditions for Sound Evaluation Planning

Educational institutions must ensure that they remain responsive to the needs and demands of society. Strategic plans are the instruments through which educational priorities and activities are set. Educational strategies state the vision and specify the policy directions of education programs. They also outline educational objectives, means of implementation, and review processes. This is where evaluation fits in. By feeding into the strategic planning process, it bridges educational governance and strategy.

At the levels of both the evaluation program and individual studies, planning is an iterative process. It depends not only on the issues to be addressed but also on the feasibility of addressing them. Allocation of scarce evaluation resources is a major responsibility of evaluation managers. It calls for expert familiarity with evaluation methods and constraints as well as for a sound understanding of the policy trends and the organizational context within which educational programs are designed and implemented.

Evaluation Programming

At the level of the evaluation program, resource allocation within an evaluation unit concerns the choice of evaluation studies and activities and the deployment of staff and funds to implement them within a given time span. This requires evaluation managers to make assumptions

about the evolution of the policy and operating context. A far sighted approach is needed since the evaluation program will generate a result stretching well beyond the programming period, and continued relevance of the evaluation program calls for skills and methods that are tailor-made to the evolving programmatic challenges.

It takes time to nurture the human assets and the relationships needed for high-quality evaluations. Hence there is a need for evaluation strategies. They help evaluation managers to identify the evaluation skills and the knowledge partnerships needed to comply with the evaluation mandate. Evaluation strategies are also used to secure sustained support from the governing authorities regarding medium-term evaluation budget plans. They reflect the evaluation managers' assessments of the strengths and weaknesses of the institutional environment.

In setting priorities for the evaluation program, evaluation managers are also guided by their policy mandate, by the lessons of evaluation experience, and by the results of their regular consultations with decision makers and other stakeholders. As organizational and policy contexts evolve, evaluation strategies need periodic adjustment while evaluation plans address shorter time periods. Where operating environments are characterized by volatility and uncertainty, flexible rolling programs may need annual updating to help redeploy scarce evaluation resources in a timely fashion (Mathison, 2007).

Evaluation programming should meet four standards of quality:

1. criticality – a portfolio of evaluations that together assess educational performance in an objective and transparent fashion;
2. additionality – a distinctive contribution to operational knowledge creation or dissemination within the education sector;
3. timeliness – the delivery of educational evaluation findings and lessons early enough to inform decision making; and
4. materiality – a deliberate focus on topics and issues that have substantial relevance to educational effectiveness.

Planning of Evaluations

Once the diverse audiences and goals of the evaluation program have been ascertained and specific choices have been made as to which evaluations should have priority, the focus of evaluation planning turns to the design of individual evaluation studies. At this level, the nature of the questions posed and their precise formulation may have to be adjusted to take account of practical considerations. As for the overall program, this implies a cyclical process designed to reconcile the scope, content, and timing of the evaluation with the constraints imposed by available funds, skills, data, and methods (Weiss, 1998).

Evaluability assessments can help to define the appropriate direction, timing, and content of the study by examining the program to be evaluated. Typically, such assessments involve an overview of the program, a cursory examination of available data, a preliminary survey of stakeholders' perceptions, and a tentative judgment as to the likelihood of program success. This approach is a good way of involving managers and stakeholders early in the evaluation process. It also helps to delineate the precise timing of the evaluation and the roles it is expected to play in improving program outcomes.

Thus, evaluability assessments may be an economical way of generating improved program design recommendations and/or enhanced monitoring arrangements. In some cases, they may preclude, preempt, or postpone the need for the immediate or comprehensive evaluation studies that were originally envisaged. At a minimum, they can help clarify the key assumptions that underlie program design, consider their plausibility and, as a result, help to identify relevant evaluation questions and to select appropriate evaluation methods.

Evaluation quality calls for an evaluation framework that identifies the most relevant stakeholders and defines an appropriate role for them in the evaluation process. The framework should also include clear and consistent evaluation objectives, agreed evaluation criteria, relevant baseline and performance indicators, judicious selection of evaluation methods, data collection and interpretation arrangements, reporting formats, and dissemination plans. Next, the skills and resources needed to bring the evaluation process to fruition should be assembled. These are the challenges that evaluation planning is expected to meet.

Evaluation coverage and terms of reference depend on the criteria to be used and the nature of questions to be addressed. These may concern one or more of the following: rationale for program scope, content and/or timing, program goals and/or objectives, choice of program instruments, relevance, effectiveness and/or efficiency of processes, compliance with regulations, performance of participants, role of contextual factors, selection of success indicators, etc. Since stakeholders usually want to know not only what happened but also how and why, desired attribution of outcomes to particular program features or to the behavior of key program participants is critical to the choice of evaluation methods and the scope of data collection.

Timing and Scope

The optimum timing of an evaluation is not a straightforward matter. The longer the time used to ascertain results the more secure the assessment of program impacts. However, accountability considerations call for early organizational feedback so as to create wholesome incentives for program participants and provide the

timely knowledge needed to adjust program designs and fine-tune the program processes. Furthermore, the role of unanticipated events and the emergence of unintended consequences tend to increase as time horizons expand.

Similarly, the scope of the evaluation must strike a balance between what is desirable and what is realistic and achievable. Evaluation techniques should be chosen to ensure as complete, fair, and rigorous answers to the questions posed as practicable. But the larger the scope of the evaluation, the harder the methodological and data challenges, and hence, the greater the risks to external and internal validity of evaluation findings. Threats to external validity occur when evaluation conclusions are extrapolated beyond their specific contexts while threats to internal validity (the correct attribution of results to particular program features) result from changes in operating contexts, assignment bias, or unintended impacts on participants' or control group behaviors.

In deciding on the direction and scope of an evaluation, evaluation managers may establish peer review mechanisms or set up advisory committees or reference groups composed of sector specialists and expert evaluators. Such mechanisms can be used for quality assurance and for advice on methods, data sources, and interpretation of results. They answer the perennial question of who evaluates the evaluators. It is desirable to provide them with adequate resources and to disclose to the public their judgments about the quality of the final evaluation report.

Methods

No standard blueprint exists for selecting the right evaluation methods: the context of the evaluation and its purposes should determine its methodology. For example, if the effects of a specific intervention have to be demonstrated with rigor, its observed results should be compared with those that would have materialized without the intervention.

Where feasible, the counterfactual should be derived through randomized control trials that measure the net impact of an educational intervention by the differences observed between learning outcomes within an experimental group subject to the intervention and those secured by a group (designated as the control group) deprived of the intervention, endowed with the same characteristics and chosen through a random selection process.

A variant method is regression discontinuity. It selects the experimental and control groups on the basis of a pre-tested characteristic measured before and after the intervention: the shift between the regression lines constitutes the net effect of the education program. Interrupted time series assess the impact of various features of an educational intervention by looking at changes in learning variables.

When random allocation is not feasible, quasi-experimental designs are used by selecting subjects that closely match the experimental group (Scriven, 1991). Matched comparisons ascertain the desired characteristics of a control group excluded from the intervention against those of program participants. Propensity scores that reflect the likely importance of contributory factors to outcomes (based on reviews of the research literature) can be used to select the experimental and control groups. Such experimental methods involve ethical risks and tend to be costly and skill intensive.

They can be useful for standard educational treatments in stable environments, but in the real world, unless rigorously handled, they can yield misleading results because of selection bias (unrepresentative treatment group), substitution bias (access to other treatments in the control group), and unintended behavioral consequences within the treatment group (Hawthorne effect) or within the control group (John Henry effect).

As they do not invariably deliver what stakeholders are interested to know – for example, the what and how of program design and the distinctive contributions of educational actors and participants – experimental methods cannot be described as a gold standard for evaluation. Depending on the evaluation objectives, other methods may be more useful. In general, the limitations of any single method may be mitigated through triangulation of data collection instruments and multi-method approaches.

Longitudinal evaluations based on information collected over a period of time (from the same group of educational respondents) may be combined with cross-sectional evaluations that assess the results obtained by different respondent groups (at the same time). Alternatively, or in addition, trend studies may focus attention on changes in key factors that are deemed to impact on educational outcomes.

Case studies are often used to evaluate the effectiveness of an educational policy (Cohen *et al.*, 2007). Well-selected and -designed case studies have the capacity of illuminating program performance by providing rich narratives of policy applications in diverse operating contexts, analyzing the linkages between policy actions and results, and identifying the contribution of various actors to observed outcomes.

Participatory approaches favor a combination of interviews, questionnaires, focus groups, tests, and simulations. For example, in evaluating the behavior of a partner engaged in an educational endeavor, it is appropriate to study it from different perspectives making use of stakeholder perception surveys as well as of qualitative information and quantitative data that test performance according to agreed benchmarks.

Similarly, in evaluating the rationale of an educational technique, theory-based approaches have considerable merit: they model the theory or theories of change

implied by the intervention, examine critically their explicit or tacit assumptions, and seek to verify the extent to which they are valid.

For example, the theory-driven evaluation of a program aimed at reducing problem behavior in the middle school of a US southern state demonstrated conclusively that improvements in social bonding, social competency skills, and school success did not materialize due to a patent lack of academic and administrative support for the changes proposed in instruction and mentoring (Rossi *et al.*, 1999).

In a globalized world, public policy benchmarks are increasingly defined with reference to international comparators. But defining such benchmarks in ways that are comparable across countries without undermining their validity at the national and institutional level poses major methodological challenges. Hence, without a detailed understanding of the specific contexts within which educational services are delivered, lessons are not transferable from one country to another.

Contracting and Managing an Evaluation Team

Evaluation relies on all the social sciences. As a trans-discipline, it connects all the disciplines relevant to the assessment of merit, worth, and value of a collective endeavor. It is also a discipline in its own right since it has developed its own concepts and practices. Thus, the skills needed to carry out evaluations are diverse and no single individual can be expected to master the full repertoire of social research findings and evaluation methods. Nor can formal evaluation training, critical as it is, substitute for learning by doing evaluations.

Evaluators' competence largely determines evaluation quality. Hence, the assembly of appropriate skills and experience to carry out an evaluation assignment and deliver a quality study is a key evaluation management challenge (Rossi *et al.*, 1999). Team leaders and members should have the competencies (e.g., educational background, evaluation qualifications, professional skills, and work experience) needed to implement the evaluation according to agreed quality standards. Trust and mutual respect should characterize the relationship between commissioners of evaluations and the evaluators that they employ.

A multidisciplinary team composed of external subject matter specialists and evaluators may have to be constructed. Where an external group or a consulting firm is employed, transparent (preferably competitive) selection procedures should be used. These procedures should avoid conflicts of interest and provide a level playing field for potential bidders. The external parties who undertake to carry out an evaluation should endorse a written agreement

to fulfill the terms of reference of the evaluation and meet the conditions set forth in a legally enforceable contract that addresses matters such as confidentiality, privacy, reporting, as well as mediation procedures, in case disagreements arise or misconduct is alleged.

Summary

Good governance of evaluation in education is embedded in policies and standards that protect the independence of the function and promote impartial and rigorous assessment of educational programs. It involves stakeholders in the evaluation process through open and transparent processes. It ensures regular tracking of implementation progress toward agreed goals through effective monitoring and it encourages utilization of evaluation lessons by program managers. Finally, it complies with ethical standards that protect the rights of stakeholders that are asked to contribute to the fulfillment of the evaluation mandate. While sound governance is critical for evaluation effectiveness, it is not a sufficient condition of evaluation excellence. For evaluation resources to be allocated judiciously, sound evaluation planning feeds into the education strategy cycle so that lessons of experience inform education program design and implementation. Tailor-made approaches adapt the scope, content, and timing of evaluations to stakeholders' needs and educational priorities. Sound evaluation management also calls for

triangulation of evaluation methods and the assembly of adequate evaluation competencies.

Evaluation Use

V G Thomas, Howard University, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Conceptual use – Using evaluation to better understand a program, policy, or related issues; issues; use to influence how key people think about a program or policy and better understand it in some significant way; no action or decision flows from the findings.

Evaluand – The thing that the evaluator is evaluating.

Evaluation misuse – Calculated and intentional suppression, misrepresented, or unbalanced use of evaluation findings to influence opinions or decisions.

Evaluation use – Application of evaluation information or evaluation process to achieve intended, desired ends.

Instrumental use – Using evaluations to directly inform a decision, improve a program or policy, develop new directions, or contribute to solving a problem.

Process use – Learning or changes resulting from participating in the evaluation process itself.

Strategic use – Using evaluation to persuade others or to gain particular outcomes.

Symbolic use – Token support for the evaluation process or findings with no real intent to take either the process or the findings seriously.

Utility standards – One of the four areas around which the 30 program evaluation standards are organized; the utility standards, consisting of seven standards, are intended to provide guidance that ensure that an evaluation will serve the information needs of intended users.

Use, or utilization, has long been recognized as a central issue in the evaluation field either as a goal of the evaluation or as a fundamental construct for discussion in theories, approaches, and research on evaluation. (In this article, as is generally the case in the evaluation literature, the terms use and utilization are used interchangeably and applied in a synonymous manner.) As an applied field, evaluation must be deeply concerned about its impact and the discipline rightfully should promote practices that advance utilization among intended audiences. During the late 1960s and 1970s, the use concept was generally accepted as a concise way of conveying

how evaluation findings affected programs and policies in ways that were clear, direct, obvious, and reasonable. Since then, discourse on evaluation use has evolved considerably. A reconceptualization of evaluation use emerged as the landscape of the field became more diversified and as increasing numbers of evaluators recognized that evaluations did not necessarily translate into immediate or direct decisions to continue, expand, eliminate, or revise programs and policies. The limited use of evaluation results, especially for improving programs, has been characterized as the Achilles heel of the profession. To address this issue, in the late 1970s and 1980s numerous studies were conducted that examined utilization with this period referred to as the golden age of research on evaluation use (Henry and Mark, 2003).

With increased theoretical emphasis and empirical study on evaluation use, by the end of the 1980s, the concept had expanded to include a more complex, multifaceted perspective beyond emphasis on use for overt decision making to also encompass other types of utilization such as conceptual, strategic, political, symbolic, and organizational learning. There was more attention given to effective utilization of evaluation rather than simply more utilization (Weiss, 1988). Further, issues related to evaluation misuse were infused into the dialog (Alkin and Coyle, 1988; Patton, 1998; Shadish *et al.*, 1991). Some of this discussion focused on the relationship between use and misuse and inherent challenges of differentiating misuse from use, particularly in view of conflicting values and disagreements about means and ends of social programs (Shulha and Cousins, 1997).

Despite changing perspectives on evaluation use, it has maintained a significant presence in the field and is listed first as one of four attributes around which the thirty program evaluation standards (Joint Committee on Standards for Educational Evaluation, 1994) are organized. These standards, currently in their second published edition with ongoing field testing of the third edition, initially emerged as the result of a 1975 pioneer project whose goal was the development of standards to help ensure useful, feasible, ethical, and sound evaluations of educational projects, programs, and materials. The standards were designed to serve as a basis for program evaluation design and implementation in North America; however, they have been translated into Spanish, German, French, and other languages for use around the world. Taken as a set, the program evaluation standards provide a working philosophy for evaluations in fields beyond education and

Table 1 Utility standards of the program evaluation standards

<i>Utility standards</i>	<i>Standard description</i>
U1 Stakeholder identification	Persons involved in or affected by the evaluation should be identified, so that their needs can be addressed
U2 Evaluator credibility	The persons conducting the evaluation should be both trustworthy and competent to perform the evaluation, so that the evaluation findings achieve maximum credibility and acceptance
U3 Information scope and selection	Information collected should be broadly selected to address pertinent questions about the program and be responsive to the needs and interests of clients and other specified stakeholders
U4 Values identification	The perspectives, procedures, and rationale used to interpret the findings should be carefully described, so that the bases for value judgments are clear
U5 Report clarity	Evaluation reports should clearly describe the program being evaluated, including its context, and the purposes, procedures, and findings of the evaluation, so that essential information is provided and easily understood
U6 Report Timeliness and dissemination	Significant interim findings and evaluation reports should be disseminated to intended users, so that they can be used in a timely fashion
U7 Evaluation impact	Evaluations should be planned, conducted, and reported in ways that encourage followthrough by stakeholders, so that the likelihood that the evaluation will be used is increased

From Joint Committee on Standards for Educational Evaluations (1994). *The Program Evaluation Standards*, 2nd edn. Thousand Oaks, CA: Sage.

they identify principles that, when addressed, are expected to result in improved evaluation practice. The seven utility standards, in particular, provide guidance for examining programs, projects, and materials in a manner that ensures that the evaluation serves the information needs of intended users. These standards are summarized in **Table 1**.

In addition to the prominence of utility in the program evaluation standards, it is also one of the key components highlighted in the mission, vision, and values statements of evaluation professional organizations, including those articulated by the American Evaluation Association (AEA), African Evaluation Association (AfrEA), Australasian Evaluation Society (AES), European Evaluation Society (EES), UK Evaluation Society (UKES), and the Canadian Evaluation Society (CES). Some of these organizations have special sections or groups that explicitly address issues related to use. For example, the AEA has a Topical Interest Group (TIG) on Evaluation Use, which is the conceptual strand of the organization focusing specifically on evaluation theorists, researchers, and practitioners interested in the nature, causes, and consequences of evaluation utilization.

In the United States, education and evaluation have long been closely connected as numerous educational interventions were initiated, especially beginning in the 1960s, with the goal of buffering the negative effects of poverty and improving educational outcomes of children from improvised backgrounds. Now into the twenty-first century, increasingly, legislators have been calling for more useful educational evaluations by urging that these studies meet high standards of scientific quality with the US Congress writing these standards into national legislation (Ginsburg and Rhett, 2003). With the push for evidence-based interventions in education, both within

and outside the US, decision makers are seeking to use evaluation results as an accountability tool that impacts the expenditure of funds related to the creation, expansion, and elimination of programs. Two examples of this increasing emphasis on educational accountability include the No Child Left Behind Act of 2001 in the US and the Education and Inspections Act in the UK which, in April 2007, established the Office for Standards in Education, Children's Services and Skills (OFSTED).

The following sections examine evaluation use, considering how it was originally conceptualized to examination of more recent perspectives encompassing a multidimensional, multifaceted view which has arguably led to an expanded understanding of the concept. Two fundamental, yet overlapping, issues that will be considered in greater detail include the centrality of use in defining evaluation success and the appropriateness of evaluation use terminology. Subsequently, a discussion of evaluation use in the field of education is provided. The article concludes with brief attention to particular issues related to evaluation use for improving the educational outcomes of students from diverse and disadvantaged settings.

Understanding Evaluation Use: Past to Present

Over the past four decades, an impressive body of literature has been published on evaluation use. Carol Weiss published the first paper on use of findings and a decade later she (Weiss, 1988) expanded her discussion of use (and sometimes nonuse) focusing on three important questions: (1) What do we mean by use? (2) What is it that is used? and (3) Who are the users? Weiss expressed concerns about underutilization and called for more empirical study of

the topic. Since then, there have been numerous developments in evaluation theory, research, and practice related to use. Notable among these include: (1) reconsideration of the use terminology, (2) expanding its scope to include use that is noninstrumental in nature, (3) recognition of contexts as critical to understanding and explaining use, (4) expansion of conceptions of use from the individual to the organizational level, (5) diversification of the role of the evaluator as facilitator, planner, and educator/trainer, and (6) consideration of the centrality of use in defining evaluation success (Kirkhart, 2000; Henry and Mark, 2003; Patton, 1998; Shulha and Cousins, 1997).

By the 1980s, there existed a coherent body of published literature on evaluation use, including several reviews and syntheses of literature shaping evaluation utilization as a field of inquiry. Studies on evaluation use identified predictors that facilitated use by intended uses. The major predictors identified include: (1) relevance, (2) credibility, (3) user involvement, (4) communication effectiveness, (5) potential for information processing, (6) clients' need for information, (7) anticipated degree of program change, (8) perceived value of evaluation as a management tool, (9) quality of evaluation implementation, and (10) contextual characteristics of the decision or policy setting (Shulha and Cousins, 1997).

Work by Cousins and Leithwood (1986) sought to go beyond simply describing predictors to assessing the relative weight of various factors in their ability to predict evaluation use. Utilizing a meta-analytic approach that considered empirical research conducted over a 15-year period on use of evaluation results, the investigators examined 65 studies in the fields of education, mental health, and social services. Based upon the results of the meta-analysis, Cousins and Leithwood developed a conceptual framework incorporating 12 factors influencing evaluation use. Six of these identified factors were associated with implementation (i.e., variables associated with designing, conducting, and reporting the evaluation) and six factors were related to decision or policy setting (i.e., variables addressing the environment in which the evaluation occurred). The six factors identified as influencing evaluation implementation include: (1) evaluation quality or characteristics of the evaluation process such as methods, rigor, and evaluation model; (2) credibility of the evaluator and process, defined in terms of objectivity and believability; (3) relevance of the evaluation to the information needs of the decision makers and the location of the evaluator; (4) communication quality, including clarity of reporting to evaluation audiences in terms of style, evaluator advocacy, and breadth of dissemination; (5) findings, that is, whether results aligned with evaluation audience expectations and their value to decision making; and (6) timeliness of the dissemination of results to decision makers. The six factors related to the decision or policy setting include: (1) information needs of the

evaluation audience(s), including the number of audiences and the perceived need for evaluation; (2) decision characteristics involving the type of decision to be made and the significance of the decision or evaluation problem; (3) political climate encompassing the political orientation of the evaluation sponsors, power struggles, and fiscal issues; (4) competing information from sources beyond the evaluation; (5) personal characteristics relative to the decision makers' organizational experience and social characteristics; and (6) commitment or receptiveness to evaluation as evidenced by the attitudes of decision makers to evaluation, organizational resistance, and open mindedness. Ranking the importance of the influencing factors on overall use as well as by various types of use, Cousins and Leithwood found that evaluation quality and decision characteristics were the most prevalent factors influencing evaluation use.

While it is beyond the scope of this article to provide a comprehensive discussion of the various issues and debates that emerged from the literature on evaluation use, two areas are examined in more detail in this article: (1) consideration of the centrality of use in judging evaluation success and (2) re-conceptualization of the use terminology.

Centrality of Use in Judging Evaluation Success

Use of results is generally one of the key assumptions underlying the planning, implementation, and dissemination of an evaluation. Traditionally, it has been assumed that a good evaluation will yield information that will be used by decision makers to take some future action. An area of debate in the field, however, relates to the centrality of use in determining the success of an evaluation. One perspective is that use is the criterion by which the success and worth of an evaluation should be defined and evaluation studies are only worthwhile if they are used.

Patton (1988) argues that evaluations should be judged by their utility and actual use. Evaluation use presents, maintains Patton, both a challenge and mandate. The underlying premise of his utilization-focused evaluation approach is that evaluators should facilitate the evaluation process and design the evaluation with careful consideration of how everything that is done, from beginning to end, will affect use. Here, use involves how real people in the real world apply evaluation findings and experience the evaluation process. Utilization-focused evaluations stress the need to move from general and abstract (e.g., from potential audiences and potential uses) to the real and specific (e.g., actual primary intended users and their explicit commitments to concrete, specific uses). Patton's emphasis was on intended use, both instrumental and conceptual, by intended users. Intended use can be classified as either instrumental or conceptual and it covers

three potential uses, including: (1) using evaluations for making overall judgments about the value, merit, and worth of program which often fulfills accountability mandates; (2) using evaluations results for program improvements; and (3) using evaluation to generate knowledge or influence thinking about the issues in a more general way.

While Weiss (1988, 1998), like Patton, acknowledged the importance of evaluation use and the need to increase use by intended users, particularly decision makers, she took a different position arguing that the success of an evaluation or the evaluator need not be tied to direct use. Evaluators, Weiss argues, should not be held accountable for the nonuse of results. She took this position acknowledging that various obstacles within a given context, having nothing to do with the evaluation or evaluator, could prevent use. These obstacles include things such as conflicting beliefs within the program's organization, disagreement over use of resources, rigidity of organizational rules and standard operating procedures, and shifts in external conditions, including budget cuts or changes in the political climate. Intense focus on the use of evaluation findings is not always viewed in a positive manner. In fact, Scriven (1991) points out that overemphasis on use can create a strong conflict for evaluators because it places undue pressure on them to adjust findings to what decision makers are willing to do rather than what they should do based on the evaluation evidence.

Others also question the legitimacy of use as a defining goal of the success of an evaluation. Henry (2000) maintains that the field does not suffer from a lack of relevance, but from heavy focus on emphasizing the short-term use. Social betterment, not use, argues Henry and colleagues (Henry, 2000; Henry and Mark, 2003; Mark and Henry, 2004), is the ultimate goal of an evaluation. Here, useful evaluations are thought to be ones that provide persuasive information that informs policies and programs aimed at alleviating human suffering and improving social conditions. Evaluations contribute to the pursuit of social betterment, according to Henry and Mark, by providing evidence and insights in determining the common good (which may be raising a social problem), selecting a course of action (which may be creating a policy or program), and adapting the course of action (which may be improving a policy, program, or organization).

Moving Beyond Use Terminology

Criticism has been lodged against the use terminology. The concept has been viewed as overgrown in the sense that the multiple forms of use (instrumental, conceptual, symbolic, and process) overlap and, in some instances, use is treated in a descriptive manner (referring to whether some consequence of evaluation did happen) and in other instances use is treated as normative concept use for

guiding the purpose of evaluation (Mark and Henry, 2004). Kirkhart (2000) maintains that the terms use and utilization have a conceptual and linguistic base that is too narrow because they promote an inappropriate imagery of instrumental use that focuses on a unidirectional, episodic application of evaluation findings. As such, she views this terminology an imprecise fit when considering nonresults-based applications and argues that work reflecting this terminology fails to adequately consider unintended results and the gradual incremental impact over time.

It has been recommended that the field abandon the use terminology replacing it with influence as the preferred concept. Influence, described by Kirkhart, is the capacity or power of persons or things to produce effects on others by intangible or indirect means. This is viewed as a broader concept that helps to create a framework for examining evaluation effects that are multidirectional, incremental, unintentional, and noninstrumental, as well as those that are unidirectional, episodic, intended, and instrumental. Taking this position, Kirkhart (2000) conceptualized an integrated theory of influence as a paradigm for rethinking the impact of evaluation by not simply holding results-based influence at the center, but instead, having multiple vantage points (instrumental, symbolic, and conceptual) for examining evaluation's influence. Kirkhart's theory of influence incorporates three overlapping dimensions: (1) the source or the active agent of change or starting point of a generative process of change; (2) the intention or the extent to which there is purposeful direction to exert a particular kind of influence through evaluation process or findings; and (3) the timing of influence, that is, if the influence is immediate, end of cycle, or long term. A theory of influence, argues Kirkhart, is good for the evaluation profession by making various types of influence visible and facilitating greater understanding of long-term evaluation impact which invariably builds credibility for the profession and generates support for evaluation.

There have been other criticisms lodged against the use concept and further expansion of frameworks emphasizing influence as an appropriate starting point of discussion. Henry and Mark (2003) view use as an inadequate motivation for evaluation and they maintain that emphasis on maximizing use is an inappropriate goal. They argue that a focus on use fails to provide a moral compass and it falls short of recognizing and promoting the ultimate purpose of evaluation – social betterment. Drawing concepts from the social science literature, Henry and Mark (2003) and Mark and Henry (2004) developed a theory of change to provide a more detailed and complex framework of influence than the perspective offered by Kirkhart. While Henry and Mark supported many of the arguments put forth by Kirkhart, they noted that her framework and other work in the field ignored the underlying mechanisms through which evaluation may achieve its influence. Attention to underlying

mechanisms, according to Henry and Mark, is an important factor that can guide evaluation practice to better influence individuals' attitudes and actions as well as aid in judging and improving policies and programs. Henry and Mark classified these underlying mechanisms into four types – general influence processes, cognitive and affective (or attitudinal) processes, motivational processes, and behavioral processes – and examined them at three levels of analysis (i.e., individual, interpersonal, and collective). Evaluation influence at the individual level involves changes in thought or actions of one or more individuals. Influence at the interpersonal level includes change arising from interactions between/among individuals. At the collective level, change is the influence of the evaluation on decisions and practices of the organization which may include agenda setting, policy-oriented learning, policy change, or diffusion. It is worth noting that shifting the ultimate purpose of an evaluation from use to social betterment has met with some resistance in the field. In particular, Cousins and Shulha (2006) maintain that viewing social betterment as the ultimate goal for evaluation is problematic because it excludes the many and valued types of evaluations that take place outside of the social policy domain.

Alkin (2003) argues that a push to replace the use concept with influence is an interesting, yet misguided suggestion and that the difference between the two concepts should be preserved. The important distinctions that Alkin poses include the use terminology as a way of capturing the evaluative setting and time frame, as opposed to influence terminology that includes other places and time. The evaluative time frame is seen as commencing when the evaluation is contemplated and concluding well beyond the completion of the report as long as the information is still thought of as stemming from the evaluation. The further removed from place and time of the evaluative encounter, Alkin maintains, the more one may view the evaluative results or processes as knowledge, and the influence might be considered knowledge use (as opposed to evaluation use, *per se*). Subsequently, King (2006) proposed a set of definitions to distinguish between evaluation use and influence. She defined evaluation use as the application of evaluation processes, products, or findings to directly produce an effect. On the other hand, evaluation influence was defined as the capacity of evaluation processes, products, or findings to indirectly produce a change in understanding or knowledge. While increased clarity in definition is certainly useful, it does not resolve the varying viewpoints in theory and research on evaluation use and influence.

Evaluation Use in Education

Programs and policies in the field of education have long been a primary target for evaluations. Evaluation in the

US educational arena can be traced back to the nineteenth century when, in 1897, Joseph Rice conducted a comparative study to evaluate the effects of spelling drills on the performance of 33 000 students. However, modern-day evaluation in education is often associated with the Tyler and Smith (1942) landmark longitudinal evaluation study on the achievement of high school students. The evaluation innovation of Tyler is credited as making the connection between educational outcomes and educators' intentions and with using evaluation as an integral part of the educational process. While educational evaluation shares commonalities with evaluation in other fields, such as criminal justice, public health, and social services, there are some distinguishable differences. Nevo (2006) documented three unique features: (1) the roots of evaluation in education are found in student testing and assessment, which has been conducted in schools around the world for centuries; (2) public involvement in the practice and use of educational evaluation is characteristically strong, since education is understood as a public good relevant to most members of society and far beyond the relevance of social services, health, and criminal justice; and (3) the role of teachers and their experience as evaluators (although mainly evaluators of students) cannot be ignored in designing and implementing educational evaluations that position teachers as evaluators, evaluation objects, and/or evaluation stakeholders.

In the United States, intense interest in utilizing social science research to evaluate educational and other social interventions was directly linked to expansion of government programs in the 1930s (described as the New Deal) and programming initiated by President John F. Kennedy and later expanded under President Lyndon B. Johnson's Great Society legislation during the 1960s. This legislation spurred a large investment of resources in education. Probably, the major stimulus for large-scale educational evaluations arose out of the inclusion of an evaluation clause in the Title I (compensatory education) section of the 1965 Elementary and Secondary Education Act (ESEA) which provided federal grants to local schools, state and regional agencies, and universities. This clause required the local education agency to submit an evaluation plan and the state agency to provide a summary report that described the effectiveness of the program. This legislation paved the way for evaluation requirements becoming an integral part of subsequent federal grants. Hence, educational evaluations expanded beyond assessment and student testing to examination of all aspects of the educational system, including instructional materials, classroom climate, school quality, teacher credentials and competency, and educational programs and activities. The increasing demand for evaluations in the field of education was coupled with discussions about how to improve educational evaluations and how such evaluations were used.

By the end of the 1960s, it was disappointing, yet evident, that evaluations of Great Society programs in education and other fields were largely ignored or politicized. Nonuse or underutilization was identified as one of the foremost problems in evaluation research at that time. Subsequently, in the 1980s and early 1990s, there was a decline in government funding for evaluation amidst a growing perception that evaluation procedures and practices were inadequate, not attuned to the realities of school situations, and generally fail to meet the informational needs of intended users.

More recently, funding for evaluation has increased and evaluation of education programs has emerged as a very deliberate research endeavor which can yield information of use and influence across multiple purposes. Thomas and McKie (2006), like other scholars, delineated major potential uses of educational evaluations, including providing information that could: (1) help shape the design and implementation of new and existing educational programs, (2) improve the management of existing educational programs and strategies, and (3) influence decision making regarding the development of educational policies and practices. The demand for instrumental use of evaluation findings for direct decision making has certainly escalated within the past decade with calls for greater educational accountability and efforts to raise the learning outcomes of all students, but particularly those placed at risk for underachievement and academic failure. More frequently, evaluations are utilized in a less direct, more subtle manner for reducing uncertainty, confirming existing points of view, or aiding in the day-to-day maintenance of a school, a program, or a system (Hofstetter and Alkin, 2003).

Over the past decade, consideration of useful evaluations in the field of education has been discussed within the context of the recent accountability movement. Utilizing a policy perspective, Ginsburg and Rhett (2003) characterized a useful evaluation as one that adds to the body of timely, relevant evidence to increase the likelihood that policy decisions improve program performance. They maintained that the value of any single evaluation is the additional contribution that it makes to the existing body of knowledge in the field. Ginsburg and Rhett noted that educational policymakers and program administrators will use findings from high-quality evaluations which are characterized by use of experimental designs, disaggregated data analyses, and new standards for literature reviews and case studies.

While evaluation scholars generally agree that scientific rigor is critically important, there is disagreement regarding the extent to which experimental designs are essential for an evaluation to be useful. Grob (2003) argues that many less-than-perfect evaluations can, in fact, be useful. He, like many others, contends that experimental designs are not always possible to achieve, can take years to

perform, and consume significant resources. Here, the usefulness of the evaluation is judged in terms of not simply the scientific rigor of the evaluation study, but also the combination of the evaluator's skilled engagement in the policy decision processes and the delivery of a sound, reliable, professional evaluation report which includes sufficient contextual information that allows readers to put things in perspective.

Evaluations in Diverse Education Settings

There is considerable evidence pointing to the failure of public schools in providing equitable and effective educational opportunities for children of color and those from low-income communities. Given increasing student diversity in US schools and the numerous reports of the achievement gap between white, middle-class students and students of color, there has been more pressure for utilizing evaluations to aid in efforts to elevate the achievement of low-performing students of color. Evaluations and evaluation use in diverse communities of color are very much social enterprises that can be best understood by taking into consideration the social, cultural, economic, and political contexts surrounding the program under consideration.

Educational evaluators working with programs serving students of color, in particular, can work in the public interest and on behalf of these communities by engaging their practice in a manner that produces high-quality data that will: (1) generate a more profound understanding of the context of education for marginalized students; (2) help educators and relevant decision makers strengthen marginalized students and the schools that serve them; and (3) enlighten and empower parents and communities from improvised areas to advocate for students. Thomas and McKie (2004) maintain that in order for evaluations to influence programs and policies seeking to enhance the achievement of students of color, evaluators studying interventions with this population must begin with a framework of designing and implementing evaluations to yield data that promote the creation of more equitable and socially just school reform practices. Further, evaluation data obtained from such a framework could provide information that moves beyond blaming the victim and by yield data and insights for improving achievement outcomes for struggling students. Some educational evaluators maintain that evaluations taking place in settings serving large numbers of students of color and other disadvantaged group should be educative inasmuch as they provide thoughtful, data-based insights into salient dimensions of schooling and contribute constructively to improvement and to a stronger and more contextually meaningful educational reform initiative (Greene *et al.*, 2006). A growing literature in the US is emerging on evaluation and evaluation use in educational settings serving students of color and those from disadvantaged backgrounds (e.g., Frierson *et al.*, 2000;

Madison, 1992; Thomas and McKie, 2006; Thomas and Stevens, 2004). Generally, this literature falls within a transformative paradigm (Mertens, 1999) that emphasizes the evaluator's role in facilitating utilization in ways that hold promise for ensuring that the inequities that created achievement gaps between white, middle-class students and students of color will be eliminated.

Conclusions

Evaluation use is a critical issue in the field. This is evident from the extensive literature on the topic ranging from Weiss's work beginning in the late 1960s and early 1970s to more recent publications in two volumes of *New Directions in Evaluation* (McLaughlin, 1988; Caracelli and Preskill, 2000), a special section of the *American Journal of Evaluation* (Sridharan, 2003), and numerous journal articles, book chapters, and conference presentations. Over the past 20 years, the emergence of more comprehensive frameworks on evaluation use has resulted in expanded conceptualization of the multiple domains of use, increased attention to the underlying motivation influencing users of evaluation, identification of specific avenues by which use takes place, and consideration of contextual factors influencing use and potential users. Such discourse has certainly advanced our conceptual, theoretical, and empirical understanding of evaluation use in multiple contexts. Given the purpose of evaluation, a conscious awareness of use-oriented effects, whether intentional (e.g., instrumental support for decision making) or not (e.g., skills development as a consequence of proximity to the evaluation or process use), must remain an important and continuing concern in the field (Alkin and Taut, 2003). Evaluators should engage their practice, from beginning to end, in a manner that promotes use and influence, both unidimensional and multidimensional, short-term and long-term and at multiple levels. Further, evaluators must maintain a delicate balance of paying sufficient attention to use without such overemphasis that it ultimately exerts influence on what findings are disclosed.

Frameworks for promoting evaluation use in the field of education, and other areas, have emerged and factors that increase the likelihood of use have been identified. Despite this reality, some critics maintain that there is still remarkably little empirical study to support many of the claims concerning evaluation use (Ginsburg and Rhett, 2003; Leviton, 2003). Leviton argues that the standard of evidence that many evaluators would not consider applying to the conduct of evaluations too often predominates in the study of evaluation use. While this suggests the need for more rigorous study of evaluation use, there is compelling evidence from case studies and meta-analytic investigations that evaluation use depends upon, among other factors, the quality of the study and evaluator

credibility. However, in large part, use, particularly in the policy arena, depends upon the situation and contextual environment impacting upon the evaluand. The evaluation is only one part of the policymaking process and often not even an important part, especially as political organization, or other changes in the environment may render the evaluation no longer relevant (Grasso, 2003). Therefore, an examination of evaluation use must incorporate a multifaceted perspective in seeking to better understand this concept and its place in evaluation theory and practice.

Moral and Ethical Issues in Evaluation

M Morris, University of New Haven, West Haven, CT, USA

Glossary

Conflict of interest – A situation where an evaluator's personal or financial interests could influence, or be influenced by, the way in which the evaluation is designed, carried out, or reported.

Stakeholder – An individual or group with a vested interest in what is being evaluated.

Virtually all forms of research are subject to moral and ethical hazards, and this is certainly true of program evaluation. Within this context, the terms moral and ethical are essentially synonymous with the latter term being more frequently used in evaluation. An ethical issue is one that deals with what is good and bad and with moral duty and obligation. In other words, it deals with what individuals should or should not do. When evaluators behave ethically, they are conforming to accepted standards for professional conduct. Consistent with prevailing practice, the terms ethics and ethical are used throughout this article.

Most evaluators report that they have encountered ethical challenges in their work. It is likely that many of those who indicate otherwise have, in fact, faced problematic situations that other evaluators would have conceptualized in ethical terms. Individuals vary in the extent to which they view events as having ethical significance, and the existence of explicit professional standards pertaining to ethical issues can be counted on to narrow this variation but not eliminate it. What one evaluator defines as an ethical issue, another might see as a political, philosophical, or methodological one. Consider, for example, the question of how involved key stakeholders should be in various phases of the evaluation. Many evaluators would regard extensive engagement as an ethical imperative. Others might see it as primarily a political matter, in terms of making choices that have implications for managing dynamics of power and influence within the evaluation. For a third subgroup, the issue may be viewed as mainly one of personal preference and values; that is, some evaluators may be ideologically committed to in-depth stakeholder involvement, while others might not be. Finally, the methodological significance of stakeholder involvement might be an evaluator's chief concern. The focus here would be the impact of stakeholder participation on the quality of the evaluation design, the adequacy of data collection and analysis, and other factors affecting

the technical soundness of the evaluation. For example, in what ways could stakeholder involvement enhance, or compromise, the objectivity needed for a credible evaluation? As we can see, answering the question 'What is an ethical issue in evaluation?' is not always as straightforward a process as it might first appear.

Professional Standards and Guidelines

One of the hallmarks of an emerging profession is the development of standards and guidelines to promote ethical practice within the field. Accordingly, the past three decades have witnessed a growing number of efforts, both within and across national boundaries, to establish standards for evaluation. For example, specific sets of standards have been crafted for use in the United States, Canada, Switzerland, Germany, France, the United Kingdom, Eastern Europe, Western Europe, Australasia, and Africa. Two of the most prominent efforts in this regard are the Guiding Principles for Evaluators and the Program Evaluation Standards, both originating in the United States.

Guiding Principles for Evaluators

The Guiding Principles, developed by the American Evaluation Association in 1995 and revised in 2004, offer guidance that is more general than specific, and are intended to be relevant to all types of evaluation. The principles target five domains where evaluators face distinctive ethical obligations:

1. Systematic inquiry – evaluators conduct systematic, data-based inquiries.
2. Competence – evaluators provide competent performance to stakeholders.
3. Integrity/honesty – evaluators display honesty and integrity in their own behavior, and attempt to ensure the honesty and integrity of the entire evaluation process.
4. Respect for people – evaluators respect the security, dignity, and self-worth of respondents, program participants, clients, and other evaluation stakeholders.
5. Responsibilities for general and public welfare – evaluators articulate and take into account the diversity of general and public interests and values that may be related to the evaluation.

Each core statement is accompanied by an elaboration focusing on the meaning and application of the principle.

These elaborations clarify the nature of the evaluator's ethical responsibilities within a given domain. Thus, the Guiding Principles can be seen as providing evaluators with a foundation for building an ethically sound practice. The systematic inquiry principle, for example, requires evaluators to conduct research that is methodologically appropriate to the questions being asked and the setting in which the research is taking place, and to clearly communicate with stakeholders concerning the strengths/limitations of the approach employed.

The competence principle is closely linked to systematic inquiry, in that one's competence is a major determinant of one's ability to carry out a methodologically credible evaluation. Ethical evaluators only take on projects for which they possess the relevant skills, background, and expertise. This is a particularly important issue in evaluation, due to the general absence of regulatory bodies that accredit training programs and license practitioners in the field. When third parties are not available to officially endorse an evaluator's training and competence, stakeholders are in a disadvantaged position with respect to assessing the suitability of an evaluator for a specific project. Thus, evaluators must guard against exploiting this disadvantage to engage in evaluations for which they are not adequately prepared.

The significance of cultural competence is also highlighted by the competence principle. Evaluators increasingly work in settings, and with populations, whose norms, values, and cultures differ from their own. When evaluations are designed and implemented in ways that are sensitive to these differences, their validity and value are enhanced. Evaluators have an ethical responsibility not only to be mindful of their own value-based assumptions, and how these assumptions interact with those of other stakeholders, but also to use this knowledge to design responsive, effective evaluations.

The issue of transparency is at the heart of the integrity/honesty principle. Throughout the evaluation, from the planning phase to the communication and utilization of findings, ethical evaluators are proactive in their efforts to ensure that all aspects of the evaluation are accurately represented to stakeholders and understood by them. Among the myriad issues that can arise here, three of the most important are conflicts of interest, the presentation of findings, and the limitations of the evaluation. Opportunities for conflicts of interest abound in evaluation. For example, an evaluator may have a personal relationship with a key stakeholder in the evaluation, or the evaluator may be asked to help design a program that he or she will also be requested to evaluate. When conflicts of interest occur, it is essential that they are acknowledged and steps taken to address them.

An evaluation is rendered worthless, or worse, when its findings are not honestly communicated. Evaluators are often pressured by stakeholders to engage in misrepresentation

(at least in the opinion of evaluators) and this pressure must be resisted, lest the credibility of the entire endeavor is undermined. Evaluators have an ethical obligation to explore with stakeholders any significant disagreements over the reporting or interpretation of results, but such exploration should never lead to evaluators taking ownership of findings or interpretations that they believe are unjustified by the data.

This issue is closely related to acknowledging an evaluation's limitations. Acting consistently with the integrity/honesty principle means that evaluators are realistic in describing the extent to which a study can answer the questions it addresses. They must not succumb to the temptation to oversell the knowledge and conclusions that an evaluation can produce or has produced, even when stakeholders appear eager to accept such exaggerations.

The fourth principle, respect for people, encompasses the domains traditionally associated with the ethical treatment of human subjects. Thus, evaluators are expected to obtain informed consent, protect the confidentiality (or anonymity) of participants, minimize risks to participants while maximizing benefits, respect participants' dignity, and, in general, strive to do no harm when carrying out the evaluation.

Informed consent is the process by which individuals exercise their right to participate, or not participate, in research after having been provided with information concerning the study, its risks, and its benefits. Indeed, under informed consent, individuals are free to withdraw from a study after they have agreed to participate in it. This provision can pose a particular challenge to evaluators as they attempt to maintain the integrity of research design and data collection strategies throughout an investigation. Circumstances such as these can tempt evaluators to misrepresent a study's risk/benefit ratio when communicating with potential and current participants, a temptation that must be resisted if ethical practice is to be preserved.

Addressing confidentiality and anonymity can also be problematic for evaluators. Confidentiality refers to the protection of an individual's privacy when reporting findings (where the individual's identity is known to the evaluator), while anonymity involves gathering data in a way that ensures individual respondents cannot be linked by the evaluator to the specific information they provide. Both of these protections can be difficult to achieve, often because of the relatively small number of individuals in certain stakeholder groups (e.g., program staff) providing data for the evaluation.

At a more general level, upholding the do-no-harm principle is frequently a complex undertaking in evaluation. Evaluations can contribute to program termination/reduction, the loss of services for clients, and the release of staff from the program and related settings. Although

these actions may, in the long run, increase the availability of resources for more effective interventions, such an outcome is by no means guaranteed, and the short-term damage to the welfare of particular stakeholder groups can be significant. What is clear is that evaluators engage, and collect data from, not just program clients, but program staff, administrators, funders, community-based constituencies, clients' families, and other stakeholders. Safeguarding the rights and responding to the legitimate needs of one group can sometimes conflict with being sensitive to the needs and rights of others, with the potential for conflict growing as the number of relevant stakeholders increases. The generality of the Guiding Principles makes it difficult to resolve these issues by simply referring to the principles themselves. Indeed, as is the case with all ethical challenges, the details of the case at hand must be thoroughly examined before reaching a decision.

Finally, the principle, responsibilities for general and public welfare, is probably the most ambitious of the five Guiding Principles. In taking the position that "evaluators will usually have to go beyond particular stakeholder interests and consider the welfare of society as a whole" when conducting evaluations, this principle assumes that the welfare of society as a whole can in fact be discerned by the evaluator. Concepts such as the public interest, public welfare, and public good are referred to in the responsibilities principle but not specifically defined. Of course, visions of what constitutes the good society can greatly vary among individuals, groups, and cultures. Thus, the responsibilities principle serves as a vehicle for evaluators to explore the relationship of their and other stakeholders' notions of social justice to evaluation practice. Indeed, a number of evaluation approaches have been developed over the years – for example, empowerment evaluation, deliberative democratic evaluation, participatory evaluation, and collaborative evaluation – that appear to be explicitly grounded in such broader visions of the collective good.

The Program Evaluation Standards

The most detailed set of professional guidelines for ensuring the ethical practice of evaluation are the Program Evaluation Standards, developed by the Joint Committee on Standards for Educational Evaluation. The Standards were first published in 1981, followed by a second edition in 1994. The third edition is likely to be officially released in 2010. The second edition consists of 30 standards organized into four groups, with each group representing a key desired characteristic of an evaluation:

1. *Utility*. These standards emphasize the importance of evaluations being responsive to the information needs of intended users. In short, a good evaluation is a useful evaluation.

2. *Feasibility*. The focus of these standards is on ensuring that evaluations are realistic, prudent, diplomatic, and frugal. Evaluations high in feasibility are ones that take into account the practical constraints, political dynamics, and resource limitations operating in the settings in which they are conducted.
3. *Propriety*. These standards examine, in more specific terms, many of the issues addressed by the Guiding Principles of respect for people and integrity/honesty: rights of human subjects, informed consent, confidentiality, conflicts of interest, fair representation of findings, etc. Propriety standards tend to be the ones invoked most frequently in discussions of the ethics of evaluation.
4. *Accuracy*. Like the systematic inquiry principle, these standards stress the importance of the evaluation's methodological soundness. For example, was the program comprehensively examined? Was valid and reliable information competently collected, analyzed, and communicated to stakeholders?

The issues addressed in the second edition of the Standards are likely to receive substantial attention in the third edition as well. The evolution of professional standards is typically characterized by continuity and incremental change rather than dramatic shifts. However, the need for evaluators to be culturally and contextually sensitive will almost certainly be accorded greater prominence in the third edition, a development that reflects, at least in part, the globalization of the evaluation profession and major demographic changes in the United States and elsewhere.

Research on Ethical Challenges

Although anecdotal reports of ethical challenges encountered by evaluators are numerous, systematic studies of the experiences of representative samples of evaluators are rare. Viewed together, these two sources of information produce a relatively coherent picture of the ethical terrain that evaluators negotiate in their work. It is clear that every stage of the evaluation process can pose ethical problems for the evaluator, with some stages appearing to be more ethically hazardous than others. The following sections provide an overview of the ethical conflicts that evaluators claim they face most frequently.

Entry/Contracting Stage

In this phase, the evaluator and key stakeholders discuss the overall focus of the evaluation and the resources needed to conduct it. This is an exploratory stage, where the evaluator is forming judgments about the wisdom of taking on the project. Ethical challenges occurring during this phase include the following:

- the evaluator believes that a core stakeholder has already concluded what the evaluation results should be

or plans to make unethical use of the results (e.g., to punish a staff member);

- a perceived conflict of interest exists (e.g., a future evaluation contract depends on positive findings emerging from the proposed evaluation);
- issues and questions that the evaluator believes should be addressed in the evaluation are deemed off-limits by a stakeholder;
- in the opinion of the evaluator, legitimate stakeholders have been left out of the planning process;
- there is conflict among stakeholders surrounding key features of the proposed evaluation; and
- the evaluator encounters problems in identifying stakeholders.

These challenges, if not successfully addressed, can fatally damage the credibility of the ensuing evaluation. For example, if a stakeholder is seeking an evaluation to support a decision that he or she has already made, the evaluator is likely to be subjected to strong, and inappropriate, pressure from that stakeholder during the communication-of-results phase. Similarly, if serious disagreements among stakeholders emerge during the entry/contracting stage, whose views should be accorded priority by the evaluator if consensus cannot be achieved? The evaluator's client? The most knowledgeable stakeholder? The most powerful stakeholder? Or the most disenfranchised stakeholder? It is here where evaluators' judgments of the nature of the public interest and collective good can play a crucial role.

Designing the Evaluation

Methodological concerns are central to this phase; the major objective is to generate a research strategy that can provide sound answers to the core questions driving the evaluation. From an ethical perspective, the struggle most frequently reported by evaluators during this stage is the failure to achieve acceptance of the overall design by stakeholders. Evaluators can feel pressured to employ a design that they believe is ill-equipped to answer the questions the study is supposed to address. Is it ethically defensible to simply share with stakeholders one's views of the flawed nature of an evaluation design while proceeding to implement it in a particular project due to stakeholder preferences? Here we can see one of the consequences of not effectively engaging stakeholders during the entry/contracting phase.

Data Collection

As one might expect, assurances of confidentiality and anonymity to research participants are often threatened during the data-collection phase, a problem that is likely to increase in frequency and magnitude as the use of large, computerized databases in evaluation grows. Although

evaluators' self-reports do not indicate that violations of informed consent are a common occurrence, observational studies of informed-consent interactions suggest that such violations are probably more frequent than evaluators realize.

It is also the case that during data collection evaluators can become aware of stakeholder behaviors that are unethical, illegal, or dangerous (e.g., misappropriation of funds or sexual harassment). What to do with this knowledge is often a vexing question, especially in view of the fact that evaluators' legal responsibilities in these circumstances are not necessarily clear. Even when they are clear, an evaluator may be strongly committed to an ethical principle (e.g., honoring confidentiality) that conflicts with the relevant legal obligation.

Data Analysis and Interpretation

This stage encompasses the technical procedures evaluators use to process the data quantitatively and qualitatively, as well as the conceptual and value frameworks evaluators employ in reaching conclusions about what the results mean in substantive terms. It is in this latter domain where evaluators report the greatest ethical difficulties. Specifically, they sometimes fear that their interpretations and conclusions may be biased by unacknowledged values and sentiments (e.g., admiration for or hostility toward program staff) that could cause them to view the study's findings, and the programs the findings describe, more positively or harshly than the data warrant. In this fashion, the evaluator's role as an honest broker is seriously compromised.

Communication of Results

Being pressured by a stakeholder to misrepresent a study's findings is, by far, the ethical challenge that evaluators claim they encounter most frequently in this or any other stage of an evaluation. Although the pressure usually focuses on making the program look better than the evaluator believes is justified by the data, occasionally the influence attempt is in a negative direction. Pressure can range from subtle encouragement to soften a finding to forceful declarations that certain results must be deleted from a final report. There can also be instances when the dispute concerns not how positive or negative the findings are, but the issue of what the findings mean substantively. The common denominator of all these episodes is that the evaluator sees the recommended changes as inappropriate, and that agreeing to them would represent a violation of ethical responsibilities involving honesty, integrity, and accuracy. Interestingly, research on the views of other stakeholders (e.g., evaluation funders) suggests that evaluators themselves can provide the impetus for misrepresentation, attempting to do whatever they believe is necessary to please the evaluation client.

Confidentiality issues also arise during the communication-of-results phase. For example, evaluators indicate that stakeholders sometimes pressure them to reveal the identities of individuals who provided particular interview responses. Threats to confidentiality, however, are not always due to stakeholder pressure. In certain instances, evaluators are concerned that the simple act of reporting findings can undermine confidentiality. This is especially likely when sample sizes are small and the breaking down of results according to multiple background characteristics (e.g., gender, race/ethnicity, and age) is being considered. Tables in final reports containing cells with few respondents can reveal more than the evaluator intends about who said what.

Utilization of Findings

In theory, evaluations are undertaken to influence decision making in the short and/or long term. This purpose generates many opportunities for ethical problems, and it is not surprising that evaluators report frequent encounters with a number of them. These include the following:

- a stakeholder suppresses or ignores evaluation findings;
- disagreements take place over who owns the raw data and/or the right to distribute/publish the evaluation's findings;
- a stakeholder uses the findings to punish another stakeholder (e.g., termination of employment) or the evaluator (e.g., harshly and unfairly criticizing the evaluation's quality);
- a stakeholder intentionally modifies the results in a way that misrepresents the substance of what was found;
- a stakeholder, operating in good faith, misinterprets the results; and
- a stakeholder (usually the evaluator's supervisor) engages in plagiarism or misrepresentation of authorship regarding the evaluation.

These utilization challenges vary on at least two dimensions. One is the degree to which the evaluator feels obligated to take action to address the situation. For example, perceptions of deliberate misrepresentation are likely to provoke a stronger response than perceptions of a stakeholder simply not using the evaluation's results. Indeed, some evaluators might view the latter circumstance as one where it is the stakeholder's prerogative to use the results or not. The second dimension involves the feasibility of responding to the situation. Correcting a benign misinterpretation is usually a much less challenging endeavor than intervening in an unjust termination. This issue highlights an important reality: of all the phases in an evaluation, the utilization-of-results stage is the one where the evaluator typically has the least amount of direct control over the course of events, ethical or otherwise.

Preventing and Responding to Ethical Challenges

The most effective strategy for dealing with ethical conflicts is to prevent them from occurring. However, problems can arise in an evaluation that even the most foresighted evaluator could not have anticipated. What follows is an overview of the major steps that evaluators can take to ensure that their practice is ethically grounded.

Actively Manage the Entry/Contracting Stage

This is the phase of the evaluation where preventive efforts are likely to bear the most fruit. Evaluators can do two things during this stage to enhance the ethical quality of the evaluation:

1. Discuss with stakeholders the implications of the professional guidelines most relevant to the proposed evaluation. Specifically, evaluators should attempt to identify potential problem areas involving ethics, and explore with stakeholders the steps that can be taken to address these issues proactively. In this regard, it is important that evaluators clearly communicate the professional standards they must uphold in conducting the evaluation.
2. Encourage stakeholders to share any ethical concerns they have about the upcoming project. Given that stakeholders often lack the experience and knowledge to feel confident in raising such issues, evaluators may need to take the lead in providing examples.

These entry/contracting activities have both content and process objectives. The former is to achieve consensus on how to address specific ethical issues in the evaluation. The latter is to generate a climate where evaluators and stakeholders are willing to bring ethical matters to the table as the evaluation unfolds. Ethical problems left unaddressed are unlikely to resolve themselves.

Apply Relevant Professional Guidelines

When ethical challenges arise, evaluators should consult the professional principles and standards they deem most relevant. For many evaluators in the United States, these will be the Guiding Principles and/or the Program Evaluation Standards. As previously indicated, a number of other countries/regions have developed their own evaluation standards, often based, at least in part, on those used in the United States. As principles and standards are inherently general and abstract, they are constrained in their ability to offer detailed guidance on how to respond in specific circumstances. Rather, their main purpose is to highlight overall imperatives that evaluators should be mindful of as they deal with ethical challenges. Reinforcing this point is

the fact that situations can arise where upholding one principle or standard can compromise the ability to adhere to another principle or standard from the same set of guidelines. Professional guidelines in evaluation typically do not prioritize individual principles or standards, leaving to the evaluator the task of choosing between them when conflicts occur, based on careful consideration of the case at hand. Although these limitations of professional guidelines are significant, they do not erode the more fundamental value that guidelines offer to the practicing evaluator.

Consult with Colleagues

Experienced colleagues in evaluation can be an invaluable resource when grappling with ethical challenges. Most importantly, they can broaden and deepen one's perspective, thereby helping one appreciate aspects of the problem that may have been overlooked. They can also expand the range of options the evaluator considers when deciding how to respond to the conflict. Seeking input from colleagues has become much easier in recent years, as Internet listservs, such as EVALTALK, have grown in the evaluation community.

Appreciate Culture and Context

As previously noted, the settings in which evaluations take place increasingly embody cultures, values, and norms that differ significantly from those represented by the evaluator. These differences can have substantive implications for how ethical issues are conceptualized and addressed (e.g., views of confidentiality and privacy in individualistic vs. collective cultures). Prudent researchers learn as much as possible about these features of the host environment prior to embarking upon an evaluation. Doing so reduces the likelihood that the evaluator will inadvertently violate the ethical sensibilities of key stakeholders, and increases the chances that the professional standards subscribed to by the evaluator can be successfully adapted to the setting.

Examine One's Own Values

Professional standards and principles represent just one of the value frameworks upon which ethical decisions can be based in an evaluation. Evaluators inevitably bring their personal values to their work, and these can play a crucial role in determining how one responds to ethical conflicts, especially when professional guidelines provide unclear or conflicting advice.

With this background in mind, it is essential that evaluators possess a highly articulated set of personal values, and understand how these values interact with professional standards and the settings in which they conduct

their work. These settings may embrace value orientations that are fundamentally at odds with the evaluator's core beliefs concerning social justice and the public interest. In such instances, evaluators must decide whether it is appropriate for them to take on a particular project. This decision can be a particularly wrenching one if the material self-interest of the evaluator will be affected in a major way by the choice that is made.

Underlying this recommendation is an essential truth: ethical issues in evaluation, and the professional standards applied to them, are inextricably linked to more general ethical questions and challenges faced by people in all walks of life. Individuals with a well-grounded sense of who they are in this broader sense are in a much stronger position to address the ethical challenges awaiting them in the field of evaluation.

The Role of Stakeholders in Educational Evaluation

Introduction

In this article, we discuss the way in which stakeholders are defined in the evaluation literature and what is said in evaluation writings about the role of stakeholders in educational program evaluation. We dichotomize stakeholder involvement into two categories that we refer to as deep involvement and broad involvement. Focusing on deep involvement, which is the framework for most of the research literature, we discuss why stakeholder involvement is important and offer a summary of key factors that lead to such involvement.

Who Are Stakeholders?

Stakeholders are all those individuals who have a vested interest in what is being evaluated. This includes evaluation clients and all those who will use the evaluation and its results for various purposes. It also includes those whose work is being studied and who will be affected by the evaluation.

How have Stakeholders Typically been Involved in Evaluations?

The extent to which different stakeholders are engaged in the process of an evaluation depends on various factors not limited to the evaluator's theoretical positioning, funding, and time. Nonetheless, stakeholder involvement can roughly be thought of as being either deep or broad. On the one hand, stakeholders are deeply engaged in an evaluation when they are closely engaged in various evaluative activities. Such activities range from determining the evaluation questions and designing the evaluation to identifying potential data sources and collecting and analyzing data. In some cases, stakeholders may even participate in writing the evaluation report. In addition, when one of the evaluation's goals is to engage stakeholders on a more significant level, the number of stakeholder groups involved is typically limited to individuals who are in positions to make decisions about what is being evaluated. On the other hand, broad involvement entails the involvement of a wide range of stakeholders in a smaller portion of the evaluation process. Unless funds are unlimited, stakeholders tend to play a more limited role. This may be only during the beginning stages of the evaluation by contributing to the development of the program theory.

Stakeholders in Educational Program Evaluation

What Do the Program Evaluation Standards Say About the Role of Stakeholders?

The *Program Evaluation Standards* developed by the Joint Committee on Standards for Educational Evaluation (1994) is a guide for what constitutes high-quality educational program evaluation practice in the United States. The second edition's 30 standards are organized around four attributes of an evaluation – utility (U1–U7), feasibility (F1–F3), propriety (P1–P8), and accuracy (A1–A12) – and have been approved as American National Standards. The *Program Evaluation Standards* reflect what the field of evaluation in this country thinks is responsible conduct and use of evaluation while staying largely independent of the theoretical and methodological preferences of evaluators. Therefore, the *Program Evaluation Standards* is a prominent source for finding out what the field of evaluation as a professional entity thinks should be the role of stakeholders in evaluation.

There are three program evaluation standards in the second edition that directly address the role of stakeholders. These are U1 stakeholder identification, U4 values identification, and F2 political Viability. The first is central to the topic and asserts that “it is crucial to identify potentially important stakeholders and, within resource and time limitations, to involve them in the planning and conducting of the evaluation” (1994: 25). This standard statement even goes one step further when it observes that “in many evaluations, special efforts may be necessary to promote the appropriate inclusion of less powerful groups or individuals as stakeholders, such as racial, cultural or language minority groups” (1994: 25). The standard statement on values identification posits that evaluators, clients, and multiple stakeholders should be involved in determining how values are assigned in the evaluation. Finally, the statement related to political viability warns against possible pressures from stakeholders and asks evaluators to prevent their involvement from biasing the evaluation and its findings.

In summary, the *Program Evaluation Standards* assigns stakeholders an important role in the conduct of an evaluation. It implies that stakeholder involvement helps increase the likelihood that evaluations are used and that evaluation also helps ensure the inclusion of less powerful groups, giving them a voice in evaluation. The *Program*

Evaluation Standards also cautions that evaluators may need to somewhat restrict the number of stakeholders to be included because of the difficulty of dealing with too many conflicting views.

Program Evaluation Theoretical Positions and the Role of Stakeholders

The *Program Evaluation Standards* attempts to represent a range of evaluation theoretical perspectives on a broader level. However, the book is designed as a guide that should be appropriately adapted to individual evaluation contexts. As such, it does not reflect the universe of theoretical positions that is reflected in the evaluation literature. To address this issue, in this section we discuss categories of evaluation theoretical positions and the role that they afford stakeholders more specifically.

The theoretical positions referred to here are use-, values-, and methods-oriented approaches, which represent the three main branches of an evaluation theory tree developed by Marvin Alkin. Use- and values-oriented approaches include those that explicitly address stakeholder involvement as their central tenet. For example, approaches that are mainly concerned with evaluation use include Michael Patton's utilization-focused evaluation and Brad Cousins' participatory evaluation. Approaches that are value laden may stress social justice concerns. Examples of these theoretical positions include deliberative democratic evaluation by Ernest House and Kenneth Howe, and fourth-generation evaluation by Egon Guba and Yvonna Lincoln. As mentioned earlier, each family of approaches involves stakeholders differently. Specifically, those that are mainly use oriented tend to emphasize deep involvement with a limited number of primary users as stakeholders throughout the evaluation process. Theoretical positions that are values oriented, those whose goal is to serve social justice, for instance, tend to involve a wide range of stakeholders on a broad level. Finally, methods-oriented approaches prioritize appropriate methods of inquiry when conducting an evaluation and typically involve a limited number of stakeholders for limited engagement – primarily at the early stages of the evaluation. Thus, they are neither deep nor broad. Huey-Tsyh Chen's theory-driven evaluation is one example of this theoretical position (also see Stewart Donaldson and Carol Weiss for others).

Christina Christie studied the extent to which current evaluation theorists say they involved stakeholders in their evaluations. None of the eight theorists included in the study saw stakeholders as mere audiences. Rather, all found stakeholders to have some kind of role, even if this role was limited to helping define evaluation issues (e.g., Ernest House). Others reported extensive participation of stakeholders in all aspects of the evaluation process (e.g., David Fetterman). It is interesting that Christie, in studying a group of evaluation practitioners, found that

their practice was more diverse in terms of stakeholder involvement, including practitioners who considered stakeholders to have no role in the evaluation except as its audience.

Although the majority of the evaluation field agrees that stakeholders should be involved at least to some degree in an evaluation, a more detailed analysis of the role of stakeholders is warranted. Following Jennifer Greene we summarize the issues to be discussed as follows: (1) How should the evaluator decide which stakeholders to involve, that is, whether to involve a few of them in depth, or a broad range less actively? (2) If the evaluator decides to involve a few stakeholders in depth, how should he or she do so, and what are the effects of such practice? Also (3) if the evaluator decides to involve a broad range of stakeholders, how should he or she do so, and what are the effects? Finally, in turning to empirical research we ask under what conditions positive effects of stakeholder involvement are maximized, and negative effects minimized, irrespective of the theoretical and practical approach implemented. We would like to elaborate on these questions in the following sections.

Deciding which stakeholders to involve and how

Some evaluation scholars have posited that both the election of stakeholders and the prioritizing of breadth or depth in their involvement are decisions the evaluator must make based on the values he or she holds relative to the main purpose or role of evaluation, for example, in furthering social justice versus promoting evaluation use for organizational learning. Two examples illustrate these different values. Ernest House, an advocate of the social justice perspective states, "I worry that the interests, values, and perspectives of the poorest, the weakest, and the less vocal will be excluded from the study [...] I worry that the evaluation study will reinforce the interests of the powerful, even if inadvertently" (House, 2003: 54). In contrast, Brad Cousins and Lorna Earl who are interested in evaluation use for the promotion of organizational learning, "see participatory evaluation as a powerful learning system designed to foster local applied research and thereby enhance social discourse about relevant organizational issues. [For them,] the requirement of direct involvement in the research process [...] will heighten opportunities for staff to discuss process and outcome data, to rethink their conceptions and challenge basic assumptions [...]" (Cousins and Earl, 1992: 401).

In the first case, social justice is clearly the evaluator's main concern, and this implies different rules for the involvement of stakeholder groups than in the second case, which is mainly concerned with the utilization of the evaluation process and results. Melvin Mark and Lance Shotland offer an excellent discussion of the role of values in stakeholder-based evaluation, differentiating two criteria for stakeholder selection: power and legitimacy.

They argue that an evaluator concerned with utilization for decision making would tend to work with high-power stakeholders, while an evaluator with a desire for social justice through evaluation would favor a large group of stakeholders, including low-power stakeholders, thus giving them voice.

Even if an evaluator intended to serve both purposes, few evaluations have the resources necessary to involve the full range of stakeholders in a just and equitable as well as deep and active manner. In other words, feasibility usually demands a trade-off between depth and breadth of stakeholder participation. Although many evaluation scholars see the decision of how to shape this trade-off as value based and therefore quite invariant over time, one could imagine an evaluator deciding situationally which value or purpose to prioritize, based on perceived needs as well as on practical and strategic considerations.

Deep involvement for the purpose of maximizing evaluation use

Participatory, empowerment, and utilization-focused evaluation are some of the approaches most inclined to involve few stakeholders actively in order to maximize positive effects such as empowerment and evaluation utilization. We cannot offer a comprehensive review of this literature here, but will include a short discussion of Michael Patton's utilization-focused evaluation to illustrate the possible actions and rationale of the utilization-focused evaluator for involving primary intended users in the evaluation.

The evaluator identifies primary intended users of the evaluation early, upon being contacted to do the evaluation. Primary intended users are people (specific people by name) who have a vested interest in the evaluation, not only as an activity to fulfill external requirements, but also to take decisions based on what they have learned from the evaluation in terms of the main purposes and uses which the evaluation serves. Importantly, it is the primary intended users' questions that the evaluator sets out to answer in the evaluation. Likewise, the evaluator plans the evaluation, defines its methods, collects and analyzes data, and interprets results in close collaboration with the primary intended users to ensure their ownership of the evaluation and commitment to evaluation use. Ownership and use are more likely to occur if intended users have been actively involved in the evaluation. The extent of involvement is subject to negotiation with primary users and is contingent on the evaluation's purpose and other situational factors, which the evaluator should be aware of and remain sensitive to throughout the evaluation. Patton refers to this cognizance and sensitivity as the "active-reactive-adaptive-interactive" approach: The evaluator's role will depend on the context and purposes of the evaluation as negotiated with primary intended users" (Patton, 2008: 122). Similar to utilization-focused evaluation, practical participatory evaluation is said to be most effective when participation

in the evaluation is limited to primary users or those with a vital interest in the program, and when these primary users exert control over the evaluation process and are actively involved in all its phases.

Broad involvement for the purpose of promoting social justice

Ernest House and Kenneth Howe, in describing their deliberative democratic evaluation approach and its three requirements – inclusion, dialog, and deliberation – acknowledge that "the procedures and techniques for meeting [these] requirements are more raw, untested, and uncertain than the technical data collection and analysis procedures developed over the past many decades. Much work needs to be done [...]" (House and Howe 2000: 11).

Jennifer Greene describes a concrete set of processes and methods to promote stakeholder involvement in a democratic deliberative evaluation. Examples include use of an evaluation committee as a forum for inclusive conversations, public forums planned as open reports on the progress of the evaluation and as open invitations for discussion and dialog, a mix of methods, sampling strategies directed toward diversity, and criteria to judge program quality that are multiplistic and broad. In the case she describes, however, these practices met with little success.

Turning to evaluation textbooks in search of more concrete advice, we find that Jody Fitzpatrick *et al.*, for example, promote the involvement of a broad set of stakeholders in the planning (divergent phase) of the evaluation and, most importantly, in the process of identifying evaluation questions. These authors propose a matrix for ranking the evaluation questions that emerge during this phase to help select those that are of most interest to key audiences, reduce uncertainty the most, and are critical to the study's scope and comprehensiveness, which they call the convergent phase.

Another example of an evaluation approach that calls for broad stakeholder involvement is stakeholder-based evaluation, as developed by the National Institute of Education (NIE). The intention of the NIE was to encourage broad involvement of stakeholders, at least in the planning phase of the evaluation. Empirical evidence regarding this approach can be found in the next section.

Empirical Research on the Effects of Stakeholder Involvement in Program Evaluation

The benefits of the participatory and utilization-focused approaches have been studied in some detail, so we limit our discussion to a few seminal studies. For example, Jennifer Greene published a set of articles on her work about stakeholder participation and evaluation utilization (Greene, 1987, 1988). She discusses three factors necessary to successfully link stakeholder participation and increased utilization. First, the evaluator should involve

appropriate stakeholders, that is, people who are legitimate program stakeholders possessing enough program knowledge (but not necessarily evaluation knowledge); who have a high, self-defined stake in the program; and who come from “organizations that are receptive to evaluation and perhaps that are democratic, decentralized, collegial, and participatory themselves” (Greene, 1987: 390). Second, the evaluator needs to use an appropriate process for involvement, that is, one characterized by frequent group discussions providing multiple, cumulative opportunities for participation and including tangible evidence that the participants contributed to evaluation-related decisions. Third, Greene (1988) highlights evaluator skills such as responsiveness, listening skills, acceptance of diverse stakeholder views, ability to invoke trust and rapport, as well as technical skills and status as an impartial, credible outsider. Greene’s research showed that stakeholders benefited in two ways from their participation. First, they learned more about their work, the program, and the organization. Second, they learned more about evaluation and developed more favorable attitudes toward evaluation. Greene links these conceptual (process) uses of evaluation to the cognitive, and, to a lesser degree, the affective dimensions of the participatory process.

Another case study discussing the positive outcomes of evaluations that deeply involve a small group of stakeholders comes from Torres *et al.* (2000). These authors summarize the benefits of their collaborative evaluation as “time for reflection, learning on numerous levels, efficiencies in data collection and program planning, deepened professional and personal relationships, and the conviction to take action” (p. 35). The authors go on to discuss the conditions necessary for these positive outcomes to become possible: “arguably the single most important requisite for collaborative, participatory evaluation was present from the outset: administrative and leadership commitment to evaluation for the purposes of learning and improvement.” In their case, this meant providing the motivation and resources, specifically time scheduled to engage in fruitful dialogs and beneficial reflections. Other studies have also provided evidence that active stakeholder participation increases evaluation use (e.g., O’Sullivan and D’Agostino, 2002; Turnbull, 1999), and more specifically, process use (e.g., Forss *et al.*, 2002; Preskill *et al.*, 2003; Taut, 2007). In addition, there is some indication that the validity of evaluation conclusions can be improved when the evaluator successfully collaborates with those stakeholders who are knowledgeable about the evaluated program; taps into their program expertise by applying appropriate methods for stakeholder participation; and ensures that no group’s expertise is ignored (Brandon, 1998).

Cousins and Earl (1992) offer a summary of a number of organizational and evaluator characteristics that provide positive conditions for participatory evaluation.

According to their review of the literature, evaluator characteristics include motivation to work directly with participants, readiness to take on the role of a teacher of evaluation, and tolerance toward problems and imperfections. Organizational requirements include an evaluation culture, time, and resources to undertake the participatory evaluation activities, and participants motivated to get involved in the evaluation. Greene summarized her experiences regarding the influence of the evaluation and program context on successful implementation of participatory evaluation as follows: “Participatory evaluation is readily accepted in contexts that share its value commitments [...]. Finding acceptance and understanding of participatory evaluation is much more difficult in contexts where (1) traditional evaluation is known and familiar and other approaches to evaluation are unknown and thereby suspect, (2) value commitments are not consonant, (3) the values of participatory evaluation are actually threatening to some stakeholders, usually those with extant decision making authority and power, and (4) there is considerable stakeholder disengagement and apathy” (see Ryan *et al.*, 1998: 106).

Despite the positive outcomes associated with the approaches described, the literature also discusses their limitations. Cousins (2003) points to the key challenges of participatory evaluation: the need for technical sophistication and external credibility of the evaluation on the one hand, and the responsiveness and extent of participation of stakeholders on the other. Regarding the issue of credibility, another challenge of active stakeholder participation is to ensure that the evaluation does not get biased by giving the advantage of direct and active involvement only to a small (and thereby privileged) group, or because the evaluator is perceived to lose independence by giving up control of the process and closely collaborating with program staff.

As for evaluations involving a broad range of stakeholders, but less actively, early evidence on the effects of the stakeholder-based evaluation approach comes from Bryk (1983). Bryk’s volume presented two case studies meant to test stakeholder-based evaluation as it had been developed by the NIE. However, the evidence shows that the two case studies did not fully implement the approach as it had been intended. Stake (1983) describes one of the evaluations, of the Cities-in-Schools program, and gives the idea that few stakeholders were actually involved (mainly program staff), and that their participation in terms of actual influence on the evaluation process was rather limited. According to Stake, “nothing was noted to suggest that use of the stakeholder approach made the evaluation study more fair, more accurate, or more efficient. [...] In summary, the evaluation team did not take full advantage of the stakeholder concept, limiting its use to information enhancement” (p. 29).

Likewise, Farrar and House’s (1983) discussion of the evaluation concerning the Push/Excel program revealed

that, “all in all, the stakeholders contributed little to the evaluation design or to the plan for disseminating findings” (p. 45). Gold (1983), on the other hand, who represented the NIE, concluded that stakeholder involvement was active (although with only marginal impact on the evaluation design itself), that the evaluation was in fact used for formative purposes, and that the approach assured access and cooperation for the evaluation. Similarly, the principal evaluator of the two programs, Charles Murray, came to the conclusion that, on the positive side, “the stakeholder approach is a useful device for getting the leading players to cooperate, for understanding a program intimately, for attracting attention to interim evaluation findings, and perhaps even for getting decision makers to take evaluation findings into account [...]” (Gold, 1983: 59).

Mercier (1997) offers a description of a stakeholder-based evaluation that neither increased the fairness of the evaluation’s conduct, nor enhanced the use of its findings by the represented individuals and agencies. The author points to a number of factors responsible for this failure. These include distrust regarding the evaluation by some groups, inequalities among the groups regarding organizational culture, status, and what was at stake for them in the evaluation, and a restrictive time frame of the evaluation. The stakeholder groups used the evaluation competitively to defend political and financial interests, and the strategy of appointing a steering committee did not help resolve these issues. This could have also been due to a lack of evaluator skills, particularly regarding group facilitation and conflict resolution. Other authors have also supported the latter point by noting that the more heterogeneous the stakeholder group, the greater were the facilitation skills required by the evaluator (Torres *et al.*, 2000; Torres and Preskill, 1999).

The literature describes other potential limitations or difficulties in the context of applying the stakeholder-based evaluation approach. For example, stakeholders would not be able to specify their information needs clearly because they lacked knowledge about what evaluation can offer; the multiple information demands of various stakeholder groups exceeded the research capacities of an evaluation; technical compromises diminished the quality of the evaluation; contamination of the evaluator’s judgments occurred; and conflicts between evaluation purposes and the interests of certain stakeholder groups could bias the evaluation (Mark and Shotland, 1985; Murray, 1983; Gold, 1983). Similarly, O’Brecht (1992) examined the use of evaluation steering committees in a government agency and concluded that broad stakeholder involvement increased evaluation costs and duration, reduced flexibility in evaluation planning, and could diffuse responsibilities and dilute commitment to the evaluation. Limitations are also due to a lack of effective evaluator strategies for involving a broad range of divergent stakeholder groups in an evaluation

(Gold, 1983). An indirect result of this observation is House’s (2003) call upon the profession to “develop methods for controlling [...] stakeholder biases, just as we have methods for controlling other biases” (p. 54).

In summary, the empirical evidence is based primarily on case studies conducted in the context of participatory evaluation (deep involvement) and stakeholder-based evaluation (broad involvement). The studies we have presented use systematic data collection in order to derive credible conclusions related to the evaluation process and evaluator and contextual characteristics that enable or hinder desired evaluation outcomes for stakeholders. The studies we reviewed show that, first of all, the implementation of evaluations prioritizing deep over broad involvement seems less prone to failure. Furthermore, actively involving stakeholders to attain evaluation use seems to have been better documented in the literature. However, approaches that tend to cursorily engage stakeholders to obtain desired outcomes, such as giving all stakeholder groups a voice, appear less so. Therefore, in the section titled ‘Synthesis and conclusions’, we focus on deep involvement approaches and summarize the factors that link deep involvement to increased evaluation use.

Synthesis and Conclusions

Conclusions on the Importance of Stakeholder Involvement

There are some who diminish the importance of stakeholder involvement. Their argument centers on concern about the introduction of political interests and competing points of view into the process, potentially compromising the evaluation’s credibility. Indeed, we would maintain that political interests and conflicting points of view are ever present in any evaluation and that the involvement of stakeholders makes explicit what would otherwise be implicit. A similar argument and rebuttal can be made with respect to the introduction of potential stakeholder bias. These arguments are also reflected in the *Program Evaluation Standards* that relate to the stakeholder topic. Further, we acknowledge the skills that are necessary to work successfully with stakeholders and recognize that the act of engaging stakeholders in the evaluation process could increase the costs of conducting the evaluation.

However, we believe that the importance of stakeholder involvement far exceeds any potential detriments. Much depends upon the extent to which stakeholder participation is fully and appropriately implemented, which in turn depends on evaluator and stakeholder characteristics and contextual prerequisites.

There are multiple ways in which stakeholder involvement is important. The first of these is that it provides stakeholder participants an opportunity to learn more about their work, about their program, about their organization and about evaluation. Second, when stakeholder

participation is real and means some degree of control over the evaluation by way of evaluation-related decision making, this results in a sense of ownership of the evaluation. Moreover, a positive evaluation experience generally leads to a more favorable attitude toward evaluation.

We maintain, further, that stakeholder involvement leads to improved validity of the evaluation conclusions. By tapping into stakeholder program knowledge and expertise the evaluator, provides a more relevant and appropriate evaluation.

Finally, increased understanding about the program, ownership of the evaluation, more favorable attitudes toward evaluation, and more relevant and valid evaluative conclusions increase the conviction to take action. Action may be on the part of stakeholders themselves or it may involve their role in getting decision makers to pay heed to evaluation findings.

Summary of Factors Linking Deep Stakeholder Involvement to Increased Evaluation Use

Some of the factors that can impact evaluation use are as follows:

1. *Whom to involve.* Not only evaluation theoretical writings, but also much of the empirical evidence presented above call for the involvement of fewer stakeholders, particularly if the intended focus of the evaluation is to foster evaluation use. When a small group of key intended users is involved, dangers such as lack of commitment, political abuse, and inflexible evaluation planning are less likely to occur. This does not negate obtaining limited input from a wide group of stakeholders prior to the active engagement phase.
2. *Participatory evaluation process characteristics.* The reviewed studies show that successful evaluation involving stakeholders must be characterized by multiple, cumulative opportunities for participation, enabling participants to effectively contribute to evaluation-related decisions. Evaluators should strive to make evaluation more efficient and effective by weaving evaluation activities into ongoing work routines.
3. *Evaluator skills for promoting effective participation.* Many authors highlight the importance of an evaluator's group facilitation and conflict-resolution skills. Jennifer Greene specifically calls for evaluators to invoke trust, show listening skills, responsiveness, and acceptance of diverse stakeholder views. Along these lines, Michael Patton promotes an active–adaptive–reactive–interactive evaluator role and stresses the importance of an evaluator's interpersonal skills.
4. *Adequate resources for participatory processes.* This is a key factor in facilitating the successful involvement of stakeholders. Evaluators often struggle with resource constraints in the sense that stakeholder suggestions for

evaluation cannot be implemented, thus giving them the feeling that they have no control over the process despite the fact that the evaluation is formally labeled participatory.

5. *Leadership support for involving stakeholders in evaluation.* Some studies mention leadership support as a major enabling factor in their work.
6. *Stakeholder knowledge about evaluation.* Brad Cousins describes quality concerns regarding stakeholder contributions to evaluation as one difficulty in conducting participatory evaluation. However, other authors do not share these concerns based on their experiences.
7. *Trust in participatory evaluation.* Some authors highlight the topic of trust between stakeholders and evaluator as a main factor for successful implementation of their participatory evaluation; others mention it as a major factor in evaluations failing to produce the desired effects. Diverse stakeholder values, especially those diverging from a participatory philosophy, are closely connected to issues of trust.

In summary, the key factors we have highlighted above have to do with evaluation process characteristics (who gets involved and how), evaluator skills, stakeholder predispositions, and contextual prerequisites. We hope to have given an overview of those factors that, according to the literature, seem crucial when trying to involve stakeholders in order to increase evaluation utilization.

Glossary

Adaptive and situated evaluation – An evaluation orientation which conceives curriculum evaluation as an adaptive, productive knowledge construction process driven by in-school, situated, specific considerations and needs but directed and conditioned by mandated and prescribed evaluation policy.

Emergent and emancipatory evaluation – An evaluation orientation aiming to influence and understand the curriculum evolution process and conceives curriculum evaluation as a continuous knowledge co-construction process in individual contexts and through social collaboration, dialogical-negotiation, and authentic experiences regarding curriculum meanings, actions, and values.

Instrumental evaluation – An evaluation orientation which conceives curriculum evaluation as a technical-rational productive and dissemination process, with an instrumental rationale, aiming and valuing control, order, and standardization.

Although linked to the general field of educational evaluation, nowadays curriculum evaluation is considered an area within curriculum development and innovation. It is consequently conceived as an intervention that can affect what is taught and learned, and which aims to describe, judge, qualify, understand, and/or enhance new knowledge concerning school curricula. The processes and outcomes of curriculum evaluation are based on the ontological, epistemological, and methodological assumptions that are reflected in the types of evaluation questions asked, and on the evaluation goals expected to be realized. They are also based on the evidence used, the type of interpretations considered valid or useful; the value system chosen and meaning ascribed to quality; the curricular context of the evaluation process and the evaluator identity and roles.

Curriculum Evaluation in Transition

Curriculum evaluation draws on two distinct and complex fields – curriculum and evaluation – both of which encompass dozens of different definitions, approaches, and methods. Thus, curriculum evaluation can neither be simple nor standardized. There are 30 different evaluation

approaches listed in the literature, each of which has a different meaning, a different form, and different factors affecting it (Patton, 1986). This shows that there is no ideal, all-purpose approach to evaluation suitable for every occasion. The multiplicity of evaluation typologies, models, concepts, and methodologies suggest a development from a monolithic conceptualization to a pluralist one containing multiple methods, measures, criteria, perspectives, audiences, and even interests. Evaluation has lost its exclusive reliance on technical and analytical procedures favoring negotiation instead. In methodological terms, this has marked a shift away from the early quantitative emphasis toward an emphasis that is less rigid and finds a variety of qualitative research methods and measures and mixed methodologies acceptable (Guba and Lincoln, 1989; House, 1993; Stake, 1995). These changes essentially reflect a departure from the traditional logical positivistic approach of evaluation as the work of a lone individual, to a constructively orientated, collaborative inquiry approach, and interpretivist philosophy in which the entire community participates to construct new knowledge.

Likewise, we are still very far from consensus on the questions of defining what the curriculum is, what it should be, how to plan and implement it, and who should make curricular decisions. Views of the meaning of the curriculum range from the narrower view, which sees the curriculum as a given set of knowledge, skills, and activities to be delivered to students, to an expanded view which takes full account of the cultures, languages, and lived and emergent experiences of the teachers and students. Curricular approaches also differ in their assumptions, values, in the epistemological, pedagogical, and organizational perspectives inherent in curriculum development decisions and practices, and in the scope of curriculum development technique (Schubert, 1996). These changes reflect a development away from an approach that is mechanistic, linear, authoritative, controlled, pre-planned and rooted in the positivist orientation, and toward a nonlinear, system-oriented, flexible, tentative, and emergent approach marked by open-ended planning and freedom to accept the challenges of spontaneity and situativity, which is grounded in constructivist and complexity theories.

However, despite the conceptual changes in both the curriculum and evaluation fields, a review of the relevant literature shows that neither curriculum evaluation practices nor curriculum evaluation methodology have changed much over the last 20 years and that curriculum evaluation still uses obsolete models and methods (Jasparro, 1998). According to Patton (1998), evaluators unconsciously tend to fall back on old familiar patterns even when facing new situations. There is thus a gap separating curriculum evaluation theory and practice. This is particularly true for federally funded and prescribed curricular programs.

Paradigmatic Orientations to Curriculum Evaluation

Based on these paradigmatic changes and generalizing from the multitude models of evaluation and the diverse meanings of curriculum, different models of curriculum evaluation have been defined. These reflect the conceptualizations of curriculum evaluators regarding the meanings, functions, methodologies, values, and uses of curriculum evaluation (Aoki, 1978; Lather, 1991; Leathwood and Phillips, 2000; Levin, 2002; MacDonald, 1974; Melrose, 1998; Norris, 1998). Each researcher reflects his/her own body of knowledge and professional experience, defining specific schemes, and using his/her own unique language to describe developments in the twin fields of evaluation and curriculum. Each differentiates between various approaches, assuming them legitimate and effective under different curricular circumstances or given different ideological assumptions.

The various approaches to curriculum evaluation can be grouped into three different orientations based on the epistemological views, educational and methodological beliefs, and axiological perspectives that they espouse. Each orientation imputes different meaning to the evaluation process, reflecting the various mindsets regarding the meaning of evaluation, evaluation goals, functions, and design structure, evaluators' identities and roles, the value system involved and the evaluation's uses. The following three orientations are characterized as follows: (1) instrumental evaluation; (2) adaptive and situated evaluation; and (3) emergent and emancipatory evaluation.

Instrumental Evaluation

The first approach to curriculum evaluation, conceived as a technical-rational, productive, and dissemination process, has an instrumental rationale. Its goal is largely one of control. Its main purpose is to provide information for instrumental reasons, dictated by an authority. This approach to curriculum evaluation is considered technical since it regards curricular decisions or actions as standardized, systematic, and objectively reached mainly by evaluation experts, based on a means-ends rationale. It is productive in that it conceives curriculum evaluation as a process whose main purpose is rendering unequivocal judgment or an absolute curricular decision. It is disseminative in that it regards evaluation as a top-down model of search for a proven model of a quality curriculum to be generalized and assimilated everywhere. Its key value is that of order and congruence, and evaluators working within this orientation often evaluate alone as an external expert or unbiased outsider. In this top-down approach, curriculum evaluation is an instrument for improving and encouraging commitment to the curriculum. It reflects an audit mentality and compliance monitoring, and as such,

its discourse contains concepts like expectations, discrepancies, fidelity, congruence, precision, satisfaction, feedback and correction, clients, and products.

This curriculum evaluation orientation assumes there is a concrete truth to be discovered regarding the worth of the curriculum and that evaluation can provide either a correct answer to a curriculum problem or show whether a curriculum should maintain its present form (Melrose, 1998). It presumes that scenarios can be predicted and contrived and that order, stability, content, and meaning are imposed on the curriculum. This orientation represents a culture that puts a predefined ideology of a centralized authoritative figure into practice and reflects a belief in power and control, the universality and stability of knowledge, and the existence of well-defined and authoritative sources of knowledge. This orientation has three main characteristics: (1) the evaluators' input is limited to technical decision making; (2) the impact on the curriculum is limited leading to little or no understanding of the specific circumstances of the evaluation; and (3) there is a monologic relationship between curriculum developers, users, and evaluators, where the set of evaluation standards authoritatively dictates expectations of a quality curriculum. In sum, this orientation applies the one-size-fits-all approach to curriculum evaluation, ignoring its danger of overlooking the specific needs of local communities and subgroups.

The basic rules guiding this orientation are standards and the search for the best practices. It employs predefined, externally mandated standards, and standardization practices. Curriculum quality is thus determined through judgment and is mainly interested in discrepancies between the planned and the achieved curriculum; whether a curriculum succeeds in producing student knowledge or skills as expected, and whether it is more efficient than a different competitive curriculum. The most important and most desired quality measures are of the curriculum's effectiveness and efficiency relative to the mandated standards. In other words, instrumental evaluation assesses the merit of a curriculum in terms of the number and quality of its outputs and the efficiency obtained in transforming inputs into outputs. Instrumental evaluation studies are therefore analytical and comparative and reflect the ideology of customer accountability.

This approach seems best suited to curricula that are defined as a program of planned activities or intended learning outcomes, or as cultural reproductions. Influenced by the behavioral objectives or goal-attainment models of Tyler (1949) and Popham (1988), this orientation corresponds with Aoki's (1978) ends-means orientation; MacDonald's bureaucratic evaluation (MacDonald, 1974); Melrose's (1998) functional evaluation paradigm; with what Lather (1991) refers to as the realist tale, and with Leathword and Phillips' (2000) quality assurance orientation.

Situated and Adaptive Evaluation

The second evaluation orientation conceives curriculum evaluation as an adaptive, productive knowledge construction process driven by in-school, situated, specific considerations and needs but directed and conditioned by mandated and prescribed evaluation policy. It thus conceives curriculum evaluation as occurring within the unique context of a school with its teachers, and students while considering their individual and curricular needs, and expectations, beliefs, capabilities, and actions, though still framed and controlled by a central authority. It combines top-down and bottom-up evaluation processes. This means that by limiting hierarchical structure and control, curriculum evaluation shares both power and control between local and centralized agents. Whereas the instrumental evaluation orientation focuses on prediction, alignment, accuracy, and control, the situated and adaptive evaluation orientation stresses understanding and seeks to improve a practice by applying situated-local wisdom. It is a flexible process whose discourse employs such concepts as circumstances, uniqueness, local needs, situatedness, responsiveness, deliberation, stakeholders, consensus, dialogue, conditionality-autonomy, and products.

This orientation mainly exists in educational contexts that conceive schools as social organisms, which struggle to adapt to curricular demands both from within and beyond their boundaries. In this sense, while broad goals and curriculum evaluation frameworks may be – and usually are – nationally or state determined, the evaluation process has the defined responsibility of transforming and/or adapting these generalities to form a specific, local-situated evaluation. Thus, the considerations driving the curriculum evaluation processes and responsibilities of this orientation cannot be determined either by relating to the individual school or with reference simply to the centralized authority's decisions regarding what schools generally are required to do. Rather a sophisticated blend of the two is needed in which schools and teachers have a wide and complex set of curriculum evaluation roles to perform. This orientation has three characteristics: (1) the evaluation experience involves questioning curricular goals and processes with a view to improving the curriculum, its relevancy, and its accomplishments for specific circumstances; (2) the evaluation process is deliberative and aims to achieve knowledge growth by responding to local perspectives and needs, theoretical considerations, and mandated guidelines; and (3) the relationship is dialogic: evaluators, authority representatives, and local stakeholders, mainly teachers, enter into dialogue aimed at understanding and influencing the evaluation processes, and arriving to a consensus concerning dimensions of curriculum quality.

Through its sensitivity to both the general and locally situated environment, this orientation conceives reality as

multiple, divergent, and interrelated rather than as the singular, convergent, and fragmented reality conceptualized by the instrumental orientation to evaluation. It conceives knowledge as an end product, but nevertheless reflects a belief that all knowledge is socially, culturally, and geographically situated. It also sees practical knowledge as constructed during a process of negotiation and recognizes a consensus among the stakeholders regarding the justification of the knowledge. In particular, it calls for consensual decision making among stakeholders based on criteria relating to contents, processes, and outcomes, and a quest for situated and adjusted evaluation criteria concerning what and how curricular components function in a given school context. Standards-setting processes are often considered participatory, with input sought from teachers and lower-level school/local administrators. Yet, this is still a top-down approach, since standards are first set at the national or state level after which they trickle down to districts and schools, which are compelled, often through incentives such as standardized testing, to adopt the official dominant standards.

Adaptive and situated evaluation seeks optimum practices which are aligned to the circumstances in which the curriculum is implemented or examined, and assumes interdependence between circumstances, goals, processes, and outcomes. It also seeks a more general knowledge that pinpoints differences and similarities between situations, aiming to contribute to a better understanding of a specific curriculum or curricular policy. Therefore, differences between required curricular goals, processes, or products and implemented and achieved ones are examined in order to understand and learn from the discrepancies rather than seeing the discrepancies as problems to be solved. In this way, curriculum quality is defined by how far the goals and expectations accepted by all stakeholders are fulfilled, taking into account the characteristics of the specific situation relative to the more general mandatory circumstances. Here, curriculum quality is based on curriculum description and curricular judgments, which are both conceived as products of equal significance with its own unique role (Stake, 1975). Typically, the main evaluative focus of this orientation is whether a curriculum succeeds in producing students' knowledge or skills as expected and whether it plans and uses locally meaningful curriculum structure and processes. It also focuses on describing and understanding how, and regarding which dimensions, the curriculum differs from, or alternatively complies with, the more general quality characteristics of the national curriculum.

Thus, for example, curriculum evaluation can engage both teachers and school-based curricular experts, who, along with an external evaluator or external evaluation team share responsibility for the evaluation. Besides the standardized evaluation goals, tools, methodology, and evaluation standards, the dialogue between the external

and internal evaluation agents should consider the specific and situated (local) evaluation processes including locally set curricular goals, curriculum sequence or structure, evaluation methodology and curriculum tools, timing, and criteria. Examining situated evaluation data in conjunction with standardized nationally determined data allows authentic and conditional curriculum evaluation knowledge to emerge. The shared evaluation wisdom orchestrated by the evaluation team (external and internal combined) reaches toward consensual evaluation decisions and is expected to provide evaluation insights that explain the value of the situated curriculum versus the normative curriculum and its appropriateness to a given classroom, school, or district. This process can enhance our understanding of the curriculum's value and flexibility and its potential for adapting different curriculum dimensions (goals, structure, instructional strategies, assessment procedures, etc.) to different situations. It can also, for example, incorporate other curriculum goals besides those implemented on a nationwide or statewide scale.

Such evaluation which integrates top-down with bottom-up guidelines is able to generate knowledge for practice, in other words guidelines for sharing, transforming, and constructing knowledge of a general curricular value that can also be of value in a variety of different situations. Naturally, though, this sort of evaluation process is not at all simple due both to its dependence on consensual decision making involving diverse stakeholders, internal and external, and its reliance on multiple evaluation modes, some of which may also conflict with the process's philosophical and practical principles.

Influenced by Stake's (1975) responsive evaluation model, Eisner's (1998) connoisseurship model, and Parlett and Hamilton's (1972) illuminative model, this orientation corresponds, though not identically, with Aoki's situational evaluation orientation; MacDonald (1974) autocratic approach; Melrose's (1998) transactional paradigm of evaluation, and with what Lather (1991) refers to as the critical tale. These models are all based on conceptions involving liberal humanism, subjectivist ethics, and communal activities: the use of mutual negotiation, communication, and partnership, aimed at and achieving consensual interpretation.

Emergent and Emancipatory Evaluation

The third orientation to curriculum evaluation entails a continuous knowledge co-construction process in individual contexts and through social collaboration, dialogical-negotiated, and authentic experience regarding meanings, actions, and values. It is also a reflective meaning-making process that is situated, systemic, and interwoven with curriculum evolution and contributes to ongoing learning and change. The approach is considered emergent in that it is not pre-planned but evolves together with curriculum

evolution through dialogue, collaboration, and praxis. It therefore represents a culture, which turns practice into ideology and knowledge, while emphasizing authenticity and emergentism. It is considered emancipatory in its combination of inquiry and action with critical insight into the social construction of human society. It expresses a concern for the moral and ethical dimensions underlying human action by asking what sorts of experiences can help lead the people involved toward a life influenced by equity, caring, and compassion. It therefore also demonstrates sensitivity to factors such as gender, culture, ability, and sociogeographic context. It identifies and exposes that which is oppressive and authoritarian by sensitively eliminating false consciousness and unjust values. It accomplishes this by considering historical, political, and social dimensions and factors relating to goals, contents, and classroom processes in an effort to change the curricular context, and by monitoring the results of the attempted changes.

Based on the social and radical constructivist and participatory paradigms, and grounded in the epistemological belief that all knowledge is socially, culturally, and geographically situated, and that truth and knowledge are created (Schwandt, 1997), this orientation holds that in order to understand the world, human beings use socially constructed dialectic strategies, which are shared through systems of language and symbols and adapted to meet the needs and intents of human activity. This orientation also believes that a system can only be understood when viewed within its wider contexts and that because each curriculum is unique due to the context of its use, it is important to know and evaluate the specific and individual biography of each curriculum. This assumption reflects Stenhouse's (1975) conditionality criteria, which emphasizes the influence of the context on the curriculum. This orientation also holds that there is plenty of room for every stakeholder: students, teachers, parents, superintendents, evaluators, and others, and therefore appreciates every voice. It expresses openness to learning at any time and from any source, and appreciates the naturalness of chaos, implying that everything is relative and therefore not always expected.

This mindset conceives curriculum evaluation as a dynamic progression that stimulates action and evolves over a long period hand-in-hand with evolutionary curriculum planning, based on the negotiated needs, goals, beliefs, and knowledge of all those involved. It proceeds through mindful and sensitive negotiation between stakeholders. In theory, the process can continue indefinitely, uniting external and internal, individual and social, process and product, not as separate entities, but as elements of mutually constituted social-educational-cultural and virtuous activities. Thus, emergent and emancipatory curriculum evaluation focuses on the whole process and the whole persons involved, students and teachers alike.

It is therefore complex, dynamic, and holistic, as well as open, flexible, context-contingent, time-dependent, and reality-based.

Emergent and emancipatory curriculum evaluation is a highly participatory mode of continuous inquiry that not only fosters a dynamic mode of curriculum planning, but also helps those more directly involved in planning the curriculum, for example, teachers and students, to achieve their individual and common goals. So, evaluators are part of a design team, functioning as an action research or learning group and helping to monitor classroom practices and outcomes, all within an evolving and rapidly changing environment of constant feedback, reflection, and change. The evaluator functions as guide, monitor, facilitator, and a critical learner. Teachers, students, and stakeholders play key roles in implementing and regulating the process (learning and evaluation). All are both subjects of evaluation and evaluators. The cardinal concepts of this evaluation approach are therefore: collaboration, inter-subjectivity, context-specificity, diversity, meaning, construction, reciprocity, pluralism, unpredictability, and participants/stakeholders. This contrasts markedly with the nature of the discourse surrounding the orientations above, which reflect modern values like absolutism, stability, objectivity, certainty, prediction, and authoritative or consensual decision making.

This orientation in curriculum evaluation does not value the traditional mores of excellence such as input standardization, consistency of intervention or implementation processes, outcome uniformity, and clarity or linearity of causal linkages. Instead it assumes a world of situated and multiple needs and causes, diversity of outcomes, inconsistency of interventions, and interactive effects at every level. It examines the individual student, teacher, classroom, school, district, and nation, and is therefore the goal of a pluralistic society. This orientation therefore offers a diversified conception of quality in which participants suggest the evaluation standards and criteria depending on the educational contexts, settings, views, and needs of their environment. Through dialogue among diverse stakeholders curriculum quality is defined as the extent to which the goals of all stakeholders are fulfilled or will be fulfilled in future, taking into account that not all goals can be simultaneously fulfilled or agreed upon. Setting evaluation standards and criteria is therefore a bottom-up adaptive process that considers not only past and present contextual factors, but also future needs and consequences. Unlike the adaptive and situated evaluation orientation, no stakeholders' consensus is required and divergent voices are appreciated. There is enough space for every voice, openness to learning at any time and from any source, and an appreciation for the naturalness of chaos. Everything is relative and therefore not always predictable, making this type of evaluation not easy to implement and often complicated to interpret.

This is due to the lack of absolute or contextual standards, to the fact that different stakeholders' views must be considered simultaneously, and to the demand for sensitivity to multiple factors such as gender, culture, ability, and sociogeographic context, which must be considered all together without the availability of compatible implementation processes.

The evaluation process is actually an internal, context-dependent, development and evaluation process. Thus, for example, curriculum evaluation might engage teachers, students, school-based curricular experts, parents, and any relevant stakeholder that the team co-opts. It progresses hand-in-hand with curriculum planning and provides a means of acquiring evaluation knowledge-in-action, of transforming or taking responsibility for this knowledge, and of producing and reproducing the curriculum. In one context students or teachers may decide on a particular curriculum path, discussing it with and convincing meaningful others who might be simply the students' teacher or teachers' colleagues that this is a worthwhile route to take. As the evaluation process unfurls additional stakeholders may follow up the development and learning process and engage in short- as well as long-term reflections on the process, its learning development, and outcomes. Each representative of the stakeholders considers the evaluation process from his/her own unique perspective. It is a process, which describes what can be done in the learning situation, what is chosen to be done, and what conditions enable it to be done. Finally, the process is likely to produce insights into the specific value of the chosen curricular path within the larger context of the evolving curriculum. The evaluation ideas, issues, and suggestions offered by the stakeholders at different points in time are thus subject to constant reconsideration and reexamination in a dialogic process embracing all relevant parties, viewpoints, and interests. In this scenario, the professional evaluator functions as a guide, monitor, facilitator, and learner, and not as a powerful decision maker. His or her standpoint carries no more weight than any of the other stakeholders.

This evaluation orientation is probably best suited to a curriculum which is considered an agenda for social reconstruction or an emergent curriculum. In terms of curriculum evaluation, the emergent and emancipatory orientation corresponds to Aoki's situational, interpretive, and critical approach; Melrose's (1998) critical paradigm of evaluation; with what Lather (1991) refers to as the deconstructionist tale, with MacDonald's (1974) democratic evaluation and with Kemmis and Hughes' (1979) conception of evaluation as self-reflection in a critical community. Thus, emergent and emancipatory curriculum evaluation is a communicative, dynamic, and holistic paradigm, and its vision is one of evaluation as both a guiding and learning process.

In sum, these evaluation orientations apply to curriculum in all subjects, as well as to interdisciplinary and multidisciplinary curricula, computer-based curricula, and to all grade levels. While the three evaluation mindsets are not entirely mutually exclusive, since some characteristics of each paradigm are present at least partially in one of the other two, they do differ in their primary purposes and uses, methodologies, and in what each considers an evaluation priority.

Purposes and Uses of Curriculum Evaluation

There are three different purposes or uses of curriculum evaluation: (1) curriculum improvement, commonly linked to formative evaluation; (2) judgment purposes, which is commonly associated with summative evaluations; and (3) knowledge generation, which involves curriculum-oriented knowledge building (Patton, 1998), commonly related to developmental evaluation, and sometimes referred to as conceptual use (Shadish *et al.*, 1991). Each has its own focus: formative evaluation emphasizes on discovering how to improve the curriculum, whereas summative evaluation focuses on appraising outcomes and deciding whether to continue or discontinue a curriculum. Developmental evaluation, on the other hand, seeks to influence thinking, deepen understanding, and generates learning by increasing knowledge of what constitutes a meaningful curriculum, based on evaluation wisdom. Thus, while formative evaluation carries a bias about making the curriculum better rather than just making it different, developmental evaluation conceives of changes in the curriculum not necessarily as an indication of progress or improvement but rather as an adaptation.

These three uses of curriculum evaluation have different meanings in the context of the different evaluation orientations. For example, the differentiation between formative and summative evaluation that holds true in the instrumental orientation does not apply in the emergent and emancipatory orientation. In the former, formative evaluation is a phase in the evaluation process, which is carried out during the early stages of curriculum development seeking to invite improvement (Lewy, 1990). Summative evaluation, for its part, focuses on determining whether a curriculum is efficient and answers identified needs. However, in the context of emerging and emancipatory evaluation this distinction between formative and summative is no longer relevant since the curriculum evaluation constantly evolves synergistically with the curriculum planning process (Levin, 2002) and therefore the more appropriate evaluation use is that of developmental evaluation, a process in which the evaluator becomes part of the development team helping to monitor

what is happening, both processes and outcomes, in an evolving, rapidly changing environment of constant feedback and change (Patton, 1994).

Multiple Objects and Multiple Representations in Curriculum Evaluation

Any discussion of curriculum evaluation must specify the objects of evaluation and the evaluative information needed. Due to the systemic nature of a curriculum, we expect curriculum evaluation to address both the trees and the forest: namely, its components, their interrelationships, and the holistic structure. In the past, mostly under the influence of Scriven's (1994) belief that in order to establish the merit of all or part of a curriculum there is no need to know how it works or why it fails to work, curriculum evaluation mainly focused on results and outcomes. Later, influenced by other evaluation models, it was argued that curriculum evaluation should reflect the fullness, complexity, and importance of a curriculum (Stake, 1980, 2004; Alkin, 1994; Stufflebeam, 1983). That is, curriculum evaluation should focus on antecedent conditions and contextual factors relevant to the curriculum act, including curricular policy and goals; classroom transactions; goals (intended and unintended), and outcomes, planned or not. It is also accepted that the objects of evaluation would include the processes that lead to the decisions taken by the participants. Furthermore, the more we see the curriculum as a complex system, rather than a linear and well-defined sequence of tasks, the more we need not only to evaluate the different evaluation objects but also to explore their interrelationships. Although this is true for all three orientations, the evaluation orientation will determine the boundaries and specifications of the evaluation components, and the depth and breadth of the evaluative process.

When we evaluate, what curriculum are we evaluating? Is it the intended curriculum, the planned curriculum, the acted curriculum, or the achieved curriculum (Goodlad *et al.*, 1979). Every layer of the curriculum has its own evaluative value for describing, judging, understanding, and explaining a curriculum's evolution, practices, and outcomes. In particular, the relationships between the various curricular representations are worthwhile exploring. For example, the relationships between the acted and achieved curriculum can offer some explanations of the results achieved, in both cases, whether the results are satisfactory or not. The relationships between the planned and acted curriculum can also provide insights into the potential possibilities for implementing a particular curriculum. However, the meaning attached to these relationships depends on the evaluation orientation. For example, evaluators employing the instrumental orientation seek

alignment and regard discrepancies between the intended and the acted curriculum as a failure in interpretation or implementation. In contrast, one expects in situated and adaptive evaluation to reveal discrepancies between the different representations and be beneficial for enhancing understanding of a situated curriculum and its alignment with a set of specific curricular needs.

Influential Levels and Methods of Curriculum Evaluation

Curriculum evaluation is influential on four different levels: societal or macro (system, nation, or state), institutional or meso (school), instructional (classroom) or micro (classroom), and individual or nano. In each case, the evaluation questions differ, as do the purposes and methodologies used. Typically, on the macro and meso levels, evaluation questions are oriented toward curricular policy, accountability and judgmental issues, aiming to construct general knowledge in the form of best practices and prescriptive models. On the micro and nano levels in contrast, curriculum evaluation often concentrates mainly on the unique characteristics of the curriculum in specific contexts, and relates to curricular needs, processes, and outcomes, as well as the webs of its contextual relationships in order to generate contextual knowledge in the form of lessons learned and principles.

Methodologically, when embedded in a positivist worldview, mostly within the instrumental orientation, curriculum evaluation applies methods and techniques to obtain objective and generalizable facts. Mandating a rigorous separation of facts and values and aiming to generalize and predict, the inquiry process adopts a clinical distance, which we usually find in the more traditional research approaches, often applying the same methods as in controlled life science experiments. The main procedures are asking questions, developing a study design, defining variables, developing instruments, collecting data as objectively as possible, analyzing data, and arriving at conclusions or recommendations through a process of synthesis. In these processes, there is substantial emphasis on achieving precision, reliability, and validity. The typical inquiry methods focus mainly on quantifiable indicators of success and failure. Within the adaptive situated orientation, some methods also incorporate qualitative measures, particularly in the descriptive part of the evaluation, and case analysis is also likely to be performed (Stake, 1995).

In terms of the emerging and emancipatory orientation, however, since the evaluation process is designed to learn from events as they occur and to help promote and accelerate change, the methodological mindset accepts the fact that prior to an investigation one cannot know all it will entail or uncover. The methods therefore

become part of a continuous interplay with new emerging data as the data collection and analysis progresses. The key processes of the evaluative inquiry in this context are: asking questions; identifying and challenging values, assumptions, and beliefs; reflection; dialogue; collecting, analyzing, and interpreting data; action planning and implementation (Preskill and Preskill, 1997). Qualitative and quantitative measurement can both be applied depending on the specific issues investigated (Stake, 2004). The data is not objective but understood in terms that invoke the interpreters' values. Informal logic thus guides the evaluation methodology within the emerging and emancipatory culture, countering formal logic within the inductive–deductive framework of the instrumental orientation to curriculum evaluation (Scriven, 1994).

Summary

As previously held beliefs and certainties blur into post-modern complexities, many of the tried and tested assumptions regarding curriculum evaluation seem unsatisfactory. Modern conceptions of curriculum evaluation encourage us to value stability, regularity, certainty, and universality. They prompt us to apply guidelines and standards and to assume that curriculum practices are predictable and carefully delineated. Nowadays, influenced by constructivist and complexity theories, and challenged by the globalization demands of new capabilities and proficiencies in cultures marked by uncertainty and pluralism, curriculum evaluation is viewed as a perpetual, dynamic, context-specific, collaborative, meaning-making developmental process. It is flexible, yet methodical, open, yet directive, sensitive to ethical dimensions underlying human action, and respectful of the diverse, complex curricular visions, needs, and constraints encountered in society, schools, and classrooms. It embodies new categories of relationships between people/stakeholders all grounded in an on-going dialogue that is open to changing events. It also establishes different meanings of quality and accountability and shifts the emphasis away from an external value system of fitting to standards, to refocus it on respecting the idea that a curriculum's intrinsic value is its meaning, and that accountability should relate to values and commitments rather than to external authoritative control. Thus, curriculum evaluation takes on different forms and different trajectories of meaning in different contexts and situations. There is no evaluation model to follow or implement, no standardized procedures or explicit guidelines. Instead, we find ideas and principles that provoke and challenge our thinking, beliefs, and routines in the dual fields – curriculum and evaluation.

Evaluating Education in Three Policy Eras

M A Peters and R Britez, University of Illinois at Urbana-Champaign, Champaign, IL, USA

Introduction: Education Policy and Policy Evaluation

In this article, we demonstrate that the question of how to analyze the relationship between educational policy and policy evaluation leads directly into the heart of theoretical positions in policy science and into historical reconstructions of knowledge and rationalities underlying educational policy and evaluation. We show that evaluation is not a neutral knowledge, just a methodological and technical knowledge for betterment in general, “designed and conducted to assist some audience to judge and improve the worth of some educational object” (Stufflebeam and Webster, 1980: 6). The word value directly raises the question of whose value? and immediately steps into the political dimension. Carol Weiss (1988a, 1988b) an early voice in the field of evaluation argued for critical perspectives, taking the context conditions and the political dimension into account.

Over the past 50 years, criteria and the question of interests, multiperspectivity, and the political dimension has increasingly come in our view (House, 1990: 24). This article shows that according to different rationalities of governing the state and the present, the knowledge base, methodology, conceptualizations and use of evaluation differ. We demonstrate this, analyzing three relationship patterns between concepts of governing the state and evaluation knowledge. Three political eras are differentiated: the welfare-state model, which is oriented toward equality and security of its citizens; the neoliberalism model of the state, where the notion of freedom implies a loss of state-based securing systems and rising levels of individual risks; and knowledge capitalism, where new mixes and practices of knowledge are to be identified. Seen from a Foucauldian perspective (Foucault, 1992, 2004), evaluation has to be analyzed as power knowledge (Bröckling, 2004; Höhne, 2006), creating specific knowledge orders, knowledge architectures, and structures of attention. In a governmentality perspective (Peters *et al.*, 2009), knowledge is analyzed as discursive, social, and political practice – taking the activity of the state and the rationality of steering and governing into account. Following this perspective, we analyze evaluation as power/knowledge within three specific policy eras of the welfare state, neoliberalism, and knowledge capitalism. It becomes clear that within three political eras, different relationships to truth, to power, to practice, and

to experience are observed in the way in which evaluation is being seen and used (see **Table 1** for summary).

The first pattern shows the relationship between education policy and policy evaluation as spheres of autonomy. Evaluation is, mostly, regarded as neutral scientific knowledge, supplying needed information and findings to society in general. In a delivery relationship, policy is donor to evaluation and customer of findings. In this relationship pattern, evaluation transfers scientific expert knowledge to society, supplying policy with relevant information. The concept of neutral science supplying society with relevant data for means of legitimation is inherent in the guiding image of the welfare state.

In a second pattern of relationship between educational policy and policy evaluation, conditions and interdependence become crucial: In this perspective, policy is to be seen as a condition and framework for evaluation activities. The function of evaluation activity changes into an active measurement function. The relationship between evaluation and policy analysis becomes closer and more intense; evaluation knowledge shifts from legitimation to control and measurement. Relevant information and findings are not primarily oriented toward the past (legitimation), but directed toward a steering function.

The third relationship pattern between educational policy and policy evaluation is to be drawn as overlapping rationality: policy rationalities shape the modeling of evaluation approaches and empirical research and in a reflexive view become visible as an epistemological relationship of power/knowledge. Evaluation is becoming a mix of visibility and learning, of quantitative ranking, and of creative and future-oriented knowledge creation.

Table 1 indicates the rationality shifts of the three eras in which evaluation practices are not necessarily empirically replacing each other totally, but overlap and coexist, and change their position, importance, and acceptance within predominant patterns of evaluation regimes.

Era of Keynesian Welfare State

The beginning of the political era of the welfare state differs according to the specific historical national backgrounds, but in a very broad perspective can be dated to the end of the nineteenth and the beginning

Table 1 The evaluation of education in three policy eras

	<i>Welfare-state era of policy evaluation</i>	<i>Neoliberal era of policy evaluation</i>	<i>Knowledge-economy era of policy evaluation</i>
Main levels of action of evaluation programs	Local National	National International	Local National Regional Global
Predominant epistemology of evaluation programs	Objectivist technocratic reproduction theory	Objectivist marginalized social-constructivist approach	Social-constructivist approach
Predominant methodology of evaluation programs	Description and measurement of input and effects	Accountability and large-scale assessment	Hermeneutic inquiry and collective truth production by inquiry and negotiation of truth and results
Predominant orientation of evaluators	Research/knowledge production	Performance measurement	Learning/collaborative knowledge production
Main objectives of policy evaluation	Legitimation Research	Legitimation Control Allocation of resources	Legitimation Policy learning Policy change

and throughout the twentieth century. The political model of the welfare state is oriented toward prevention or solution of poverty, social security, and aims at diminishing social inequalities by money transfers as well as social services, health services, labor politics, legal regulations, and restrictions. This approach goes along with the concept of a state-steered economy, developed by John Maynard Keynes. Esping-Anderson (1990) differentiates three types or regimes of welfare states: liberal regimes (USA, Canada, Switzerland, and Japan), conservative regimes (France, Italy, Germany, and Austria), and social democrat regimes (Sweden, Denmark, Norway, and Finland). In this classical categorization, the relationships between state and market differ with regard to the transfers of social services, the mode and quality of services, and the effects of social policy on social stratification and power in society. The welfare state in its ideal type should offer social security to every citizen. Welfare states are securing societies establishing complex strategies to care for their citizens, formal education of citizens being part of those strategies.

In a Foucauldian notion we can see that the steering rationality of the welfare state has been based on hegemonial disciplinary knowledge (Peters *et al.*, 2009), like, for example, psychological knowledge of testing and measurement. This disciplinary knowledge produces specific relationships of the subject of the diagnosis and diagnostics. Survey rationality became the prominent movement of the 1920s and 1930s. It grew along with the rise of psychology as a discipline and it was based within a specific concept of science as natural science, where experimental and causal logic rationality is promoted. Linear thinking, test theoretical approaches, and the notion of measurement were institutionalized in education – for example, in the Cincinnati public schools as early

as 1929 (Felix, 1979). Evaluation as measurement was proposed by Tyler (1950), viewing educational objectives as changes in behavior and following the concepts of behaviorism.

The rise of the welfare state grew along with the rationality of planning and measurement, and in the discourse of human capital, education was regarded as a matter of investment and predictable prosperity. Education was seen as both a capital and a consumer good (Kogan, 1979: 20), as functional investment for social equality and economic growth. In this phase of optimism and rationalism, educational policymaking followed an expansionist idea (Kogan, 1975). For example, US investment in education grew around 20 times and investment in social politics like housing in 1980 was 129 times higher than in 1950, while the United States population increased only by half. Given the extraordinary input in the phase of 1950–1980, Murray (1994: 14) calls it a generous revolution. This phase of massive welfare states' financial investment was true for other Organization for economic Cooperation and Development (OECD) areas as well. OECD, World Bank, and the United Nations Educational, Scientific and Cultural Organization (UNESCO) supported the world expansion of education. In OECD reviews, remarkable parallelisms of national development are observed, although countries had adopted various policy/planning approaches and operational strategies (Kogan, 1979:16).

In general, policy at that time was driven by a state approach, where political strategies were defined and driven by the state. Political strategies were input- and top-down oriented. At that point in time, strategies were not developed with the participation of citizens in a bottom-up mode. Peoples' acceptance of top-down strategies and their lack of participation in education were not

questioned. In this political climate of steering optimism, science and scientific methods for program planning and evaluation arose. Within the so-called war on poverty, large state programs were set up. In order to bring about large-scale effects, social action programs in social security, health and education (Rogers-Dillon, 2004: 8) like Elementary Secondary Education Act (ESEA), Headstart, or Follow Through were established. At that point in time, few OECD background reports linked their statements of goals to an evaluation of how they were implemented (Kogan, 1979: 27). At the national level in the US, legitimation for welfare and education programs was a need. Political strategies therefore needed evaluation. Following the rationalist model of planning, predominant evaluation concepts directly referred to the – already established – scientific-measurement movement with its attendant objectivity and reliability (Jemelka and Borich, 1979: 264). Assuming measurability of learning and change, until the 1970s, evaluation rationality followed a mechanist and objectivist input-output model.

Under the shock of economic recession, the political and economical climate shifted into uncertainty, pessimism (Kogan, 1979: 19), and into a second generation of evaluation (Ravitch, 1983), and bottom-up multiperspectivity and qualitative approaches became more acceptable. Legitimation-oriented evaluation ceased to be seen as producing the information required to alter either program or policy. As Ginsburg *et al.* (1992: 24) show, criticisms of large program evaluation are related to four points:

1. Evaluations showed a preoccupation with measuring overall program impacts, particularly test score changes.
2. Evaluations focused almost entirely on federally funded services and failed to recognize that federal programs are part of a larger service-delivery system.
3. Evaluation studies were frequently funded as single large-scale studies. Study findings were not well integrated into decision making. A common complaint from congressional staff was that studies were completed out of phase with the legislative cycle.
4. Evaluations were criticized as designed and operated without any involvement from staff in the program office. Therefore, in the 1970s, programs were asked to open up more to multiperspectivity. Comprehensive change started to be regarded as necessary (Ravitch, 1983: 258).

Disciplinary dominance of psychology and professional dominance of academia's program evaluators (Concliff-Lagemann, 1997) began to be increasingly questioned. Scientists lost their status of being assumed as value-neutral experts. Between quantitative and qualitative advocates, battles were hard fought (Boruch and Riecken, 1975). In the expanding and professionalizing field

of evaluation, a discipline and profession of evaluation emerged. Although the evaluation market was still retained by powerful stakeholders, evaluation became publicly politicized, and the voice of qualitative approaches became louder, criticizing the troubles of this troubled crusade (Ravitch, 1983). Major differences in the field of evaluation were seen between qualitative versus quantitative methodology, accountability versus policy orientation, and client participation versus nonparticipation (House, 1990: 26). Even when representing stakeholders' views in evaluation became more common, the critical political question still remained – whose interests did the evaluation serve (Guba and Lincoln, 1982)? The political question of evaluation policy now became a topic to address (Braybrooke and Lindblom, 1970).

Due to the cuts in the social programs, 1980s was a quiet decade. Neutrality and objectivity became political priorities again. The formulated purpose of centralized accountability was renewed by hiring international evaluation staff and establishing standardized achievement testing. Evaluation knowledge shifted from legitimation of the past to controlling of the present. Testing and measurement once more showed to be instruments of discipline than of diagnosis (House, 1990: 24). International comparison studies like the Program for International Student Assessment (PISA) and the Trends in International Mathematics and Science Study (TIMSS) contributed to establish a European space of modularized knowledge. Within the political climate of the activating state, transnationalization in educational policy accelerated. Within a transnational framework, pre-given political parameters and standards applied pressure on national states. The OECD and the World Bank emphasized the policy of neoliberal modernization from above and evaluation became an effect of globalization. Following House (House 1990: 25), "what had begun as an era of social consensus dissolved into an age of conflict and diversity." It was seen that policy no longer orientated toward inclusion of marginalized groups. The function of evaluation changed toward a medium of exclusion and selection (Höhne, 2006).

Neoliberal Paradigm

As we have mentioned in the introduction, we explore the three eras of policy evaluation welfare, neoliberal, and knowledge economy. In this article, we follow Pollit's example of not ascribing hard edges to any of those broad periodizations. We can see that the origins of policy evaluation as a systematic and formalized practice of government activity can be traced to the early 1960s. Fischer (1995) indicates that the development of policy evaluation today is associated with the expansion of many of the governmental programs of this period. During this time,

the evaluation of policies became a formalized practice of public agencies, as policy-analysis studies increasingly influenced and informed the decision of policymakers and public-policy debates. The relevance that social research and policy analysis studies acquire in the public debate about education can be observed in the publication of the 1966 report *Equality of educational opportunity*, also known as the Coleman report (see Coleman *et al.*, 1966). In the United States, Lyndon Johnson's Great Society and War-on-Poverty programs, as well as the expansion of other government bureaucracies, were driven by the common belief of policymakers that the "decision-making process could be effectively rationalized," through rigorous analysis enabling access to information capable of improving the decisions of public organizations (Fischer, 1995: 4).

The history of policy evaluation as a formalized government practice, informed by different philosophies of governance, has followed different trajectories across countries and agencies in different periods. However, the rationale for the implementation of public-policy-evaluation practices follows the common assumption that rigorous rational-policy analysis could improve the effectiveness of public organizations. In those terms, policy analysts then followed a technocratic approach to evaluation.

The advantages of the development and use of policy-analysis capabilities soon became clear, and policy evaluation rapidly became a common mandate for public agencies. For instance, in the 1970s, the US Congress legislated legally mandate program evaluations (Fischer, 1995: 5) for public agencies. It is during this period of expansion that we observe the transition toward the neoliberal era in policy evaluation.

The economic crisis of the 1970s not only signaled a profound crisis in the model of the welfare state and the ascension of its critics, but also triggered a criticism of the rationale of types of policy analysis associated with the implementation of welfare-state programs. Associated with this critique was a desire by opponents of the welfare-state model to create alternative uses for the tools of policy analysis. In the United States and United Kingdom, critics of the welfare-state government programs such as the Great Society began to develop and fund policy research and institutes suited to their own political needs (Fischer, 1995: 5) (e.g., in the US, the Heritage Foundation, American Enterprise Institute (Fischer, 1995) and in the UK, the Centre for Policy Studies and Adam Smith Foundation (Pollitt, 1993)). In short, the same policy-analysis tools used for implementing and coordinating the 1960s' government programs were used for eliminating them in the 1980s.

The victories of Margaret Thatcher in 1979 and a year later the ascension of Ronald Reagan to the US presidency signaled 1980s as the opening of the neoliberal era of

policy evaluation. This was an era of evaluation dominated by the following philosophy of governance:

Government had taken on more than it could handle . . . decentralized decisions of the market-place should whenever possible replace the inevitably inadequate plans of central or local government (Pollitt, 1993: 12).

Following this philosophy, policy evaluation was to be concerned with measuring the effectiveness, in economic terms, of policy programs. In other words, the interest of the preceding era to identify effectiveness and impact was replaced with a focus on evaluating the efficiency and economy (Pollitt, 1993: 13) of policies. We would like to mention three main features of this evaluation era:

- First, there was a new concern with the management of the allocation of public resources, which in the case of education, serves to justify cuts in the direct financing of public programs, as well as to link educational outcomes to the requirements of the economy. Furthermore, this concern for the control of the allocation of resources affects not only the methods but also the purposes of evaluation. Evaluators increasingly became auditors rather than analysts, with a methodological emphasis on the measurement of the economic performance of the policies evaluated.
- Second, the new public management (NPM) school emerged as one of the most relevant evaluation approaches. Neoliberal government reforms looked for the emulation of business ideas and purposes in public sectors that required the modes of evaluation supported by NPM. In other words, the goal of the government reform was "transplanting business management ideas and practices in the public sector" (Saint-Martin, 1998: 324), thus allowing for the subsequent rationalization and privatization of state efforts. In that sense, it is not surprising that governments looked for the kind of skills and expertise that professionals educated in the NPM provided. It was an expertise that mirrored the expertise of managers, professionals who in the past were employed by private business consulting firms.
- Finally, the rapid globalization of this perspective on evaluation and governance in education can be associated with the increasing influence on international organizations (IOs) and the drive to implement international comparative studies. For instance, Kellaghan and Greaney (2001) describe the globalization of assessments of performance results across national educational systems in the last decades. Such assessments have become frequently associated with the provision of baseline data for educational reforms (p. 90), and their implementation has been actively supported by intergovernmental organizations (IGOs) such as the World Bank, UNESCO, and the OECD.

Those IOs were among the first institutions to shift toward neoliberal positions. For instance, Klaus Armingeon points out that the OECD "...from the mid-1970s until the end of the 1990s, ... exerted a unidirectional effect on national welfare states, supporting the idea of welfare-state retrenchment and an increased bonus on individuals and families to shoulder greater personal responsibilities for their security in times of need" (Armingeon, 2004: 227).

At the same time, in educational policy, the information supplied by IOs influenced national policymakers in specific directions. The common denominator was a shared instrumental view of education as serving the national economic development of countries, while linked to individual success in the global economy. Comparative assessment provided comparative quantitative indicators of the knowledge skills deemed economically competitive. An example of this type of assessment is the PISA.

The neoliberal era of policy evaluation is preeminently positivistic and economic, supporting what Fischer (1995) calls a technocratic world view that claims the value neutrality of the evaluation and the authority of the manager as policy expert. As an instrument of analysis, the objectives of the evaluations were limited to those outcomes considered of interest to the neoliberal paradigm – a paradigm that states that education is a private economic good. It was only in the mid-1990s that one started to observe a process of transition toward what appeared to be a new era in policy evaluation.

Era of Knowledge Economy

The focus of the OECD's (1996) influential view based on the early work of Machlup (1962), Porat (1977), and new growth theory (Romer, 1994) emphasized the importance of question of knowledge codification (know what, know why, know how, and know who), the dimension of tacit knowledge, the need for continuous learning, and the importance of knowledge networks with strong policy implications for employment policy. As the OECD report suggests: the economy becomes a hierarchy of networks, driven by the acceleration in the rate of change and the rate of learning. Accordingly, government policy and its evaluation should aim at (1) enhancing knowledge diffusion, (2) upgrading human capital, and, (3) promoting organizational change to increase flexibility, particularly relating to work arrangements, networking, multiskilling of the labor force, and decentralization. In this context, evaluation policies have focused on performance management and related research-performance-monitoring of staff in higher education together with increased global benchmarking and active management of knowledge-assets management including the careful audit of intellectual property. Much of the human-capital thrust has led to

the design of competency criteria both for teachers, teacher education, and for students. Student assessment increasingly emphasizes what is called competence-based assessment, focusing on the assessment of the competences to learn and to create new knowledge in the learning community, such as the ability to apply and create knowledge to solve problems, the ability to communicate domain knowledge to various audiences, and the ability to work with others of diverse backgrounds.

The OECD report is divided into three sections, focusing on trends and implications of the knowledge-based economy, the role of the science system in the knowledge-based economy, and indicators, essentially a section dealing with the question of measurement. In the summary, the OECD report discusses knowledge distribution (as well as knowledge investments) through formal and informal networks as being essential to economic performance, and hypothesizes the increasing codification of knowledge in the emerging information society. In the knowledge-based economy, innovation is driven by the interaction of producers and users in the exchange of both codified and tacit knowledge. The report points to an interactive model of innovation (replacing the old linear model) which consists of knowledge flows and relationships among industry, government, and academia in the development of science and technology. With increasing demand for more highly skilled knowledge workers, governments will need to enhance the capacity to learn and the knowledge-distribution power of the economy through collaborative networks and the diffusion of technology.

The science system – public research laboratories and institutions of higher education – is seen as one of the key components of the knowledge economy, and the report identifies the major challenge as one of reconciling traditional functions of knowledge production and training of scientists with its newer role of collaborating with industry in the transfer of knowledge and technology. Economies are more strongly dependent on knowledge production, distribution, and use than ever before and that knowledge-intensive service sectors (especially education, communications, and information) are the fastest-growing parts of Western economies, which, in turn, are attracting high levels of public and private investment.

New growth theory, in particular, demonstrates that investment in knowledge is characterized by increasing rather than decreasing returns, a finding which modifies the neoclassical production function which argues that returns diminish as more capital is added to the economy. Knowledge also has spillover functions from one industry or firm to another; yet types of knowledge vary: some kinds can be easily reproduced and distributed at low cost, while others cannot be easily transferred from one organization to another or between individuals. Thus, knowledge (as a much broader concept than information) can be considered in terms of know what and know why,

broadly as what philosophers call propositional knowledge (knowledge that), embracing both factual knowledge and scientific knowledge, both of which come closest to being market commodities or economic resources that can be fitted into production functions. Other types of knowledge, what the OECD identifies as know how and know who, are forms of tacit knowledge (after Polanyi (1967); see also Polanyi (1958)), which are more difficult to codify and measure. The OECD report indicates that “Tacit knowledge in the form of skills needed to handle codified knowledge is more important than ever in labour markets” (p. 13) and reasons that, “Education will be the centre of the knowledge-based economy, and learning the tool of individual and organisational advancement” (p. 14), where learning by doing is paramount.

It is argued that the knowledge economy is different from the traditional industrial economy because knowledge is fundamentally different from other commodities, and that these differences, consequently, have fundamental implications both for public policy and for the mode of organization of a knowledge economy. Following the New Keynesian, Joseph Stiglitz (1999), we can analyze the knowledge economy in terms of the scarcity-defying characteristics of ideas. Stiglitz argues that knowledge is a public good because it is nonrivalrous, that is, knowledge, once discovered and made public, operates expansively to defy the normal law of scarcity that governs most commodity markets. Knowledge in its immaterial or conceptual forms – ideas, information, concepts, functions, and abstract objects of thought – is purely nonrivalrous, that is, there is essentially zero marginal costs to adding more users. While nonrivalrous, knowledge can be excluded – the other property of a pure public good – from certain users through various forms of legal protection. Yet, even though knowledge is not a pure public good, there are extensive externalities (spillovers) associated with innovations, which do not necessarily accrue to the innovators.

Higher education, and in particular, the universities, are at the heart of the new policy developments surrounding the concept of the knowledge economy. There is a move toward a system rationalization at all levels, with an accent on enhancing and rewarding the quality of research. The transformation of higher education in many Western countries from a universal welfare entitlement, first, into a private investment in human capital and, second, to a fully consumer-driven system, has followed a now-familiar pattern: a transparent alignment of the university system to reflect the needs of an emerging postindustrial economy, with increasing demands for highly trained, multiskilled, tertiary-educated workers; new forms of corporate managerialisms have been introduced with the emulation of private-sector management styles; and, the introduction of user charges, student loans, has led to the creeping privatization of the system as a whole.

The massification of higher education has been based on new funding mechanisms involving an everincreasing proportion of income from student fees and contestable research funding. Even with the diversification of funding sources, universities have struggled to cope financially. Increasingly, institutions have been forced not only to compete with each other in the market for student places but also to absorb the cost of providing extra, unfunded student places, at declining levels of state funding. With the emergence of the policy concept of the knowledge economy, universities are struggling to take competitive advantage in a new, complex environment that no longer privileges national or regional sites.

Neoliberal market fundamentalism which holds that markets are self-correcting has been discredited and it is important to revisit the goals of knowledge-economy policies and their evaluation in the Obama era. The move to state-centric policies and to forms of federal regulation in the United States and elsewhere now seem almost inevitable. Government intervention is now suddenly back in fashion and on the books at the International Monetary Fund (IMF) and the World Bank. The move to federal regulation and a reform of the financial system seems to chime with the development of state capitalism elsewhere, especially in East Asia, and other forms of state centrism seen as necessary for job creation and national reinvestment in infrastructure (Peters, 2008a). The Obama administration is aware that investment in education and America’s social infrastructure is an important part of the successful recipe for long-term growth and recovery. Obama’s policy advisors are also aware that education policies and their successful evaluation now depend upon the recognition of alternative modes of social production and the developing international networks of collaboration that are important for the recovery and continued success of American science and technology.

Openness has emerged as an alternative mode of social production based on the growing and overlapping complexities of open source, open access and open archiving, and open publishing. It has become a leading source of innovation in the world global-digital economy increasingly adopted by world governments, international agencies, and multinationals as well as leading educational institutions. It is clear that the free software and open-source movements constitute a radical nonproprietary alternative to traditional methods of text production and distribution. This alternative nonproprietary method of cultural exchange threatens traditional models and the legal and institutional means used to restrict creativity, innovation, and the free exchange of ideas. In terms of a model of communication, there has been a gradual shift from content to code in the openness, access, use, reuse, and modification reflecting a radical personalization that has made these open characteristics and principles increasingly the basis of the cultural sphere (Peters, 2008b).

Increasingly, in this context, the evaluation of education policy must take into account the huge reversal of neoliberalism and the shift toward new Keynesianism and especially the connection between investment in education and its relation to high-skill job creation in the vital sectors of energy and new technologies. Evaluation of education policy therefore must acknowledge the changing conceptions of education in relation to dominant economic theories and take into account shifts in ideology. In the era of knowledge economy, policies must be designed with an understanding of the logic of networks and evaluation itself must be an indigenous part of the question of design.

Conclusion

In this article, we have described how evaluation of education policy differs according to policy era and in response to the main underlying policy values. We have analyzed the three main policy eras in education policy – the welfare state, the neoliberal era, and the era of the knowledge economy. In each of these policy eras, education has been seen as fulfilling different functions. Evaluation in each case differs accordingly. One of the metatheoretical questions for policy evaluators is the extent to which their theories and methodologies recognized macro policy changes and match the era and the policy evaluated.

Evaluation of Mathematics Education Programs

Mathematics Education as a Discipline

While mathematics has been a subject of study in school for many centuries, mathematics education is a relatively new field of study. Early in the twentieth century, it was established as an independent field of research. The most significant milestone was establishing The International Commission on Mathematical Instruction (ICMI) in 1908. In 1969, the first International Congress on Mathematical Education (ICME) was held in Lyon. Since then, the ICME is held every four years under the auspices of the ICMI. The aim of the Congress is to present the current states and trends in mathematics education research and the practice of mathematics teaching at all levels. In 2008, the 11th ICME was held in Monterrey, Mexico.

In its first century, the field of mathematics education has prospered, particularly in the past four decades. The publications of research journals and training doctoral students are two indications for the prosperity of mathematics education as a field. So far, the field has launched nearly 20 research journals, such as *Journal for Research in Mathematics Education*, *Educational Studies in Mathematics*, *ZDM-International Journal on Mathematics Education*, *For the Learning of Mathematics*, *Mathematics Education Research Journal*, *Mathematical Thinking and Learning*, *Journal of Mathematical Behavior*, *School Science and Mathematics*, *Journal of Women and Minorities in Science and Engineering*, *Journal of Mathematics Teacher Education*, *Statistics Education Research Journal*, *Journal of Computers in Mathematics and Science Teaching*, and the *International Journal of Mathematical Education in Science and Technology*. Many institutions of higher education around the world have doctoral programs in mathematics education.

Mathematics education, as a field of study, is multidisciplinary as well interdisciplinary and deals with theories, practices, policies, curriculum, and issues about the teaching and learning of mathematics. It is multidisciplinary, because the field adopts methods and perspectives in other disciplines, such as psychology and education, to study issues in mathematics education. In recent years, there is a major shift to interdisciplinary collaboration. For example, a group of cognitive scientists, educational researchers, and mathematics educators bring their respective expertise together to explore a particular issue in mathematics education.

Research in mathematics education is quite varied, ranging from studies of young children to adults, from

large-scale experimental designs to single-subject case studies, from studies in a local context to studies involving multiple nations, and from studies by single authors to studies involving international collaboration.

Formative and Summative Evaluations in Mathematics Education

The evaluation of mathematics education programs is an integral part of mathematics education. Evaluation is the process of judging the value or worth of something. Like in any evaluation, the critical words in the evaluation of mathematics education programs are value or worth. When we evaluate a mathematics education program, we engage in a process designed to provide information to help make a judgment about the program. In evaluating such programs, the worth or value is usually related to students' learning.

Sometimes in mathematics education, evaluation has been used interchangeably with assessment and testing, without a clear distinction (National Council of Teachers of Mathematics, 1989). In fact, assessment is a broad term defined as a process for obtaining information that is used to make decisions about students, curricular programs, and policy (National Council of Teachers of Mathematics, 1995). Thus, assessment can provide information to evaluate a mathematics education program, but is not always involved in the judgment of worth. A test is defined as an instrument or systematic procedure for observing and describing one or more characteristics of a student. In other words, a test is a special form of assessment using a formal instrument, but an assessment does not have to involve a test because we can assess a student's learning through informal observation. Test scores are usually used to judge how well students perform or how effectively teachers teach. Please note that testing itself is neutral and does not involve any value judgment. As a result, a test is a powerful tool for evaluating mathematics education programs.

Generally speaking, every evaluation process involves an object to be evaluated, a scale of value, and a way of collecting information so that the object can be placed on the scale of value for judgment (Eisner, 1994; Fitzpatrick *et al.*, 2004). The ultimate goal of program evaluation is to improve students' learning of mathematics. To reach this goal, both formative and summative evaluations are needed.

An evaluation is defined as formative if the primary goal is to provide information for program improvement. For example, if the goal of evaluating teaching of mathematics is to improve teaching, then it is formative evaluation. Formative evaluation determines if a mathematics education program is delivered appropriately and then determines ways for improvements if they are needed. In the formative evaluation of teaching, for example, the evaluation provides a way to understand teachers' current way of teaching and then creates a plan to enhance their professional growth (Fitzpatrick *et al.*, 2004; NCTM, 1991).

An evaluation is defined as summative if the primary goal is to determine the effectiveness of a mathematics education program. It looks at the results. It is common to speak of short-term and long-term outcomes for a mathematics education program. For example, we can evaluate if a particular instructional intervention is effective within one year (short-term outcome) or in four or more years (long-term outcome).

Curriculum and Mathematics Education Programs

In mathematics education, even though the term program is used in a rather broad sense, it usually refers to a curricular program. Curriculum plays a significant role in mathematics education because it influences what students learn and when and how well they learn it. Advocates of mathematics education reform often attempt to change classroom practice, and thereby students' learning, by changing the curriculum. Historically, curriculum conveys what students should learn and at the same time also serves as an agent for instructional improvement (Howson *et al.*, 1981; Senk and Thompson, 2003).

Since the International Association for the Evaluation of Educational Achievement (IEA)'s First International Mathematics Study (Husen, 1967) used three levels of curriculum (intended, implemented, and attained), these distinctions of the curriculum have been widely accepted in mathematics education. The categorization in the first IEA international study highlights the differences in what a society would like to have taught, what is actually taught, and what students have actually learned (Akker *et al.*, 2003; NRC, 2004; Pinar, 2003; Senk and Thompson, 2003).

The intended curriculum refers to the formally written documents that set system-level expectations for learning of mathematics. It usually includes goals and expectations set in the educational system with textbooks, official syllabi or curriculum standards, and course. The intended curriculum deals at the system level.

The implemented curriculum refers to school and classroom processes for teaching and learning of mathematics as interpreted and implemented by teachers,

according to their experiences and beliefs for particular classes. It deals at the classroom level. The classroom is central to students' learning since students acquire most of their knowledge and form their attitudes from classroom instruction (Robitaille and Garden, 1989). Regardless of how well a curriculum is designed, it has little value unless it is implemented in the classroom.

The attained curriculum refers to what is learned by students and is manifested in their achievements and attitudes. It is at the student level. The attained curriculum deals with the aspects of the intended curriculum that are taught by teachers and actually learned by students.

The conceptualization of the three levels of curriculum is widely used in evaluating curricular programs in mathematics education (NRC, 2004). In the following sections, evaluating the curriculum at each level is discussed separately. However, it should be remembered that all three levels are related to one other and each one supports the other in the evaluation process, as shown in Figure 1.

Evaluation of Intended Curriculum

The intended curriculum specifies goals, topics, sequences, instructional activities, and assessment methods and instruments. The evaluation of the intended curriculum should be guided by the goals of mathematics education. Recently, a set of new goals for mathematics education has been discussed, with an emphasis on the importance of thinking, understanding, reasoning, problem-solving, connections, applications, and communication (e.g., National Council of Teachers of Mathematics, 1989, 1991). These goals stand in contrast to a more conventional view of mathematics education, which involves memorizing and reciting decontextualized facts, rules, and procedures, with an emphasis on the application of well-rehearsed procedures to solve routine problems. For example, in the United States, the National Council of Teachers of Mathematics (1989) proposed five new goals for students to learn in school mathematics:

1. they learn to value mathematics,
2. they become confident in their ability to do mathematics,
3. they become mathematical problem-solvers,
4. they learn to communicate mathematically, and
5. they learn to reason mathematically.

Figure 1 The conceptualization of the three levels of curriculum.

In other countries too, there are similar goals for school mathematics (e.g., Basic Education Curriculum Material Development Center, National Ministry of Education, 2001; Cockroft, 1982; Treffers, 1987). The new goals of mathematics education represent a major shift from traditional practice in mathematics instruction (NCTM, 1989), including shifts:

- toward classrooms as mathematical communities – away from classrooms as simply a collection of individuals;
- toward logic and mathematical evidence as verification – away from the teacher as the sole authority for right answers;
- toward mathematical reasoning – away from merely memorizing procedures;
- toward conjecturing, inventing, and problem-solving – away from an emphasis on mechanistic answer-finding; and
- toward connecting mathematics, its ideas, and its applications – away from treating math as a body of isolated concepts and procedures.

In measuring the effectiveness of a curricular program at the intended level, we must determine if all the relevant contents are covered and if they are sequenced in a coherent manner so that the curriculum meets the goals of mathematics education. For example, in determining if the curriculum includes the goals of developing students' problem-solving, reasoning, and communication abilities, we need to evaluate how these processes are integrated across different mathematical topics.

The evaluation of intended curriculum must take into account the quality of activities, their use in instruction, and their frequency of use. If an intended curriculum claims to be problem-based, we should expect to see a large proportion of cognitively demanding tasks. When evaluating the effectiveness of a standards-based mathematics curriculum in the United States, for example, Cai *et al.* (in press) analyzed instructional tasks in both standards-based mathematics curriculum (called Connected Mathematics Program or CMP in short) and a more traditional mathematics curriculum (called nonCMP). The intent of CMP curriculum is to build students' understanding of major ideas in numbers, algebra, geometry, measurement, data analysis, and probability through explorations of real-world situations and problems. We classified the instructional tasks from CMP and nonCMP curricula into four increasingly demanding categories of cognition: memorization, procedures without connections, procedures with connections, and doing mathematics (Stein and Lane, 1996). As **Figure 2** illustrates, the CMP curriculum had significantly more higher-level tasks (procedures with connections and doing mathematics) ($\chi^2(3, N = 3311) = 759.52, p < 0.0001$) than the nonCMP. Such an analysis of the intended

Figure 2 Percentages of various types of tasks in CMP and nonCMP curricula.

curriculum provides insightful information to distinguish different curricula.

The most common method of evaluating an intended curriculum is content analysis which involves judging the quality of contents and their presentation in a curriculum. The National Research Council proposed a list of factors to consider when conducting content analysis to evaluate the intended curriculum (**Table 1**). When doing this, we may focus on one or more factors, depending on the specific purpose of the evaluation.

Because of the conceptual and procedural nature of mathematics, it is important to achieve an appropriate balance between concept development and computational proficiency in a curriculum (NCTM, 1989). An inordinate emphasis on skill proficiency at the expense of a strong conceptual framework to support such skills renders curricular materials inappropriate. On the other hand, it is equally inappropriate to overemphasize conceptual understanding at the expense of basic mathematical skills.

Besides the factors mentioned for evaluating an intended curriculum, we may also consider the qualifications of both, the authors of the curriculum and the qualifications of evaluators. It is ideal to create a team of evaluators with diverse areas of expertise, including mathematicians, mathematics educators, school mathematics teachers, curriculum developers, and school administrators, in the evaluation of an intended curriculum.

Evaluation of Implemented Curriculum

The implemented curriculum concerns both, the mathematics that is taught and how it is taught. One of the ideas about the implemented curriculum acknowledges that what teachers teach may or may not be consistent with what is intended in the curriculum. The implemented curriculum then can be evaluated in terms of what teachers actually do in the classroom with respect to the curriculum.

Table 1 Factors to consider in content analysis of mathematics curriculum materials

Listing of topics
Sequence of topics
Clarity, accuracy, and appropriateness of topic presentation
Frequency, duration, pace, depth, and emphasis of topics
Grade level of introduction
Overall structure: integrated, interdisciplinary, or sequential
Types of tasks and activities, purposes, and level of engagement
Use of prior knowledge, attention to (mis)conceptions, and student strategies
Reading level
Focus on conceptual ideas and algorithmic fluency
Emphasis on analytic/symbolic, visual, or numeric approaches
Types and levels of reasoning, communication, and reflection
Type and use of explanation
Form of practice
Approach to formalization
Use of contextual problems and/or elements of quantitative literacy
Use of technology or manipulatives
Ways to respond to individual differences and grouping practices
Formats of materials
Types of assessment and relation to classroom practice

Adapted from NRC (National Research Council) (2004). *On Evaluating Curricular Effectiveness: Judging the Quality of K-12 Mathematics Evaluations*, p. 42. Washington, DC: National Academy Press.

Evaluating the implemented curriculum includes examining the congruity between the instruction to students and the goals (also called fidelity of implementation). It is possible that teachers may vary widely in their commitment to the intended curriculum. Therefore, it is important to determine whether, how, and to what extent the intended curriculum influences the instruction of the teachers who use them in evaluating the implemented curriculum. The factors listed in **Table 1** can also be considered in examining the fidelity of implementation. For example, we can determine an implementation level (high, medium, or low) according to the extent of coverage of the curricular materials, the consistency between the intended and implemented curricular goals, and the congruence between instructional sequence and curricular sequence.

In classroom instruction, it is possible that teachers may supplement the intended curriculum extensively. Thus, to judge the extent to which a curriculum is being implemented as intended by the program, it is necessary to document in detail the degree to which the curriculum has been used in the classroom and to see if teachers supplement the curriculum, and if they do, what supplementary materials they use.

A faithfully implemented curricular program may not be effective for students' learning. Therefore, in evaluating the implemented curriculum, it is important to examine how mathematics is taught by analyzing

the experiences students and teachers undergo in the classrooms as they use the intended curriculum. Research has shown that high quality mathematics instruction should not only provide students with the opportunity to learn important mathematics and participate actively in the processes of constructing knowledge, but should also provide a setting for students to explain and justify their thinking and challenge the explanations of their peers and teachers (NCTM, 1991; NRC, 2001). Students' ability to reason, solve problems, and use mathematics to communicate their ideas will develop only if they actively and frequently engage in these processes. Whether students come to view mathematics as an integrated whole instead of a fragmented collection of arbitrary topics and whether they ultimately come to value mathematics will depend largely on how the subject is taught (NCTM, 1991). Therefore, evaluating classroom instruction also requires a careful analysis of the classroom events that instructionally guide students' learning of important mathematics.

In mathematics education, different paradigms and methods have been used to identify important features of classroom instruction. One of the important constructs to study classroom teaching is the instructional task presented and implemented in the classroom. The term instructional tasks has been referred to by other researchers as academic tasks or mathematical tasks (Doyle, 1983). Mathematical tasks can be defined broadly as projects, questions, problems, constructions, applications, or exercises in which students engage. Mathematical tasks provide intellectual environments within which students can learn and develop mathematical thinking. Tasks help regulate not only students' attention to particular aspects of content but also their ways of processing information. However, only worthwhile problems give students the chance to solidify and extend what they know and stimulate mathematical learning (NCTM, 1991). In the classroom, actual opportunities for students to learn depend on the type of mathematical tasks presented and implemented. Regardless of the context, for a task to be worthwhile, it should be intriguing and should provide a level of challenge that invites speculation and hard work. Most importantly, worthwhile mathematical tasks should direct students toward explicit learning goals by encouraging them to investigate important mathematical ideas and ways of thinking. NCTM (1991) has recommended that students should be exposed to truly problematic tasks in classrooms so that they can practice mathematical sense-making. Doyle (1983) argues that tasks with different cognitive demands are likely to induce different kinds of learning. Mathematical tasks that are truly problematic have the potential to provide intellectual contexts for students' rich mathematical development. Such tasks can promote their conceptual understanding, foster their ability to reason and communicate mathematically, and capture their interests and curiosity (NCTM, 1991).

For example, in evaluating the effectiveness of a standards-based curriculum in the United States, we analyzed instructional tasks implemented in the classrooms using both CMP and nonCMP (mentioned earlier). Using the same scheme developed by Stein and Lane (1996), we classified the instructional tasks from classrooms, using CMP and nonCMP curricula, into four increasingly demanding categories of cognition: memorization, procedures without connections, procedures with connections, and doing mathematics (Cai *et al.*, in press). **Figure 3** illustrates the percentage distributions of the cognitive demand of the instructional tasks implemented in CMP and nonCMP classrooms. A chi-square test shows that the CMP and nonCMP percentage distributions are significantly different ($\chi^2(3, N=1390)=209.42, p<0.0001$). The difference is due to the fact that the CMP classrooms had implemented a larger percentage of high cognitive demand tasks (procedures with connection or doing mathematics) than the nonCMP ones ($z=13.79, p<0.001$). On the other hand, the nonCMP classrooms had implemented a larger percentage of low cognitive demand tasks (procedures without connection or memorization) than the CMP ones. This analysis of instructional tasks is quite informative to examine the curricular programs at the classroom level.

In evaluating an implemented curriculum, it is important to collect various types of information, such as sustained classroom observations, interviews with teachers, written self-reports by teachers, questionnaires, analysis of lesson plans, and summaries of peer observations. Because teachers are at the heart of using curricular materials and making instructional decisions for teaching, they should be active participants in evaluating the implemented curriculum. In particular, the teachers' own reflections of their teaching could be a valuable source in the evaluation process, especially as it relates to formative evaluation.

Evaluation of Attained Curriculum

The ultimate goal of educational research, curriculum development, and instructional improvement is to

Figure 3 Instructional tasks implemented in CMP and nonCMP classrooms.

enhance student learning. Thus, the evaluation of a mathematics education program at the student level – evaluation of attained curriculum – is of critical importance. To evaluate the attained curriculum, we must address the different facets of mathematical thinking (Sternberg and Ben-Zeev, 1996). Mixed methods, such as observing students doing mathematics, performing tasks, and taking tests, can be used to collect information to evaluate the attained curriculum. In particular, evaluators must pay special attention to the selection of assessment tasks and employment of analysis methods in the evaluation of mathematics education programs.

Assessment tasks

Even though various methods can be used to measure students' learning, the heart of measuring mathematical performance is the set of tasks on which students' learning is to be evaluated (NRC, 2001). It is desirable to use various types of assessment tasks, thereby measuring different facets of mathematical thinking. For example, different formats of assessment tasks (such as multiple-choice and open-ended tasks) may be used to measure students' learning. Multiple-choice tasks have many advantages. For example, more items can be administered within a given time period, and scoring responses can be done quickly and reliably. However, it is difficult to infer students' cognitive processes from their responses to multiple-choice items. Thus, in addition to multiple-choice tasks, open-ended tasks may be used. For open-ended tasks, students are asked to produce answers as well as show their solution processes and provide justifications for their answers. In this way, the open-ended tasks provide a better window into the thinking and reasoning processes involved in their learning of mathematics. Of course, a disadvantage of open-ended tasks is that only a small number of these tasks can be administered within a given period of time. Also, grading students' responses is labor-intensive. To help overcome the disadvantages of using open-ended tasks, a matrix sampling design of administering open-ended tasks to students is recommended. In this way, we can reduce both testing time and grading time but still obtain a good overall estimate of students' learning of mathematics.

Analyses of mathematical performance

It is useful to know the learning outcomes of students in terms of mean scores on various types of tasks. However, comparing their performances from different mathematical programs in terms of correctness of individual tasks is not particularly revealing unless the reviewers explore the thinking and methods that led students to their correct answers. For example, two students may receive the same mean score but use very different solution strategies. Also, two students may receive the same mean score but may make very different errors. Therefore, in evaluating their

learning outcomes, it is important to examine the cognitive aspects of their problem-solving, such as solution strategies, mathematical misconceptions/errors, mathematical justifications, and representations. In fact, examining solution strategies can reveal the qualitative aspects of the mathematical thinking and reasoning of the students, such as how they go about formulating goals and purposes in their learning and mathematical problem-solving (Sternberg, 1991). Similarly, the examination of solution justifications and representations reveals the ways that students process a problem and express their mathematical ideas and thinking processes.

In addition, the unit of analysis should be appropriately selected in analyzing students' performance. In evaluating mathematics education programs at the student level, a reasonable number of students from different classes with different teachers in different schools, or even different school districts, is needed. To examine the impact of a program, pre- and post-tests are usually used and statistical analyses conducted. In traditional analysis using *t*-test or analysis of covariance (ANCOVA), each student in the sample is treated as the same. This implies that students from different classes with different teachers in different schools are considered to have similar experiences with the program. However, the reality is that students from different classes with different teachers in different schools are likely to have different experiences with the program. Thus, in evaluating mathematics education programs, researchers must select an appropriate unit of analysis, take into account the degree to which a program is implemented as well as the relationship between the degree of implementation and students' achievement. Advanced analysis techniques, such as hierarchical linear modeling, can be used to examine the impact of a curriculum on student-learning at the intended (system level) and implemented level (classroom level) simultaneously (Raudenbush and Bryk, 2002; Tarr *et al.*, 2008).

Conclusion

This article discussed the evaluation of mathematics education programs at three levels (intended, implemented, and attained) for both formative and summative purposes. While evaluating mathematics education programs can be discussed and conducted at three levels, the evaluation process at each level should reflect the ultimate goal: to improve and maximize students' learning. Put another way, learning of important mathematics by students should be an important source of information when evaluating a mathematics education program.

It should be indicated that since teaching is a cultural activity, students with different ethnic and cultural backgrounds may respond differently to a new program in

mathematics education. Globalization makes new mathematics education programs more accessible for students around the world. A critical component of any mathematics education program is that all students have an equal opportunity to take advantage of the full benefits of the program (NCTM, 1989). So, the question arises: to what extent does implementing a new mathematics education program improve the learning of mathematics for all students, regardless of the gender, ethnicity, cultural background, language use, and nationality? Clearly, program evaluations in mathematics education should include indicators that specify if the program is meeting these essential criteria. In addition, the evaluation of mathematics education programs should provide information to foster equal access to the programs.

Evaluation of Science-Education Programs

Science Education and Basis for Evaluation

At present, science education is one of the primary requirements of a literate society where students should be strengthened with basic scientific skills. They should develop curiosity and excitement as well as positive attitudes toward science in order to understand the natural world around them, use scientific processes in dealing with their personal decisions, cope with the scientific and technological aspects of today's world, and, eventually, act as scientifically literate persons to contribute to productivity in society (Buxto and Provenzo, 2007; Carin and Bass, 2001; Gregory and Hammerman, 2008). Therefore, a science program should stimulate the engagement in science by emphasizing the processes in the making of science, organizing scientific ideas, and developing a scientific temper through inquiry rather than imparting mere scientific knowledge (Bloom, 2006; Freeman and Taylor, 2006). Within this context, evaluation becomes a process dealing with all the possible indicators of a successful implementation through a systematic procedure which consists of a formal appraisal of the quality of educational phenomena (Popham, 1993). This is the program-accountability issue (Scheerens *et al.*, 2007). Thus, program accountability is established through appraising the quality in line with the program's overall planned conceptual framework in terms of its scope and good choice of objectives, its implementation practices in line with planned activities, and the level of attainments of the objectives (Scheerens *et al.*, 2007). For program accountability, it is also important to consider the satisfaction of various stakeholders, education policymakers, experts, and any other agency dealing with the program outcomes, since every program should serve the intellectual and social development of a society (Marsh and Willis, 2007). Thus, evaluating a science program is a dynamic process in which any information about the quality will provide continuous feedback to its conceptual framework as well as the implementation practices.

Steps for evaluating a science program

In general, a program evaluation attempt needs to address the quality issue – in terms of input, process, and output (Posner, 1995). **Figure 1** represents the model for evaluating a science program.

As it is seen in **Figure 1**, program evaluation in science consists of three general phases, such as a contextual

evaluation of the program's overall framework with its goals and objectives, evaluation of the implementation process, and evaluation of the program's output. For creating a base in program accountability, the evaluation attempts should be (1) comprehensive in collecting information from all the related elements and stakeholders, (2) combinations of different program evaluation approaches, and (3) using both qualitative and quantitative data collection and analysis procedures.

For ensuring comprehensiveness of the information collected, program accountability should also rely upon judgmental evaluation of experts, teachers, school administrators, education policymakers, stakeholders, and customers, besides student-related learning outcomes (Gredler, 1996; Morris *et al.*, 1987; Posner, 1995; Stecher and Davis, 1987; Worthen *et al.*, 1997).

Even though evaluation approaches vary in terms of research methodologies, criteria to be focused on, nature of the data collected, and standards to be addressed for quality indicators, all the approaches try to collect as much evidence as possible to prove that the program under investigation operates as intended (Herman *et al.*, 1987). Thus, a unified approach with the combination of various evaluation methods would provide a wider range of information with regard to the quality of a science program.

The use of both quantitative and qualitative approaches should be favored since any important finding in quantitative analyses could be probed via qualitative techniques.

On the other hand, as seen in **Figure 1**, the successful implementation of a science program also relates to student and teacher background characteristics, as well as the infrastructure of the school, as intervening variables.

Evaluation is a decision-making process through which a judgmental conclusion is drawn, based on information collected at different phases of the program-evaluation model, as depicted in **Figure 1**. The most critical issue in this process is selecting appropriate criteria to decide about the quality of the program. When the steps of the science evaluation model is considered, coverage of the standards defined in the conceptual framework of the program – with respect to basic skills and knowledge universally accepted in science education, valid and congruent implementation of instructional modes, materials, laboratories, etc., in the classroom – and attainment of skills and attitudes by students, could be the major focus of the evaluation process.

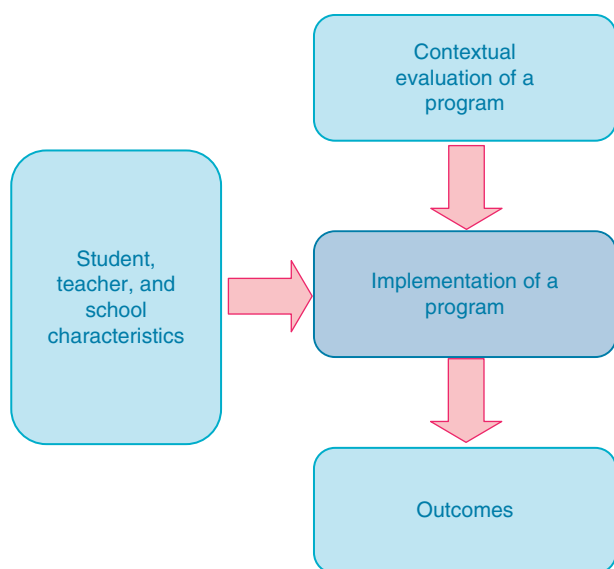

Figure 1 Steps for evaluating a science program.

A program evaluator should consider the following for each phase of the program evaluation:

1. Determining the tasks to be evaluated.
2. Planning the process to collect information about the tasks.
3. Determining criterion against which the quality will be addressed.
4. Integrating all the information collected.
5. Judgmental decision with regard to the overall success of the program.

The following sections provide examples for the tasks to be evaluated as well as criteria to be considered in each step of the evaluation model given in **Figure 1**.

Contextual evaluation

This phase, basically, focuses on the definition of the program. Successful implementation of the program requires a well-defined overall goal, instructional objectives, and planned activities. There are always differences between the program's overall planned structure and what is being implemented in practice (Marsh and Willis, 2007). Thus, before evaluating the program implementation and outcomes, the contextual evaluation of a science program constitutes a base for the program implementation.

In the definition of a science program, there should be at least two dimensions to consider: subject matter and cognitive processes.

The selection of appropriate subject matter and their sequence and organization are the primary tasks to be considered at this very first stage. Selection of subject matter is a function of age and grade levels, but it is linked to cognitive processes as well. In general, subject matter in science consists of facts, concepts, and principles. For

meaningful learning to take place, the subject matter should be in congruence with the developmental level of the students. Any concept which is too abstract for the learners will hinder meaningful learning. This issue is rather the validity of the subject matter domain and its significance with reference to the needs of the students and society (Oliva, 2001). A program evaluator should take the developmental stages of the students into consideration as well as the needs of the stakeholders in assessing the appropriateness and sequential organization of the subject matter.

Cognitive processes, on the other hand, are the higher-order thinking processes which are inquiry skills in science that are required through all the age and grade levels. After clarifying the overall goal of a science program, the primary concern of the program developer is to link the cognitive processes with the subject matter, through the program's objectives, as learning outcomes.

For an evaluator, the major questions to ask at this phase are: How well was the program planned and designed in line with the subject matter and cognitive process? Were the objectives correctly selected and defined? In a science program, the objectives could be planned and designed with respect to various approaches, such as behaviorist or cognitive (Klopfer, 1971; Marzano *et al.*, 1988; Royer *et al.*, 1993). With the increasing impact of constructivism on program-development attempts, science programs could be designed in spiral curriculum format – through which the same cognitive skills can be repeatedly introduced to students through all the grade levels (Henson, 2006). Since the evaluation of this domain constitutes the appropriateness of the program's overall structure, no matter which approach is being used, the primary concern should be the content of the cognitive processes program covers. No matter which program-development approach is used, besides basic conceptual understanding, the science program should emphasize inquiry skills in stating its objectives.

Table 1 exemplifies the higher-order and inquiry skills and their definitions.

There are, actually, two criteria in deciding the quality of the content of the program in this phase. The first criterion is external in nature in which the curriculum or syllabus of another traditional or alternative program constitutes the main source. Similarly, there could be criterion reflecting societal needs with regard to the outcomes of a science program which are described at the national level and that is congruent with the internationally accepted criteria. The National Standards in Science Education (National Research Council, 1996) could be a good example and source for this kind of assessment. In this task, the evaluator needs to conduct a content-wise comparison to justify the congruence of the content of the science program with reference to globally accepted standards.

The second criterion is internal, through which consistency among different components of the program is

Table 1 Examples of science process skills

Process skills	Explanation
Transfer	Converting one form of information into another.
Prediction	Based on a criterion anticipating a future condition.
Relating	Link at least two body of information with each other.
Providing examples	With reference to a given situation proposing a novel example.
Classification	With reference to at least two groups of information, locating or naming a given case.
Hypothesizing	Based on an observation result proposing a statement which is testable.
Observing	Based on five common senses describing attributions or properties of a given event or object.
Conducting experiments	Based on a hypothesis, designing an experimental apparatus.
Data collection	Collecting or analyzing data with reference to a given hypothesis.
Drawing conclusion	Providing a statement that may support an experimental hypothesis or observations.

assessed. The tasks to be actualized in this phase are whether: (1) the program emphasizes development of inquiry-based thinking skills in the overall goal, (2) the program provides well-defined objectives in line with these skills, (3) there is congruence between the overall framework and the objectives, (4) there is congruence between the objectives and the subject matter selected, and finally (5) there is congruence between the objectives and the activities planned to achieve these objectives. Well-defined science objectives are those that are attainable at the respective age level and should be stated in a way that reflects higher-order cognitive and inquiry skills acquisition of which can help students perform to a minimum acceptable level (Henson, 2006).

The cognitive processes are not the only concern at this step. A science program should also cover objectives and tasks to develop students' skills in conducting experiments with safety precaution. Development of attitudes, values, and beliefs is also considered for a successful science program. In this context, conceptions about the nature of science, positive attitudes, and interest toward science are the basics to be covered in order to develop scientific curiosity in students. It is expected that a science program with inquiry emphasis would also develop these psychomotor and affective components of the program. All the procedures suggested above for cognitive skills are also valid for these outcomes.

At this particular step, the appropriateness of the program's content should be assessed by the panel of experts consisting of related stakeholders, such as experts in science education, education policymakers, school

administrators, teachers, and parents. This phase of the program evaluation requires a qualitative description of the content of the program and content-wise comparison with the existing internal or external criteria. A detailed report for the tasks given above will help in deciding the quality of the program in terms of its relevance (Scheerens *et al.*, 2007). Within this context, opinions of the related experts, policymakers, and teachers could be used as supportive information for making a contextual analysis.

Evaluation results in this phase will be useful input for the following phases of the program-evaluation process.

Evaluation of program implementation

The implementation, primarily, focuses on the process with actual settings. In this respect, an evaluator should deal with the possible sources of barriers and limitations which could hinder the attainment of program goals (Rossi and Freeman, 1985). The program implementation, basically, uses formative evaluation techniques through which the evaluator should obtain an answer to the question "How well is the program being implemented?" Thus, answering this question requires close interaction of the evaluator with the school administrator, teachers, and students. Interaction includes all sorts of activities being carried out in the classroom environment as well. Adequacy and effectiveness of materials, such as textbooks, worksheets, and laboratory equipment, have to be assessed in this phase of evaluation. As a result of this interaction, the evaluator needs to prepare a detailed description of the program operations (Patton, 1987). Thus, questionnaires, open-ended in-depth interviews, direct observation of the process, and contextual analyses of written documents and anecdotal records are used to describe the program operation. On the other hand, the evaluator could also collect quantitative information through structured questionnaires. Since the major concern is to understand the strengths and weaknesses of program implementation, any problem singled out as a result of quantitative analyses could be further analyzed by qualitative methods, in order to understand the possible sources of the problems that hinder successful implementation. For instance, if teachers and students report that they do not spend much time on student-based experiments in science classes, further in-depth interviews with teachers may provide information on the reasons for this particular outcome found in the quantitative questionnaire. Thus, in this phase, qualitative analyses provide further evidence to support the general findings reported by quantitative data.

Table 2 indicates examples of the possible formative evaluation tools and how they could be designed to collect information about the implementation of science programs.

The techniques proposed to use in process evaluation – such as questionnaires, interviews, observations, and analyses

Table 2 Examples of formative evaluation tools for program implementation

<i>Decisions</i>	<i>Source</i>	<i>Instrument</i>	<i>Rating</i>
<i>Congruence of activities with respect to program objectives</i>	Student	Questionnaire	Frequency/likelihood of activities carried out in the classroom/laboratory
	Teacher	Questionnaire	Frequency of activities
	External evaluator	Observation record	Frequency and quality of laboratory or classroom activities
<i>Quality of the instructional materials and laboratory equipment</i>	Teacher	Interview	How teachers value textbooks and other instructional materials being used
	Student	Interview	How students perceive the instructional process and the materials they use
<i>Adequacy of materials, laboratory equipment</i>	Teachers and school principals	Interview	How they value the adequacy of the materials and laboratory equipments and their effective use in the classroom
<i>Impact of program implementation on student learning</i>	Student	Unobtrusive measurement	Student response on questions embedded in the instructional processes
	Teacher	Interview	How teachers appreciate the impact of ongoing programs on student development and emphasize on the strengths and weaknesses of the program implementation

of written documents – have their own advantages and disadvantages with respect to information provided and the technical characteristics such as reliability and validity of the results (King *et al.*, 1987). Since results obtained in these techniques are relatively less reliable and valid than assessment of cognitive skills, the key feature in this particular step should be comparing the results on similar issues across the groups, such as students, teachers, and school administrators. For instance, information on the frequency of student-based inquiry experiments in the classroom could be obtained from a students and teachers, and a comparison of their responses provides evidence for the validity of the information collected. Similarly, triangulation is necessary for the qualitative data for increasing the strength and rigor of the information collected (Patton, 2002).

In this phase of the evaluation, equity and economic use of resources are two important features that have to be considered by the evaluator. As indicated in **Figure 1**, this is one of the primary concerns of the evaluation process since the variations in the infrastructure among schools will reflect the quality of the program implementation. The success of the program will partly be dependent upon equity in sharing resources among schools. Thus, this particular variable might be controlled in anticipating the quality of the program's output.

Evaluation of outcomes

The major focus in this phase is “How much of the objectives are attained by the students?” Answering this question, as the major task, includes the summative evaluation of objectives related to cognitive and affective domains.

The summative assessment of students' attainment of cognitive objectives could be performed in norm-referenced and criterion-referenced approaches. The norm-reference approach ranks the students, and, in general, overall mean of the group or the percentile scores of the students are used as the criteria to make a decision regarding the success of the program. Outcome evaluation is, generally, carried out by an experimental design in which a new program is compared with the traditional one in terms of students' summative test scores. However, this approach seems quite misleading since, in general, summative tests used for the comparison is biased against the traditional group since, in general, tests used for this particular comparison are designed in line with the objectives of the new curriculum. On the other hand, the mean difference between traditional and experimental groups does not indicate for which cognitive skills the students' attainment is different across two groups being compared. Similarly, surveying the achievement of students across a new science program and the traditional one without any experimental control may be misleading as well. The mean could be different in favor of the new science program but it may not display a satisfactory level of attainment of the objectives. Mere ranking of students with respect to their achievement levels does not give a clear picture concerning the quality of new science programs with reference to attainment of the cognitive skills. Thus, a more elaborative assessment is needed to interpret the skills possessed by the students who were exposed to new science programs.

Elaborate assessment could be carried out by criterion-referenced interpretations of the test scores. The criterion-referenced approach would be very informative

with regard to the success of a program if the cognitive skills corresponding to different score levels are clearly defined (Hambleton and Jurgensen, 1990). Definition of score intervals – in line with the cognitive skills achieved by the students – is possible through item-mapping procedures (Ercikan, 2006; Karantonis and Sireci, 2006). Using this approach indicates not only the achievement difference, but the level of attainment of the program objectives at different score levels as well. This kind of information can be gathered through the use of item-response-theory models – in which probabilistic interpretations of the correct response rate at different score intervals are available (Hambleton *et al.*, 1991). Moreover, having a score level and cognitive process link in any assessment program is also helpful in describing the minimum standards students should achieve in science education throughout the country.

In this summative evaluation process, students' individual or group products – such as laboratory reports, project papers, workbooks, concept maps, portfolios, etc. – can also be used as informative documentation with regard to the success of the program. This is a rather content-wise evaluation of the quality of the products produced by students, which may provide clues regarding the attainment of program objectives. For improving the reliability and validity of product evaluation, a panel of experts and teachers could develop the standards for assessment, and at least two independent groups of scorers could evaluate the content of student products.

In terms of affective domain outcomes, attitudes toward science and science instruction, interest, academic concept in science, student willingness to engage in science in their careers, nature of scientific concept, value given to science etc., have to be assessed in this phase. The assessment of affective variables is, generally, carried out with Likert-type scales. The comparisons between the new science program and traditional or alternative programs, with respect to these affective variables, may also provide information about the success of the program output. As in the case of cognitive measurement, the criterion-referenced interpretations of the mean scores could also be used in evaluating the results of affective measurements. The scale mean on a five-point Likert-type scale could be used as the success or failure of the program in terms of attainment of affective objectives.

Considering Background Characteristics in Evaluation

The success of a science program depends on some external factors – such as the school's infrastructure, socioeconomic level of the parents, students' needs and preachievement in science, and qualifications of science teachers. The school's infrastructure includes variables such as science-teacher-student ratio, facilities in science laboratories, availability of

instructional materials, etc. The information concerning these characteristics could be assessed through the use of written documents, or via interview or questionnaire data obtained from school principals. The socioeconomic characteristic of a student is an important factor related to science achievement. The educational level of parents and facilities at home, such as the number of books and the availability of separate study desks are the primary indicators of this particular variable (Kohr *et al.*, 1988). This could be assessed through the student questionnaire used in the second phase of the program evaluation. Students' needs and expectations in science education, and their preachievement levels as assessed by the teacher grades or standardized tests could be important inputs for a successful implementation. Finally, teachers' experience in teaching science, their efficacy in science, their understanding of the content and aim of the new science program, their understanding with regard to the nature of scientific concepts, etc., are the variables that might reflect the quality of program implementation that an evaluator needs to assess and control in the program-evaluation design.

These external variables are either controlled experimentally – if the program evaluation is based on experimental design – or statistically – if the evaluation design is primarily based on a survey. The covariance analysis could be used to infer success of the program when school-, teacher-, and student-related factors are statistically removed from the output variables. Alternatively, these variables could be the major concern of the evaluator in assessing the success of the science program under different conditions, such as experienced versus nonexperienced teachers and high versus low socioeconomic status. The gender variable, on the other hand, should be specifically taken into consideration for a science program since gender differences in science achievement are, generally, reported across all countries (Martin *et al.*, 2008). A successful science program should be effective for both gender groups.

Data Analysis and Reporting the Results

As stated previously, program-evaluation data are both qualitative and quantitative in nature. Thus, two broad evaluation reports need to be developed. However, these two data sources should be aggregated to compensate each other. For the rigor of the evaluation attempt, there are two concerns for the evaluator: reliability and validity of the data collected and generalizability of the results.

Reliability and validity of the measurement results could be enhanced by triangulation of qualitative data and by using reliable and valid standardized tests or questionnaires in quantitative analyses. For quantitative data, outcomes of a program could also be partly evaluated with respect to available data sources at the national and international level such as National

Assessment of Educational Progress (NAEP), The Third International Mathematics and Science Study (TIMSS), and Program for International Student Assessment (PISA).

For generalizability of the results, the evaluator should consider representativeness of the sample. Based on the design of the study, samples should include all the strata in the population.

There needs to be an analysis design for the qualitative and quantitative data sets. The evaluator needs to combine these two sources of information in a way to support the validity of the conclusions derived. The qualitative reports should be providing supportive evidence to the findings reported on quantitative data. On the other hand, the quantitative data could be analyzed via descriptive statistical techniques, as well as inferentially. Descriptive analyses can document all the descriptive statistics across different strata of the sample – such as schools, urban and rural areas, and gender groups. In the inferential analyses, the linear structural model or the hierarchical linear model could be used to aggregate all the variables and data sources collected through tests and questionnaires (Jöreskog and Sörbom, 1993; Raudenbush and Bryk, 2002). In the modeling process, the major problem is the criterion through which one can generalize with regard to the effectiveness of the new science program. The models comparing traditional and new programs could help to infer the effectiveness of the new science program. If there is no alternative or traditional program to compare, the evaluator might constitute a model based on pretest and posttest design. Considering the difficulty of the experimental approach, a criterion-referenced interpretation of the test and questionnaire scores could help to decide on the quality of the science program. Since the effectiveness of the program could be observed in time, a time-series statistical design to follow-up student development in cognitive and affective areas could constitute a valid basis for evaluation.

A program has a dynamic nature. Any feedback from an evaluation attempt could be used for revising the program structure, as well as the implementation process. Thus, program evaluation in science should be considered as a continuous process to enhance the quality of program structure and implementation.

Evaluation of Social Studies and Civic Education Programs

S G Grant, Binghamton University, State University of New York, Binghamton, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Center for civic education – A California-based organization that promotes the civic knowledge and awareness.

CityWorks – A curriculum package developed by Constitutional Rights Foundation to promote civic knowledge and awareness.

Civic education – A field of academic endeavor intended to promote students' knowledge and understanding of government, the political process, and citizenship rights and responsibilities.

Committee on the social studies – A group of US academics enlisted in 1916 by the National Education Association and empowered to draft a set of curriculum guidelines for a new school subject called "social studies."

Constitutional rights foundations – An organization based in California that develops curriculum and instructional materials to promote student understanding of the US Constitution and Bill of Rights.

Documented-based questions – A form of test task that asks students to use primary and secondary documents in the construction of their responses to an essay prompt.

Man: A course of study – A social studies curriculum package developed in the 1960s.

National center for history in the schools – A curriculum development center located at the University of California, Los Angeles that develops and promotes curriculum and instructional resources around the teaching of history.

National council for the social studies – The leading professional organization for educators interested in social studies education.

No child left behind – US national legislation created in 2002 featuring a standardized test-based approach to educational reform.

Social studies – The broad label for a series of school coursework that features attention to history and the social sciences.

We the people – A curriculum package designed to promote students' civic knowledge and dispositions developed by the Center for Civic Education.

The evaluation of social studies and civic-education programs in the United States is both challenging and rare. The first challenge is curricular: Social studies and civic education curricula have long been contentious and hide-bound fields. Many would argue that the lines within and between the two fields are murky at best. A second set of challenges surrounds social studies and civics assessments. There, the key issues are the validity and reliability of differing assessment systems as well as a set of larger concerns related to interpreting what children know and understand. Finally, uncertainty abounds at the classroom level. In that realm, we find that teachers are paying some attention to the state curriculum guides and to state-level tests. But in each case, there is as much variability in their responses as there is consistency. Each of these challenges undercuts the potential for robust curriculum evaluation. Moreover, although there have been evaluations of some foundation-sponsored curriculum projects (e.g., We the People and Kids Voting USA), these projects are almost exclusively civics oriented, small scale, and unrelated to the recent drive to create state curriculum.

A Contentious Curriculum

Not only are the current manifestations of social studies and civic education contentious (so contentious in fact that neither is among the areas to be tested under the No Child Left Behind legislation of 2002), but there is considerable and continuing disagreement about the legitimacy of social studies as a distinct school subject. Civic education has longer history, but even advocates write about it in ways that blur the distinction with social studies.

Although they trace its antecedents back to the late 1890s, most curricular historians (Barr *et al.*, 1977; Hertzberg, 1989; Jenness, 1990; Wattras, 2002) date the birth of social studies as a school subject to 1916 and the Committee of Social Studies (sponsored by the National Education Association) report whose aims included the "development of an appreciation of the nature and laws of social life, a sense of the responsibility of the individual as a member of social groups, and the intelligence and the will to participate effectively in the promotion of the social well-being" (National Education Association, 1916). Born of twin impulses – a need to enliven the pedantic teaching of history and a desire to help students engage more directly with their

social environment – the founders of social studies (e.g., Thomas Jesse Jones and Arthur Dunn initially, George Counts and Harold Rugg later) hoped to create a school curriculum that served both progressive and patriotic ends (Wattras, 2002). Among the curricular changes offered was the high school problems-of-democracy course which supporters envisioned as a way to engage topics of “immediate interest to the class and [of] vital importance to society” (Hertzberg, 1989: 87).

What the Committee on Social Studies and subsequent reformers have failed to do, however, is install a single, coherent program of studies. Instead, social studies tends to be a blanket term for a wide range of disciplinary elements (e.g., history, geography, political science, and economics) and for a wide range of courses. There is something of a *de facto* curriculum (see Table 1), but variety has been more the norm than consistency.

The history of curriculum-reform efforts demonstrates a stubborn resistance to real change (Dow, 1991; Jenness, 1990). In fact, recent efforts have only added to the curricular incoherence. The most comprehensive of those efforts, the National Council for the Social Studies (National Council for Social Studies, 1994) *Expectations of Excellence* and the National Center for History (National Center for History in the Schools, 1996). *National History Standards* illustrate the scatter plot that exemplifies social studies. The National Center for History *Standards* offers a K-12 sequence of history-based topics (e.g., Living and working together in families and communities, Now and long ago for grades K–4 and Contemporary United States for grades 5–12). The authors of the National Council for the Social Studies standards, by contrast, forswear a particular sequence of course topics in favor of a list of 10 standards (e.g., time, continuity, and change and science, technology, and society).

The variety evident in the national standards documents is echoed in the various state social studies curricula (Grant, 2006). Many feature elements of the *de facto*

curriculum listed in Table 1, but considerable variation exists. For example, depending on which state one is looking at, the seventh-grade curriculum could be world history and geography (California), US history and geography (New York), or Asia, the Middle East, and Africa (Georgia). Civics, which is generally included in state social studies curriculum sequences, may or may not be identified as such. For example, twelfth graders in California take a course titled Principles of American Democracy while the course their peers in New York take is called Participation in Government. By contrast, states like Florida and Georgia list courses of study like Civics, American Government, and American Government/Civics, but they do so as topics to be taught anywhere from grades 9–12.

The conceptual elasticity of a catch-all term like social studies can be viewed as an asset: certainly, few of the social situations we encounter are political or economic or geographical alone, so the capacity to think and act across disciplinary boundaries makes sense. The extant social studies curriculum sequences (which typically include civics), however, offer little in the way of rich, sustained study. The crazy-quilt quality evident in most state social studies curriculum meanders in and around history and civics at the secondary level (with some attention to geography) after a vague expanding-horizons curriculum at the elementary level (Jenness, 1990).

The expansive social studies/civics curriculum scene, then, poses problems for curriculum evaluators in that one is seldom sure what curricular area to bring into focus. For example, the concept of voting could be considered a civics idea, a history idea, or a generic social studies idea. Further complicating the evaluation of curricular efforts, however, is the rise of state-level, standardized testing, which in many instances eclipses the relevance to state-level curriculum efforts.

A Problematic Testing Program

For most of its history, social studies and civics have been untested areas. True, they are often part of general achievement tests and some states, like New York, have a long history of state-level exams in history and geography. But while many states have long-standing programs of literacy and mathematics testing, only recently has this been the case with social studies/civics. Given this relatively recent attention, it should surprise few readers to learn that there are a range of psychometric and interpretive challenges associated with social studies exams (Horn, 2006). These challenges undercut the potential for useful evaluation of social studies and civics curriculum programs.

The testing challenges stem largely from the circumstance that the basic psychometric principles of validity and reliability are so elusive. True, no test of social behavior can be perfectly valid nor can any set of results be

Table 1 Typical sequence of social studies courses K–12 in the US

Grade	Course topic(s)
Kindergarten	Myself and my family
Grade 1	My family and my neighborhood
Grade 2	My local community
Grade 3	Communities around the world
Grade 4	My state
Grade 5	The United States, Canada, and Mexico
Grade 6	Area studies (e.g., Europe, Asia)
Grade 7	Area studies, civics, law-related education
Grade 8	US history
Grade 9	World history, social studies electives
Grade 10	World history
Grade 11	US history
Grade 12	Participation in government, civics, electives

perfectly reliable. Those conditions notwithstanding, it is important to understand how problematic the social studies/civics testing landscape really is.

On the validity side, questions arise primarily about the validity of test items. Although it seems reasonable that propositional knowledge can be measured with objective-style questions, a number of observers argue that the inferential quality of some dimensions of some curricular areas (e.g., history) and the dispositional quality of some others (e.g., civics) cannot. Since few observers would argue that social knowledge ought to be reduced to a parade of easily tested facts, social studies/civics test designers immediately run into validity roadblocks.

Although those validity roadblocks can come in any form (i.e., content, criterion, and consequential), it is construct validity that proves most challenging. Horn (2006) notes that, “in the case of history tests, assessing construct validity determines the extent to which a test accurately and adequately captures how much a student knows or can do related to the specific area of interest” (p. 64). In order to determine the construct validity of an exam, the National Research Council (National Research Council, 1999) proposes four key questions: Are the right things being measured in the right balance? Is the scoring system consistent with the structure of the domains about which inferences or predictions are being made? Are the scores reliable and consistent across the different contexts for which they are used, as well as across different population groups? What are the short-term and long-term consequences of score interpretation and use?

Horn (2006) offers a set of more pointed questions that begin with: how is a competent student of social studies/civics defined and how does the test define what a competent student will demonstrate during the test to show that she or he is indeed competent? These would be daunting questions even in the most coherent field of study. Given the struggles social studies and civics educators have faced in defining their fields, the answers to these key questions remain elusive. As a result, although students’ social studies and civics knowledge can be assessed through standardized measures, few observers have confidence that those assessments measure something more than surface-level knowledge (Burroughs *et al.*, 2005).

A different challenge emerges on the reliability front. There, the issue is one of commensurate assessments. Not only have social studies and civics not been regularly tested subjects, but the assessments given typically have not remained the same long enough to provide reliable data over time or from state to state. On the national scene, students’ knowledge and understanding of history and civics have been tested on the National Assessment of Educational Progress (NAEP) exams on multiple occasions. However, the structure of the exams has changed with each administration, so that it is impossible to track

the progress of students over time. State-level tests vary on two dimensions – within and across states. For example, the New York state high school history and geography exam administered at grades 10 and 11 underwent a dramatic change in the late 1990s through the addition of a document-based question (DBQ) and a series of constructed response questions tied to the DBQ documents. This structural change resulted in changes to the scoring rubrics such that comparisons with students who took the old exam could no longer be made. Even less reliable is any comparison of one state’s test scores with those of another state (Burroughs *et al.*, 2005). In effect, the exams vary to such a degree that achieving any kind of equivalency across state scores is out of the question. As an example, consider the differences between the eighth-grade exams in New York and Wisconsin. First, the New York test focuses only on US history and geography whereas the Wisconsin exam covers a broad range of social studies content. Second, the New York exam offers a range of question formats: multiple-choice questions, a thematic essay, constructed-response questions, and a DBQ. The Wisconsin exam, by contrast, consists entirely of multiple-choice questions. Finally, the eighth-grade New York students take an exam that closely parallels the one they will take in eleventh grade. Eighth graders in Wisconsin, however, take a general battery of social studies questions that are unrelated in focus to the tenth-grade exam. The net result is that observers interested in comparing student performance from state to state will find no points of coherence.

The validity and reliability problems present an interpretive challenge: How are we to understand what students know and understand about social studies and civics when the available instruments are both flawed and incompatible? Yet, vexing as these issues are, they pale when compared with the larger issues associated with assessing students in the areas of social studies and civics.

One concern is that, in some cases, students appear to know and understand different things, even over a relatively short period of time (Grant, 2007; VanSledright *et al.*, 2006). In other words, the knowledge that children demonstrate over time seems to change – ideas that once appeared to be solidly held may be forgotten or may mutate into something unrecognizable (VanSledright, 1995). A second concern revolves around the phenomenon that, when asked different kinds of questions about the same topic, children’s responses suggest that they know different things (Grant, 2007; Nuthall and Alton-Lee, 1995; Rogers and Stevenson, 1988). The idea here is that how one probes children’s ideas can influence what they appear to know. One last concern centers on the notion that what children think they know can be a powerful factor in determining what they need to know (VanSledright and Brophy, 1992). Prior knowledge is potent force; what we know shapes what we learn. But

prior knowledge can be faulty and, unless it is challenged effectively, the inaccurate ideas we bring to bear can override more useful new learning. Findings like these ought to give pause to anyone who claims to know what children know about social studies and civics: Not only are our instruments flawed, but the nature of knowing is a fluid construct at best.

Given these challenges – some general, some specific to social studies/civics – it is not surprising that state-level social studies/civics curriculum have been largely ignored by curriculum evaluators.

Uncertainty at the Classroom Level

As noted above, the current tendency to pair curricular revisions with new, and often more assertive assessments, complicates an evaluation of the effect of those revisions on teachers' classroom practices. Teaching is a complicated act: minimally, teachers plan, enact, and assess lessons and units, but each of these actions is only a label for a much more complex situation. As teachers respond to new curriculum and new testing programs, then, it should surprise few observers to learn that these changes produce no single, coherent, or consistent effect. In brief, curricular and testing changes influence teachers' content, instructional, and assessment decisions differently. As a result, the particular effect of any new curriculum program may be difficult to discern.

New curricular and testing programs seem to have the largest effect on teachers' content decisions; they have the least effect on teachers' classroom assessments. Most surprising is the relatively modest effect that the new curriculum and assessments seem to have on teachers' instructional planning and delivery. The notion that testing (and curriculum) drives teaching may make a convenient sound bite, but it neither makes good educational policy nor does it make sense as a way to capture the essence of good teaching.

Curricular and Testing Influences on Teachers' Content Decisions

In terms of pedagogical effects, it appears that new social studies and/or civics curriculum and tests have the biggest impact on teachers' content decisions. The subject matter changes they report range from small (i.e., adding or eliminating a historical person, group, or event) to large (i.e., adding or eliminating whole eras). As state curriculum and state tests send clearer messages about what to teach rather than how to teach it, this finding should surprise few observers.

Although novice teachers struggle with the content choices they make that will benefit their test-taking students most (Segall, 2006; van Hover, 2006), so too do veteran

teachers (Fickel, 2006; Salinas, 2006; Vogler, 2006). Despite the evidence of curriculum narrowing (McNeil, 2000) associated with the new testing programs, many teachers withstand the temptation to tailor their curriculum to either state curriculum or state exams. These teachers plan units on topics covered on state exams, but they also plan units on topics barely mentioned (Bolgatz, 2006; Grant, 2003, 2006). Some researchers find that many teachers assert content control over the elective courses they teach (Fickel, 2006; Gerwin and Visone, 2006), others have documented the work of teachers who resolve the content dilemmas they face by choosing to teach more ambitiously in classes that enrol students of all levels (Gradwell, 2006, 2003).

Curricular and Testing Influences on Teachers' Assessment Practices

The clear, but modest impact that new social studies and civics curriculum and tests are having on teachers' content decisions is not mirrored in terms of teachers' assessment plans. Teachers are making adjustments in the assessments they give, especially in response to state-based tests, but their general approaches to assessing their students seem largely consistent.

On the whole, few teachers appear to be making wholesale changes in their student assessments (Grant, 2003, 2006). This finding is less remarkable than it might seem on the surface: Social studies and civics teachers typically employ test questions that mirror those of state exams – multiple-choice questions, short-answer tasks, and essays. However, teachers are not designing test-based exams exclusively; instead, they use state-like exams as part of their larger assessment plans (van Hover, 2006).

Although they are not making radical changes in their assessment strategies, teachers are not sanguine about the state tests they administer: They dislike the pressure on their practices and on their students, the ways that scores are used, the kinds of test items employed, and the mixed messages that tests send about what is important. Yet, few teachers dismiss outright the idea of a state-level test. Many protest one or more features of state-test construction or the ways in which scores are interpreted; few protest against the very existence of a test. Many reasons support this conclusion – coercion by school and district administrators, pressure from parents and the public, and uncertainty about what seems like an inevitable trend in American education. If these explanations account for the lack of teacher resistance to the concept of testing, so does one other: Most Americans accept the validity of tests as a means of judging student performance. Like the public at large, teachers seem to accept the premise that tests are useful and that multiple-choice questions and essay prompts represent reasonable ways of judging what students know and understand.

Testing now may be an inextricable part of the US school landscape but, if it is, so too is the idea that tests have limited utility. Tests can provide an efficient screening mechanism, presumably separating those who know from those who do not. At the same time, they are a screen with a wide mesh: most Americans can recite a litany of students whose accomplishments were inaccurately predicted by their standardized test scores. In the end, an odd schizophrenia surfaces – faith in tests coexisting with doubts about their relevance.

Curricular and Testing Influences on Teachers' Instructional Practices

In many ways, the most notable finding in the research literature is the uncertain influence state curriculum and testing programs seem to have on teachers' instructional decisions (Au, 2007; Grant, 2003, 2006). Again, new tests seem to be cited as far more influential than new curricula but, in any event, the effects are far from predictable.

More than social studies and civics curriculum, standardized tests are a factor in teachers' practices: Some teachers are engaged in more test preparation than they would prefer, some are discontinuing activities that they have done in the past, and some are using more pedantic approaches than they think wise (Burroughs *et al.*, 2005; McNeil, 2000; Vogler, 2006). The consternation that a Virginia teacher expresses when he observes that “it's facts—names, dates, places. I used to be a good teacher—now I'm cramming this stuff down their throats” (Smith, 2006) echoes throughout a survey of Mississippi teachers' test-influenced instructional practices (Vogler, 2006).

As fact laden as social studies and civics curriculum and tests are, it would surprise few observers to see teachers take the path of least resistance by centering their teaching around rote recall. There are teachers taking and justifying this approach.

Schools are complicated places, however, and simple cause–effect assumptions rarely surface: within the research that demonstrates considerable test-based influence on teachers' instruction are signs of practices that buck this trend. In fact, many teachers continue to teach in ways they think are most appropriate for students to learn powerful ideas (Bolgatz, 2006; Gradwell, 2006; Grant, 2006). Existing alongside lectures, rote recitation, and other seeming concessions to state-level testing are debates, projects, and class discussions (Fickel, 2006; Smith, 2006). It is not the case that tests are inconsequential; it is the case that there is little evidence demonstrating wholesale instructional change toward test-centric instructional practices (Au, 2007).

Although this finding may cause critics of test-based reforms to cheer and the proponents to wince, both groups would be wise to proceed cautiously. Critics of standardized testing (and the accompanying curriculum)

suggest that teachers would routinely plan and enact substantive and engaging lessons were it not for state-level tests that inhibit this creativity (Ohanian, 1999). As sensible as this presumption is, it fails to explain the fact that researchers described much of instruction in social studies and civics classrooms as pedantic at best (Cusick, 1983; Goodlad, 1984). Test-based reforms may not inspire ambitious teaching, but neither do they destroy it (Gradwell, 2006; Grant, 2003, 2006; Libresco, 2005). Instead, new social studies and civics curriculum and tests are no more likely to induce large-scale instructional change as any other innovation (Tyack and Cuban, 1995). Critics ought not to rejoice, however, for although weak teachers may be no more likely to invoke test-influenced practices than their more ambitious peers, that does not mean that their students are any better served.

The overall effect of new state-level curriculum and testing programs on teachers' instructional decisions, then, seems uncertain. Although research evidence exists to support the conclusion that reforms, especially test-based reforms, are provoking considerable change and in less ambitious directions, equally persuasive evidence points in the opposite direction (Au, 2007).

Evaluations of Social Studies and Civics Education Programs

As noted above, the number, range, and scope of evaluations of social studies and civics curriculum are limited. To date, there have been no large-scale, empirical studies of the various state-level social studies/civics curriculum efforts. There have been studies conducted on a small number of civics-specific curriculum projects sponsored by national foundations, but the only government-developed curriculum project to be evaluated in social studies is the Man: A Course of Study program developed in the 1960s.

Civics education is a more narrowly defined area than social studies, so groups like the Center for Civic Education and the Constitutional Rights Foundation have developed and introduced curriculum projects into schools and then commissioned evaluations of the effect. For example, Brody (1994) studied the We the People curriculum created by the Center for Civic Education and found that the students exhibited greater political tolerance than average American citizens. Similarly, Kahne *et al.* (2006) found that students who participated in the Constitutional Rights Foundation CityWorks curriculum exhibited stronger interest in civic participation than their peers.

Broad-based social studies curriculum proposals rarely have been evaluated. Perhaps the best example is the Man: A Course of Study program funded by the National Science Foundation. Although well-funded and promoted widely, the program soon failed. The common view is that social conservatives killed the effort based on their

perception that it promoted cultural relativity (Dow, 1991). Others, however, cite the major problem as the seeming attempt to create a teacher-proof curriculum, one in which teachers have very little control over what is taught (Cort and Peskowitz, 1977).

Recommendations

Anyone making recommendations for more ambitious social studies and civics education programs faces a daunting challenge: as these areas are left out of the No Child Left Behind testing apparatus, school and state-level leaders have little incentive to elevate these elements of the curriculum. Most states have curriculum and standardized tests for social studies, if not specifically for civics, but because the test scores do not figure as prominently as reading and mathematics scores do, many educators focus their attention elsewhere.

That said, two recommendations are offered for improving the quality of social studies and civics-education programs. The first is to appropriate more time and money to teacher professional development. Smith and Niemi (2001) make a compelling case for the relationship between teachers' instructional practices and student performance on standardized tests – that is, ambitious teaching practices are strongly correlated with high student test scores. It follows, then, that investments in teachers' subject matter and pedagogical expertise may offer large academic returns.

The second recommendation relates to the structure of standardized testing. Such tests may not be terribly authentic, but they fail as an assessment only when they are the only assessment. With no serious challenge to state-level testing on the horizon, the issue of how to mitigate the worst effects of testing looms large. Imagine, then, a situation in which sets of more authentic assessments (e.g., a position paper on a local or state-level issue) were used in conjunction with the extant state exams. Imagine also that students had to present a portfolio of their work on these assessments to local committees of teachers, parents, and community members and that these committees held the power to decide when students were ready to graduate. Making decisions about students' success based only on state-mandated exams disenfranchises the people who have the greatest stake in their schools – students, teachers, parents, and community members. A social studies and civics education that expands both the kinds of assessments used and the authority over those assessments would offer powerful incentives for teachers and students to engage in rich and ambitious teaching and learning.

Conclusion

Although social studies and civics are largely ignored in the national No Child Left Behind legislation, these are

subjects that have generated considerable activity in terms of state-level curriculum and testing. These efforts, however, have not been coherently or consistently evaluated. Most of the recent curriculum work has occurred at the state level; yet, most of the curriculum evaluation has been focused on narrowly defined, foundation-sponsored projects. These evaluations demonstrate some effect, but the challenges of assessing the large state-level curriculum efforts have thwarted any real sense of the impact.

Evaluation of Teacher Quality and Practice

W Robinson, University of Exeter, Exeter, UK

J Campbell, University of Warwick, Coventry, UK

Glossary

Context specificity – In evaluating teachers, this means to give high importance to the particular circumstances (organizational structures, culture, characteristics of students, etc.), within which teachers work.

Credentialism – The use of the level of qualifications held by teachers as a major variable in evaluation.

Multilevel modeling – A set of complex statistical techniques developed to enable researchers to attribute the contribution made to variance in student achievement to factors at different levels in hierarchical structures, such as in schools, leadership, classroom, and in individual student.

Proletarianization – A neologism used to mean the reduction of teaching from full professional status, in which working conditions are controlled by the professional bodies, to a status where conditions are imposed from outside the profession, usually by government.

Value-added – The gain in student attainment from an agreed baseline attributable to the individual teacher or the school, or a combination of both.

In the literature on teacher evaluation, there has been a distinction between teacher quality and teacher practice. Teacher practice is seen as an empirical or descriptive concept referring to all the work of teachers, both inside and outside the classroom. A large number of studies have attempted to delineate the constituent elements of teachers' work, identifying the time given to work overall, and to different activities, such as teaching, planning, assessing, pastoral care, and participating in meetings, within it. These studies have shown that teaching, meaning face-to-face contact with students in classrooms, occupies only about a third of teachers' work, the rest of the time being taken up with planning, marking administration, and other activities. Some studies have attempted to use the data gathered to demonstrate the causes of teacher burn-out, stress, and overconscientiousness, while others have shown that some of teachers' practice is spent on low-level administration and clerical activities that could be carried out by support assistants. Related studies used this

kind of data to analyze teachers' working conditions. (International Labour Office, 1991). Other studies of teacher practice have attempted to describe and analyze the nature of teachers' behavior in classrooms, constructing from observational data different styles of teaching, for example, democratic, child-centered, and progressive, class enquirers, individual monitors.

Teacher quality, by contrast, is a normative concept, concerned with the role of the teacher in enhancing or hindering students' learning, motivation, self-esteem, and aspirations, thereby raising educational attainment. The focus has been almost exclusively upon how the teachers achieve, or fail to achieve, these goals through their interactions with students in classrooms. In these terms, the concept is twofold: what teachers should know (subject knowledge) and what they should be able to do (pedagogical skills). It has therefore, by definition, been concerned with what is thought, by evaluators, to be good practice rather than the routine day-to-day business of teaching, even though there is some overlap between the two concepts.

Although both teacher practice and teacher quality are in principle able to be evaluated, most approaches to teacher evaluation use teacher quality as their organizing focus.

The Purposes of Teacher Evaluation

The last three decades have seen the growth of interest worldwide in formal arrangements for teacher evaluation. Although the forms of such evaluation may vary by education system, and by levels within systems, there are three commonly articulated purposes for it.

The first is that it serves a performativity ideology, whereby public-sector services, including schooling, are required to develop greater accountability to their stakeholders, including parents, students, tax payers, and policy-makers. The defining characteristics of this accountability are primarily economic; teachers are expected to deliver increased productivity, enhanced value for money, and improved educational attainment by their students. This constructs teacher evaluation as part of a wider evaluation of the education system as a whole, attempting to measure and increase the system's efficiency, especially in relation to its ability to provide a skilled workforce. The principal critique of this view is that it has led, under modernizing capitalism, to the proletarianization of teachers and the

intensification of teaching, leading to reduced quality of teaching and learning, as teachers are pressed to cut corners to achieve efficiency (Apple, 1986).

A second purpose is to provide robust evidence upon which teachers' promotion and career development can be equitably supported. Although many education systems retain elements of informal, or even nepotistic, arrangements for promoting teachers, drawing mainly on the inexplicit judgments of inspectors or principals, without observation of teaching, modernizing systems have attempted to develop more apparently rational models; they use formally established arrangements with explicit criteria, appraisal interviews and direct observation of teaching, leading to an official record indicating strengths and weaknesses. This constructs teacher evaluation as a process focused on rewarding or penalizing the individual teacher. In those systems where performance-related pay has been implemented, this aspect has taken increased significance. Where teacher self-evaluation is part of this process, it is designed to improve teachers' skills, expertise, and overall professional development.

However, the rational planning models underlying evaluation for promotion and career development have been criticized as being divorced from the political and economic realities of teacher supply and demand. When economies are booming, the supply of teachers is restricted because of competition from other more lucrative professions, yet schools need to fill teaching positions even if the teachers' quality has been judged to be poor. When economies decline, recruitment of highly qualified graduates into teaching improves. Even in these economies, however, teachers of subjects with high market value, such as mathematics and physics and information technology, are in short supply in education. Thus, the rational models of teacher evaluation, though promising greater equity, have less effectiveness than they imply. Moreover, where there are strong and effective teacher unions, the forms, nature, and consequences of teacher appraisal have to be negotiated with them rather than be imposed on their members. Such negotiations have tended to lead to conservative evaluation procedures that carry few, if any, career consequences.

Third, teacher evaluation serves as an important element in assessing school effectiveness. This purpose envisages the teacher in the classroom as part of the wider school context. Teacher evaluation thereby is constructed as, potentially, a major mechanism for school improvement, assuming it is used formatively.

A main problem with this approach is empirical; it arises from the history of separate development of teacher effectiveness research, school effectiveness research, and the school improvement movement. All three have until recently developed as separate and largely unconnected fields of endeavor, relatively uninfluenced by each other.

There is now a strong movement to link teacher and school effectiveness research, in order to examine the interaction of school and teacher effectiveness variables, and to tease out the contribution made by individual teachers to student learning, drawing on methodological advances in research, such as multilevel modeling. In theory, this would provide a much stronger evidence-based approach to teacher evaluation, although there is further research needed in this respect. In current approaches to school improvement, there remains a strong emphasis on school leadership development as the major mechanism, with the consequence that in almost all countries, the movement has not drawn sufficiently upon the strong evidence base of the educational effectiveness research. This has more than academic interest, since the competing models have substantive consequences for teacher evaluation; the educational effectiveness research identifies the teacher operating at the classroom level as contributing most to student outcome, and therefore prioritizes student learning as the major focus for teacher evaluation.

Forms of Teacher Evaluation

It is common to draw a distinction between formative and summative purposes for evaluation, the former designed to serve an improvement function, the latter a comparative one. However, as can be seen from the preceding paragraph, teacher evaluation arrangements can take both forms; they are complementary rather than oppositional.

A second distinction is between self-evaluation and external evaluation. Self-evaluation is developed within the individual school, often with informal protocols and instruments, and tends to rely on qualitative methodologies and outcomes. Typically, it has drawn upon the teacher's own statement of objectives for the lesson as a basis for observation, or even the teacher's preferred focus for the observation (e.g., quality of the teacher's questioning techniques, or the teacher's use of information and communications technologies) and has concluded with a confidential oral feedback by the observer, who is often a peer rather than a superior. Its principal purpose is the improvement of the quality of the individual teacher's teaching skills, and the evaluation outcomes are confidential to those involved, in order to prevent the process becoming high stakes.

High-stakes evaluation is a term taken to imply that the evaluation will lead to serious and potentially damaging consequences for those teachers whose outcomes are negative. These consequences may include harm to professional reputation, compulsory retraining, reduced promotion prospects, and, in extreme cases, redundancy. The obverse side of the high-stakes coin is sometimes

forgotten; those teachers receiving positive ratings may gain both material and reputational benefits and improved career prospects.

External evaluation is conducted by national, regional, or local inspection agencies operating with official or quasi-official status and formally agreed instruments and protocols. It tends to rely primarily on quantitative methodologies, typically using rating scales of teaching quality, following classroom observation, attainment test data, and estimates of the value added to students' attainment by the quality of teaching. In some systems, the inspection process has statutory force, and the principal purpose is to provide data that can be used for comparing the performance of schools or individual teachers. This makes it high stakes.

A third distinction is between generic and differentiated models of evaluation, with the former being a one-size-fits-all model for evaluation, and the latter more tailored to the different contexts and needs of the individual teachers. The generic model, empirically based on teacher effectiveness research in the USA and UK, has been the most common in practice, for two reasons: it enables the development of fairly simple instruments and carries the appearance of equity, with all teachers being evaluated by identical instruments and procedures; and it has been developed out of the most robust evidence base.

More recently, as teacher evaluation has begun to spread through the whole of schooling, the differentiated model has attracted attention (Campbell *et al.*, 2004). This proposes that five different aspects of teaching may require differences in evaluation. These are the backgrounds of the students taught, the nature of the subject taught, the range of role demands, students' characteristics including age, and the cultural and organizational context within which teaching occurs. For example, the differentiated model proposes that the skills and knowledge required to teach a university doctoral class and a kindergarten class are different. Likewise, in terms of the subject being taught, the methods appropriate for teaching mathematics differ from those needed for teaching drama. There have also been studies suggesting that different teaching methods may be needed with students of different socioeconomic and ethnic backgrounds. It follows that teachers should be evaluated in ways that take account of such differences. A particular interest here has been whether teachers' values and purposes for teaching and learning can be taken into account through a differentiated model. Although there is considerable interest among researchers and scholars in a differentiated model, it has yet to gain widespread adoption in school systems. This is for two reasons: it has the appearance of being too complex to be implemented in practice; and the evidence base is too limited as yet for full development.

Policy Framework

Until recently, teacher evaluation procedures have been derived from specific programs and therefore have been ad hoc, lacking not only a robust evidence-based justification, but also a robust theoretical basis. This remains the state of play in many systems, including the USA, which is thought to be at the forefront of innovation. A wide-ranging analysis of teacher evaluation by a Washington-based think tank, reported that it was still common to use credentialism, that is, the qualifications of teachers, sometimes with a fleeting classroom visit from the principal, as the basis for evaluation in many states (Toch and Rothman, 2008). They point to the need for multiple methods of evaluation, linked to student learning.

However, an important study using data on teacher evaluation procedures in five countries, has attempted to remedy this defect, by proposing the adoption of formal policy linkages between variables found in teacher effectiveness research, teacher evaluation, and school improvement research (Teddle *et al.*, 2003). This demonstrated the relatively loose links between these three in most countries, with the best-established links having been developed in the USA, both because of the longer history of education research there and because researchers in school effectiveness and in school improvement collaborated early, and were able to embed research perspectives into some of the policies driving school reform movements there.

In most other systems, according to Teddle and his colleagues, the links are merely between two elements in the framework, school effectiveness research and teacher evaluation instruments, for example, or are nonexistent. Developing approaches to teacher evaluation which incorporate the key variables from school and teacher effectiveness research, and linking it to teacher and school improvement, could give teacher evaluation the empirical and theoretical justification currently lacking. It might also, through standardizing models and instruments, provide a methodological improvement needed to conduct robust comparative studies.

This latter aim, to develop rigorous and appropriate instruments for teacher evaluation, is nonetheless extremely ambitious. There are myriad instruments and procedures, many of them developed in the 1970s and 1980s as part of state-mandated evaluation systems, and most focusing on observable teacher behavior in classrooms. After criticisms that these instruments tended to focus on teacher behavior rather than student learning, a new generation of instruments is being developed, primarily in the USA, designed to capture the connections between teaching and learning. Although these promise significant improvement and conceptual sophistication over earlier approaches, they remain system specific, and it is an open question whether they could be transferred to other systems, without cultural distortion.

Evaluation and Professional Autonomy

The research shows that the main variation across systems is the extent to which teacher evaluation is controlled by the state and imposed in a standard way upon all teachers or is subject to a degree of professional autonomy at the level of the individual teacher or school. The origin of these differences lies in the political culture of countries. The clearest example in the literature is a study of teacher evaluation in China and Hong Kong after the latter became a Special Administrative Region (SAR) of China in 1997 (Lee *et al.*, 2003). This showed that in Hong Kong SAR each school was expected to design its own staff appraisal system, whereas in the People's Republic of China each teacher was evaluated according to a national model, comprising four domains with agreed maximum scores: morality (10), diligence (5), abilities (45), and student performance (40).

The highest degree of school autonomy in teacher evaluation is reported to operate in the Netherlands, where there is a strong political commitment to decentralization of schooling. Teacher evaluation is usually devolved to the school principals, whose responsibility is to develop and implement an appraisal system according to their own priorities. Although annual appraisal discussions between principals and individual teachers occur in many schools, not all are based on classroom observations. Therefore, there is little standardization in practice and Dutch analysts report that teacher evaluation is mainly formative, is not linked to salary or promotion, and contributes little to systematic teacher improvement. Although there is an inspectorate in the Netherlands, its prime focus is on the quality of schools rather than individual teachers (Reezigt *et al.*, 2003). It is ironic that, alongside this *laissez faire* approach to evaluation, academics in the Netherlands have made one of the most distinguished contributions to research into the measurement of educational effectiveness.

The most-centralized, comprehensive, and penetrative model of teacher evaluation was developed in England through the government's Office for Standards in Education (OFSTED) set up in 1992. The model had statutory force. All publicly maintained schools were inspected every 4 years, on a protocol which required each teacher to be observed teaching up to four lessons by trained inspectors, and each lesson to be graded on a seven-point scale, with the last two grades being considered as unsatisfactory. The evaluation process also involved interviews with students and analysis of students' assignments. The inspectors' grades were made available to the teacher, the governing body of the school, and were entered onto a government-controlled database. The OFSTED methodology gave very strong emphasis to direct observation of teaching and learning in classrooms, with observation schedules that resonate with the teacher effectiveness research in the USA in the 1980s. The report on the quality of teaching

and learning in the school by the inspectors was made public and schools were ranked on league tables, to provide comparative performance data for parents and others to use for school choice. Originally restricted to maintained primary and secondary schools, the inspections have been extended to further-education colleges, teacher-training providers, local authorities, nursery and other preschool settings, residential care homes, private schools, and specialist education agencies.

As the system is high stakes, it was criticized for causing stress and lowered morale among teachers, leading to substantial numbers of teachers, including those rated highly, leaving the profession. However, among most parents the system was widely supported, and as experience with this evaluation system grew, there was a shift to more school self-evaluation, especially for those teachers and schools which the series of external inspections had shown to be consistently good.

At the same time, the quality of teaching in universities was subject to evaluation by a national agency, the Quality Assurance Agency (QAA), with quality ratings being awarded out of a maximum of 24. Although universities whose departments scored highly under this system were pleased to publicize the fact, the system has been criticized as being overly bureaucratic, with the QAA spending undue effort on reading documentation, and interviewing staff, but relatively little time observing teaching. It was also seen as undermining the long-standing tradition in universities, enshrined in their regulations, of academic autonomy. Despite this, the QAA system had greater validity for evaluating university teaching than the common practice of relying on anonymous student evaluations, which have been found to reflect tutors' popularity, personality, and the ease of high-grade achievement, rather than teaching quality.

Professional Standards

The development of formally articulated professional standards has provided teachers and their evaluators with published criteria by which teachers can be assessed. In most modernizing societies, these take the form of hierarchical levels, each level representing improved professionalism. A widespread concern has been that these kinds of standard are technicist reflecting a lack of interest in professional values, judgment, and experimentation, thereby promoting a view of teaching which is, at best, semiprofessional and, at worst, robotic. There is also the argument that such approaches do not reflect the complexity of modernized professions (Scriven, 1988). The dissonance in relation to teacher evaluation implied in technicist models, and others stressing degrees of teacher autonomy, is substantial.

In the USA, it has been argued that historically the focus of competency standards has changed from articulating the moral qualities of teachers, through licensing people to teach, through classroom teaching skills, to, recently, students' learning. An example of the emphasis on learning is reflected in the development of the National Board for Professional Teaching Standards, which in 2009 was basing its standards on five core beliefs, rather than a set of classroom behaviors. These were: commitment to student learning; knowledge of their subjects and how to teach them; responsibility for managing and monitoring student learning; systematic thinking about their practice and learning from experience; and membership of learning communities.

In England, nationally applicable standards were developed by a government agency, the Teacher Training Agency, later the Training Development Agency for Schools (TDA). By 2008, these were designed to assess competency at five career stages: initial training, core standards after the induction year, post-threshold standards, excellent teachers, and advanced skills teachers. Each set of standards comprised three elements: professional attributes; professional knowledge and understanding; and professional skills. The intention was to evaluate and support the progression of teachers holistically through their career, using increasingly complex criteria building on achievement in preceding stages. The emphasis is, like in the USA, upon evidence about teachers' impact on their students' learning and their own professional development, and has the advantage of specifying in considerable detail what a teacher needs to do to obtain a successful evaluation.

The developments in both countries resonate with emerging concerns in Australia, where it has been argued that the practice of evaluating teaching by econometric methods, which make connections between teacher qualifications, or teachers' classroom behavior and student test outcomes is simplistic and methodologically flawed. What is proposed as improvement was an evaluation approach with two elements: building teacher capacity and the articulation of professional standards emphasizing learning (Ingvarson and Rowe, 2008).

A problematic aspect of these new-generation evaluation schemes, despite their significant advances on preceding attempts, is that it remains very difficult, technically, to disaggregate the value added to student learning by individual teachers from that added by school factors (Reynolds *et al.*, 2003).

Toward a Typology of Teacher Evaluation

Overall from this wide range of research, it is possible to generate a tentative threefold typology of teacher evaluation, based primarily on differing conceptions of teaching quality. Although the classifications are not pure, it can be

hypothesized that they reflect historical changes, with the first type being found in systems where there has been only limited change toward modernization, and the last being found in systems that have begun to implement modernized education systems, reflecting the complexity of teaching in highly differentiated contexts.

Teaching as a craft, in which evaluation is carried out by connoisseurship, with inspectors or principals exercising their judgment based on professional experience. The accountability is top down and runs the risk of not being open to challenge. It is exclusively external evaluation.

Teaching as a science, in which evaluation is conducted on the basis of scientifically established teaching behaviors and their contribution to standardized test scores. The accountability is technicist, and uniform, and open to challenge only if the procedures adopted can be shown to be erroneous. It is largely external evaluation.

Teaching as a science of an art, in which evaluation is conducted on the basis of its contribution to student learning and linked to teachers' professional improvement, as judged by the teacher. The accountability is open to individual interpretation, personalized, and seen as focused on the student. It is primarily self-evaluation.

Problematic Issues

Despite the progress made, there remain seven unresolved and problematic issues in teacher evaluation. These are:

1. to improve validity and reliability, especially in high-stakes models, where the evaluations carry career implications, and also to highlight the contested nature of teaching quality;
2. to take account of context specificity through developing further a differentiated model of teacher evaluation without undue complexity;
3. to broaden the range of performance indicators so as to incorporate other educational objectives in addition to narrow cognitive ones, such as character development, problem solving, attitudes to learning, meta-cognitive attributes, and self-esteem;
4. to demonstrate that external evaluation can lead to sustainable teacher improvement;
5. to overcome the democratic deficit implicit in almost all evaluation procedures to incorporate recognition of different educational values and purposes held by individual teachers, as against the dominance of organizational purposes;
6. to gain recognition from policymakers and researchers of the absolute impossibility of devising appropriate evaluation schemes to take into account, and value, the personal power of individual teachers, that is,

“the personal flair, instinct or intuition. . . those qualities often referred to as gifts” (Robinson, 2004); and

7. to resolve the tensions between personal/professional development and high performativity. The dominant drivers for much current teacher evaluation tend to be associated with high performativity and run counter to models of reflective self-evaluation and professional development.

Priorities for Future Research

There are three categories of research where further investigation is particularly required. The three are different in character and substance:

1. Conceptual and philosophical investigations, including the educational values reflected in, or absent from, current models of teacher evaluation, and the basis for a differentiated model.
2. Sociological and political investigations exploring the social functions, intended and unintended, of teacher evaluation on professional practice, and the power relations between government, state, regional bodies, and teachers and their associations in developing, implementing, and revising teacher evaluation procedures (Stronge and Tucker, 2000), and the assumptions made about accountability.
3. Technical investigations, attempting to develop improved reliability and validity in instruments and procedures (including self-evaluation methods), to identify the scope and limitations of evaluation data for judging teachers and for predicting future performance (Goldstein, 2001), and to contribute to the development of comparative studies within and across education systems.

International Evaluations

A Schleicher, OECD, Paris, France

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Parents, students, and those who teach and run education systems seek good information on how well their education systems prepare students for life. Many countries now monitor students' learning in order to provide answers to this question: for example, among 36 countries with comparable data – including the 30 members of the Organization for Economic Cooperation and Development (OECD) – 22 countries undertake student examinations and/or assessments and 17 require schools to be evaluated (either self-evaluations and/or inspections by an external body) at regular intervals. For student-performance measures, student assessments (evaluations without direct consequences for an individual student's further educational career) are used in 17 countries, whereas national examinations are used in ten OECD countries (OECD, 2008).

Comparative international evaluations can extend and enrich the national picture by providing a larger context within which to interpret national performance. They have gained prominence – over recent years – since the benchmarks for public policy in education are no longer solely national goals or standards, but, increasingly, the performance of the most successful education systems internationally. International evaluations can provide countries with information that allows them to identify areas of relative strengths and weaknesses, and monitor the pace of progress of their educational system. They can also stimulate countries to raise aspirations by showing what is possible in education, in terms of the quality, equity, and efficiency of educational services provided in other countries or regions, and they can foster better understanding of how different education systems address similar policy challenges.

Following a brief introduction to the history of international evaluations, this article sets out the potential that international evaluations offer for educational policy and practice as well as some of the methodological challenges they face in providing valid, comparable, and reliable evidence.

History of International Evaluations

While efforts to compare education systems internationally can be traced back to the early nineteenth century (e.g., Jullien, 1817), the discourse on international comparisons of learning outcomes started to emerge during the 1950s

and 1960s. In 1958, an expert group led by William Douglas Wall and including prominent researchers, such as Benjamin Bloom, Robert Thorndike, Arthur Wellesley Forshay, Arnold Anderson, Gaston Mialaret, and Torsten Husen, met under the auspices of United Nations Scientific, Educational, and Cultural Organization (UNESCO)'s International Institute of Education, in Hamburg, to launch a feasibility study to compare student performance internationally. The feasibility study involved 12 000 13-year-olds in 12 countries and its results were published in 1962 (Forshay *et al.*, 1962). The International Association for the Evaluation of Educational Achievement (IEA) emerged out of this collaboration which then conducted a series of international evaluations (see Siniscalco, 2007). The most prominent regular surveys conducted by the IEA are now the 4-yearly Trends in Mathematics and Science Study (TIMSS) and the 5-yearly Progress in Reading Literacy Study (PIRLS).

In 1988, the Education Testing Service in the United States conducted the International Assessment of Educational Progress (IAEP) (Lapointe *et al.*, 1989) and a follow-up study in 1991 (Lapointe *et al.*, 1992).

The latest generation of international evaluations has been developed by the OECD as part of the Program for International Student Assessment (PISA). PISA surveys have been conducted every 3 years, since 2000, in key content areas – such as reading, mathematics, and science – but they also cover cross-curricular domains, such as problem solving, and digital reading, as well as a range of non-cognitive outcomes. The latest PISA survey, in 2006, tested over 400 000 students who represented more than 20 million 15-year-olds in 60 countries that made up close to 90% of the world economy.

Research Frameworks of International Evaluations

The international evaluations of the IEA and OECD contextualize measures of student-learning outcomes with background information collected from students, school principals, and, sometimes, teachers and parents in order to interpret the observed variation in learning outcomes between students, classrooms, schools, and education systems. To facilitate this, they operate with research frameworks that provide data at up to four levels of the education system, namely: (1) the education system as a whole; (2) the educational institutions and providers of educational services; (3) the classrooms or instructional setting; and (4) the learners themselves (see **Table 1**).

Table 1 Research frameworks for international assessments

	<i>Education and learning outputs and outcomes</i>	<i>Policy levers and contexts shaping educational outcomes</i>	<i>Antecedents or constraints that contextualize policy</i>
Individual participants in education and learning	The quality and distribution of individual educational outcomes	Individual attitudes, engagement, and behavior	Background characteristics of individual learners
Instructional settings	The quality of instructional delivery	Curriculum, pedagogy, and learning practices and classroom climate	Student learning conditions and teacher working conditions
Providers of educational services	The output of educational institutions and institutional performance	School environment and organization	Characteristics of service providers and their communities
The educational system as a whole	The overall performance of the educational system	System-wide institutional settings, resource allocations, and policies	The national educational, social, economic, and demographic contexts

The research frameworks of the international evaluations typically address different classes of research issues: (1) A first class relates to simple comparisons of learning outcomes at each of the four levels. (2) A second class provides information on the policy levers or circumstances which shape the outputs and outcomes at each level of the education system. This includes, for example, measures of attitudes and behaviors at the level of students, measures of student learning and teacher working conditions and human and material resources at the level of instructional settings and institutions, and measures of structures and resource allocation policies and practices at the level of the educational system. These policy levers and contexts, typically, have antecedents – factors that define or constrain policy, and which are represented in a third class of research areas. (3) This third class which, for example, provides information on the socioeconomic context of students, schools, or systems, is particularly important in an international comparative context, as it allows to ensure like-with-like comparisons, that is, comparisons of schools that have a similar socioeconomic intake or countries that operate under similar socioeconomic conditions. Each of the cells resulting from cross-classifying the above two dimensions can then be used to address a variety of research issues from a comparative perspective relating, for example, to the quality of educational outcomes and educational provision; to issues of equality of educational outcomes and equity in educational opportunities; or to the adequacy, effectiveness, and efficiency of resource management.

The Potential of International Evaluations for Policy and Practice

The design and conduct of international evaluations was, originally, motivated by research objectives. More recently, governments too have begun to attribute growing importance to international evaluations and have invested

considerable resources into their development and implementation. This interest derives from several considerations:

- By revealing what is possible in education in terms of the performance levels demonstrated in the countries with the highest performance levels, international evaluations can enhance the quality of existing policies but also create a debate about the paradigms and beliefs underlying policies.
- While international evaluations alone cannot identify cause-and-effect relationships among inputs, processes, and educational outcomes, they can shed light on key features in which educational systems show similarities and differences, and make those key features visible for educators, policymakers, and the general public.
- In some countries, international evaluations are also used to set policy targets in terms of measurable goals achieved by other systems, and seek to identify policy levers and establish trajectories as well as delivery chains for reform.
- International evaluations can assist with gauging the pace of educational progress, through assessing to what extent achievement gains observed nationally are in line with the achievement gains observed elsewhere.
- Last, but not the least, international evaluations can support the political economy of educational reform, which is a major issue in education where any payoff to reform almost inevitably accrues to successive governments, if not generations.

These issues are examined more closely in the remainder of this section.

Revealing What Is Possible in Education and Identifying Factors that Contribute to Educational Success

The level of public awareness raised by comparisons has, in some countries, created an important political momentum and engaged educational stakeholders – including

teacher or employer organizations – in support of policy reform (Hopkins, 2008). International evaluations have, sometimes, had a significant impact in countries that found themselves confronted with results that differed from how educational performance was generally perceived. In Germany, for example, equity in learning opportunities across schools had often been taken for granted, as significant efforts were devoted to ensuring that schools are adequately and equitably resourced. The results from the PISA 2000 evaluation, however, revealed large socioeconomic disparities in educational outcomes between schools. Further analyses that separated equity-related issues between those that relate to the socioeconomic heterogeneity within schools and those that relate to socioeconomic segregation through the school system suggested that German students from more privileged social backgrounds are directed into the more prestigious academic schools which yield superior educational outcomes whereas students from less privileged social backgrounds are directed into less prestigious vocational schools which yield poorer educational outcomes, even where their performance on the PISA evaluation was similar. This raised the specter that the German educational system was reinforcing – rather than moderating – socioeconomic background factors. Such results – and the ensuing vivid public debate – inspired a wide range of equity-related reform efforts in Germany, some of which have been transformational in nature. These include giving early-childhood education, that had hitherto been considered largely an aspect of social welfare, an educational orientation and better institutionalizing early-childhood provision; reducing the degree of tracking in some of the German states; establishing national educational standards for schools in a country where regional and local autonomy had long been the overriding paradigm; introducing full-day schooling in a system where half-day schooling had been the norm for centuries; or enhancing the support for disadvantaged students, such as students with a migration background.

For many educators and experts in Germany, the socioeconomic disparities that PISA revealed were unsurprising. However, it was, often, taken for granted and outside the scope of public policy that disadvantaged children would fare less well in school. The fact that PISA revealed that the impact which the socioeconomic background has on students and school performance varied considerably across countries – and that other countries appeared to moderate socioeconomic disparities much more effectively – showed that improvement was possible and provided the momentum for policy change.

Showing that strong educational performance and improvement is possible seems to be one of the most important aspects of international evaluations. Whether in Asia (e.g., Japan, Korea, and Singapore), in Europe (e.g., Finland, and the Netherlands), or in North America (e.g., Canada),

many countries display strong overall performance in the international evaluations conducted by the IEA and OECD and, equally important, some of these countries also show that poor performance in school does not automatically follow from a disadvantaged socioeconomic background. Last, but not the least, some countries show that success can become a consistent and predictable educational outcome: In Finland, for example – the country with the strongest overall results in PISA – the performance variation between schools amounted, in 2006, to only 5% of students' overall performance variation. So, parents can rely on high and consistent performance standards in whatever school they choose to enroll their children. Considerable research has been invested into the features of these educational systems. In some countries, governments have used knowledge provided by PISA as a starting point for a peer review to study policies and practices in countries operating under similar contexts that achieve better results (Döbert *et al.*, 2004). Such peer reviews – each resulting in a set of specific policy recommendations for educational improvement – are also being carried out by the OECD, the results of which have been published so far for Denmark and Scotland (OECD, 2005, 2007).

As a result, the benchmarks for public policy in education are no longer national goals or standards alone, but, increasingly, the performance and achievement gains of the most successful education systems internationally.

Putting National Targets into a Broader Perspective

International evaluations can also play an important role in putting national performance targets into perspective. Often, educators are faced with a dilemma: if, at the national level, the percentage of students achieving good exam scores in school increases, some will claim that the school system has improved; others will claim that standards must have been lowered, and behind the suspicion that better results reflect lowered standards is, often, a belief that overall performance in education cannot be raised. International evaluations allow those perceptions to be related to a wider reference framework, by allowing schools and educational systems to compare themselves with schools and educational systems in other countries. Some countries have actively embraced this perspective and systematically related national performance to international evaluations, for example, by embedding the components of the PISA or TIMSS evaluations into their national evaluations.

Assessing the Pace of Change in Educational Improvement

A third important aspect is that international comparisons provide a frame of reference to assess the pace of change

in educational development. While a national framework allows progress to be assessed in absolute terms, an internationally comparative perspective allows an assessment of whether that progress matches the pace of change observed elsewhere. Indeed, while all educational systems in the OECD area have seen quantitative growth over past decades, international comparisons reveal that the pace of change in educational output has varied markedly.

A Tool for the Political Economy of Reform

International evaluations can also support the political economy of reform. For example, in the 2007 Mexican national survey of parents, 77% of parents interviewed reported that the quality of educational services provided by their children's school was good or very good. However, in OECD's PISA 2006 evaluation, roughly half of the Mexican 15-year-olds who are enrolled in school performed at or below the lowest level of proficiency established by PISA (IFIE-ALDUCIN, 2007; OECD, 2007). There may be many reasons for such a discrepancy between perceived educational quality and performance on international evaluations. For example, in part, this may be due to the fact that the educational services which Mexican children receive are significantly enhanced over the quality of schooling that their parents experienced. However, the point here is that justifying the investment of public resources into areas for which there appears to be no public demand poses difficult challenges for the political economy of reform. One recent response by the Mexican presidential office has been to include a PISA performance target into the new Mexican reform plan. This performance target that is based on the outcome of an international evaluation and that is to be achieved by 2012, will serve to highlight the gap between national performance and international standards, and monitor how educational improvement feeds into closing this gap. It is associated with a reform trajectory and delivery chain of support systems, incentive structures, as well as with improved access to professional development to assist school leaders and teachers in meeting the target. Such reforms draw on the experience of other countries. Brazil has taken a similar route – providing each secondary school with information on the level of progress that is required to perform at the OECD average performance level on PISA, in 2021.

Japan is one of the best-performing educational systems on the various international evaluations. However, PISA revealed that while students tended to do very well on tasks that require reproducing subject-matter content, they did much less well on open-ended constructed tasks requiring them to demonstrate their capacity to extrapolate from what they know and apply their knowledge in novel settings. Conveying that to parents and a general public who are used to certain types of tests, poses a challenge for the

political economy of reform too. One policy response in Japan has been to incorporate PISA-type open-constructed tasks into the national evaluation, with the aim that skills that are considered important become valued in the educational system. Similarly, Korea has recently incorporated advanced PISA-type literacy tasks in its university entrance examinations, in order to enhance excellence in the capacity of its students to access, manage, integrate, and evaluate written material. In both countries, these changes represent transformational change that would have been much harder to imagine without the challenges revealed by PISA.

Design of International Evaluations

The design of international evaluations of learning outcomes needs to fulfill different, and, sometimes, competing demands:

- First, international evaluations need to ensure that their outcomes are valid across cultural, national, and linguistic boundaries and that the target populations from which the samples in the participating countries are drawn, are comparable.
- Second, they need to offer added value to what can be accomplished through national evaluation and analysis.
- Third, while results from international evaluations need to be as comparable as possible, they also need to be country specific so as to adequately capture historical, systemic, and cultural variation among countries.

Some of the design issues involved in meeting and balancing these various demands are laid out in the remainder of this section.

Cross-Country Validity and Comparability in the Evaluation Instruments

International evaluations necessarily are limited in their scope. This is because:

- There is no overarching agreement on what fundamental competencies students in a particular grade or at a particular age should possess.
- Any evaluation can only capture a selection of competencies.
- Various methodological constraints limit the nature of competencies that are currently amenable to large-scale evaluation.

International evaluations have made considerable progress toward assessing knowledge and skills in content areas such as mathematics, reading, science, and problem solving. However, they are still limited in the coverage of important cognitive outcomes – in particular, the

assessment of creative competencies. Similarly, the tension between achieving high degrees of objectivity in the evaluations – which tend to favor multiple-choice tasks that can be scored without human judgment, on the one hand – tends to detract from the evaluation of the higher-order competencies and the production of knowledge – which require open-ended evaluation tasks, on the other. At times, international evaluations have also sacrificed validity gains over efficiency gains by giving undue weight to assessment tasks that can be easily administered and scored, to make the evaluations affordable. Even less progress has been made to assess interpersonal dimensions of competencies which are, often, recognized as of increasing importance, such as the capacity of students to relate well to others, to manage and resolve conflicts, or to respect and appreciate different values, beliefs, or cultures. Last but not least, international evaluations provide only very crude self-reported measures of intrapersonal dimensions of competencies.

Even in established content areas, comparative evaluation poses major challenges. Countries vary widely in their intended, implemented, and achieved curricula. Inevitably, international evaluations need to strike a balance between narrowing the focus to what is common across the different curricula of school systems, on the one hand, and capturing a wide enough range of competencies to reflect the content domains to be assessed adequately, on the other. Leaning toward the former – as has been the tendency for the international evaluations of the IEA – ensures that what is being tested internationally reflects what is being taught nationally. At the same time, such an approach drives assessments toward the lowest common denominator of national curricula – at the expense of important aspects of curricula that are not taught in all countries. Leaning toward the latter – as is the case for the evaluations of the OECD with their focus on the capacity of students not merely to reproduce what they have learned but to extrapolate from what they have learned and apply their knowledge and skills in novel settings – enhances content validity but risks that students are being confronted with evaluation material they may not have been taught.

In whatever way the various international evaluations have struck these balances, they have tried to build them through a carefully designed interactive process between the agencies developing the assessment instruments, various international expert groups working under the auspices of the respective organizations, and national experts charged with the development and implementation of the surveys in their countries. Often, a panel of international experts led – in close consultation with participating countries – the identification of the range of knowledge and skills in the respective assessment domains that were considered to be crucial for student's capacity to fully participate in and contribute to a successful modern

society. A description of the assessment domains – the assessment framework – was then used by participating countries, and other test development professionals, as they contributed assessment materials, which typically involved:

- The development of a working definition for the assessment area and description of the assumptions that underlay that definition.
- An evaluation of how to organize the set of tasks constructed in order to report to policymakers and researchers on performance in each assessment area among 15-year-old students in participating countries.
- The identification of a set of key characteristics to be taken into account when assessment tasks were constructed for international use.
- The operationalization of the set of key characteristics to be used in test construction, with definitions based on existing literature and the experience of other large-scale evaluations.
- The validation of the variables, and assessment of the contribution which each made to the understanding of task difficulty in participating countries.
- The preparation of an interpretative scheme for the results.

Once the assessment framework is established and agreed – which tends to be the most challenging aspect of an international evaluation – assessment items are developed to reflect the intentions of the frameworks and they need to be carefully piloted prior to the establishment of final assessment instruments. To some extent, the question to what extent the tasks in international evaluations are comparable across countries can be answered empirically. Analyses to this end were first undertaken for the IEA TIMSS (Beaton *et al.*, 1996). The authors compared the percentage of correct answers in each country according to the international evaluation, as a whole, with the percentage correct in each country on the items reported by the country to address its curriculum in mathematics. Singapore, for example, had 144 out of 162 items that were said to be covered by the Singaporean curriculum. The percentage of items correct on the whole test and on the items covered in the curriculum was 79 in both cases. Singapore also scored between 79% and 81% correct on the items that other countries considered as covered in their own curricula. These ranged from 76 items in Greece to 162 items in the United States. For most countries, the results were similarly consistent – suggesting that the composition of the tests had no major impact on the relative standing of countries in the international comparisons. Such analyses have also been conducted for PISA, and yielded similar results.

International evaluations pay close attention to reflecting the national, cultural, and linguistic variety among participating countries. OECD's PISA evaluations employ

the most sophisticated and rigorous process to this end. The agency charged with the development of the instruments uses professional test-item-development teams in several different countries. In addition to the items developed by these teams, assessment material is contributed by participating countries that is carefully evaluated and matched against the framework. Furthermore, each item included in the assessment pool is rated by each country: (1) for potential cultural, gender, or other bias; (2) for relevance to the students to be assessed in school and nonschool contexts; and (3) for familiarity and level of interest.

Another important aspect concerns the nature and form of the evaluation – as reflected in the task and item types. While, as noted before, multiple-choice tasks are the most cost-effective way to assess knowledge and skills, and have, therefore, dominated earlier international evaluations, they have important limitations in assessing more complex skills – particularly, ones that require students not just to recall but to produce knowledge. Moreover, since the nature of assessment tasks – and, in particular, student familiarity with multiple-choice tasks – varies considerably across countries, heavy reliance on any single item type, such as multiple-choice tasks, can be an important source of response bias. The PISA evaluations have tried to address this through employing a broad range of assessment tasks, with about 40% of the questions requiring students to construct their own responses. These tasks require students to either provide a brief answer (short-response questions) or to construct a longer response (open-constructed-response questions) – allowing for the possibility of divergent individual responses and an assessment of students' justification of their viewpoints. Partial credit can be given for partly correct or less complex answers, with questions assessed by trained specialists using detailed scoring guides which gave direction on the codes to assign to various responses. Open-ended assessment tasks, however, raise other challenges – in particular, the need to ensure inter-rater reliability in the results. For PISA, subsamples of the assessment booklets are coded independently by four coders and examined by the international contractor. In order to examine the consistency of this coding process in more detail within each country and to estimate the magnitude of the variance components associated with the use of coders, an intercoder reliability study on the sub-sample of assessment booklets is being applied and homogeneity analysis is applied to the national sets of multiple coding. Similarly – at the between-country level – an international coding review is implemented to check on the consistency of application of response coding standards across all participating countries, with the objective to estimate potential bias (either leniency or harshness) in the coding standards applied in participating countries.

In order to cover the intended broad range of content while meeting the limits of individual assessment time, assessments, such as PISA or TIMSS, are now using multiple forms which are administered to students in a matrix design, with sufficient overlap between the forms to relate their results psychometrically.

Ensuring that international evaluations are comparable across countries is one thing, but the more important challenges actually relate to their external validity – which involves verifying that the assessments measure what they set out to measure. An important question is whether the knowledge and skills that are being assessed are predictive for the future success of students. In the case of PISA, the Canadian Youth in Transition Survey (YITS) – a longitudinal survey which investigates patterns of and influences on major educational, training, and work transitions in young people's lives – provided a way to examine this empirically. In 2000, 29 330 15-year-old students in Canada participated both in YITS and PISA. Four years later, the educational outcomes of the same students – then aged 19 – were assessed and the association of these outcomes with PISA reading performance at age 15 was investigated. A strong relationship between performance at age 15 and subsequent success in access to higher education and successful labor-market transitions, even after accounting for the socioeconomic background (Knighton and Bussière, 2006), was revealed.

Comparability of the Target Populations

Even if the assessment instruments are valid and reliable, meaningful comparisons can only be made if the target populations being assessed are also comparable. International evaluations, therefore, need to use great care when: (1) defining comparable target populations; (2) ensuring that they are exhaustively covered with minimal and well-defined population exclusions; and (3) ensuring that the sampled students do participate in the evaluation.

With regard to defining target populations, important tradeoffs need to be made between international comparability, on the one hand, and relating the target populations to national institutional structures, on the other. Differences between countries in the nature and extent of pre-primary education and care, the age of entry to formal schooling, and the institutional structure of educational systems, do not allow the establishment of internationally comparable grade levels of schooling. Consequently, international comparisons of educational performance, typically, define their populations with reference to a target age group. International evaluations of the IEA have defined these target groups on the basis of the grade level that provides maximum coverage of a particular age cohort (such as the grade in which most 13-year-olds are enrolled). This gives an advantage that a grade level can be easily interpreted within the national institutional structure and provides a cost-effective way toward assessment – with

minimal disruption of the school day when administering the assessment to students of the same grade. However, a disadvantage is that slight variations in the age distribution of students across grade levels, often, lead to the selection of different target grades in different countries – or between educational systems within countries – raising serious questions about the comparability of results across – and, at times, within – countries. In addition – because not all students of the desired age are usually represented in grade-based samples – there may be a more serious potential bias in the results if the unrepresented students are typically enrolled in the next higher grade in some countries and the next lower grade in others. This excludes students with potentially higher levels of performance in the former countries and students with potentially lower levels of performance in the latter. To address these problems, the evaluations of the OECD use an age-based definition for their target populations, that is, a definition that is not tied to the institutional structures of national educational systems. For example, PISA assesses students who were in the age range of 15 years and 3 (complete) months and 16 years and 2 (complete) months at the beginning of the assessment period and who were enrolled in an educational institution, irrespective of the grade levels or type of institution in which they were enrolled, and also irrespective of whether they were in full-time or part-time education. The disadvantage of this age-based approach is that selecting students of an age cohort from different grades is more costly and disruptive, and it is more difficult to relate the results of an age cohort to the classrooms from which these students were drawn.

The accuracy of any survey results also depends on the quality of the information on which national samples are based as well as on the sampling procedures. For the latest international evaluations, advanced quality standards, procedures, instruments, and verification mechanisms have been developed that ensure that national samples yielded comparable data and that the results could be compared with confidence.

Last, but not the least, even the best international samples will only translate into comparable results if the sampled schools are willing to take part in the evaluation. At times, schools do not perceive to receive sufficient benefit from an evaluation that only yields national or subnational outcomes. Some countries have started to link international evaluations more closely to participating schools – either through providing them with school-level outcomes from the evaluation or the related questionnaires, or through the provision of better information on the objectives and nature of these evaluations. Incentives or feedback that have been deployed include: (1) better explanation of the context and usefulness of international evaluations at the start of the process to help engage teachers and schools; (2) preparing a briefing pack to prepare teachers, schools, pupils, and parents to overcome

initial anxieties of pupils and stimulate better communication within schools; (3) setting up an international buddies scheme with schools doing the international evaluations in other countries – in particular, for sharing ideas for using the results to improve; (4) giving out student certificates on the day; and (5) preparing electronic versions of feedback.

Comparability in Survey Implementation

Last but not least, well-designed international evaluations require to be well implemented to yield reliable results. The process begins with ensuring consistent quality and linguistic equivalence of the assessment instruments across countries. Precise translation and adaptation guidelines are supplied, also including instructions for the selection and training of translators. For each country, the translation and format of the assessment instruments (including test materials, marking guides, questionnaires, and manuals) are verified by expert translators appointed by an agency charged with the development of the assessment instruments (whose mother tongue was the language of instruction in the country concerned and who were knowledgeable about education systems) prior to their use.

The evaluations then need to be implemented through standardized procedures. Comprehensive manuals, typically, explain the implementation of the survey, including precise instructions for the work of school coordinators and scripts for test administrators for use during the assessment sessions. In the case of PISA, specially designated quality monitors visited all national centers to review data-collection procedures and school quality. Monitors from the international agency visited a sample of 15 schools from each participating country or region during the assessment. Marking procedures are designed to ensure consistent and accurate application of the internationally agreed marking guides.

Conclusions

In a globalized world, the benchmarks for public policy in education are no longer national goals or standards alone, but, increasingly, are the performance of the most successful educational systems internationally. International evaluations can be powerful instruments for educational research, policy, and practice by allowing educational systems to look at themselves in the light of intended, implemented, and achieved policies elsewhere. They can show what is possible in education – in terms of quality, equity, and efficiency in educational services – and they can foster better understanding of how different educational systems address similar problems. Most importantly – by providing an opportunity for policymakers and practitioners to look beyond the experiences evident in their own systems

and, thus, to reflect on some of the paradigms and beliefs underlying these – they hold out the promise to facilitate educational improvement. As this article shows, designing and implementing valid and reliable international evaluations pose major challenges – including defining the criteria for success in ways that are both comparable across countries while remaining meaningful at national levels, establishing comparable target populations, and carrying out the surveys under strictly standardized conditions. However, more recently, international evaluations have made significant strides toward this end.

Glossary

Achievement levels, scale scores – Ideally, scale scores measure what students know and can do, achievement levels (often presented as descriptive terms, such as basic, proficient, or by level) are performance standards showing what students should know and be able to do.

National Assessment Governing Board (NAGB) – An independent bipartisan board appointed by the secretary of education, sets policy for NAEP and is responsible for developing the framework and test specifications.

National Assessment of Educational Progress (NAEP) – Also known as the nation's report card, it is a large nationally representative assessment of what America's students know and can do.

National Center for Education Statistics (NCES) – A federal statistical agency, located in the Institute for Education Sciences, the research arm of the US Department of Education.

PISA, the Programme for International Student Assessment – An assessment of the literacy of 15-year-olds administered by the Organization for Economic Cooperation and Development.

TIMSS, Trends in International Math and Science Study – An international assessment of science and math skills of fourth and eighth graders administered by the International Association for the Evaluation of Educational Achievement.

National testing programs of students are fairly common around the world. They can have different purposes, ranging from deciding which students go on to which secondary or postsecondary school, to being a core component of accountability systems, designed to find out which schools are doing a better job than others, to acting as a more general indicator of how well a province, a region, or a country is doing over time.

In the United States, the National Assessment of Educational Progress (NAEP), also known as the nation's report card, is a large nationally representative assessment of what America's students know and can do. NAEP is administered by the National Center for Education

Statistics (NCES), a federal statistical agency, located in the Institute for Education Sciences, the research arm of the US Department of Education.

Tests differ in the consequences they have for students, schools, or governments. For students, in particular, tests can vary widely in their impact. Some tests have very high stakes – for example, a growing number of states are putting into place high school exit tests that a student must pass in order to get a diploma. In contrast, for students, NAEP is a no-stakes test – there are no rewards or punishments for performance – indeed, there are no individual student-level scores.

For individual American states, the stakes are somewhat higher – when NAEP releases state results, there is an inevitable series of horse-race stories about who is winning and who is losing. While there are no direct consequences for doing well or badly on NAEP, governors and heads of state education departments can be embarrassed by declining scores or poor performance.

NAEP has also become a highly visible indicator of the nation's progress toward meeting the 100% proficiency goal set by the national No Child Left Behind (NCLB) Act for all students by 2014.

The Commissioner of Education Statistics, who heads the NCES, is responsible for carrying out NAEP. However, the National Assessment Governing Board (NAGB), an independent bipartisan board appointed by the secretary of education, sets policy for NAEP and is responsible for developing the framework and test specifications. By law, NAGB is designed to balance various education interests and its members must include governors, state legislators, local and state school officials, researchers, educators, business representatives, and members of the general public. There is an inevitable tension between NAGB and NCES, with NAGB given the major policy role, but NCES and its commissioner charged with maintaining the technical quality and validity of NAEP. Moreover, NCES contracts for and supervises operations that turn policy guidance into actual assessments. In addition, NCES is ultimately responsible for the fiscal integrity of NAEP and making sure that the sometimes overly ambitious goals of NAGB can be met within existing resources.

There are two main strands of NAEP: long-term trends (LTT) and main NAEP (which itself has national, state, and urban school district components).

Long-Term Trend NAEP

The NAEP LTT assessments have been administered nationally every 4 years (more or less) since the early 1970s. While LTT has assessed other subject areas, it now focuses on student performance in mathematics and reading at ages 9, 13, and 17. (An LTT science study was conducted from 1969 through 1999, but the framework was viewed as too outdated to continue. LTT writing was also administered six times between 1984 and 1996, but was dropped for technical reasons.) NAEP first assessed reading in 1971 and mathematics in 1973. The next LTT assessment results (for 2008) will be released in 2009.

The main advantage of LTT is the length of the time series and the use of the same framework since its inception. Preserving trend is the very reason for LTT and keeping the framework in place is the result of a specific policy decision to present a consistent long-term view of the progress of American students in two key subjects. As we note below, balancing the desire to update frameworks and the need to preserve trend data are perennial issues in main NAEP.

Both NAEP's and LTT give us a picture of the performance of American students and suggest some of the challenges of doing low-stakes assessments. This is evident in **Figures 1** and **2**, which are examples of recent LTT findings. In LTT (and in many other NAEP tests), gains in performance are much more noticeable in younger cohorts (defined by age or by grade) and they are more noticeable in math than in reading. For example,

in reading, since LTT was first administered in 1971, reading scores have increased significantly among 9- and 13-year-old students (with a greater gain among the youngest students) and stayed flat among 17-year-olds. These patterns raise the issue of motivation: since NAEP is a low-stakes test, as students get older, they have been found to be less engaged with NAEP tests, which may account for poorer performance in older students. NCES has conducted several studies about how to increase student motivation (e.g., through payments for correct answers), but how well these methods could scale to a full assessment is a serious question.

For math, as in reading, the size of the gains among younger students is larger than the gains among older ones. For many, the increase in math scores has been linked to improved math instruction but also to more time on task. The fact that math scores have moved up faster than reading is also often interpreted as showing that teaching math is easier than teaching reading, in part because math is a more school-based skill while reading draws on a wide range of cognitive skills that young children need to absorb in a wider range of venues than just the classroom.

These patterns, which are reinforced by the main NAEP results, have become part and parcel of policy debates around the US curriculum and the effects of NCLB. Both critics and supporters of NCLB have looked at the same trend lines and have found evidence that NCLB is working or that it is not. This highlights one of the fundamental problems with NAEP – it is best viewed

Figure 1 An example of NAEP long-term trends (LTT) in average reading-scale scores for students ages 9, 13, and 17: 1971–2004.

Figure 2 An example of NAEP LTT in average mathematics-scale scores for students ages 9, 13, and 17: 1973–2004.

as a benchmarking exercise and it is really too blunt an instrument to answer many important policy questions (a point returned to below).

Scale scores versus achievement levels

Both main NAEP and LTT NAEP report scale scores and achievement levels.

Scale-score results are reported either on a 0–500- or a 0–300-point scale, overall and for each of the subscales that may be included in an assessment. (The 0–500 scale is usually used for cross-grade assessments, such as reading and math in grades 4, 8, and 12 in main NAEP and at ages 9, 13, and 17 in LTT, while the 0–300 scale is used for within-grade assessments in main NAEP.) In the most recent reading assessment, these subscales were defined as contexts: reading for literary experience and reading for information. For mathematics, there were five content areas, including number properties and operations, measurement, geometry, data analysis and probability, and algebra. The balance of items across these contexts or content areas differs from grade to grade, as determined by the assessment framework.

As NAEP scales are developed independently for each subject and for each content area within a subject, the scores should not be compared across subjects or across content areas within the same subject. This is a constant problem when NAEP scores are released because people see similar numbers and want to make the kind of comparisons just presented above (i.e., where it is stated that the gains in math were greater than the gains in reading – to

make sense of the comparisons, these scores should be turned into standardized effect sizes. However, only on rare occasions does NAEP report these standardized difference measures). (While effect sizes would improve one's ability to make comparisons across content areas, it would not eliminate incompatibilities across content areas that have items of differing difficulty and depth.)

To help the public and policymakers have a better understanding of the meaning of main NAEP results, the NAGB sets specific achievement levels for each subject area and grade. While scale scores ideally measure what students know and can do, achievement levels are performance standards showing what students should know and be able to do.

In LTT, for each of the subject-area scales, performance levels are set at 50-point increments from 150 through 350. The five performance levels – 150, 200, 250, 300, and 350 – are described in terms of the knowledge and skills likely to be demonstrated by students who reached each level. As an example, these are the achievement levels for math:

- Level 150: Simple arithmetic facts.
- Level 200: Beginning skills and understandings.
- Level 250: Numerical operations and beginning problem solving.
- Level 300: Moderately complex procedures and reasoning.
- Level 350: Multistep problem solving and algebra.

In main NAEP, results are reported as percentages of students performing at or above the basic and proficient

levels and at the advanced level. Below are the core ideas that define main NAEP's achievement levels:

- Basic denotes partial mastery of prerequisite knowledge and skills that are fundamental for proficient work at a given grade.
- Proficient represents solid academic performance. Students reaching this level have demonstrated competency over challenging subject matter.
- Advanced represents superior performance.

The simple user-friendly names and description of achievement levels in main NAEP make them far more compelling than the levels as defined by LTT (or by the numbered levels used by the best-known international assessments – the Programme for International Student Assessment (PISA) or the Trends in International Math and Science Study (TIMSS)). However, there has been controversy over these achievement levels. The current advisory that appears in NAEP reports reads: “As provided by law, NCES, upon review of congressionally mandated evaluations of NAEP, has determined that achievement levels are to be used on a trial basis and should be interpreted with caution. The NAEP achievement levels have been widely used by national and state officials.” As with many aspects of the high-visibility NAEP program, technical cautions are often ignored in the face of pressing needs of policymakers and the public for usable and understandable information.

Main NAEP

NAEP has been testing a variety (some would say too wide a variety) of subjects with differing degrees of frequency and consistency since 1969. Some subjects have come and gone (career/occupational development in 1973; an index of basic skills in 1974); some have run into trouble (foreign language); others appear with an irregular frequency, depending on money as well as political interest and pressure (civics, geography, economics, and the arts). The core subjects of NAEP, not surprisingly, are reading and math, a focus reinforced by the provisions of the NCLB, but writing and science are, if not by statute, then by practice, at the core of NAEP's testing program.

With the passage of NCLB, NAEP's budget increased dramatically and is now in the vicinity of US\$100 million per year. This budget growth allowed the growth of NAEP, including an expansion in the range of subjects assessed, the creation of state representative samples for several of NAEP's assessments, and the assessment of performance in a number of large urban districts. We describe state NAEP and the trial urban district assessments (TUDA) in more detail below, but first we need to describe some of the characteristics of how NAEP is administered.

First, while NAEP's LTT is based on age-defined samples, main NAEP results are based on representative samples of students at grades 4, 8, and/or 12. NAEP collects data on subject-matter achievement, instructional experiences, and school environment for populations of students (e.g., all fourth-graders) and by defined policy-relevant subgroups (most notably, gender, race/ethnicity, and income). (Income is measured by participation in the federal free and reduced-price lunch program. This has been an increasingly weak indicator of income, and NCES has undertaken studies trying to identify better measures.)

NAEP does not provide scores for individual students or schools. This is fundamental to the design of NAEP, which, because of its large number of test questions, uses matrix sampling and a focused balanced incomplete block (BIB) or partially balanced incomplete block (pBIB) design in which blocks or groups of cognitive items are assigned to a set of student booklets.

Given this design, NAEP can sample enough students to obtain precise results for each test question within an average test time of about an hour and a half per student. As a result, while the full framework is covered, there are no individual student-level test scores. This design was a major measurement technical breakthrough in the early days of NAEP and allowed the testing of a wide range of skills without forcing students to sit through hours upon hours of testing. However, the cost is the absence of individual-level scores. (This also solved a political objection: since no individual student scores were calculated, privacy concerns were sidestepped, removing one of the bones of contention that were raised (and continue to be raised) about NAEP.) Without individual scores, NAEP does not allow for longitudinal analysis, which is increasingly the way in which researchers prefer to measure progress. NAEP shares this research design (and its shortcomings) with the major international assessments, such as PISA and TIMSS.

Despite this limit (and it is a severe one), the most powerful aspect of NAEP is that it is the only nationwide test administered uniformly to all participating students using the same test items and procedures. As a result, NAEP serves as a common yardstick against which state assessments can be compared. This allows NAEP to serve as a comparative tool to gauge the rigor of individual state-assessment standards. This role was central to the NCES report *Mapping 2005 State Proficiency Standards onto the NAEP Scale* (National Center for Education Statistics, 2007).

Under the NCLB, states are required to report the percentages of students achieving proficiency in reading and mathematics for grades 3 through 8 (and at least once during grades 10 through 12). But they do so using their own assessment instruments. For each subject and grade combination, the percentages of students reaching proficiency (or any other achievement level) vary widely

across states. However, because NAEP is a uniform test, at grades 4 and 8, state percentages can be compared to the percentages of students achieving proficiency on NAEP, providing a gauge of the rigor of state standards.

In the 2007 report, large discrepancies in state versus NAEP proficiency standards were reported for both grades 4 and 8 in math and reading. For each of the four subject and grade combinations, the NAEP score equivalents to the states' proficiency standards varied widely, spanning a range of 60–80 NAEP score points (roughly two standard deviations in the NAEP test). But far more importantly, most of the NAEP score equivalents fall below the cut-point corresponding to the NAEP proficient standard, and many fall below the cut-point corresponding to the NAEP basic standard. **Figure 3** shows how NAEP can be used as a yardstick to identify differences in state proficiency standards, using eighth-grade reading as an example.

State NAEP

State NAEP is based on large state-wide representative samples of students taking NAEP. This allows state scores to be calculated and changes in state performance measured over time (remember, the P in NAEP stands for progress). The assessments given in the states are the same as those

given nationally, allowing states to compare themselves to the nation and to one another.

Until 1990, NAEP reported only the academic achievement of the nation as a whole and student groups within the nation. In 1988, Congress authorized a voluntary trial state assessment, in which state-representative samples of students were selected from each state or jurisdiction that agreed to participate in state NAEP. These trial state assessments were conducted in 1990, 1992, and 1994, after which time the state component was no longer labeled a trial. Between 1990 and 2002, state NAEP was a mix of testing at grades 4 and 8 in reading, math, science, and writing. For example, in 1990, only math at grade 8 was tested. In 1992, 1994, and 1996, math was assessed in volunteer states at grades 4 and 8, but math was not assessed at all in 1994 and 2002. State assessments in science were conducted at grades 4 and 8 in 1996 and 2000.

In short, the state testing program was erratic. The NCLB regularized state assessments. Beginning in 2003 and continuing through the present, states that accept federal title 1 monies must participate in statewide assessments in reading and math in grades 4 and 8 every other year. (Title 1 of the Elementary Secondary Education Act of 1965, as amended most recently by the NCLB, is the primary vehicle by which the US federal government

Figure 3 Mapping state proficiency standards using NAEP as a common yardstick. Grade 8 reading. From Lee, J., Grigg, W., and Dion, G. (2007). *The Nation's Report Card: Mathematics 2007 (NCES 2007-494)*. Washington, DC: National Center for Education Statistics, Institute of Education Sciences, US Department of Education. <http://nces.ed.gov/nationsreportcard/pdf/main2007/2007494.pdf>.

supports local schools. The program provides financial assistance to school districts and schools with high numbers or high percentages of poor children. Title 1 represents about 1/3 of total federal expenditures on elementary and secondary education, an annual budget allocation of well over US\$10 billion.) In addition to these mandatory state tests, since passing the NCLB, NAEP has offered (and paid for) state assessments in science at fourth and eighth grades in 2005 and writing at grade 8 in 2007.

As noted, since 1990, state NAEP has assessed students at grades 4 and 8, but not at grade 12. However, a pilot program has been funded by the US Congress, so that 11 states will participate at the twelfth-grade level in 2009 and get reading and math scores.

Even though NAEP produces state scores, like all NAEP assessments, it does not produce individual scores for the students or schools assessed.

NAEP TUDA program

Just as in the 1990s when a trial state testing program was launched, NAEP now has a TUDA program that is designed to explore the use of NAEP to assess the performance of public school students at the district level.

TUDA began with five urban districts in 2002 – Atlanta, Chicago, Houston, Los Angeles, and New York City – and has since added Austin, Boston, Charlotte-Mecklenburg, Cleveland, and San Diego. The District of Columbia is included in many TUDA reports.

Since the TUDA assessment is administered as an expanded sample of students being tested for state NAEP, the subjects tested in the urban districts coincide with state assessments. In 2002, six urban districts participated in reading and writing at grades 4 and 8. In 2003, nine districts participated in reading and math. In 2005 and 2007, ten districts reported math and reading scores. In addition, the District of Columbia, which appears in state NAEP also appears in these TUDA assessments.

In 2005, district science scores were released and in 2007, district grade 8 writing scores. (The District of Columbia is too small to support science and writing oversamples and was not included in those TUDA reports.) TUDA has been used to track changes in performance in areas of the country where many of the challenges of education are the most severe. In 2009, Congress authorized sufficient funds to add several more urban districts.

NAEP special studies

In addition to the assessments, NAEP coordinates a number of special educational studies. Perhaps the most important is the NAEP High School Transcript Study (HSTS) which goes beyond just scores, gathering information about school practices and how these practices might affect performance outcomes (Shettle *et al.*, 2007). As the

HSTS was conducted in 1982, 1987, 1990, 1992, 1994, 1998, 2000, and 2005, NAEP HSTS provides a wealth of information about changing course-taking patterns over time. The 2005 report presented data from transcripts collected from a nationally representative sample of 26 000 high school graduates.

The report presented information about the types of courses 2005 graduates took during high school, how many credits they earned, and the grades they received. As the 2005 results were the most recent in a long line of such transcript studies, the results were compared over time and differences among graduates by race/ethnicity, gender, and parent education were examined.

Among the most notable findings, the report showed that students were taking more academic courses and more rigorous ones (at least judging by their titles) than ever before. As an example, the study found that 2005 graduates took about 360 additional hours of instruction during their high school careers than their 1990 counterparts. Increased percentages of White, Black, Hispanic, and Asian/Pacific Islander graduates completed at least a mid-level curriculum in 2005 compared with 1990. However, differences by race/ethnicity persisted: in 2005, both Black and Hispanic graduates were less likely than White graduates to have completed calculus or advanced science courses.

Conclusions

The US NAEP serves as the nation's report card. Since the passage of the NCLB, NAEP has become a central tool in measuring educational progress in the United States as a whole, in individual states, and in a growing number of large urban districts. Moreover, while NCLB mandates testing in reading and math at grades 4 and 8 at the state and national levels, state-level testing in science and writing has been and will likely continue to be high priority. NAEP also tests a range of other academic subjects on a less regular basis, including civics, history, and economics. NAEP unsuccessfully tried to assess foreign languages in 2004, and in 2008, NAEP assessed the arts, although a previous arts assessment in 1997 was very expensive. The budget for NAEP increased more than threefold with the passage of NCLB and, as it has established itself as the nation's report card, Congress has appropriated further funds to support its testing program.

While on many levels this signals a successful national assessment program, there are challenges facing NAEP.

Any large-scale assessment is shaped by its framework, and every framework has to be both forward-looking (what skills should students have tomorrow) and also reflective of what skills they need today. This is complicated by the fact that, as noted, the P in NAEP stands for progress – and measuring progress implies maintaining

the framework and the skills tested over time. However, at some point, today's skills become yesterday's, and the framework and the assessment need to change. The challenge is to make these changes while somehow continuing to report on trends. While LTT is specifically designed for this purpose, and has, thus, kept changes to its framework to a minimum, it has been eclipsed by the far more visible and frequent main NAEP, which is not as committed to keeping a stable framework. Introducing new frameworks, while making the assessment more relevant, has costs.

As an example of how jarring the effects of a new framework can be, consider the 2005 report on 12th-grade reading and math. While that year's reading test has a depth of trend analysis, the math report notes that "Because of changes in assessment content and administration, the results for 2005 could not be directly compared to those from previous years" (see Grigg *et al.*, 2007). In turn, the report released relatively little information, such as presented in **Figure 4** below.

NAGB made the policy decision that the old 12th-grade math framework was too far out of line with modern math curricula and skills and that breaking trend was a cost worth absorbing. Breaking trend for the mandated NCLB testing areas (reading and math, grades 4 and 8) was considered by NAGB, but the political costs of doing that were far higher than for the 12th-grade (nonNCLB mandated) assessment. In turn, NCES has spent considerable time and resources trying to work out mechanisms to introduce changes into these assessments while still preserving trend.

While pedagogical changes continually challenge NAEP frameworks, technological challenges also loom. Despite some advances, especially in the upcoming NAEP science assessment, which has a large interactive computer-based component, NAEP is still a paper-and-pencil test. Moving NAEP to computer-based assessments poses a new set of challenges.

Some of the challenges are logistical: the computer infrastructure of the 100 000 or so schools in the US varies

widely. NCES discovered that assessing computer capacity in schools was like an archeological dig. Not only was the world divided into Apples versus PCs, but in the PC world there were layers upon layers of Windows operating systems (although NCES did not find any DOS-based machines, there were machines running Windows 95, 98, 2000, VISTA, and all the permutations of each). There were also differences in the support staff available. In one school the NAEP team visited to assess the possibility of computerized assessment, the IT person excused himself at 2:30, promising to return at 4:30 – because he had to drive a school bus to take students home!

There is also a question of how moving to a computer-based assessment might affect performance. If some groups are more familiar with a technology than other groups, then construct-irrelevant variance can be introduced – that is, some set of skills extraneous to the purpose of the assessment might bias results.

Even more important is the changing nature of assessments themselves. Recall NAEP is based on matrix sampling and a BIB design. This design allows a whole framework to be tested, while not forcing any student to sit through the hours-long exam that would be required to accurately assess their skills across the whole framework. But this also means that there are no individual-level scores.

For many subjects, especially math, there are more elegant solutions. In the last few years, computer-based adaptive testing has made great strides and NAEP should be moving toward that approach to better assess student skills. In addition, longitudinal data on student performance has become the new gold standard. But NAEP is a cross-sectional measurement without individual student scores. This means that NAEP is not amenable to some of the most interesting work using growth models to measure progress and to identify what works and for whom.

Another looming issue is how NAEP will fit into an increasingly global environment. The concrete manifestation of this is the role of NAEP versus the three big international assessments: the Program for International Reading Literacy (PIRLS), TIMSS, and the PISA. PIRLS is a fourth-grade literacy assessment and TIMSS tests students in grades 4 and 8 in science and math. While on different cycles than NAEP, both are testing in the same grades and there is considerable overlap in their purposes, frameworks, and actual items. The bigger question is the growing importance of PISA, an assessment administered through the Organization for Economic Cooperation and Development (OECD), which includes all 30 OECD countries plus about an equal number of nonOECD jurisdictions.

PISA is a yield study of reading, math, and science competencies. The students tested and the basic ideas motivating PISA do not align as closely with NAEP as do TIMSS and PIRLS. Indeed, while NAEP is designed

Figure 4 An example of how changing a NAEP framework resulted in limited information. 2005 12th-grade math. From US Department of Education, Institute of Education Services, National Center for Education Statistics, National Assessment of Educational Progress (NAEP), and 2005 Mathematics Assessment.

to reflect (more rather than less) the curricula goals of American schools, PISA is much less concerned with assessing school-based knowledge. Rather, as a yield study, PISA is designed to measure the cumulative product of all educational activities in a given country in developing student competencies to apply knowledge to real-world situations.

As state governors now want to compare their students to those in Korea or Germany rather than Kansas or Georgia, PISA has gained national attention. Indeed, many states have considered administering PISA to a statewide representative sample to benchmark their student performance against students from countries around the world. (To date, no states have actually signed up for state-level PISA, although a number of states have considered it and the National Governors Association has been supportive of the idea. Note that in the 2007 TIMSS, two states (Massachusetts and Minnesota) did have state representative samples and were able to compare their states' students to the USA as a whole and to other nations which administered TIMSS. See the 2008 report *Benchmarking for Success: Ensuring U.S. Students Receive a World-class Education* as an example of the tension between NAEP and these international assessments (National Governors Association *et al.*, 2008).) NAEP is designed for state benchmarking; if attention continues to be focused on international comparisons, one of NAEP's key functions may lose its prominence.

Finally, there is the perennial issue of the role NAEP can play as a research database. As noted above, NAEP is the nation's prime method for assessing national educational progress and for benchmarking performance over time and across jurisdictions. Despite the challenges it faces, NAEP still performs that benchmarking function admirably. However, given the size of the database, its quality, and the fact that it is repeated on a regular basis, NAEP tempts many to use it for research and policy analysis. The problem is that it is far too easy to ignore the limits on NAEP and use it for purposes for which it is not suited. Most notably, state-assessment systems that track individual students over time and are suitable for things such as growth and value-added modeling, are more likely to yield reliable policy-relevant results than NAEP, despite its size, its cost, and its prominence.

Evaluation Terms

At the risk of oversimplification but for the purpose of clarification, we present here the fundamental components of evaluation and corresponding examples.

1. *An evaluation problem.* This relates to situations containing issues that interfere or seem to interfere with meeting expectations. A decision has been made to examine these issues in a focused way. Some examples are:
 - a. Despite the fact that additional resources are allocated to certain schools, why are student test scores not improving?
 - b. In districts with a high first-year teacher turn over what can be done to reduce it?
 - c. Can closer collaboration between a high school's principal and counselor improve the quality of the counselor's contributions to students' well-being?
2. *An evaluation purpose.* This refers to learning about something (or someone) and judging the level of success obtained by something (someone) in order to make a decision about it. Some examples are:
 - a. to determine the most effective and efficient ways of utilizing added resources for improving student test scores;
 - b. to plan stronger support systems for first-year teachers; and
 - c. to develop ways for the principal and counselor to learn more about each other's training, role, and educational philosophy in order to improve the quality of the contributions of the counselor to the students' well-being.
3. *An evaluation object.* This refers to the specific thing or person about which information is gathered. Some examples are:
 - a. ways in which additionally allocated funds are used to improve student test scores;
 - b. nature of first-year teacher support system and rate of first-year teacher turnover; and
 - c. nature of the interactions between the principal and the counselor and the counselors' perceptions about the effect of these interactions on their contributions to the well-being of students.
4. *Evaluation information.* This refers to the data describing the objects that is being evaluated. Some examples are:
 - a. documents depicting fund allocation and student test scores;
 - b. first-year teachers' perceptions about the support system that the principal establishes for them and percentages of pre- and post- (support system establishment) rates of turnover; and
 - c. perceptions of counselors and principals about their interactions and the counselors' perceptions about the pre- and post- (interaction activities) quality of their student counseling work.
5. *Evaluation criteria.* These refer to the standards by which something is judged. Some examples are:
 - a. the manner and the extent to which using additional allocation of resources helps improve student test scores;
 - b. the manner and the extent to which stronger support systems of first-year teachers helps reduce their turnover; and
 - c. the manner and the extent to which the principal and counselor learning about each other's training, role, and philosophy help improve the quality of the counselor's contributions to students' well-being.
6. *An evaluation-based decision.* A formal judgment and a conclusion made with regard to what action(s) has (have) to take place as a result of an evaluation. Some examples are:
 - a. Whether to continue or modify the use of the additional funds, or the amount of allocated additional funds?
 - b. Whether to continue or modify the first-year teacher support system?
 - c. Whether to continue or modify the nature of the principal/counselor interactions, or the nature of the student counseling services?

Selected Publications on Principal Evaluation

Two literature-based and detailed chapters on principal evaluation have been published in recent years (Glasman and Heck, 1996, 2003). We first offer current reflections on the data, conclusions, and suggestions presented in each of these publications.

The 1996 Publication: Role-Based Evaluation of Principals – Developing an Appraisal System

Compared to earlier years, increased attention to principal evaluation between the 1970s and the early 1990s

came about because of the general increased interest in evaluation in the field of education. In fact, politically mandated evaluation was part of a great number of categorical federal and state funding allocations to school districts.

Research work on educational evaluation theories, models, and principles intensified during this period. It was mostly psychologists, researchers in the area of learning, and newly trained professional evaluators who designed methods for evaluating educational programs and personnel. Emphasized in these designs were the selection of evaluation purposes, objects to be evaluated, and standards to which evaluators must adhere.

In the late 1980s and early 1990s, specific attention focused on teacher evaluation and its relation to principal evaluation. Teachers and principals were identified as being pivotal in relation to the curricula, programs, student behavior, and student learning. Therefore, the need to evaluate their performance seemed obvious. At the same time, some structural changes in the governance of education were implemented. The state acquired additional curricular and budgetary authorities in relation to educating the increasing number of new immigrants. In addition, the federal government increased its funding of support programs for these children. Increased government funding required increased auditing too. Principals' responsibilities expanded and the need to monitor their activities became apparent.

Role-based evaluation of the principal became an important concept used in guiding research. For example, some writing suggested that it is unfair to evaluate principals on the basis of their performance of responsibilities if they possess insufficient authority to carry out these responsibilities. Evaluation of principals' performance, it was argued, should be limited only to tasks over which principals have or can have full control. This led to research on the evaluation of primarily inherent personal traits rather than on actual performance. However, the usefulness of such evaluations was questioned. Not many school districts are known to have engaged in this kind of principal evaluation and not many resulting decisions are known to have occurred.

The 2003 Publication: Principal Evaluation in the United States

It is generally agreed that until the 1980s principal evaluations were mostly role based. Items to be evaluated were typically selected from the school-district-prepared formal job description. Various scales were selected as evaluation criteria. For example, a common evaluation item might be: guides teachers and provides support to them. This item would require a rating on a scale of points ranging from poor to excellent.

In the late 1980s, contextual forces emerged that brought about changes in the nature of the practice of role-based principal evaluation. Parents, legislators, and other policymakers made demands that schools become accountable for how well students learn.

This implied that the evaluation of teachers (and later, also, principals) does not remain as just role based (assessing the quality of the activities), but also as outcome-based (assessing the results of the activities). Accountability demands implied that student outcomes would be included as items to be assessed in the evaluation of school personnel.

Teachers strongly resisted these demands. They considered themselves to be professionals who must be evaluated on what they do in the classroom and how well students do in relation to what teachers teach. Principals were in a difficult position. They could not respond to the new demands without the cooperation of the teachers. On the other hand, the demand for student-learning-based accountability became a mandated policy.

Within a short time, teachers began to insist that their principals agree with their arguments and even serve as the teachers' advocate to external stakeholders. Evaluation policymakers did not accept this argument but agreed to hold the school as a whole accountable for student learning. This notion implied that teachers alone would not be accountable for student learning. Teachers' resistance was reduced but not eliminated. However, in the context of school-wide and outcome-based accountability, the evaluation of the person who carries the overall responsibility for the school received increased attention. Thus was born the notion of principal accountability. It gave rise to studies focusing on the intersection of evaluation and the school principal, a new academic inquiry.

These contextual forces impacted principal evaluation in new ways. No longer were the principals serving only as educational officers whose evaluation was a perfunctory activity, if it occurred at all. From now on their role was also conceived of as leaders who need to have authority and exercise influence. The differentiation between the principals' leadership and managerial tasks was first conceived of in relation to principal evaluation: Which of the two is more important to evaluate?

The next step in the design of principal evaluation included a more detailed examination of:

1. the criteria by which information is selected about the object to be evaluated;
2. the merit of the information judged for use in the evaluation; and
3. the ways by which the raw findings, such as scores and statements, are utilized in the evaluation process.

Thus, educational evaluation utilization emerged as an important new field of investigation.

Research at that time increasingly focused on the formal positions of those who conducted the evaluation, including their authority to conduct it, their qualifications to evaluate, and the evaluation consequences.

A Summary of Suggestions Made in the Two Publications

The publication titled 'Role-based evaluation of principals' proposed one possible sequence of principal evaluation activities that focuses on principal performance (Glasman and Heck, 1996: 387–388). The sequence included six steps, with some detail given for each. The steps were: setting the agenda, delimiting the scope of the evaluation, developing evaluation standards, specifying criteria for selecting information, measuring and collecting data, and making an evaluation decision.

The publication 'Principal evaluation in the United States' offered a conceptual framework for examining the principal's stage of employment (Glasman and Heck, 2003: 650, 651). The first stage is the period of his/her hiring and assignment. Evaluation activities include setting expected tasks, selecting types of data to be collected, and choosing indicators to measure the extent to which expectations will be met. The second stage is the improvement stage. Formative evaluative activities include data gathering, comparing them to expectations, judging the value (if needed) to adjustments that the principal makes, and (if needed) fine-tuning the evaluation activities themselves. The third stage involves summative evaluation of the principal's performance and the use of the results of this evaluation as inputs to making specific decisions pertaining to the principal's future career.

Stakeholders Define the Meaning of Principal Evaluation

Multiple meanings have been attributed to the concept of principal evaluation. Generally speaking, a definition is a function of how the vested interest of a specific stakeholder shapes it. For example, the vested interest of the Council of Chief State School Officers' (2005) has been to expand the number of states that examine school administrators for licensure purposes according to agreed-upon indicators. The Council developed six professional standards that constitute a very detailed definition. Each of the standards includes dozens of kinds of knowledge, personal attributes, and behaviors.

Another example shaping definitions of principal evaluation is the influence of a very large number of stakeholders, namely the public, and particularly, parents of school children. Most of what these people want is that student learning is at least satisfactory. Low student test

scores disturb this group. Through their political representatives, these stakeholders have called for increased school accountability. As student test scores did not significantly improve and as the clarity of how to implement school accountability policies was lacking, the evaluation component of these policies soon took centerstage and focused on principals' responsibilities (Fowler, 2000 ch. 11; Glasman and Glasman, 2007: 3–4; Wong *et al.*, 2007: 33–35; 160–169). In this case, principal evaluation has essentially been defined as ascertaining the degree to which principals are responsible for student learning. With stronger emphasis on outcome-based accountability, some principals have faced the challenges of the results of high-stakes testing of students (DeMoss, 2002), which has indicated using student scores on norm-referenced tests as the central input to judging and deciding about the success of principals, students, and schools. As a result, principals' professionalism has been seen as being damaged (Firestone and Riehl, 2005: 117–118).

Multiple other stakeholders have also shaped the nature of principal evaluation activities. Among them are the principals' superiors in the district office, the principals themselves, the staff members who work in their schools, various principals' professional organizations, members of their district boards of education, local business and industry employers, as well as other lay people who have had a general interest in the relation between school and society. However, systematic research has not been carried out on the processes by which these stakeholders have shaped the nature of principal evaluation.

Professional evaluators have usually been trained in economics, psychology, statistics, or administration. They engage in evaluation activities such as education costs and programs, teachers and student achievement, but only very little in principals' performance (Popham, 2006). School principals as evaluators rather than those who are being evaluated is another matter and should not be confused with principal evaluation as it is considered in this article.

Most publications in the area of educational administration have reported the existence of almost total agreement among stakeholders about the pivotal role that the principal plays in education. One would assume that this fact alone should have accelerated the progress in studying and in improving the practice of principal evaluation; however, progress has been slow. There is little consensus among stakeholders as to what principal evaluation should mean. Moreover, the nature of the principal's role itself has been changing.

In the professional educational evaluation literature only two central contributions have been made to principal evaluation: (1) standards were developed by which evaluation of educational personnel should be conducted and (2) also a range of possible purposes for which personnel evaluation could be conducted was specified

(The Joint Committee on Standards for Educational Evaluation and Stufflebeam, 1988).

Four groups of standards have been proposed:

Propriety standards imply suitability and honesty of the evaluator. Utility standards include usefulness of the evaluation results as input to decisions that are to be made on the basis of the evaluation. Feasibility standards refer to the availability of resources to conduct the evaluation and the probability of attaining the desired information. Accuracy standards consider the validity and reliability of the findings and the analyses of the data. As to the possible purposes for which personnel evaluation could be conducted, this includes making decisions about entry to training, certification, role defining, selection, tenure, staff development, professional feedback, accountability, merit awards, promotion, and termination (p.17).

Twenty years after these standards and purposes were published it is still not generally known who has made use of these contributions other than evaluation professionals.

A General Working Definition of Principal Evaluation

To the best of these writers' knowledge, there is no specific definition of principal evaluation to which all stakeholders would subscribe. However, there might be an acceptable one if it is sufficiently general in scope. This kind of a definition would allow for multiple specific interpretations so as to suit multiple stakeholders as they shape their own specific terms. One such possible definition is as follows:

Principal evaluation involves gathering information in the educational context about a principal and judging her/his performance on the basis of this information for the purpose of making a decision about his/her future.

An acceptance of such a definition, these writers feel, might allow most stakeholders of principal evaluation to comfortably subscribe to the following guiding assumptions:

1. A specific and agreed-upon administrative purpose of the principal evaluation needs to be articulated by those who are involved in performing it (e.g., improvement, reassignment, and release from responsibilities).
2. Specific and agreed-upon objects to be evaluated that describe and relate to the principal need to be articulated (e.g., personal characteristics, knowledge, skills, visions, behaviors, attitudes, decisions, actions, task accomplishments, performance, general direct and/or indirect impact, general performance, and specific objectively measured effects).
3. Evaluation information and criteria of performance (that are directly relevant to the specific evaluation purpose) need to be selected for assessing the performance (e.g., degree of satisfaction of parents regarding

the quality of education their children are receiving and the extent to which the principal enhances the quality of education as the parents perceive it; degree to which the principal reports success in resolving conflicts and the perceptions of the parties to the conflict about that resolution; teachers' perceptions about the degree to which the principal is effective in achieving school goals given the resources that are available to him/her to accomplish these goals; and percentage of students that score at or above expected levels and the principal's perceptions about helping teachers understand the scores for improvement purposes).

4. Maximum amount of suitable, possible, useful, and accurate information should be collected.

Objects to be Evaluated for Principal Evaluation

Depending on the purpose of the principal evaluation, a number of selections may be made as to what the objects to be evaluated will be. Two general rules can be followed. One rule applies to a situation where the purpose of the evaluation is quite specific. In such situations, specific objects to be evaluated could be selected in correspondence to the purpose. Two examples of specific purposes are: (1) assessing the principal's capacity to make the school accountable to parents and (2) judging the principal's knowledge and skills regarding managing the school's finances effectively and efficiently.

In the first example, specific objects that could be evaluated include (a) parental satisfaction with how well the principal works with teachers on students' problems and (b) parental reports about how well the principal has responded to requests that they have made of her/him. In the second example, where the specific evaluation purpose is determining the principal's knowledge and skills dealing with finances, the specific objects that could be evaluated include (a) how effectively (extent to which a goal has been achieved with a given amount of money) does the principal spend available funds and (b) how efficiently (the most benefit for the least cost) does the principal spend available funds.

The other situation is where the evaluation purpose is insufficiently specific. An example of such a situation might be learning about the role of the principal in improving the school climate. In such a situation, some goal-free, unstructured and open-ended exploration needs to be done. The needs are to become familiar with (1) the dimensions of the climate that are characteristic to the particular school whose principal is to be evaluated (e.g., a tradition of formal interpersonal communication; a high principal turnover) and (2) the principal's connections with any or all of these elements. Only after acquiring a closer familiarity with the situation, can more specific objects be

selected. Correspondingly, these could include (a) the extent to which each dimension of the school climate is central to the school overall climate and (b) what the principal does or does not do in relation to the dimension described in (a).

In many school districts no specific purpose for principal evaluation is established. Evaluation activities are mandatory, routinely conducted, and nonconsequential. Typical evaluation objects are articulated in broad terms, similar to the way items are listed in the principals' job descriptions. In such cases, a yes or a no answer to each item on the evaluation instrument is considered sufficient. At times evaluation is done by grading on a scale of ordinal numbers that have no verbal descriptions corresponding to them.

Over the years, scholarly attention has been paid to some of these job-description-related evaluation objects. Particularly close attention has been given to objects about which the principals themselves have reported and those that have included district-expected outcomes. These evaluation objects included such activities as carrying out responsibilities of instructional leadership, administration of pupil services, financial dealings, legal matters, and ethical principles. (Rebore and Walmsley, 2007). Others objects include making decisions, solving problems (Zey, 1992; Glasman, 1994), communicating, interpersonal relations, as well as behaviors and attitudes (Hoy and Miskel, 2008). In the past 30 years, in addition to the knowledge principals possess in these administrative areas, principals' corresponding skills in using the knowledge have also been considered as appropriate objects to evaluate (Glasman, 1979, 1985, 1986, 1994; Glasman and Glasman, 2007; Glasman and Nevo, 1988).

In addition, over the years, the general title (as it is recognized in textbooks and conversations among professionals) of the professional work in which principals engage has gradually changed. It used to be called administration. Now, it is referred to as leadership and management. Perhaps changing times and expectations were the general determinants of this change in wording. What has now become clear, however, is that governing schools today includes both leadership and management, where the two complement each other: guiding and handling, providing direction, and controlling the operation.

A Special Case of the Principal's Leadership as the Object to be Evaluated

Studying successful leaders and defining leadership as what leaders actually do, Bennis and Nanus (1985) suggest that the potential for effective leadership is more widespread than is generally believed. Nanus (1989) followed this up by asserting that institutional leaders need to possess mega skills if they are to shape institutions effectively. These mega skills include:

- *Farsightedness*. Future creating, operating in the future, always searching for possible opportunities and threats.
- *Mastery of change*. Skilled in regulating the direction and rhythm of the institution so that its changes match the external pace of events.
- *Ability to design the organization*. Determining the human context, establishing the policy guidelines, fixing the setting, designing the structure and support system, and implementing and making adjustments as needed.
- *Anticipatory learning*. Of what is important, how the world works, how to increase the clarities of sources of uncertainty, new options, how much lead time is available for making decisions.
- *Initiating skills*. Being curious, inquisitive, and genuinely interested in what clients say so as to feel their intentions, frustrations, and needs.
- *Mastery of independence*. Skills associated with inspiring people, learning to trust them, developing commitments, communicating, and seeking collaboration.
- *Possessing high standards of integrity*. Undertaking a sacred trust and communicating ethical and even ennobling visions and action.

For the purpose of evaluating school principals as institutional leaders, some adjustments need to be made to the list of mega skills that Nanus has offered. Nanus derives his suggestions from studying executives and skills that they need in order to succeed. The executives he studies typically lead organizations that are hierarchical in nature and whose product is clearly defined and accurately measured (financial profit). Schools are nonhierarchical organizations. There is neither agreement on what their central output is nor on the criteria with which to measure it. Power is highly distributed in schools. Besides, principals do not teach students in the classrooms. Principals might possess different degrees of the corresponding two mega-skills: (1) designing institutions and (2) being masters of change. However, principals' limited authority and their only indirect influence on student outputs imply that their evaluators must adjust accordingly the information that they decide to collect about them (e.g., Firestone and Riehl, 2005; Glasman and Glasman 2007).

In this connection, Firestone and Riehl (2005) focused on skills related to supporting teachers and incorporating communities as contexts of student learning. Glasman and Glasman (2007) focused on skills related to meeting eight more specific challenges that include a total of 23 areas that could describe the skills required by principals. The first major challenge is setting clearly defined and achievable annual goals. The second goal is enforcing safety. This could be viewed as a managerial challenge, but a closer look at the specific relevant tasks identifies leadership behaviors, such as becoming comfortable with acting from authority and helping teachers to feel the same way.

The third challenge is helping students to maximize the benefits they derive from school such as knowledge and social skills. The fourth challenge is helping to solve problems, primarily by reflecting on possible decisions and how to communicate them, learning how to market the school and learning to make decisions more from the heart (than what is customarily done). The fifth challenge involves taking fiduciary responsibility. The sixth challenge is providing comfort when needed. The seventh is adjudicating conflicts. The eighth challenge is making beneficial uses of student achievement data.

These and similar suggestions about objects (or principals' behaviors, attitudes, and activities) that might be evaluated have brought about controversies. Some disagreements focus on the possible lack of sufficient appropriateness of the object as it relates to the evaluation purpose. Other disagreements involve the questionable fairness about including a particular item over which principals have little or no control. In regard to the fairness issue, the most controversial expectation has been that, since some studies have shown that principals have positive effects on students, principals should be evaluated on the basis of these effects (e.g., Gonzales *et al.*, 2002: 274–277). Those who believe that such expectations are unfair point to numerous other studies that show that principals do not have positive effects on students or that positive effects were not found. Furthermore, it should be of note is that of the 60 studies reported in the Gonzales *et al.*, (2002) publication, 12 were theoretical arguments and 39 focused on only one case study. Only nine studies were literature reviews. In very few of the studies mentioned above did the data lend themselves to developing generalities. Those who do not accept such reviews as strong evidence that principals have positive effects on student achievement feel, therefore, that it is unjustified to evaluate principals on the basis of such effects.

Collecting Information about the Object and Performance Criteria

There are an infinite number of information items that might describe the object to be evaluated. The items that are selected must correspond to the evaluation purpose and describe a characteristic of the principal. The capacity to become aware of teachers' needs for the purpose of guiding and supporting them is an example of one of many items that relate to evaluating the instructional leadership of the principal. The possession and use of qualities that match those that are needed in a newly constructed school is an example of a set of items that relates to evaluating the suitability of a principal being appointed to head a new school. Information about the object to be evaluated could be provided by several sources, including evaluation instruments.

There are probably thousands of ways in which school districts might collect principal evaluation information. No recently published data exist that delineate specific ways of collecting evaluation data about principals. Such an effort would require developing a useful conceptual framework for guiding the collection of such data and a very large funding base and full cooperation by school districts to collect the data. Specific ideas about purpose-related principal characteristics to be evaluated have recently been offered in the context of outcome-based principal accountability (Gonzales *et al.*, 2002; Firestone and Riehl, 2005; Glasman and Glasman, 2007).

Evaluation of each object requires information that is specific to it. However, triangulations are possible and at times desirable. For example, consider the object to be evaluated interpreting conflicting demands to improve student learning. This constitutes a highly complex object. One type of information might include answers to questions such as what, how, and to whom the principal presents interpretations. Another type of information may be generated from instances in which the principal exchanges ideas about these accountabilities (say political and professional) with the staff or with superiors. But it would still be necessary to conceptualize meritorious information about interpretations and exchanging ideas that include direct links to the improvement of specific student-learning component of the object to be evaluated.

To be placed in a situation of conflicting demands to improve students, forces the principal to make difficult choices about what he/she considers a justified object on which to be evaluated. In this situation, one object on which to be evaluated includes responses to political accountability demands. Another object to be evaluated includes responses to teachers' professional accountability demands whose hallmark claim is that no one should evaluate them as professional educators on the basis of student end of the year test scores. Several other factors (besides what teachers do with students), such as those related to students' families, significantly contribute to the level of student achievement. In this situation of conflicting demands, an ethical principal cannot tell politicians what the school, the teachers, and her/himself really cannot do about certain aspects of student achievement.

Of note also is that there are numerous validity and reliability issues associated with testing student improvement itself. This raises another set of issues regarding the use of student improvement as the object on the basis of which principals are evaluated (e.g., Amrein and Berliner, 2002).

Another example of an object to be evaluated might be making beneficial uses of student achievement data. Here, too, it is not difficult to conceive of, gather data about, and judge data's merit requiring what principals can do as a result of looking at the data and discussing them with teachers, parents, district office personnel, and community

leaders. However, the problem is that many principals have had no training in these areas and, therefore, either do not engage in such activities or engage in them in a perfunctory level. It would be unfair to use these kinds of activities as an object on the basis of which principals would be evaluated. These are specialties and one needs training in order to practice them. Assessing student test results and making inferences from them is one of these important set of skills (Popham, 2006).

Delimitations, Implications, and Suggestions

This article does not include an analysis of any of the probably hundreds of existing formal or informal principal evaluation procedures. Neither does it cover the probably hundreds of ideas that conceptualize and design specific principal evaluations.

In order to make significant progress in thinking about and performing useful principal evaluations, we need to interconnect evaluation knowledge and skills with those of school principals. Here is a suggested way to do it. Begin with evaluation, narrow it down to evaluation in education, and further narrow it down to evaluation of educational personnel. Simultaneously, start with education, narrow it down to educational leadership and management, and further narrow it down to school principals. At the end of these two imaginary lines, they intersect each other. This intersection is crucial to the understanding that although the cultures of those two theories and practices have been different, they must merge if the dual theory/practice of principal evaluation is to expand and improve.

We believe that the following might serve as a useful first step:

1. School principals as leaders/managers must become experts in certain specializations (such as analyzing student test scores, dealing with financial matters, and handling violence) while maintaining their generalist roles.
2. Evaluation of school principals for educational accountability involves primarily the assessment of what they say and do in attempting to enhance student outcomes.
3. Because of local contextual variables, principal accountability-related evaluations vary.
4. Nonconsequential accountability demands to evaluate principals might constitute a simple procedure involving asking an evaluator or the principal her/himself to respond to a few questions with a yes or a no answer.
5. Parental requests to evaluate principals for information and discussion purposes might involve more detailed and also partly open-ended evaluation questions.
6. School outcome-based principal evaluations might include information about some school parameters that

are independent of the principals (student backgrounds, teacher availability, and salary schedule) and information about what principals say and do to enhance the outcomes in light of those parameters.

7. Finally, the evaluation of principals on their performance to enhance the climate of their schools and on the growth of all students in their schools might include a principal-initiated strategic plan (written with her/his faculty and other service providers in the school) for initiating, maintaining, and evaluating a multiyear set of relevant activities. This would require a special financial grant.

Program Evaluation

C A Christie, University of California, Los Angeles, California, USA
L A Fierro, Claremont Graduate University, Claremont, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Evaluation is the process of characterizing and appraising something of interest. In everyday life, we evaluate naturally. For example, we make evaluative judgments about the type of milk we buy in relationship to a set of standards – fat content, calories, taste, etc. This type of everyday evaluation is distinct from formal evaluation, which involves the systematic study of some evaluand (the object of the evaluation) to address questions related to the merit, worth, value, and impact of the evaluand. While in education we evaluate personnel, products, and programs, most of the theoretical, conceptual, and practical evaluation work that has been done over the years is grounded in evaluation of programs. Thus, the field that is now known as evaluation has evolved primarily from program evaluation.

In education, program evaluation is mostly concerned with the study of curriculum, programs, and policies. These programs can be examined in relation to their process, outcomes, and impact. The primary purpose of a process evaluation is to examine the development and implementation of the program. This information helps to explain what program components worked and why. In addition, this information is useful for monitoring program implementation, and more generally for program improvement. A process evaluation focuses on what services were provided to whom and how, and describes how the program was implemented, who was involved and what problems were experienced.

Gomby and Larson describe the evaluation of a complex school-linked service collaboration among a number of child-serving agencies and suggest several roles for a process evaluation. For example, a process evaluation might examine how the agencies interacted during implementation and document changes in relationships among social and health-service providers, educators, and client families. A process evaluation might also document system change as evidenced by new intake procedures, new forms, memoranda of understanding, or interagency linkage agreements. In some cases, changes in relationships and systems may be specifically planned goals of the program. In other cases, such changes may only be intermediate outcomes accomplished *en route* to the outcome of most interest to the program – changes in the students.

Outcome evaluation examines the program's benefits to recipients – the direct effects of the program on participants. For example, an outcome evaluation would examine whether participants in a 3-month program designed to teach adolescents to practice safer sex can demonstrate

the skills successfully. This type of evaluation is not unlike what happens when a teacher administers a test before and after a unit, to make sure the students have learned the material. However, the scope of an outcome evaluation can extend beyond knowledge or attitudes to examine the immediate behavioral effects of programs.

Impact evaluations look beyond the immediate results of the program to identify possible longer-term effects. An impact evaluation typically examines whether a program's immediate positive effects on behavior were sustained over time. Many school districts limit their evaluations to process and outcome studies. However, there are other agencies that are interested in and have the resources to examine whether program activities affect participants over time. For example, in the USA, there has been a desire to understand the longer-term impact of early childhood education programs such as Head Start on students' academic skills over time. Thus, academic outcomes of students who attended Head Start have been studied through high school and beyond.

A significant proportion of educational program evaluation takes place in traditional school settings (e.g., K-12 schools and higher education). In the USA, federal, state, and local departments of education support a great number of studies investigating the impact of educational programs so that policy and other decision makers can modify or enhance existing programs and initiate new education initiatives. Information generated from educational program evaluations can be used formatively, meaning that the information generated is used to improve programs on an ongoing basis. Summative evaluations may also be conducted, generating information that enables schools to determine, for example, which reading curriculum has the greatest impact on student literacy scores. Hence, summative evaluation conducted in the school setting is an endpoint evaluation of a particular program that has specific and expected outcomes.

Ralph Tyler conducted one of the first large-scale educational evaluations in the USA. Known as The Eight Year Study (1939–41), this longitudinal study of progressive education through the 4 years of secondary school and the 4 years of college is still considered to be one of the most significant evaluations of the twentieth century. Tyler's work on this study has been described as one of the best available examples of how evaluators can work cooperatively with teachers to clarify instructional objectives and develop indicators of students' continuous progress on a range of learning outcomes.

While other important studies of school-based programs were conducted during the 1940s and 1950s, it was not until the Great Society legislation of the 1960s that a broad and coordinated effort to evaluate federal programs was supported. This legislation introduced new programs into US classrooms and appropriated funds specifically for evaluating their impact. The same stipulation was placed upon other large social initiatives designed to support people and the communities in which they lived (e.g., Aid to Families and Dependent Children (AFDC)). This new demand for evaluation served as the foundation for the professionalization of evaluation, which continued to grow and mature during the 1970s. Reductions in federal spending during the 1980s translated into less funding for program evaluation and, as a result, a decline was experienced in the number of program evaluations conducted. This changed however in the 1990s, during which the US federal and state government spending for evaluation increased. This increase in available funds for program evaluation resulted in renewed energy for studying social and educational programs. This energy continues today.

Defining Program Evaluation: What It Is and How It Is Different from Research and Assessment

The evaluation literature includes a diversity of opinions about the ultimate purpose of program evaluation. While these differences are subtle, they are meaningful and become clearer when reviewing how some leading academicians describe program evaluation in their texts. For example, Michael Patton defines evaluation as the systematic collection of information about the characteristics, activities, and outcomes of programs to improve program effectiveness, make judgments about the program, or inform decisions about future programming. Peter Rossi, Mark Lipsey, and Howard Freeman not only highlight the importance of using information generated from evaluations for decision making, but also emphasize the role of evaluation in promoting social betterment. Others focus on the use of evaluation to identify causal outcomes of programs, that is, the systematic assessment of the extent to which a program caused the observed results. Amid these differences, one striking similarity emerges – the systematic nature of evaluative inquiry. To this end, evaluators employ the same methodological tools used by researchers such as study designs, data collection, and analysis techniques. Yet, research and evaluation differ in important ways: the origin of study question(s) and the purpose for which study information is gathered.

With respect to the origin of study questions, evaluation questions are typically elicited from program stakeholders, whereas research questions originate from

a researcher or research team. That is, researchers hypothesize about phenomena, and then develop research studies to answer their question. Regarding study findings, evaluation generates information for program improvement and decision making; that is, evaluation is decision oriented and is intended for use by individuals seeking the information. Evaluation studies, then, are designed to offer decision makers, such as program directors and policy-makers, systematic information about a program so that some actions can be taken, such as whether to continue a program. Alternatively, research is conclusion oriented. That is, the information generated from research studies is intended to enhance our general understanding of an area. The study of learning and cognition, for example, includes consideration of basic psychological theory, educational issues, and application. By and large, researchers generate hypotheses about phenomena with the purpose of producing information that can be generalized across context, people, and time, whereas evaluators typically serve an identified group of stakeholders (e.g., program staff) with the goal of providing information that will be useful for making decisions about specific programs within a relatively defined timeframe.

Evaluation is also different from assessment. While the terms assessment and evaluation are often used interchangeably in our everyday vernacular, in the context of education, assessment and evaluation are two distinct (although related) activities. Assessments are tests that are developed and administered to measure student performance. They are often used to measure specific student outcomes in the context of a broader educational program evaluation. An assessment system consists of some combination of norm-referenced, criterion-referenced, alternative, and classroom assessments reported to inform decisions about students, schools, districts, or states. What distinguishes an assessment system from the more general program evaluation is the focus on testing; assessment systems use tests as the basis for decision making. In evaluation, information about program processes and outcomes is generated for decision making using any combination of quantitative and qualitative data-collection techniques, which may or may not include testing.

Models and Frameworks for Program Evaluation

In 1967, Edward Suchman, a sociologist at the University of Pittsburgh, wrote a founding book on evaluation research citing Campbell and Stanley's 1963 manuscript, *Experimental and Quasi-Experimental Designs for Research* as the appropriate guide for developing evaluation designs. This citation brought experimental and quasi-experimental designs to the center of evaluation. Given that most of the evaluations at the time were being conducted by

university-based social scientists, these designs were valued as scientific and thus, desirable. Rather quickly, however, many individuals conducting evaluations began to recognize that, for a variety of reasons, experimental designs were very difficult to implement in educational settings. The school context, and the districts in which they operated, were not necessarily conducive to the Campbell and Stanley designs, particularly the randomized experiment. Evaluators acknowledged that in many contexts, experiments are not achievable, ethical, or desirable. Even the alternatives to the true experiment, quasi-experimental designs, that were developed to deal with the messy world of field research, were not always practical or popular. Alternative approaches for conducting evaluation were developed in response to these critiques and observations. Today, a diverse set of ideas and beliefs exist about how to best conduct evaluation in the educational setting.

The vast majority of evaluation approaches (referred to as models, frameworks, or theories) offer principles, rationales, and organizational structures for the procedural choices made by evaluators thereby orienting them to the issues and problems with which they must deal. By and large, they are qualitative models, points of view, persuasions, and approaches to the process of evaluation, which are intended to guide practice rather than explain phenomena. The US Centers for Disease Control and Prevention (CDC) developed a framework for program evaluation with input from hundreds of professionals and practitioners working in evaluation and research in universities as well as local communities. This framework describes the general steps involved in designing and conducting evaluations of social and educational programs. Although developed by a public health agency, the steps are generic and easily adapted for use in a variety of program contexts, particularly educational settings.

The framework consists of six-steps:

1. engage stakeholders,
2. describe the program,
3. focus the evaluation,
4. gather credible evidence,
5. justify conclusions, and
6. ensure use and share lessons learned (see **Figure 1**).

During each of these steps, evaluators are encouraged to apply the program-evaluation standards of utility, feasibility, propriety, and accuracy as described by the Joint Committee on Standards for Educational Evaluation. These standards assist evaluators in making difficult decisions encountered in evaluation practice; therefore, it is anticipated that use of these standards will result in high-quality evaluations. The linear arrangement of these steps is intended to clarify how program evaluations are structured and to emphasize the importance of fully addressing each step prior to making final determinations in subsequent steps. However, it is recognized that some of

Figure 1 Centers for Disease Control and Prevention (CDC) evaluation framework.

the steps residing at the end of the framework may be addressed earlier in the process (e.g., how the evaluative findings will be used is often considered when engaging stakeholders).

Engaging Stakeholders

Stakeholders are people who have a vested interest in the evaluation findings. However, the level of interest stakeholders have in the program or its evaluation can differ. For this reason, stakeholders are sometimes categorized based on their relationship to the evaluation: primary stakeholders are in a position to use findings from an evaluation to alter a program's course (e.g., program designers and program staff); secondary stakeholders are likely to be affected by programmatic changes (e.g., teachers, parents, and students), and tertiary stakeholders may be interested in the findings from the evaluation but are not directly impacted by its results (e.g., superintendents of other school districts interested in adopting the program).

Two key considerations associated with stakeholder engagement include when to involve stakeholders and which stakeholders to involve. Program evaluators vary in the breadth with which they engage stakeholders – some evaluators focus solely on including primary stakeholders whereas others make extensive efforts to engage secondary and tertiary stakeholders. When making determinations about which stakeholders to involve, it is helpful to consider how nontraditional partners may contribute to the evaluation process. For example, it may be tempting to limit stakeholder involvement to individuals who directly influence the program (e.g., program managers), yet, their experiences may differ greatly from those who receive program services. It may also seem counterintuitive to

involve individuals who are not supportive of the program. However, engaging these nontraditional evaluation stakeholders may result in a richer program description, identification of important evaluation questions that would have been overlooked, and lend greater credibility to evaluation findings to a broader audience. Despite the potential value that each stakeholder perspective can bring to the table, evaluators need to carefully balance the value of adding more stakeholders with the need to make progress in the evaluation.

Program evaluators also vary with respect to the depth with which they engage stakeholders. Some evaluators involve stakeholders in every step of an evaluation, including data collection, analysis, and interpretation whereas others limit the scope of stakeholder involvement to the early stages of an evaluation (e.g., defining the program and determining evaluation questions). This variation in practice is a result of evaluator characteristics (e.g., the evaluator's beliefs about the ultimate purpose of evaluation or the evaluator's training) and logistical considerations associated with the evaluation (e.g., deadlines, funding levels, or access to stakeholders).

Describing the Program

Studies of evaluation practice show that it is common for program evaluators to engage stakeholders in developing

a description of the program. A common technique used to do this is logic modeling, in which a pictorial description is developed with stakeholders to clearly articulate how program activities will lead to fulfillment of programmatic goals. A general depiction of a logic model is provided in **Figure 2**.

When developing a logic model, evaluators may review existing program documents, conduct observations, and meet multiple times with stakeholders to obtain information from various perspectives about what constitutes a successful program. Logic models vary in their composition and structure; however, common components include inputs, activities, outputs, as well as short-term, intermediate, and long-term outcomes. Logic models sometimes also include a description of programmatic assumptions and denote the external forces that have the potential to impede or enhance progress toward reaching the stated program outcomes.

While developing the logic model, it may be discovered that the theory underlying the program is underdeveloped, unclear, or is unlikely to produce the anticipated results based upon findings from previous research studies. In these instances, the program may be modified prior to embarking upon an evaluation. In the event that the evaluation continues, as is typically the case, the presumed causal pathways expressed in the logic model can be helpful in generating appropriate and useful evaluation

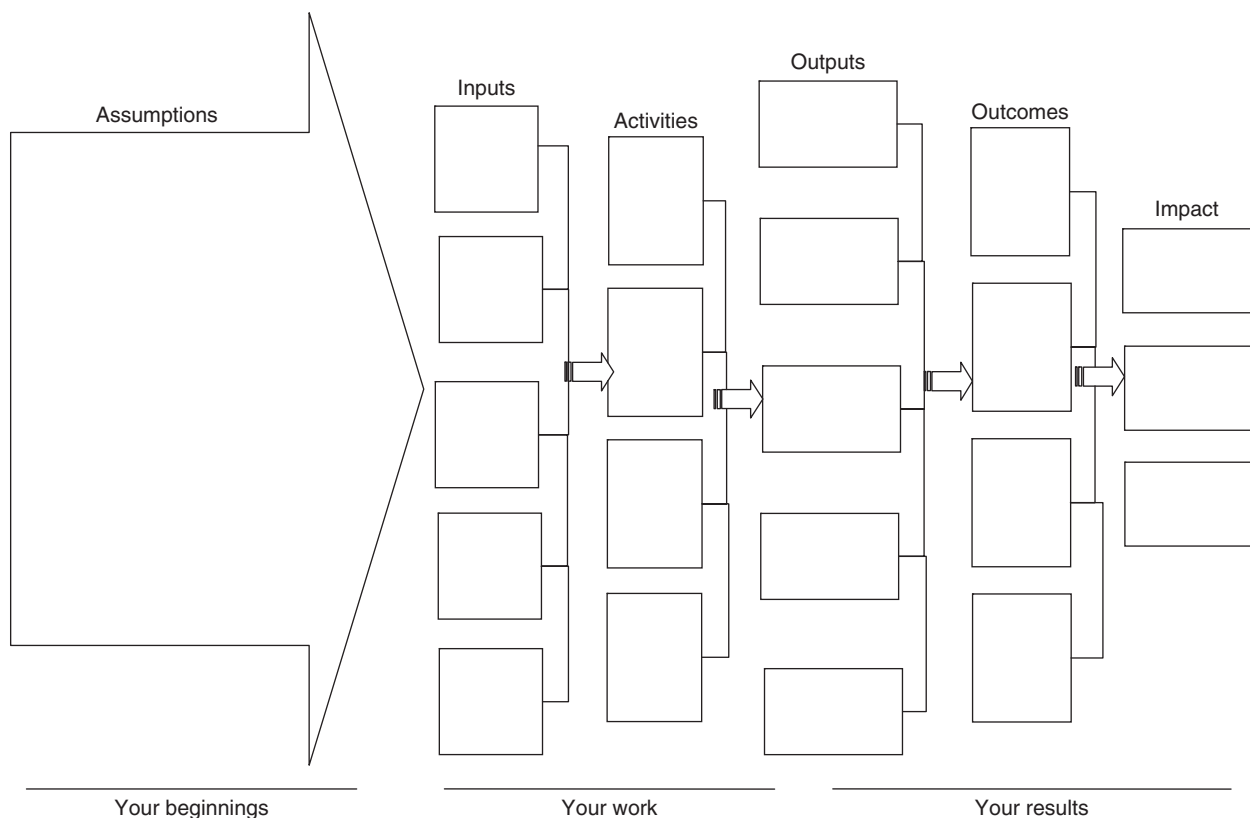

Figure 2 Logic model template.

questions, selecting an evaluation design, identifying appropriate time periods to collect data on the variables in the model, and ultimately in communicating findings. Logic modeling is only one approach to describing a program; related techniques include but are not limited to program theories, action models, and impact models, all of which are discussed as part of an approach to evaluation known as theory-driven evaluation and described in detail by evaluation scholars such as Peter Rossi, Huey-Tsyh Chen, and Stewart Donaldson.

In addition to developing a logic model, or a similar programmatic representation, evaluators may also work with stakeholders to elucidate and document additional factors that are important to fully describing the program. Specifically, it is important to place the description of the program itself within a broader context. Clearly articulating the need(s) addressed by the program, the context in which it resides (e.g., budgetary considerations or political considerations), the length of time the program has been in operation (i.e., whether the program is in a planning or implementation phase), and the degree of interconnectedness that exists between this program and related endeavors can help the evaluator and stakeholders in designing, implementing, and interpreting the findings and implications of the program evaluation.

Focusing the Evaluation

When focusing the evaluation, evaluators work with stakeholders to clarify the intended purpose of the evaluation, generate a list of clearly articulated evaluation questions that align with the intended purpose, prioritize the questions on this list, and select an appropriate evaluation design. This process requires a thorough understanding of why the evaluation is being commissioned and how stakeholders who are in a position to use evaluation findings actually intend to use the findings. During this step, the evaluator works with stakeholders to carefully balance considerations based upon the program evaluation standards of utility, feasibility, propriety, and accuracy.

As previously mentioned, the logic model developed with stakeholders can be used to generate a list of potential evaluation questions. As part of this process, it is likely that a number of evaluation questions will be raised; however, practical considerations, such as the length of time the program has been in operation and the resources available to conduct the evaluation (i.e., staff and money), make it unlikely (and in some cases inappropriate) to address all of the questions proposed. After a limited number of meaningful and useful evaluation questions have been prioritized with the stakeholders, an evaluation design that is capable of addressing these questions is selected. Evaluation designs include those that are experimental (e.g., randomized controlled trials),

quasi-experimental (e.g., pretest–posttest control group), or nonexperimental (e.g., ethnography) in nature.

Gathering Credible Evidence

During this stage of the program evaluation, consideration is given to the types of data that will be collected as part of the study as well as the specific data-collection methodologies that will be employed. In the previous step, the evaluator worked with the stakeholders to articulate the purpose of the evaluation and to generate and select a set of clearly worded evaluation questions. The data collected should contribute directly to answering the evaluation questions selected and should produce credible evidence to answer them.

Data-collection strategies used by the evaluator may include the collection of new data (i.e., primary data) through such methods as surveys, interviews, observations, or focus groups. Evaluators may also choose to use data that is already available (i.e., secondary data), which might include archival information from existing electronic or paper records, or analyzing data that is used to monitor, for example, student progress (e.g., student-assessment data). The credibility of data gathered through these methods can be affected by the procedures used to train individuals in data collection, the validity of the instruments used to gather data, the reliability of the measures used, and the quality-control procedures used to monitor data integrity and accuracy. Additionally, it is important for evaluators to adhere to ethical standards associated with the protection of data, and to maintain confidentiality and anonymity in instances where these protections have been assured.

The credibility of evaluation evidence is, at least in part, in the eye of the beholder. To develop an evaluation that is regarded as credible to the stakeholders, many evaluators will work with stakeholders to gain a clear understanding as to what constitutes credible evidence from their perspectives. Stakeholders may have a preference for the type of design selected in the previous step (e.g., view randomized controlled trials as the gold standard) as well as the type of data that are collected for the evaluation (e.g., qualitative, quantitative, or both). Engaging stakeholders in discussions to better understand the expectations they hold about what types of evaluative data will be collected is an important step in an evaluation, and can help to increase the likelihood that evaluative findings will be used.

Justifying Conclusions

After data have been collected the next step is to analyze, synthesize, and interpret the findings from the evaluation. To prepare for this step, evaluators will often work with stakeholders during the design phase to determine what level of achievement constitutes programmatic success.

These shared value statements form the standards that can be used to judge the evidence produced through the evaluation. When interpreting the findings, the evaluator and/or stakeholders may embark on a process in which they critically examine the proposed reasons for why the specific evaluative findings emerged and attempt to find alternative rationales (e.g., plausible rival alternative hypotheses). Additionally, they may choose to see how their results measure up to similar indicators of program performance – such as their performance on the same indicator in a previous time period or an aggregate measure of performance at a state or national level.

Irrespective of the method of interpretation used, it is important to consider what the practical implications of the findings are for the program and how the findings can be used to make changes or inform decisions about the future of the program. Any next steps or recommendations made during discussions with stakeholders should be firmly grounded in the analysis and synthesis performed on the credible evidence gathered in the previous step. Moreover, findings from a program evaluation should be applied in other settings with caution. Generalizability of the findings should be done in accordance with the limits imposed by the evaluation design and statistical sampling techniques employed (if any).

Ensuring Use and Sharing Lessons Learned

Although ensuring use and sharing lessons learned reside within the final step of the framework, considerations about how to facilitate the use of evaluative findings should begin early in the process of developing the evaluation and continue throughout the evaluation process. For example, when focusing the evaluation, it should become clear as to how the stakeholders ultimately anticipate using findings from the evaluation as well as their information needs. Thus, the evaluator should work early in the evaluation process to determine the types of decisions that might result from the evaluation. For example, will the information from the study be used to determine whether the program will be continued or if it may be implemented in other geographic regions and if so what changes might need to be made to the program so that implementation elsewhere is successful. This interaction aids the evaluator in tailoring the evaluation in a manner that increases the likelihood that findings will be used when the evaluation is complete.

Other steps can be taken throughout the evaluation process to prepare stakeholders for using the evaluation results. For example, interim findings or information about the progress that is being made in the evaluation may be shared with the appropriate stakeholder group(s). These interactions can help to prevent surprising the stakeholders with unanticipated findings, which may lead to stakeholders rejecting the final results. Additionally, the

evaluator can engage stakeholders in mock scenarios while the evaluation is underway. During these scenarios, the evaluator presents fallacious, but realistic, evaluative findings to the stakeholders and works with them to think through how they would interpret these findings and take action.

Another technique used to facilitate the use of evaluation findings is the development of a communication and reporting plan that is tailored to stakeholder needs. A communication and reporting plan clearly describes when, how, and with whom communications about the evaluation will be shared and identifies the specific methods that will be used to communicate with stakeholders. Potential communication methods include but are not limited to hard copy reports, presentations, e-mails, working sessions, and newsletters. As is demonstrated through these examples, communications range in their level of formality (i.e., informal emails to formal presentations) as well as in their level of interaction (i.e., highly interactive working sessions to static newsletters).

Summary/Conclusion

The evaluation of social and educational programs play an important role in understanding which programs are effective and why. A range of approaches has been developed to help guide evaluators in the conduct of program studies, which are intended to generate reliable, valid, and relevant information for decision makers to use when determining which programs to revise, expand, or terminate. To this end, it is critical that evaluation information is timely, meaningful, credible, and accessible to all that have a stake in both the program and its evaluation.

School Based Evaluation: Purposes, Protocols and Processes

J MacBeath, University of Cambridge, Cambridge, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Over a century ago, Arnold Tomkins, a New York administrator wrote the following:

The organisation of the school must be kept mobile to its inner life. To one who is accustomed to wind up the machine and trust it to run for fixed periods, this constantly shifting shape of things will seem unsafe and troublesome. And troublesome it is, for no fixed plan can be followed; no two schools are alike; and the same school is shifting, requiring constant attention and nimble judgement on the part of the school leader. (Tomkins, 1895: 4)

This is an apt description of school-based evaluation, the purpose of which is to keep a school mobile to its inner life, a continuing process of reflection and search for improvement. A school's values and the priorities that count are implicit in the way people (teachers, students, and administrators) think and talk about their work, but evaluation is what they do to make their practice explicit, discussable, and subject to a valid form of measurement. The latter is a term that has to be approached with some caution as it has connotations with a mechanistic or numerical accounting, whereas exploring the inner life of schools and classrooms is a much more complex and messy business. This is not to gainsay the need for rigor; indeed, the greater the recognition given to the subtleties and complexities of measurement, the more rigorous the approach is likely to be.

Evidence from countries in many different parts of the world leads to the same conclusion – schools that know themselves, that adopt a systematic and critical approach to evidence are schools that are able to take charge of change rather than be controlled by it. Self-evaluating schools are likely to be more effective and to improve more rapidly than ones that rely on external sources to validate their quality (Stoll and Myers, 1997; Ouston and Davies, 1998; Rosenthal, 2001).

What constitutes school-based evaluation is, however, problematic. It has been defined in a number of different ways and enjoys a confusing lexicon of terms – self-assessment, self-review, audit and quality assurance, for example. It is a useful point of departure however, to make some distinctions among this varied terminology:

1. *Audit*. The origins of audit lie in financial practice designed to ensure that the organization's books are kept rigorously and ethically. It has also connotations of

stock taking and in a school context, implies an overview of the educational stock or available resource. It is essentially summative in nature.

2. *Quality assurance*. This is a form of audit. The term denotes a systematic examination of quality, usually by an external body and, like audit, is essentially geared to accountability in return for the investment (financial and moral) in the school. It is primarily summative although it may be followed by recommendations for improvement.
3. *Self-review*. This tends to be used synonymous with self-evaluation although a distinction may be made between one-off review or snapshot and self-evaluation as an ongoing process. The term tends to be used summatively but may also be formative.
4. *Self-assessment*. This is a term also used interchangeably with self-evaluation although in many regimes, important distinctions are made between assessment and evaluation, the former referring to judgments of student performance whereas the latter refers to broader judgments of organizational effectiveness. Both terms are used summatively and formatively.
5. *Inquiry*. This is a term with a North American resonance denoting an open-ended process, not necessarily tied down to prespecified criteria. A form of this, known as appreciative inquiry, sets out to understand the strengths of a school within its own frame of reference. It is essentially formative rather than summative.
6. *Self-evaluation*. This is a term with growing currency in European and Asia-Pacific countries. Interpretations of its form and purpose vary widely but the self in question applies to the school as an institution and is primarily a formative process. A simple singular definition is:

A process of reflection on practice, made systematic and transparent, with the aim of improving student, professional and organisational learning and rendering an account to key stakeholders.

Three Driving Motives for Self-Evaluation

There are essentially three driving motives for advocating or adopting self-evaluation. These are the improvement motive, the accountability motive, and the economic motive.

The improvement motive rests on a belief that, to build the school's capacity to respond to and manage change

cannot be achieved without a commitment to self-evaluation. Lack of self-knowledge and self-delusion work to the detriment of students and staff and mislead parents. Social capital is built through a continuing commitment to knowledge creation, drawing on the hidden capital within a school enabling it to become more intelligent than its individual members. Soo Hoo described one source in this way:

Somehow educators have forgotten the important connection between teachers and students. We listen to outside experts to inform us, and, consequently overlook the treasure in our very own backyards, the students. (Soo Hoo, 1993: 389)

The origins of the accountability motive, born out of school effectiveness research and the increasing availability of performance data, have acquired a sharper edge in an international climate in which nations are compared according to the performance of their students. As politicians and policymakers do not wish to be taken by surprise by external evaluations undertaken by the Organization for Economic Cooperation and Development (OECD) or by other influential agencies, systematic self-knowledge and reporting of achievements assumes a high priority.

There is a compelling economic rationale for school-based evaluation. It is much easier on the public purse for schools to provide performance evidence than for this to be the job of external policing bodies such as inspection teams and external review agencies. In England, the Gershon Report of 2004 recommended a saving of over 50 million pounds by, among other cost-cutting devices, shifting the responsibility from an inspectorate to schools, holding them responsible for their own self-evaluation (Gershon, 2004).

While the rationales for each of these three motives may ultimately serve the same end, there are nonetheless tensions among them. What a school deems to be an improvement priority may not accord with the accountability agenda or meet what are seen as the pressing professional-development needs of staff. Writing in a Canadian context, Ben Jaafar (2006) describes the tensions between economic bureaucratic accountability and ethical professional accountability. These can, she argues, be addressed by inquiry-based accountability. In this model evaluation at classroom, school and external levels are used as entry points for professional discussions about learning experiences, opportunities, and outcomes and the priorities for the young people that schools are expected to serve. Self-evaluation then functions as the handmaid of professional development so that staff become more self-aware, more reflective, and more self-critical by virtue of the tools they use to monitor their own professional growth and the accounts they render to their colleagues, communities, and paymasters.

What these varying approaches have in common comes down to some key ideas – that:

- schools themselves require some form of internal review of their own quality and effectiveness;
- internal processes of review/evaluation take account of evidence from a range of data sources and stakeholders;
- evaluation strives for consensus and common understanding while welcoming differences in perspective as growth promoting;
- it is forward looking and essentially formative in nature;
- its findings provide the base for development and improvement planning; and
- its concern for evidence promotes and strengthens both internal and external accountability.

These are, however, demanding principles and for many schools present a challenge that cannot easily be met without guidance and support from external sources.

The Need for Critical Friends

The notion of the self-evaluating, self-improving school may be more of an aspiration than a reality in a context where the weight of policy and the pace of change conspire to keep teachers preoccupied and make reflective and collegial dialog something of a luxury. In the United States, Apple (2006) argued that as teachers work in increasingly intensified conditions and, those who consult or collaborate with them have to act as story tellers and secretaries, intermediaries who help teachers and school leaders help give shape to their stories and enable their voices to be heard.

Such external support is crucial, conclude Baker *et al.* (1991), who compared schools in the United States which drew on external support and those that did not. Their finding received confirmation from research undertaken in Scotland between 1997 and 2000 in which researchers and critical friends worked with 80 Scottish schools, collecting and feeding back data to support schools in their own self-evaluation and improvement planning (MacBeath and Mortimore, 2001). Half of the schools had the support of a critical friend who advised on collection and use of data, feeding back findings and helping headteachers and staff to make sense of that information. The importance of informed, supportive, and challenging critical friendship was one of the main findings of that study.

One of the key foci common to these various studies was the schools' capacity for what Argyris (1978) has termed double-loop learning, that is, the willingness and ability to stand back from the processes of seeking evidence and data gathering to reflect more deeply on the evaluation experience itself. The double loop is one of the distinguishing marks of ongoing self-evaluation as against the more routinized process of self-inspection. While the

latter adopts a single-loop process of data collection – interpretation – target setting and improvement planning – the double loop offers an escape route from that cycle, keeping its own evaluation activity under continuing and critical review. It is in this respect that the visitor's eye view as the Icelanders call it, is significant.

The argument that schools need friends who both support and challenge now seems beyond dispute. Such friendship does not, however, guarantee an accountability to a government agenda, as critical friends may be drawn from universities, private agencies or colleagues in other schools, bringing with them no necessary allegiance to government targets or time scales. As a consequence, most administrations have seen the need for some form of marriage between internal, school-based evaluation and external review or inspection.

While a judicious combination of internal and external evaluation is widely seen as the way forward, aligning improvement, accountability and economics, no country can claim to have found the ideal relationship. There is, however, a strong emerging consensus that external review works best when there is robust self-evaluation in place and that effective self-evaluation is bolstered by well-designed external support. A 2004 study conducted by the Standing International Conference on Inspection (SICI) (SICI 2004) in Europe found that:

The school visits conducted as part of the project have shown that self-evaluation is most effective in countries that have the strongest external support to the process and thus have created a culture and climate for effective school self-evaluation.

Models of Self-Evaluation and External Review

The Norwegian academic, Trond Alvik identified three models which describe the relationship between internal and external evaluation, to which may be added a fourth, the supporting model.

Parallel systems are those in which the two systems run side by side, each with their own criteria and protocols. While schools pursue their own evaluation criteria, inspection or review carries out its own system, perhaps entirely independently of the school's own internal efforts. This is true of systems in which inspection is fairly new or in which self-evaluation is not yet widely developed as, for example, in Poland, Slovenia, or some Swiss cantons. In such systems, self-evaluation is entered into voluntarily and with a focus on improvement rather than accountability, while the balance of power rests entirely with the inspectorate who set the criteria, the nature, and timing of the visit and reporting of outcomes. France is archetypical in this. While there are schools with

their own approaches to whole-school evaluation, inspectors evaluate and grade classroom teachers' performance, a grade which carries high stakes for the teacher because it affects the speed at which his or her career progresses.

Parallel systems may, however, be the seedbed for the growth, as they mature developing a more coherent joined-up approach. This is dependant on the extent to which inspection regimes are willing to investigate and learn from school-led innovation while schools are able to adapt and learn from external protocols.

Supporting systems are those in which the role of the administration (district, state, or national body) is to provide support for schools in carrying out self-evaluation more effectively. These forms of support tend to be characterized by a power-sharing relationship and schools are involved in a more or less voluntary basis. As there is a greater sense of ownership on the part of the school, the stakes are low and decisions about public reporting tend to be negotiated. In Italy, for example, there are myriad bodies and clusters of schools pursuing their own forms of self-evaluation with support from universities and provincial advisers, with an explicit focus on improvement rather than accountability. Similar approaches may be found in Denmark (Larsen and Højdalthe, undated) the Czech Republic (SICI, 2001), and some German Lander (Stern and Dobrich, 1999), although in these states and countries there are moves toward a more sequential system. Accountability tends not to be emphasized, although internal, or professional, accountability may be seen as integral to the process of self-evaluation.

Sweden's Skolverket is a rare example of a supporting system at national level. The focus of external review is on classroom practice but in a collegial relationship, where the power dimension is minimized and inspectors neither criticize nor grade teachers. The inspection process is primarily one of professional discussion rather than summative judgment. Inspectors cannot tell teachers what to do, but they can direct them to best practices elsewhere. Their role is, through collaborative conversations with teachers, to stimulate school-wide improvement. This may be seen as a soft option but these conversations are challenging, drawing on sources of evidence, using results, statistics, and observation to engage the discussion with teaching staff.

Sequential systems are those in which external bodies follow on from a school's own evaluation and use that as the focus of their quality-assurance system. The excellence model in Singapore, adapted from a business excellence model, exemplifies one of the most comprehensive approaches to self-evaluation within a sequential paradigm. Schools are provided with extensive guidelines, indicators, and tools for self-appraisal which they use to evaluate themselves, their scorecard comprising a source of evidence for external review. Schools complete their own scorecard (SEMS), also available in an electronic

version, with a given set of criteria and allocation of marks under each of six key performance domains – cognitive, physical, esthetic, social and moral, student leadership, and student morale.

The sequential model is the model favored by the SICI, evidence for which can be found in Portugal, Ireland, England, and Scotland. There are also examples in a number of Australian states where inspection was firmly rejected by academics and teacher professional bodies in favor of a more supportive form of external review such as the continually evolving process of independent external verification in Victoria (Cairns *et al.*, 2009).

The model adopted in Hong Kong as SSE/ESR (school self-evaluation and external school review) is also exemplary of this model, evolving in response to independent research findings (MacBeath, 2007). After a systematic evaluation of the system over a 4-year period, the education bureau has moved to a system which is responsive to the school's own context and development priorities rather than working to a prescribed common template. In these various sequential systems, SSE precedes external review but, as in the case of Israel, for example, the sequence may be reversed with inspection providing the impetus to self-evaluation.

Cooperative systems are those in which external agencies cooperate with schools to develop a common approach to evaluation. It is in the last of the four types of evaluation above that the power balance is most equitable. As a cooperative system implies, the power issues are not covert but explicit from the outset so that there are no hidden agendas, no nasty surprises, or resentment. These systems are characterized by reciprocity, what the Dutch academic Van Leeuw calls "me-too-you-too" principle because the arrangement is voluntary and negotiated on a collegial footing. While the Swedish system has some of the hallmarks of a cooperative system, it is not cooperative in the sense of constituting a peer relationship in which the nature and conduct of the review is entirely open to negotiation and mutual consent.

In the USA, examples of this can be found at state level or district level. In Rhode Island, the School Accountability for Learning and Teaching (SALT) scheme takes as its focus, teachers' practice evaluated by teachers from another school. The review team is composed of practicing Rhode Island teachers together with a parent, an administrator, and a member of university staff. The team spends 4–5 days in the school, writes a report which is then negotiated with school staff, a process of which can be lengthy but is highly valued in teasing out evidence and the basis for judgments made. The team then draws up a compact for learning, the purposes of which are to ensure that school staff have the capacity to implement improvement. Strategic Inquiry in Trenton, New Jersey, is a cooperative process in which the external team act as critical friends, spending an intensive week in the school,

suspending judgment, getting to know the school by shadowing students, taking lunch with them and the staff, observing in classrooms, and participating in professional-development sessions. They report back to the school not with a set of categorical judgments but with a set of questions to stimulate further dialog and planning for improvement.

Another example of a cooperative model is KEYS, a self-evaluation program and one which schools can buy into. Developed at the University of Washington, it is a process involving a wide variety of stakeholders and vested interests – teachers unions, the school district, the community, as well as school leadership and taking as its starting point the individual interests of staff members. KEYS aims for honest appraisal through self-reflective renewal activity using a framework which holds up a mirror to the school, opens up issues of preexisting beliefs and patterned behavior, and invites staff to reconsider the assumptions on which they rest. One of the strengths of this approach is its factoring in of the changing context and dynamic of school, leadership turnover, community conflict, previously engaged projects, and trying to create conditions that pave the way for new ways of working.

Reciprocity and the Balance of Power

As can be seen from these examples, systems do not fall discretely into one of these four models (Alvik's three plus one). There is always a mix of purposes and matters of emphasis. The twin purposes of self-evaluation and inspection have provided a constant source of tension in different countries and official documents place the emphasis on different facets. However well chosen and rational the model devised, every regime is subject to political pressure whether from change of government, by virtue of the particular individuals who are in power, and in response to pressure groups such as professional bodies and teacher unions. There are also the highly influential supranational bodies such as the OECD, the United Nations Educational Scientific and Cultural Organization (UNESCO), and the European Commission, whose comparative data on school performance are treated with extreme seriousness by politicians and policy advisers. Factored into this mix are the media, watched increasingly closely by political parties for whom reelection depends on the nature of the stories told in the press and on television. Educators are aware that there is always a distance between espoused theory and theory in practice, between what is desirable and what is pragmatically possible and politically acceptable.

The balance of power between the inspection teams and school teams and the weight given to the external report and the internal narrative differ widely, although virtually by definition, a government body is likely to have

the last word. The last word of course, carries quite different significance in countries where the outcomes of review are publicly available, are competitive, and high stakes as against places where the data are seen purely for the school itself. It is the inequality of the relationship in many regimes that prompted the Dutch academic Leeuw (2001) to argue for a reciprocity of relationship, what he calls the “me-too-you-too” principle. In other words, if external evaluators are to make judgments about school or classroom practice, professional principles require that judgments be mutual, negotiated, and shared on an equal basis.

Questions of Power, Provenance, and Processes

The questions we may ask of these systems are, for example:

- The voluntary or statutory nature of the process – Are schools required to self-evaluate and to prove evidence of that or is that a matter of the school’s choosing?
- The balance of power between the school and the review body – Who has the final say? How much credence is given to the school’s own judgment?
- The low- or high-stakes nature of the process and outcomes – Do sanctions or tangible rewards follow from external review?
- The nature of central direction as against flexibility for the school self-determination – Who decides on the focus, agenda, and timing of the school’s report and the team’s visit?
- The constitution of the inspection/review team – Is it led by a government body, an independent agency, trained inspectors, lay people, or peers?
- The framework and structure of protocols, indicators, and success criteria to be used by the school – Who decides them?
- The frequency, length, and intensity of the external visit – How often, for how long, and with what advance notice?
- The focus of external review – Whole school, departments, or individual teachers?
- The transparency, public recognition, or confidentiality of the report – Is the report publicly accessible or restricted to particular stakeholders?
- The balance of essential purpose – Where is the explicit emphasis – accountability or improvement? What is the impact and feeling of those on the receiving end?

As self-evaluation becomes more embedded in school practice and increasingly mandated by governments, its form tends to move from grounded bottom-up processes to more tightly defined top-down formulae. In longstanding inspection regimes, such as in the UK countries, governments keen on standardization, devolve their own

frameworks to schools, providing the goals, criteria, and protocols with the consequence that schools begin to engage in a form of self-inspection. Self-inspection and self-evaluation may be characterized (**Figure 1**) as arising from quite different assumptions about the nature of improvement.

The paradox is that the more the governments provide the frameworks, indicators, and tools, the less inventive and spontaneous the process at school and classroom level. Self-evaluation becomes a ritual event, a form of audit in which senior leaders assume the role of an internal inspectorate applying a set of common criteria.

The previous chief inspector in England now permanent undersecretary at the Department for Children, Schools and Families (DCSF) said this:

I have always been cautious in saying that inspection causes improvement because, frankly, we don’t. But it has to be an important part of our thinking about inspection . . . To say inspection causes improvement is fundamentally unprovable. I think there are examples of where you have greater evidence of improvement being brought about by inspection, but again it’s still not quite the same as saying it causes it. For example, our monitoring of schools with special measures is not causing improvement but most headteachers say to us that the process of professional debate and discussion with HMI brings some real bite to the improvement process. I think it’s a bit too simplistic to say that either OFSTED does cause improvement or OFSTED doesn’t cause improvement. (MacBeath, 2006: 30)

The keywords in this statement are the process of professional debate and discussion.

This is where school-based evaluation comes into its own and where internal accountability is nurtured. As Elmore (2003: 17) has argued, without a strong sense of internal accountability, schools and teachers will always be subject to external pressures and remain reactive to externally driven change. They are more able to counteract the local, national, and international forces at work when there is shared understanding of the difference

Self-inspection	Self-evaluation
<p><i>Top down</i> A one-off event</p> <p>Provides a snapshot at a given time Is time-consuming Is more about accountability than improvement Applies a rigid framework Uses a set of predetermined criteria Creates resistance Can detract from learning and teaching Encourages playing safe</p>	<p><i>Bottom up</i> Is continuous and embedded in teachers’ work Is a moving and evolving picture Is time saving Is more about improvement than accountability Is flexible and spontaneous Uses, adapts, and creates relevant criteria Engages and involves people Improves learning and teaching Takes risks</p>

Glossary

Education quality – The quality of education received by students within an education system.

Specific factors influencing quality include the effectiveness of teaching and learning and leadership arrangements within a school.

External evaluation – The assessment of the quality of structures and processes operating within a school as judged by an outside agency or perspective.

Internal review/self-review – A review conducted by members of the organization to assess the effectiveness of structures and processes in place.

International education – Of relevance to more than one educational system. Drawing on examples from a range of systems.

Ofsted – The Office for Standards in Education is the inspection agency responsible for the systematic inspection of schools (and other providers of education and child care) in England.

School effectiveness – The extent to which a school adds value to students. An effective school is a school where students achieve more than might be expected after a range of background factors have been taken into account.

School evaluation – The evaluation of the effectiveness of the structures and processes in place within a school.

School improvement – The processes and strategies associated with improving student outcomes and creating the capacity for enhanced effectiveness.

School inspection – The process of examining a school's structures, processes, culture, and capacity for improvement.

Self-inspection – The process of examining or reviewing a schools' strengths and weaknesses conducted by members of the organization using an existing inspection framework rather than one devised by the school.

outcomes – but there is still considerable discussion about the best ways of achieving this. Among educationists and policymakers, the school improvement debate often centers around the relative importance of the processes of external review compared with those of internal school evaluation. Those advocating external evaluation systems associated with school inspection, whom we might refer to as hawks, see self-evaluation as soft-centered; they argue that without the hard-edged external probing that inspection brings, difficult questions and judgments will always be shirked. On the other hand, the doves remark that unless schools are in charge of any process of evaluation, then change will remain superficial as there is the need for ownership of the school improvement process. We argue that there is a need for a combination of both external inspection and self-evaluation and that promoting a culture of restless self-evaluation, a feature of improving schools, should be a key feature of any national inspection system.

MacBeath (1999) has utilized Alvik's three categories of external and internal school evaluation in a wide-ranging account of practice worldwide:

- *Parallel*. Both school and the external review body conduct their own evaluations. They may afterwards share and compare findings.
- *Sequential*. The school conducts its own evaluation and then the external body uses it as a basis for its review. It can also work in the opposite direction with the external body giving feedback to the school or offering its main findings for the school to work on.
- *Cooperative*. The two parties discuss and negotiate the process and different interests and viewpoints are taken into account simultaneously.

Learmonth (2000) uses these three categories to discuss arrangements in Scotland, USA, the Channel Islands, the Netherlands, Victoria in Australia, and a London borough where there have been attempts to get the balance right between the external and internal perspectives. However, systems of external inspection or review, the focus of this article, are established for a number of reasons; school improvement is only one of the many functions an inspection system can perform. School inspection or external review may emphasize one or more of several functions (see below) and any national system of school inspection may give greater prominence to one or another at different points in its history.

Introduction

Education systems throughout the world are being asked to improve – to raise standards and increase pupil

The Purposes of Inspection

The purposes of inspection are given below:

- Information giving – to parents and the local community; for regional and national government.
- Monitoring – assessing the performance and improvement of schools.
- Accountability – for quality, standards, and use of resources; the effective use of public funds.
- Improvement – by identifying strengths and weaknesses and the action to improve.

The functions outlined above can be used to illustrate how inspection varies across different education systems. In other words, how different systems view the main function of inspection. For example, is inspection for school improvement or to hold schools to account? Inspection systems might also differ according to the degree to which they are delivered or administered by central or local government agencies, the extent to which they are staffed by private contractors or civil servants, their levels of public exposure, and the importance they are given within the system. Differences also exist between inspection systems with regard to the degree to which they encourage schools to improve by giving advice, offering recommendations, and identifying key issues for action. In some cases, national or local inspectorates act as in-service trainers for teachers. The level of monitoring for compliance with legal regulations and the emphasis given to accountability may also vary from one inspection system to another. To what extent, for example, is inspection high stakes and part of an accountability framework?

A number of educational systems around the world have adopted external evaluation systems or approaches based on high levels of accountability. For example, in the United States, high-stakes testing and the No Child Left Behind policy tend to dominate a culture of performativity and accountability. A number of systems in developing countries have also adopted such approaches. For example, in African countries, such as Malawi, systematic inspection has been introduced as a lever for school improvement and several European countries have developed various accountability systems which are underpinned by the elements of inspection combined with use of performance data and target setting.

In an overview of the characteristics of school inspectorates in Europe, Standaert (2000) shows how in Portugal, Denmark, and France the range of school inspections varies from full inspections of both schools and individual teachers, to inspections of specific subjects only. However, all schools in England, Scotland, Flanders, the Czech Republic, and Northern Ireland receive systematic, full inspections. As noted above, some inspection systems see themselves as being complementary to the processes of internal self-evaluation, while others give greater

emphasis to the monitoring and accountability functions than they do to institutional improvement. Many claim to do both, although the extent to which school inspection leads to school improvement is hotly contested and the mechanisms used by national inspectorates to realize the goal of improvement vary from country to country.

Case Study: School Inspection in England

The history of school inspection in England can be traced back to the 1800s but the current regime emerged from the 1992 Education (Schools) Act which provided the legal framework for the launch of the Office for Standards in Education (Ofsted). This policy was implemented by the Conservative government and the underpinning rationale was that if schools had to attract students, then standards would automatically rise in the face of local competition (Learmonth, 2000). Ofsted's early years were not without controversy. Some commentators claimed the Conservative government had legitimately pitted public interests against the self-interest of the educational establishment in an attempt to demystify the closed world of schools and classrooms. Others from within the educational establishment argued that the process was demoralizing and de-professionalizing (Gray and Wilcox, 1995). A number of studies challenged the value of the Ofsted system of inspection, but Ofsted has developed its own research and publications arm to support the claim of improvement through inspection (e.g., Ofsted, 1994, 2000).

In 1996, the Conservative government outlined a new framework, but for the most part implementation would be left to their successors, New Labour, who were elected in May 1997. The new framework marked a number of changes to the system including: the stretching of the cycle from 4 to 6 years for most schools, a reduction in the notice of inspection to 6–10 weeks and an entitlement of individual feedback to teachers on their lesson performance. The new framework moved Ofsted further into the terrain of school improvement by promoting “school improvement by identifying priorities for action” (Ofsted, 1996: 2), as well as assessing the schools capacity to manage change and review its internal systems (Earley *et al.*, 1996). However, in many cases, the key elements of trust and mutual respect between the inspecting and the inspected remained limited and restricted Ofsted's contribution to school improvement, therefore the improvements made because of inspection continued to be challenged (Cullingford, 1999).

Despite calls for change from within the educational establishment, the election of the New Labour government in 1997 heralded more of the same. Intervention in inverse proportion to success continued as an overt policy with schools being identified as failing or at risk of failing, being subjected to compressed inspection cycles and

public exposure through extravagant local and occasionally national media headlines. However, many teachers and schools were becoming tired of the treadmill of inspection cycles and the process seemed to be losing some of its potency. Teachers began to realize for the most part inspections came and went, policies and plans were prepared, and reports published but unless there was a crisis not much changed.

A government response to this situation was to create a cycle for continuous improvement through a new relationship with schools. The Minister for School Standards outlined the three key aspects of the relationship as being rigorous, ongoing, self-evaluation combined with focused external inspection all linked into the improvement cycle of the school. It was argued that this simplified improvement process underpinned by a single conversation with a school improvement partner to discuss and negotiate appropriate targets, priorities for development, and strategies for support provided the high challenge and high support environment necessary to deliver the progress and performance necessary to become a world class education system (MacBeath, 2006). The new relationship with schools led to significant changes in the inspection system including an increased focus on self-evaluation.

Self-evaluation is currently at the heart of the new inspection arrangements in England because Ofsted believes that schools are best placed to recognize their own strengths and weaknesses, and have designed an online self-evaluation form (SEF) for them to do so. This is not statutory, but all schools seem to use it which is not surprising as their inspection is largely based around the SEF, which includes the school's performance data. The form asks schools to evaluate themselves under seven headings:

1. characteristics of the school;
2. views of learners, parents/carers, and other stakeholders;
3. achievement and standards;
4. personal development and well-being;
5. the quality of provision;
6. leadership and management; and
7. overall effectiveness and efficiency.

Schools can edit, save, and submit their online interactive SEFs as many times as they wish through the secure password system. They are asked to grade themselves on a four-point scale (grade 1: outstanding; grade 2: good; grade 3: satisfactory; and grade 4: inadequate) on each of these aspects:

- learners' achievement and standards in their work;
- learners' personal development and well-being;
- quality of teaching and learning;
- quality of the curriculum and other activities;
- quality of care, guidance, and support for learners;
- effectiveness and efficiency of leadership and management;

- overall effectiveness;
- capacity to make further improvement;
- improvement since the last inspection; and
- quality and standards in foundation stage (Ofsted, 2004).

A study recently conducted by the National Foundation for Educational Research highlighted that the SEF should be "something that should be carried out collaboratively, in an ongoing, continuous way, reflecting developments across the school" (McCrone *et al.*, 2006: 8). Just over half of the NFER survey respondents reported that they had attended local authority training on how to complete the SEF. In just under one in five schools an independent consultant was brought in to help. This study found that in one in ten schools the headteacher had completed the SEF alone, but that staff were consulted about the SEF in most schools and made an input in over three-quarters of schools. There were similar levels of governor involvement, with over 90% being consulted and two-thirds making an input.

The SEF has become the driver of a streamlined inspection that now lasts no more than 2 days, focuses on the core systems and senior managers, and is informed by statistical data and lesson observations, rather than being led by them (Bubb *et al.*, 2007). The size of the inspection team is smaller than in the past, and likely to be led by an experienced Her Majesty's Inspector. Notice of an inspection was also reduced to 2–5 days and schools can expect to be inspected once every 3 years. Inspection reports have also been streamlined from over 30 pages in length to five or six pages and they are presented to the governing body (in at least draft form) the same week of the inspection. Rather than preparing a response to the key issues raised, schools now incorporate their response into the school development plan.

In 2008, Ofsted published a consultation document when further changes to the inspection framework were proposed. The consultation sought views to proposed changes which included inspecting good and outstanding schools every 6 years, the possibility of unannounced inspections, national surveys which capture the views of children, school staff and parents, school leaders playing a greater part in inspection by shadowing the inspectors, giving more attention on the achievement of different groups of pupils, taking more account of the capacity of the school to improve, continuing to use contextual value added (CVA) as a measure of schools' progress, and the impact of partnerships on outcomes for pupils. (Contextual value added is the difference between the predicated and actual academic attainment made by an individual after taking into account the individual's prior attainment, characteristics and background, and the school's prior attainment.) In addition, the consultation asked should the inspectors' recommendations focus more precisely on the action the school should take to become good or better?

The ever-changing nature of Ofsted inspections has made it difficult to research its effects. However, researchers have attempted to explore the relationship between inspection and institutional development. To reflect on this fundamental issue, we draw on evidence from two national systems – England and the Netherlands.

Inspection and School Improvement

The matter of how or whether school inspections contribute to school improvement has been studied systematically in very few countries. The only country with any research tradition in this area is England and to a lesser extent the Netherlands. However, the findings of these research studies are not consistent and there is a dearth of research, as opposed to hyperbole, into the effects of school inspection and how it impacts upon school improvement.

England

Since its introduction in the early 1990s Ofsted has undergone a number of developments, reflecting the changing demands of the political and educational landscapes; in terms of experience and tone current, future school inspections bear little resemblance to those conducted in the early 1990s. However, despite structural and cultural shifts and the evolution of a more streamlined process, the budget needed to sustain inspection in England remains considerable, totaling £238 million in 2007–2008 of which £90 million has been allocated to education (schools, teacher training, and joint area reviews of children's services). Essentially, inspections of English schools are intended to identify strengths and weaknesses so that schools may improve the quality of education they provide and raise the educational standards achieved by their pupils.

During the early years of Ofsted, there was little independent research investigating inspection's contribution to school improvement (Earley, 1996). However, the agency itself produced, and continues to produce, a plethora of literature to support its claim of improvement through inspection (Matthews and Sammons, 2004; Ofsted, 2000), the extent to which (or not) Ofsted inspection contributes to school improvement remains contested at a number of levels. One key issue is that of reliability of judgment. Fitz-Gibbon (1998) argues that inspectors make inaccurate guesses about progress and the effectiveness of schools. Richards (2001: 9) observes that inspection "involves the interpretation, not just the reporting, of activities". He states that "crucially it's about making judgments as to the worthwhileness of what is observed, collected and reported" and notes that "to be valid interpretations such judgments need to be informed by an understanding of the aims and values of the activity or organization being inspected and of how these relate to the aims and values of the educational system

itself" (Richards, 2009: 9). If it is the case that judgments are not reliable, then national educational policy may have been based on inaccurate data (Fitz-Gibbon, 1998) obtained through potentially unreliable methodologies (Gray and Wilcox, 1995; Richards, 2001). In turn, this may lead to inappropriate priorities for improvement being identified and, subsequently, important opportunities for improvement overlooked.

Some researchers have considered the impact of inspection prior to the inspection period, arguing notice of inspection can trigger improvements during the run-up period. Improvement efforts include smartening up school buildings and the preparation of new interactive displays of the pupils' work mounted on walls, high quality of lesson preparation, and marking by teachers but that these improvements are likely to be short lived with "normality returning when the inspection is over" (Gray and Wilcox, 1995: 82). It would seem the reduction in notice time is likely to have further eroded any potential for improvement during the build-up period. However, the publication of a 3-year cycle allows school leaders to predict when they should be inspected and to prepare accordingly.

Other researchers have chosen to examine post-inspection impact. Lowe (1998) focuses on the implementation of recommendations 1-year after inspection. This research highlights a wide variation in how schools respond to inspection and the extent to which recommendations related to teaching and learning are tackled. Other research takes an alternative perspective on classroom change. Brimblecombe *et al.* (1996) and Chapman (2001) report approximately one-third of teachers intend to change their practice as a result of inspection and of those, most report they intend to do so as a result of the direct feedback they receive from inspectors (Chapman, 2001). However, despite an entitlement to feedback, considerable variations in quality and in quantity to feedback persist (Ferguson *et al.*, 2000). It would seem that lesson observation and quality feedback are potentially important levers for improvement but these have progressively been lessened as the length of inspections has shortened and the number of observations per inspection reduced.

One area where we may expect to see inspection making considerable contributions to school improvement is in the weakest or badly underperforming schools. Here, inspection and performance data suggest that schools identified as failing within the system are more likely to sustain the improvement they make after inspection than those that are relatively more effective but still causing concern (Matthews and Sammons (2004)). However, we also see a number of schools being removed from special measures, only to find themselves being placed back in the category after subsequent inspections (Gray, 2000) and in England there are a number of cases where despite significant intervention including compressed inspection

cycles and high levels of additional Her Majesty's Inspectorate (HMI) monitoring visits schools have not managed to establish the momentum to bring about significant improvement. Perhaps, for these schools the odds were so highly stacked against them that any intervention was doomed to failure? Alternatively, maybe the inspection process lacked the potency or sensitivity to pull the appropriate levers for change in their particular contexts? For many of these schools within the English education system the reality becomes a structural solution whereby the school is closed, and reopened as an academy, or joined with another school in a federation or collaborative restart.

The Netherlands

In the Netherlands, schools are inspected annually and an inspection lasts between half a day and 1 day. Inspectors have responsibility for about 100 primary schools or 40 secondary schools and each school will know its inspectors, thus ensuring that the inspection is not carried out by a stranger, as it is under the English system of privatized or contracted inspection teams. There is therefore a continuing relationship between the school and its inspector.

The Dutch Supervision Act of 2002 states that "through inspection the government guarantees that schools will deliver a satisfactory level of educational quality for all citizens," and that as a result of inspection "the government stimulates schools to develop their own quality assurance systems, which will lead to improvement in the quality of education." The inspection framework for assessing school performance includes aspects of the teaching-learning process, the school's results and the school organizational conditions (e.g., policies and processes). Three core aspects of school inspection which, in the Supervision Act, are assumed to promote school improvement are: quality assessment, proportionate inspection, and the publication of inspection findings.

When a school is deemed to be failing or underperforming, the Dutch inspectorate can only take action if the school does not comply with the legal regulations. Schools in the Netherlands have considerable freedom and autonomy; central government and the inspectorate have a reserved role compared to their English counterparts. Whereas action plans are obligatory in England, and follow-up school visits in cases of school underperformance will take place regularly, this is not always the case in the Netherlands. Dutch schools may also be requested to describe the implementation of their school improvement action plans which should be monitored by the school's inspector. In both countries, school inspection reports are published on the Internet.

Research shows that school inspectors vary in the ways they inspect schools and stimulate improvement. As Ehren and Visscher (2008) note:

Some inspectors assess schools more thoroughly than others, some also explain more than others about the methods they use, and some focus more on improvement suggestions, some especially put effort into agreements and improvement plans, while yet others invest more in monitoring the school following the inspection visit. These differences were interpreted as variations in inspection style which were labelled as 'directive', or 'reserved'. (p. 211)

The researchers conclude that:

School inspections probably lead to improvement processes if school inspectors give feedback about those aspects on which the school underperforms, if school inspectors assess these aspects as unsatisfactory, and if they make appointments with the school about improving on aspects of underperformance. (p. 236)

The authors stress the limitations of their research but suggest that the combination of techniques in some sort of integrated approach to school inspection is effective in promoting school improvement and their research is a useful addition to the existing knowledge base regarding the effects of school inspection. They also found that the amount of inspector feedback provided "does not contribute significantly to school improvement, but the way it is given does: in a directive sense, together with unsatisfactory assessments in the school report, and agreements about improvement of the weak aspects of functioning within a certain period" (p. 236).

Conclusion

National systems of inspection can perform a number of functions but school improvement and the raising of standards is often an important one. However, assuming that external inspection alone will automatically improve schools is naive, and few people now would adopt such a simplistic stance to school development. Contingencies are significant: a major study in England found that features of school inspections, which influenced school improvement, included such things as the inspector's attitude, the perceived inspection quality, the manner in which the inspector provided feedback, the extent to which the inspection report is perceived by the school as relevant and correct, and the congruence between the inspector's recommendations and the school culture. Interestingly, this study by Ferguson *et al.* (2000) used the term school self-inspection in preference to self-evaluation. Similarly, in the Netherlands, Standaert (2000) notes that the impact of inspections depends, among other things, on the school staff's attitude and capacity to change, whereas Matthews and Sammons (2004), writing about Ofsted inspections, point to the importance of strategic leadership and effective

action planning including the identification of necessary resources.

The inability of some schools to secure improvements despite frequent inspection and high levels of associated intervention may suggest some contexts are so challenging, the odds stacked so highly against the school that no amount of external intervention can secure improvement through inspection. However, what is particularly depressing for school improvers is that inspection does not operate in isolation. In these schools, additional resources including continuing professional development focusing on teaching and learning, target setting, and use of data are all common features of standard school improvement initiatives. Therefore, the lessons would seem to suggest that however one quantifies inspection's contribution to improvement, inspection alone is an insufficient ingredient for success and, in this case, the framework for continuous improvement drawing on inspection combined with a raft of additional resources and school improvement initiatives were also insufficiently powerful to overcome the challenging circumstances faced by some schools and communities. This can only support the arguments made in the literature (Muijs *et al.*, 2004) for linking school and community interventions.

School improvers, researchers, and policymakers are still discussing the right combination of external and internal review processes. The doves and the hawks are still to be found but now self-evaluation (or is it self-inspection?) plays a significant part in virtually all inspection arrangements. Matthews and Sammons (2004) offer a cautionary note in their recent evaluation of Ofsted's contribution to school improvement:

Ofsted will need to be vigilant, however, as the contribution of self-evaluation to the inspection process becomes more prominent, to guard against any 'halo' effect, in which self-evaluation grades have an undue influence on the judgements of inspectors. This is particularly important given the evidence that institutions tend to make more favourable judgements of their own practices. For these reasons, validated school self-evaluation should not be regarded as a substitute for inspection. (Matthews and Sammons, 2004:93)

In the international race to raise achievement and to improve standards, we need to consider carefully the role of external inspection and how it can best be related to internal processes of school self-evaluation and review. Without doubt, we need internal review and external inspection – they complement each other – but the extent or prominence of one or the other in any education system will depend on a number of factors, including the system's maturity, the individual school context, and the competence of schools to self-evaluate effectively. The era of school self-evaluation requires schools to

invest in the professional development of their staff in reflection and self-evaluation skills.

In sum, an important general conclusion can be drawn from this article about external school inspection. It does encourage school improvement but under specific conditions and in certain circumstances. We would argue that there should always be a role for the external eye or outsider perspective. The expertise and authority of school inspectors may place them in an excellent position to promote school improvement as well as perform the other functions that systems of external inspection perform.

Introduction

The globalization of the economy and the relation between economic growth and education has increased interest in education and the results of educational research, in particular comparisons between countries with respect to educational outcomes. International studies undertaken by the International Association for the Evaluation of Educational Achievement (IEA) and the Organization for Economic Cooperation and Development (OECD), such as the Third International Mathematics and Science Study (TIMSS), the Progress in International Reading Literacy Study (PIRLS), and the Program for International Student Assessment (PISA) study revealed that there are huge variations in student outcomes from country to country. This raises questions regarding the identification of factors associated with variation in student outcomes. However, secondary analyses of comparative studies reveal that most of the variations situated at the country level remain unexplained. This can be attributed to a number of methodological weaknesses of these studies (Kyriakides and Charalambous, 2005; Lassibille and Gomez, 2000) and especially to the fact that more attention should be paid to investigating the dynamic interaction between children and educational systems by understanding education as experienced by children at the point of delivery (Reynolds, 2006). This argument is also supported by the findings of studies conducted in different countries which revealed that the classroom effect is more important than the school effect in explaining variation on student achievement in both cognitive and affective outcomes. Effectiveness studies have also revealed that quality of teaching is the most important factor at the classroom level (Brophy and Good, 1986; Kyriakides, 2005a).

Unless data on the quality of teaching are collected, researchers and policymakers cannot easily interpret the results of these comparative studies and may attribute variation in student outcomes to variables that show differences between countries, but are not necessarily related to student outcomes. For example, when the results of PISA 2000 study were announced, policymakers in different countries attempted to emulate parts of the educational policy from Finland in their own countries.

However, results achieved in one country cannot be replicated in another country by a simplistic transplant of educational factors to another context, especially if these factors were not found to explain variation in achievement from country to country. Therefore, effort should be put into developing valid instruments which are able to measure quality of teaching.

Although national-observation instruments have been developed and validated in some countries, there is no internationally valid teacher-observation instrument available. Moreover, in an international study on educational effectiveness (Reynolds *et al.*, 2002), it was discovered that one of the most commonly used instruments in USA (i.e., the Virgilio Teacher Behavior Inventory (Teddlie *et al.*, 1990)) did not produce valid data on quality of teaching in several of the participating countries. This implies that in the construction of an international teacher-observation instrument, different views on quality of teaching should be taken into account for identifying important aspects of teacher effectiveness shared in different countries, as well as aspects that are more important for specific countries.

In this context, the main aim of the International System for Teacher Observation and Feedback (ISTOF) was to develop a valid international instrument for assessing teacher effectiveness that can be used for conducting comparative studies which may help us to understand the reasons why some countries are more effective in education than others. Since national studies reveal that teacher factors are important predictors of educational outcomes, a comparative study measuring teacher effectiveness may also reveal which aspects of the quality of teaching can explain variation on student outcomes across countries and which aspects are context specific (i.e., they demonstrate relationships with student outcomes in specific countries only). Thus, similarities in characteristics of effective teaching will be identified. At the same time, differences between countries in what constitutes effective teaching will be identified and they will help us understand the conditions where specific reform policies could contribute to learning.

Therefore, the main aim of this article is to inform readers about the background and the rationale for the ISTOF project and to present its major outcomes. We also

draw implications of the findings of this project for developing international instruments that can measure effectiveness factors operating at different levels, such as the school and the system. In this way, valid instruments may be developed for use in comparative studies seeking to identify factors that explain variation in student outcomes across countries. In the next section, we describe the rationale upon which the design of ISTOF is based by referring to four techniques used in developing ISTOF.

The Rationale for Designing ISTOF

Technique 1: Merging Inductive and Deductive Procedures

We decided to make use of both inductive and deductive procedures for the development of ISTOF. The inductive procedure involved the collection of input from different groups of participants in as many countries as possible with regard to the components of effective teaching, their indicators, and the items that can be used to collect data for each indicator. On the other hand, the use of deductive procedure implies that the knowledge base on teacher effectiveness, which emerged through syntheses of research findings, should guide the development of the conceptual map, the list of indicators, and the items of the instrument. By using both approaches, we tried to take into consideration not only research findings concerned with teacher effectiveness, but also the viewpoints of different groups of experts in different countries (i.e., researchers, professionals, and policymakers) on what makes an effective teacher and how this can be measured. The reasons for using this approach in developing ISTOF are discussed below.

First, in many countries, studies looking at teacher effectiveness have been conducted only recently, if at all. By using only the deductive approach, it is possible to overemphasize views stemming from specific countries where there is a long tradition in teacher-effectiveness research (TER) such as the USA where TER originated in the 1960s and 1970s (Gage, 1977; Brophy and Good, 1986). By using deductive methods based only on the existing TER literature, we may not take into consideration contextual differences that can affect the way research is framed.

Second, by using the inductive approach, you can take into account the experience and views of different stakeholders in different countries who are currently involved in the training, evaluation, and counseling of teachers. In this way, we can combine the knowledge and experience of professionals and policymakers within and between countries and identify whether consensus can be achieved. Therefore, this approach helps us establish an instrument capable of generating meaningful and useful data for different countries and different groups of stakeholders.

Third, the use of both the inductive and deductive approaches facilitates the search for elements of effective teaching that are considered important by stakeholders in different countries and are also in line with the knowledge base of educational effectiveness research. This enables us to generate a part of the instrument (i.e., the common part) that can be used across different countries for collecting valid and meaningful data with respect to teacher effectiveness. Another goal of ISTOF was to identify elements that are more country specific, meaning that these characteristics of effective teachers are important in only some countries. The country-specific part of the instrument may generate data that can explain the conditions under which the common aspects of effective teaching operate in improving learning.

Finally, the use of inductive and deductive approaches for developing ISTOF gives us the opportunity to examine the internal validity of the procedure used to define components of effective teaching, and generate their indicators and items per indicator. Moreover, it demonstrates the value of using both quantitative and qualitative approaches in collecting and analyzing data. If similar results emerge from both approaches, one can assume that it is likely that both have generated valid data.

Technique 2: Using the Mixed-Methods Approach

We also decided to conduct a mixed-methods study to develop ISTOF. The reasons for using such an approach are related to our intention to use both inductive (qualitative) and deductive (quantitative) techniques in developing the instrument. Specifically, in order to find out how each expert participating in the country panels understands effective teaching, appropriate qualitative methods such as individual and group interviews were used and the data were analyzed using qualitative strategies. In this way, different views of effective teaching emerged and were taken into account in generating the instrument. But since our intention was to also develop a common part of the instrument, it was important to use appropriate quantitative methods (i.e., administering questionnaires and analyzing numeric data). The quantitative approach emphasizes the identification of those aspects of effective teaching that are considered important across the entire group of country-based expert panels.

Technique 3: Using a Modified Delphi Technique

Activities for developing ISTOF centered on an iterative, multiple-step, Internet-based, modified Delphi technique (Teddle *et al.*, 2008). Modified means that the ISTOF queries asked experts their opinions about what constitutes effective teaching, whereas the original Delphi technique

asked experts to forecast events in the future (Gordon and Helmer, 1964). There are three main reasons for using this technique. First, it enables us to determine whether consensus can be reached among members of an expert panel. In the case of ISTOF, we used the Delphi technique to generate the components, indicators, and items related to teacher effectiveness. The items that constitute the common part of ISTOF are those for which consensus about their perceived importance could be reached within and between country-based expert panels. Second, the Delphi technique has been applied in many settings, such as educational policymaking and even in previous studies on what constitutes effective teaching and it was found to be useful for reaching consensus among groups of participants. Finally, using this technique, feedback is given to members of the country panels consisting of the results of analyzing data that emerged from each stage of developing ISTOF, combined with lessons drawn from analyzing the literature. Then, by applying the Delphi technique, consensus could be reached about the final product of the activity and a new round based on the results of the previous one could be initiated.

Technique 4: Using Generalizability Theory to Analyze Data

Since the findings of the ISTOF project are based on the responses of the panel of experts in each country, it is important to evaluate the dependability (reliability) of the behavior of each member and/or interest group in the panel of each country. At the same time, the issue of reaching consensus among the panel of experts is very important for generating the common part of the ISTOF. Therefore, the analysis of quantitative data must identify the extent to which such consensus was established in each step of the process. Generalizability theory provides answers to these two issues (dependability and degree of consensus) and it is for this reason that it was used for developing ISTOF.

The conceptual framework underlying generalizability theory involves an investigator asking about the precision or reliability of a measure because she/he wishes to generalize from the observation in hand to some class of observations to which it belongs (Shavelson *et al.*, 1989). In the case of ISTOF project, it was considered important to determine the extent to which the responses of each member of the panel of experts to the questionnaire items depend on his/her professional status (e.g., researcher, teacher, teacher-educator, policymaker, or evaluator) and/or on his/her origin from a particular country. Specifically, this analysis helped us to identify the extent to which experts from different countries agreed among themselves about the appropriateness of: (1) the components of effective teacher, (2) their indicators, and (3) the

items designed to measure the set of indicators of teacher effectiveness. Therefore, the use of generalizability theory gave answers to questions concerned with the extent to which the conceptual map of the ISTOF is in line with the opinions of experts in different countries who belong to different groups of stakeholders.

Taking into consideration the rationale given above, the following procedure was used to develop ISTOF by first generating components of effective teaching, and then producing indicators for each component and finally creating items associated with each indicator.

Description of Six Steps/Queries

At the beginning, in each participating country, panels of experts were established. There was a general procedure and requirements for selecting group members and the team leader that each country followed. Details about this procedure are contained in Teddlie *et al.* (2006). Countries participated in the project are as follows: Argentina, Belarus, Belgium (Flanders), Brazil, China, Cyprus, Denmark, Finland, India, Ireland, Japan, Malaysia, Netherlands, South Africa, Turkey, United Kingdom, and the United States of America. This sample of countries is very diverse but due to contextual differences between countries, there were no strict guidelines with respect to the composition of expert panels, but country coordinators were advised to include representatives of the three main categories: researchers, practitioners (i.e., teacher trainers, teacher evaluators, and advisors), and policymakers. Then six Internet-based queries were formulated to guide the development of ISTOF.

Query 1 asked the country-based expert panels to generate broad components of effective teaching in their country and give clear definitions of them. Seventeen country teams sent in lists of 103 components with definitions in response to this query. Using the qualitative data analysis program ATLAS.ti, two different teams of analysts conducted content analyses of these responses by following the constant comparative method (Denzin and Lincoln, 1998). The two lists generated by the teams were reconciled and resulted in a final list of 11 components with definitions (see **Appendix 1** for the list of components and their definitions).

Query 2 asked each country team and its members to assess each of the components by (1) rating how important each component was on a five-point Likert scale and (2) rank ordering the 11 components. Responses to query 2 were received from all participating countries and 257 individual participants. The main aim of the analysis was to identify those components of effective teaching which were regarded as the most important by all participating countries. Using both parametric and nonparametric tests for each part of the questionnaire respectively, it was found out that all components were

rated highly by each country team and by each category of experts. Moreover, it was not possible to classify these components into different groups according to their perceived importance (see Kyriakides, 2005b). These components were then subjected to a generalizability analysis (Shavelson, *et al.* 1989). Specifically, the country and the professional status of each participant were the two facets, which were taken into account. Using the GENOVA software (Crick and Brennan, 1983), a random effects component X (expert:countries), analysis of variance was initially performed. Thus, this analysis makes explicit the country facet acknowledging that experts share some characteristics and help us identify the extent to which the responses of experts depend on their origin from specific countries. Although it was found out that failing to include the country facet led to an overly optimistic estimate of the precision of the measurement procedure during query 2, the component of effective teaching by country and the component by expert (nested in countries) effects were very small. These findings justify our attempt to analyze the data of query 2 by looking at differences across countries. It also reveals only a small effect of the country of origin of each expert upon his/her responses during the query 2. By introducing the facet of professional status, we also attempted to identify the extent to which the response of each member of the panel of experts depends on his/her professional status (i.e., researcher, teacher, teacher-educator, policymaker, or evaluator). The results of this study revealed that failing to include the professional-status facet in the analysis has minimal impact on the estimated error variance.

Comparison of the components with the research literature on teacher effectiveness resulted in minor amendments with respect to the definition of some components and the grouping of them (see Teddlie *et al.*, 2006). Decisions also occurred regarding how each component could be measured especially since four of the components could not be measured through observation. Other ways of measuring each component, such as student ratings, documentary analysis, and self-reports were recommended.

Query 3 asked the country team members to generate up to five indicators for each of the 11 refined components. Altogether, the team members generated about 65 indicators per component, which resulted in almost 750 indicators for the entire set of components. Following the same procedure as in query 1, content analysis of these indicators resulted in a reduced set of 43 indicators (the number of indicators per component ranged from two to six).

Query 4 asked the country team members to assess the importance of each of the 43 indicators generated through query 3 on a five-point Likert scale. Altogether there were 213 individual responses from the participating countries. The procedure for analyzing the data was similar to the one that was used with respect to query 2. It was

determined that 21 indicators, which were seen as highly appropriate from each country, were sufficient for collecting data with respect to the seven observable components of teaching (i.e., clarity of instruction; instructional skills; promoting active learning and developing metacognitive skills; assessment; differentiation and inclusion; classroom climate; and classroom management). Moreover, eight indicators were seen as appropriate by each country panel for collecting data with respect to the nonobservable components (i.e., planning of single lessons; long-term planning; teacher knowledge; and teacher professionalism and reflectivity). However, these components were not utilized in conducting queries 5 and 6, which deal with the development of the observation instrument.

Queries 5 and 6 were concerned with generating items per indicator for the observation instrument. The country coordinators and experts from different countries were split into four groups, which then drafted an average of about three items for each of the seven observable indicators. These items were exchanged for comments and critiques. A final set of 45 items emerged through consensus reached within and between the four groups. Input from experts in the construction of the teacher-observation instruments was also provided and contributed to the development of the final version of the observation instrument.

Main Results

ISTOF resulted in different products which can be used independently from each other. First, as a result of queries 1 and 2, a conceptual map of components of effective teaching that are considered highly important from experts in 17 countries was produced (see **Table 1**). This conceptual map refers to 11 components of effective teaching that are grouped into five overarching factors. It is important to note that the 11 components do not refer exclusively to teacher behavior in the classroom. For example, the fifth overarching factor refers to the professional development of teachers, which is seen as a characteristic of effective teachers by stakeholders in different countries, but only some aspects of teacher knowledge and teacher professionalism and reflectivity could be measured through observation of teacher behavior in classroom. This indicates that beyond demonstrating specific behaviors in the classroom, effective teachers are also expected to develop their knowledge further with respect to teaching (i.e., subject, pedagogy, and pedagogical content knowledge) and to develop themselves further as professionals through reflection and other practices (see components 10 and 11, respectively, in **Table 1**). This view of the country panels seems to be in line with the continuous learning model (Cheng and Tsui, 1999) which assumes that teachers are effective if they can adapt to external and internal changes, cope with different challenges, meet

Table 1 Conceptual map of ISTOF components, with overarching factors of effective teaching

Components from Deductive Committee	Ways of measuring the component				Overarching factors
	Observation	Student ratings	Documentary analysis	Self-reports	
1 Clarity of instruction	√	√			Quality of teaching
2 Instructional skills	√	√			
3 Promoting active learning and developing metacognitive skills	√	√			
4 Assessment and evaluation	√	√	√	√	Adaptive teaching
5 Differentiation and inclusion	√	√			Classroom environment
6 Classroom climate	√	√			
7 Classroom management	√	√			Planning
8 Planning of single lessons		√	√	√	
9 Long-term planning			√	√	
10 Teacher knowledge (subject, pedagogy, and pedagogical content knowledge)					Teacher as a professional
11 Teacher professionalism and reflectivity					

diverse expectations, and develop themselves through continuous learning.

The other two components which are not directly related to teacher behavior in the classroom refer to short- and long-term planning activities (see components 8 and 9 in **Table 1**). This implies that stakeholders in different countries expect their teachers to be competent in planning their activities and in working according to those plans. These two components may also be related to the components concerned with teacher professional development especially since a cycle of planning, acting, and evaluating through reflection is assumed to contribute to the learning of teachers and ultimately to improve the quality of teaching.

The first seven components are more directly associated with the teaching process and they are in line with the working-process model, which assumes that the effective teaching and functional learning processes help teachers to achieve the predetermined objectives measured through students' cognitive and affective learning outcomes (Brophy and Good, 1986). Consequently, teachers are judged as effective when they can ensure the quality of their teaching. Based on the results from the queries, it appears that stakeholders in different countries agreed regarding these first seven components of effective teacher and their definitions. These components were also found in the reviews of the TER literature that accompanied this research project.

Specifically, looking at the three components of the first overarching factor, we observe that they are not only in line with the tenets of structured or direct teaching (Joyce *et al.*, 2000), but also with approaches associated with constructivism (Schoenfeld, 1998). This implies that

stakeholders believe that an integrated approach to teaching should be adapted rather than focusing exclusively on a specific approach. This view of stakeholders is supported by recent findings of effectiveness studies which have shown that by adapting an integrated approach to teaching, teachers can become more effective (Kyriakides and Creemers, 2008). Moreover, stakeholders across a large number of countries agreed that formative assessment is an important component of effective teaching (see component 4 in **Table 1**). Again, empirical evidence from a number of studies provided strong support for this component (Kyriakides, 2005a).

Furthermore, stakeholders in different countries underlined the importance of differentiation in teaching, thereby agreeing with published research and theoretical models that treat differentiation and inclusion as important elements of effective teaching (see component 5 in **Table 1**). Finally, the classroom-environment overarching factor and its two components indicate that stakeholders believe that effective teachers should organize and manage the classroom environment as an efficient learning environment and thereby maximize engagement rates (Creemers and Reezigt, 1996; Doyle, 1986). With respect to this overarching factor, the two components (i.e., classroom climate and classroom management) are seen as important for measuring teacher effectiveness by both the stakeholders and the research literature, indicating that the classroom environment should not only be businesslike but also needs to be supportive for the students (Walberg, 1986). Therefore, effective teachers are expected not only to manage their classroom in order to keep students on task but also to create a positive, learning-centered environment with an atmosphere of mutual respect between

students and between students and the teacher (Creemers and Kyriakides, 2008).

Results from the first two queries point to the fact that consensus about what constitutes effective teaching among stakeholders from different professional groups was easily achieved in a large number of countries, and all of the components which were generated were seen as very important by all the country panels. It was, therefore, not possible to treat any of them as country specific. Since only a handful of effectiveness studies had been conducted in most participating countries, most of the members of the country-based expert panels were not aware of the knowledge base of effectiveness research. Despite this, these country-based panels conceived of teacher effectiveness in the same way as more experienced members and researchers. Therefore, reaching consensus easily among the participants in the ISTOF project can be interpreted as a strong argument for the existence of a common understanding of what constitutes effective teachers.

These results are also in line with the findings of a recent collaborative work by inspectorates of education in Europe, which reveal that the quality of teaching in four countries could be compared in a reliable and valid way with regard to constructs such as a safe and stimulating environment, clear instruction, adaptation of teaching, teaching-learning strategies, and classroom management (Van de Grift, 2004). The constructs that emerged from that European study are similar to those identified through ISTOF where a larger number of countries from different parts of the world participated. These findings imply that there are factors which can describe the process of teaching and learning that are common in different educational settings irrespective of their specific social and cultural context (see also Creemers and Kyriakides, 2008).

A list of 43 indicators for these 11 components of effective teaching emerged from queries 3 and 4. Again, consensus within and between the country panels was reached, but only 29 out of 43 were seen as very important from all the participating countries and the various groups of stakeholders. We, therefore, decided to retain these 29 indicators in the common part of ISTOF and treat the others as country specific. This overall pattern of results indicates that although there is a common understanding among stakeholders in the participating countries on what constitutes effective teaching, some indicators are seen as appropriate in specific countries only due to social and cultural reasons. For example, only the Chinese team treated the time that each teacher spends on his/her career (e.g., hours spent at students' home-visits or for assisting students in his/her spare time) as an indicator of his/her professionalism.

On the other hand, indicators which were rated as very important by each country panel can be used not only for establishing the common part of ISTOF but also for

helping policymakers collect evaluation data. For example, policymakers and practitioners in different countries may make use of them to establish their own instruments based on a more specified frame that is applicable across countries. Moreover, they can create a basis for comparative studies concerned with the effectiveness of teaching practices in their countries.

Three indicators associated with two different observable components (i.e., Components 1 and 3), which were used for the construction of the common part of ISTOF, are presented below as an illustration of the common indicators which were developed:

Component 1: Assessment and evaluation

- *Indicator 1.1.* The teacher gives explicit, detailed, and constructive feedback.
- *Indicator 1.2.* Assessment is aligned with goals and objectives.

Component 3: Clarity of instruction

- *Indicator 3.1.* Lessons are well structured.

The final product of ISTOF was a high-inference observation instrument consisting of 45 items associated with the 21 indicators of the observable components. Each indicator is represented by two or three items which are rated on a five-point Likert scale. Together with the instrument, guidelines for training observers to use the instrument were produced. We recommend in the guidelines that observers should be familiar with the 45 items on the observation instrument before conducting any observations. The guidelines also stressed that during the training, each indicator and each item of the observation instrument should be discussed by the trainees before using the instrument. In addition, we have advocated that trainees should conduct observations using the instrument and the training should be continued until interrater reliability (computed using Cohen's kappa) at 0.70 level is achieved. Two items used for measuring two indicators are given below to illustrate the content and form of the observation instrument:

- *Indicator 3.3.* Lessons are well structured.
- *Item 13.* The teacher presents the lesson with a logical flow that moves from simple to more complex concepts.
- *Indicator 4.2.* The teacher possesses good questioning skills.
- *Item 18.* The length of the pause following questions varies according to the difficulty level of questions (e.g., a question calling for application of abstract principles requires a longer pause than a factual question).

ISTOF was conceived as a protocol that would employ mainly observational items. While this is the case, there are components of effective teaching that were generated through queries 1 up to 4 that are unobservable. The country teams indicated that planning, teacher knowledge, and teacher professionalism and reflectivity should be included on the ISTOF protocol even if it meant

developing alternative data sources. For this purpose, alternative methods of measuring these components have been developed and a student questionnaire is currently being validated in different countries.

Conclusions

The final section of this article draws implications from the ISTOF project for the process of developing valid international instruments that can be used in comparative studies searching for multilevel factors that may explain variation on student outcomes in different countries. We believe that the use of both inductive and deductive approaches in developing ISTOF made important contributions in producing both the common and the country-specific parts of the instrument. Specifically, the inductive process, facilitated by the use of modified Delphi technique, made it possible to identify and classify the views of different stakeholders and relate them to each other. That process served the purpose of identifying those views that are shared by the great majority of stakeholders in different countries, as opposed to those that are supported either by individuals or a few stakeholders in only a small number of countries. Then by comparing the results of the inductive approach with the results of the deductive approach, which is concerned with establishing consensus from all the available empirical evidence including that from the literature, the common part of the instrument was produced. This common part of the instrument, therefore, consists of constructs/indicators/items that are supported both by the general research evidence and the experts/stakeholders from ISTOF. At the same time, this comparison revealed the importance of generating country-specific constructs/indicators/items. However, it should be acknowledged that using both inductive and deductive approaches in developing the framework of an international instrument can be problematic both in terms of collecting data from a large number of stakeholders in different countries and in terms of establishing consensus among them. Nevertheless, our experience with ISTOF indicates that the Internet-based approach that characterizes much of the project contributed greatly to its success.

The use of both deductive and inductive approaches in developing the ISTOF resulted in an effective teaching framework that is shared by a large number of countries in different parts of the world and with different experience in educational effectiveness research. Countries where there is not much of a research tradition in educational effectiveness can use this framework as a point for departure for launching their own research. In fact this research is not only relevant for their countries, but can also contribute to the knowledge base of the field. Therefore, using inductive and deductive approaches to developing

international instruments concerned with effectiveness factors operating at different levels (e.g., school climate, school self-evaluation, and parental involvement) may result not only in establishing valid instruments that are meaningful for different countries, but may also contribute to the development of a program for future research in parts of the world where it did not exist before.

Finally, it is important to acknowledge the dilemmas that may arise when using this approach. Given that there is huge variation in experiences and knowledge in the participating countries, the danger for more experienced researchers to impose their agenda on other participants is an issue that has to be considered. Ultimately, bringing together stakeholders and researchers from different countries should result in establishing a learning environment where participants can develop knowledge and experience further by cooperating with colleagues from different countries. At the same time by advocating this international cooperation, we do not imply that quality standards for educational research should be ignored or disregarded. The lack of experience in some countries may be compensated by undertaking some tasks centrally (e.g., using advanced qualitative and quantitative techniques to analyze data). In such cases, the presentation of the outcomes of these tasks should be done in a way that is meaningful for all members and that allows participation of all country panels in the discussion about the meaning of these results, or even the need for further analysis of data and further development of the project. Thus, this article demonstrates that although projects aiming to develop international valid instruments are complicated, such projects can also contribute significantly in the further development of policy, practice, and theory of educational effectiveness.

Appendix 1: Definition of ISTOF Components of Effective Teaching

Clarity of Instruction

The teacher is able to communicate clearly and directly with students and is able to adapt her/his communication to student's levels of understanding and their individual differences. The teacher clearly explains the purposes of class activities. The teacher has good listening skills and is a good facilitator who is able to draw out student potential.

Instructional Skills

The teacher uses a variety of methods and strategies effectively. S/he has also basic instructional skills including orientation, structuring the lesson, presentation, questioning, listening, balancing teacher input and student activity, and making use of appropriate teaching aids.

Promoting Active Learning and Developing Metacognitive Skills

The teacher is able to connect the learning contents to the students' prior knowledge about the world. The teacher makes use of students' own views on their learning as well as their self-conceptions as learners in different learning domains and promotes active involvement of students in her teaching and instructional practices. S/he also fosters metacognition, critical thinking, creativity, self-regulation, and reflection. S/he also helps students develop their own strategies for solving different types of problems.

Assessment and Evaluation

The teacher uses various techniques to assess and evaluate student learning during and after teaching sequences, in order to check whether learning goals have been reached, and to adapt teaching to student needs and progress. Based on information gathered from student assessment, the teacher also evaluates herself/himself and makes decisions on how to improve her/his teaching skills and practice. Assessment procedures include immediate and formative feedback, aimed at enhancing student self-evaluation and metacognitive skills.

Differentiation and Inclusion

The teacher is aware of, and adapts instruction to, the individual needs of her/his students. S/he focuses on their individual development, while making sure all are included and empowered in the learning community.

Classroom Climate

The teacher creates a positive, learning-centered environment with an atmosphere of mutual respect between students and between students and the teacher. The environment is both safe and caring. High expectations exist for all students and are clearly communicated to students by the teacher. The teacher expresses genuine affection for children, and all students feel valued and experience enhanced self-concepts.

Classroom Management

The teacher manages the classroom effectively. S/he has good time management, establishes a purposeful lesson flow, and allows all students learning opportunities through effective behavior management, which includes clear and accountable procedures and rules while allowing students to exercise autonomy.

Planning of Single Lessons

The teacher effectively plans instruction and the creation of a challenging learning environment to foster student learning. S/he bases her/his teaching on clear and explicit goals that are communicated to students. The teacher is well prepared with materials and resources ready at the outset.

Long-Term Planning

Long-term planning is the organization of the curriculum and especially of the content to be covered over time within grade level and over grades. It refers to the time needed to cover the curriculum and the emphasis given on topics and objectives. It asks from the teacher not only to look forward but also to see what she has done and to change her teaching plan if necessary.

Teacher Knowledge (Subject, Pedagogy, and Pedagogical Content Knowledge)

The teacher has a good knowledge of relevant subject content, pedagogy, theories of learning, motivation and human behavior, and is able to use this knowledge to shape her/his practice. S/he applies these knowledge bases in the classroom within an organized curriculum that facilitates student learning.

Teacher Professionalism and Reflectivity

The teacher reflects critically on her/his own and others' practice, engages in dialog with peers, is committed to lifelong learning, and regularly updates her/his knowledge and skills. S/he is able to work in a fast-changing environment and adapt to policy initiatives and is characterized by proactivity toward innovation.

Glossary

Causal inferences – A conclusion about whether a program directly leads to some outcomes in a target population.

Cost-efficiency studies – Studies aimed at evaluating the long-term benefits, effects, feasibility or perceived utility of a program or policy intervention in monetary terms. Examples include cost–benefit, cost–effectiveness, cost utility and cost–feasibility studies.

Ecological validity – The extent to which evaluation results are pertinent in real settings where the program is likely to operate.

Educational evaluation – Systematic inquiry processes used for monitoring, improving, and/or appraising the quality of educational entities in stakeholder contexts.

Evaluability assessments – A pre-evaluation study, conducted to examine the extent to which a program is ready for a formal evaluation.

Evaluand – The object of inquiry in an evaluation.

Evaluation research – The systematic use of a variety of social research methods and tools of inquiry for answering evaluation questions, guided by stakeholder needs for information about programs or policies.

Evaluation researchers – See the definition of the glossary term ‘evaluators’.

Evaluation utility, evaluation use – The extent to which the results of an evaluation are meaningful and useful to stakeholders and help improve prevailing educational or social conditions.

Evaluators – Professionals, usually with graduate-level training in social research methods, who

provide evaluation research services to clients and stakeholders.

Evidence hierarchies – Related to policies in evidence-based practices, this term refers to a research design hierarchy linked to the quality of evidence that particular research designs yield. In a widely-used evidence hierarchy, randomized experiments are considered best for generating impact evidence on programs.

Evidence-based education (EBE) – A policy that requires educators to use practices, programs, and interventions that are supported with empirical evidence obtained via research and evaluation studies. The policy is also called evidence-based practice (EBP).

Formative evaluations – Evaluations in which results are used for refining and improving an entity.

Generalizability – The extent to which evaluation results can be extrapolated from smaller samples of observations to the larger population.

High-stakes testing – A policy or practice where results from test administrations are used by authorities to impose sanctions or grant rewards to students, teachers, or leaders in an education system.

Impact evaluations – Studies aimed at monitoring effects and evaluating the expected outcomes of a program or policy intervention.

Large-scale assessments – School-wide or system-wide testing of student achievement outcomes in order to document trends or assess present status, usually driven by public accountability requirements.

Logic models – Causal path diagrams revealing assumptions about how an entity is expected to work

in actual contexts (see the definition of the glossary term ‘program theory-driven evaluation’).

Needs assessments – Evaluation studies intended to determine the scope and dimensions of a social or educational problem, where results are typically used to plan or inform the design of a new program or policy intervention.

Performance assessments – Systematic procedures designed to observe and rate the quality of performances (e.g., classroom behaviors of students and teachers).

Process evaluations – Evaluation studies aimed at monitoring the implementation processes of a program or policy intervention.

Product assessments – Systematic procedures designed to rate or classify the quality of an educational product (e.g., teacher-developed instructional materials).

Program theory-driven evaluation – An approach to evaluation design that uses causal path models to depict and test the underlying assumptions of how a program is expected to work, identifying key variables and expected relationships (see also the definition of the glossary term ‘logic models’).

Replications – Repeated studies conducted with different samples to verify results.

Social research methods – Formal tools of inquiry used in the social sciences, including those employed in quantitative, qualitative, and mixed-method research designs.

Summative evaluations – Evaluations in which findings are used to make a final judgment of the merit or worth of an entity.

Systemic evaluation – A comprehensive evaluation design that examines a program’s context, inputs, processes, or outcomes within the organizational or community system.

Unit of analysis – The units that are formally selected, observed, described, analyzed, or appraised in an evaluation.

Educational evaluation, also called evaluation research in education, involves inquiry processes that rely on a range of social research methods. Evaluative inquiry is aimed at answering questions relevant to making decisions in educational practice and policy contexts. The primary goal of educational evaluation is to monitor and gauge the effectiveness of various educational programs and to improve their functioning. Educational evaluations are also intended to appraise the extent to which students learn and attain educational goals, both in and out of formal school settings.

While there are long-standing debates about what types of methods are most useful for particular evaluation

purposes and problems, there is widespread agreement that some form of systematic and formal methodology is necessary to support most kinds of evaluation research (Cronbach *et al.*, 1980; Guba, 1969; Stake, 1984; Campbell and Stanley, 1963; Eisner, 1994; Cook, 2002). A variety of research tools, procedures, and approaches have, thus, emerged over time to serve the needs of educational evaluation.

Purpose

This article provides a broad overview of methodological approaches available today for the conduct of educational evaluations and discusses their applications, advantages, and limitations. To set the stage, it first discusses the unique characteristics of evaluative inquiry, stressing on issues surrounding the object of inquiry, units of analysis, and question-method alignment. The article aligns different classes of research methods with guiding evaluation questions and decision-making contexts where the evidence is likely to be used. It concludes by touching on the interdependence of evaluation methods, use and values; the role of stakeholders; and the methodological issues relevant to current movements of evidence-based education (EBE), comparative international assessment, and the globalization of the education enterprise. Salient terms are defined in the text or glossary.

To examine how the use of various methods fits within the larger scheme of conceptualizing, designing, and conducting evaluations, consider **Table 1**. The table shows a range of possible educational objects that could be the focus of evaluations, linked to corresponding questions and decision-making contexts. Although not an exhaustive list, the table serves as a starting point for discussing key evaluation methodology issues.

The Nature of Evaluative Inquiry

Understanding the Object of Inquiry

A first concern in conducting an evaluation is the object of inquiry (see **Table 1**). Michael Scriven coined the term ‘evaluand’ to refer to what we evaluate in an evaluation (Scriven, 1991). A precondition to appropriate choice and application of evaluation methods is to have a sound grasp of the evaluand and a clear specification of the purposes for doing an evaluation.

In most educational evaluations, the evaluand is a program implemented in a school setting (**Table 1**, example 1). As shown in **Table 1**, however, the focus of an evaluation can include a variety of other entities (see **Table 1**, examples 2–7). Recently, there is growing recognition that many field-based educational interventions have socially complex and multivariate configurations. Further, they

Table 1 Educational evaluation: Evaluand types, evaluation questions, and decision-making contexts

<i>What is evaluated: Evaluand type</i>	<i>Specific example</i>	<i>Evaluation question(s)</i>	<i>Possible decision-making contexts</i>
1. A curriculum, program, or educational service	A new science curriculum for K-12 grades	Is the new program more effective in improving student achievement than the current one?	Actions on program adoption or continuation
2. A system-wide policy	Class size-reduction policy in elementary schools	How consistently is the policy being implemented in schools? To what extent does the policy help improve students' academic achievement when consistently implemented?	Decisions on improving policy implementation levels
3. An institution or school	A college undergoing national accreditation	Do services, operations, and outcomes of the institution meet standards of quality set by external accreditation boards? What are the areas in which improvements or changes are needed?	Decisions on institutional accreditation Strategic planning and goal-setting in programs and in the institution
4. Personnel	Teachers and staff in a school	Does staff performance meet criteria valued in the institution?	Conducting annual performance reviews of personnel Giving formative feedback to individual staff
5. Individual Students	Elementary-level students	Have the students met expectations set by the teachers and school authorities to move to the next level? What are the students' strengths and weaknesses in different domains?	Decisions on student promotion Individual educational planning
6. An education system, group of institutions or programs within institutions	Secondary schools in a system	What percent of students, in different subgroups, meet the achievement standards set by local or public authorities?	Decisions related to public accountability
7. An educational product	An Internet-based science curriculum	Does this product meet quality criteria set by relevant experts?	Actions on curriculum adoption
8. A joint policy and program package	School-level class size-reduction policy combined with classroom-level curriculum delivery strategies	What types of curriculum delivery strategies work best under different class size conditions?	Resource-allocation decisions in a system to reduce class sizes and utilize effective curricular strategies

frequently operate in open organizational systems with multiple levels.

A complex intervention example from **Table 1** would be a class-size reduction policy implemented at an upper organizational level, operating in unison with a teacher-delivered, classroom curriculum (example 8). Both these entities jointly target a common outcome, improving student achievement. Curriculum resources, delivery processes, teacher characteristics, and infrastructure supports, are all potential factors influencing outcomes. Some factors could interact with one or both intervention elements. These multiple and dynamic variables together define the program and its context.

Not all entities evaluated are as complex as example 8. Regardless, a thorough understanding of the evaluand is necessary to ensure that it is appropriately specified in the

conceptual framework underlying an evaluation design. A limited or erroneous specification of the object of inquiry poses barriers to formulating relevant evaluation questions, and leads to inadequate data-gathering tools and analytic approaches. Findings might miss the mark in such circumstances and lose their utility in decision-making contexts. A common error in specifying complex programs is in the form of a binary variable (denoting its presence or absence) that oversimplifies an entity's multi-factor composition.

Program theory-driven evaluations (also 'logic models' in glossary) are useful heuristic mechanisms for improving evaluation designs of complex programs like example 8. Logic modeling techniques appeared in the methodological literature in the 1990 (Chen, 1990; Donaldson, 2007; Rossi *et al.*, 2003; Weiss, 1997).

Basically, logic models are flow charts. They help identify major variables that define a program and its context, and show how these variables logically lead to outcomes in specified populations. In doing so, logic models reveal the implicit and explicit assumptions underlying how particular programs are expected to work. Logic models make it easier for researchers to focus on relevant variables, to formulate better questions, and to test hypotheses about various interrelationships and effects. A program's logic may be based on some underlying social science theory or on beliefs of the developers and users.

Units of Analysis in an Evaluation

A related but not always overlapping factor with the object of inquiry is the unit of analysis in an evaluation. It is the units of analysis that are formally selected, observed, described, analyzed, or appraised in an evaluation. The examples in **Table 1** illustrate differences in the units of analysis in different evaluation problems.

In an evaluation examining effects of an intervention on school populations, the units of analysis are typically the students on whom outcomes are measured (see examples 1, 2, and 6 in **Table 1**). In a study of a school undergoing accreditation, on the other hand, the institution as a whole would serve as both the unit of analysis and object of inquiry (example 3, **Table 1**). When a product is being evaluated, such as a packaged curriculum, the unit as a whole is again the object of inquiry (example 7, **Table 1**). When measuring outcomes at different levels of an organization, units of analyses can be taken from multiple levels of the system (example 8, **Table 1**). We could sample students as units from classrooms. We could also sample classes as units from schools or larger education systems.

Identifying appropriate units of analysis is an important concern from both a conceptual and methodological standpoint in designing evaluations. Inferences and overall conclusions ultimately pertain to these units. As evident, the units relate directly to the object of inquiry even when they are not one and the same.

Aligning Evaluation Purposes and Questions with Methods

Along with clarity on the evaluand and units of analysis, the evaluation purposes and specific evaluation questions must be clear to both evaluation researchers and users of the information. The motivating purposes of an evaluation directly affect the choice of methods. Well-framed questions instantly point to the methods that are most appropriate.

Traditionally, four main categories of evaluations have been identified in the literature, based on their guiding purposes: needs assessments; process evaluations and

implementation monitoring studies; impact evaluations; and (cost) efficiency studies. Yet another type of study, labeled as an evaluability assessment, is driven by a need to assess the readiness of a program to be evaluated. Evaluability assessments occur before an entity is subjected to a formal evaluation (Rossi *et al.*, 2003). More comprehensive evaluation design frameworks have also been proposed, and these frameworks combine the above purposes to different degrees and in different ways.

A more general classification of different evaluations, given by Scriven (1991), distinguishes between formative and summative evaluations. This dichotomy is based on the decisions and actions taken with results. Formative evaluations utilize results for developing, modifying, or improving the evaluand (see the second question in example 3 of **Table 1**), while summative evaluations use findings for making some definitive or final judgments of worth (see example 1 in **Table 1**).

A possible range of evaluation questions associated with different types of evaluands is shown on the right-hand side of **Table 1**. To elaborate on the principle of question-method alignment, let us review the examples closely.

In **Table 1**, the first example “Is the new program more effective than the current one?” is an example of an impact evaluation question. The interest here is in a program's effects in terms of outcomes on some target population. The framing of the question clearly suggests a need for comparative experimental tools to assess a new program against an existing one.

The second question in **Table 1**: “How consistently is (a) policy being implemented in schools?”, on the other hand, reflects a process evaluation problem. Here, useful methodological tools would help describe the implementation processes of a policy in schools against the expected policy theory.

The third question, showing an accreditation example, reflects a need for an in-depth examination of an institution as a self-contained unit. Here, case study methodology may be the best match.

Product and performance assessments are common tools for curriculum and staff evaluations. Product or performance reviews call for valid and reliable assessment instruments that tap into relevant constructs, generating data that can be interpreted meaningfully and reliably.

In contrast, altogether different methodological approaches would help answer needs assessment questions. Needs assessment problems are not represented in **Table 1** call for evaluations of the scope and dimensions of a community-wide problem, such as, and how widespread is the high school dropout problem in New York? The information can be fed into the planning and development of a suitable intervention to address the issue. Large-scale survey methods, archival data analyses, and focus group interviews are common approaches for conducting needs assessments.

Integrated designs that are more ‘systemic’ have been recommended for educational program evaluations, both in the past and, more recently, in the context of evidence-based education. A well-known systemic framework is the context, input, process, product (CIPP) model (Stufflebeam, 2004). The CIPP approach is a developmentally oriented and organization-focused approach to evaluation, with an aim to improve rather than simply prove whether an entity and its parts work (p. 247).

Systemic designs are particularly necessary when the evaluand has a complex definition and operates in a complex environment. Because of their breadth, systemic evaluation questions demand the integration of multiple research methods, including necessary tools to gauge program effectiveness (Chatterji, 2005). Such evaluations may call for a layered set of questions aimed at capturing how, why, and when complex entities work. For a school-based program, guiding questions might look like this: What types of delivery practices produce the desired effect? Under what conditions, and with what type of student are the effects realized?

Evaluation Design Options and Methodological Tools

We now turn to three broad classes of research designs that offer methodological options to evaluation researchers to address a range of questions: quantitative, qualitative, and mixed-method designs. The three design categories are characterized based on the research purposes they best serve, underlying assumptions, and their strengths and limitations in applied contexts.

Quantitative Design Options

In the quantitative tradition of research, data on all variables are collected, coded, and analyzed in numeric terms. This tradition is founded on logical-positivistic and post-positivistic philosophies of science. The purpose of science, from this perspective, is the pursuit of universal laws that explain cause and effect relationships and natural covariations. A basic belief in this tradition is that there is an objective reality outside the researcher that can be investigated (Robson, 2002; Best and Kahn, 2003).

There are three main methodological options in this category for evaluation researchers: randomized experiments, quasi-experimental designs, and nonexperimental or observational designs. The degree of certainty with which each allows causal inferences depends on how well their assumptions are met and how rigorously the methods are executed in field settings.

Manipulation, comparison, and control are the hallmarks of a sound experiment aiming to detect causal effects of programs. When a clean, causal link can be established between a manipulated experimental variable

(say, a mathematics program) and a desired outcome (mathematics achievement in students), the study is said to have ‘internal validity’. An isolated effect is a ‘net’ effect with extraneous or confounding factors eliminated or controlled; otherwise, effects are described as ‘gross’ (Rossi *et al.*, 2003). When the effect generalizes to other units in the population or to different settings, the findings are said to have ‘external validity’. These two validity considerations have to be balanced in designing and executing field-based impact evaluations (Campbell and Stanley, 1963).

Randomized field experiments

In a randomized experiment, participants are placed in a treatment (usually, a new program) or a control group using procedures that ensure each person an equal chance of belonging in either condition. Case assignment is independent. Each participant in the experimental group is then exposed to the program, while with the control group is withheld from the same.

When randomization is well executed and there are enough participants, the procedure results in groups that are equivalent on pre-existing factors. Without any treatment, average outcomes are expected to be the same in both groups. If outcome means differ at the end of the experiment and favor the experimental group, the method permits a direct causal inference that the program caused that effect.

The main assumptions of experimental designs are:

- presence of a well-defined and manipulated treatment;
- stable and authentic delivery of the treatment;
- conditions that control or hold all other factors constant; and
- use of defensible outcome measures.

In theory, the experimental method may be applied in any impact evaluation seeking to make causal inferences linking a program to outcomes. The guiding questions for such studies are typically framed as follows: Does the entity have a statistically significant effect on measured outcomes, on average, as compared to a control program? What is the size and direction of that effect?

Strengths and limitations

Randomized experiments originated as a laboratory method. When assumptions are met, they are considered the most powerful designs for confirming cause–effect relationships (Schneider *et al.*, 2007). However, assumptions are difficult, often impossible, to meet under field conditions (Cook, 2002). Common threats to internal and external validity include poor execution of the randomization procedure; differential levels of subject attrition resulting in nonequivalent comparison groups; poor specification of evaluand; poor fidelity in program

implementation; treatment noncompliance (e.g., due to student absenteeism); nested, hierarchical, and open systems unaccounted for in designs that violate independence assumptions; overlooked or mis-measured environmental factors in analytic models; inaccurately interpreted effects of treatment; compromised external validity due to very tight controls; and inadequate sampling of relevant units, conditions, and time points (Chatterji, 2007; Shadish *et al.*, 2002; West *et al.*, 2000).

Quasi-experimental designs

A range of quasi-experimental designs offers different ways to address some of the preceding challenges in conducting field experiments under real-world conditions. Quasi-experiments are also the best design option when randomization is precluded due to ethical, logistical, or other barriers. Three designs are considered the best alternatives to randomized experiments for making causal inferences in impact evaluations (Shadish *et al.*, 2002; Schneider *et al.*, 2007; West *et al.*, 2000). They are:

1. matched, nonequivalent groups designs;
2. regression discontinuity designs; and
3. interrupted time series designs.

In the matched, nonequivalent groups design, two or more groups are identified and they are exposed to different conditions, one of which is the treatment under investigation. Randomization is not used for group assignment, as procedures for subject placement are often not in the researcher's control. The groups are matched on a few selected variables to establish equivalence, so that on average, they are similar (say, within a range of half a standard deviation unit). An example of an off-cited study compared the achievements of students attending public and private schools, and was done by Coleman, Hoffer, and Kilgore in 1982.

Both groups are usually measured before and after the treatment. Internal validity is instituted through statistical controls or matching methods using preexisting characteristics known to influence the outcome variable. A traditionally used matching variable is a pretreatment measure, such as prior achievement scores. Mean outcome measures are compared at the end of the experiment.

Several statistical adjustment techniques are available to correct for selection biases in applying quasi-experimental approaches. These include the analysis of covariance (ANCOVA), ANCOVA with correction for unreliable measurement; gain score analysis; and a number of regression-based econometric methods, such as propensity score matching. Unlike traditional matching described above, propensity score matching involves matching on multiple covariates that are probabilistically predicted to be most pertinent for establishing group equivalence. The use of instrumental variables is another econometric method that is now a part of an education evaluator's toolbox.

The regression discontinuity design is applicable when placements are deliberately made to nonequivalent treatment groups based on a prior quantitative measure, usually a test to determine merit or a special need for treatment. For example, students may be placed in English as a Second Language (ESL) classes due to a diagnosed language deficiency, based on a cut-score on a placement test. Suppose, the outcome of interest is reading achievement administered at the end of the term. In applying this design, the reading outcome measure would be regressed on the placement measure when the experiment ends. If the ESL intervention works, a break would be evident in the regression line at the cut-point separating the treatment and control groups (see West *et al.*, 2000 for details).

In the last design option in this category, the interrupted time-series design, measurements on the outcome variable are collected at equally spaced intervals in a selected group. The intervention program is then introduced at particular points in time, breaking the series. In a graphic representation of the series of data points, spikes would be observed during each intervention spell, if the latter was effective.

Time-series analysis would be a useful method to examine changes in levels of achievement of children originally attending a public school, who are subsequently rezoned to a charter school. Time-series analyses can be enhanced with the use of comparison groups, so that changes in outcomes can be attributed more definitively to the intervention.

Strengths and limitations

Quasi-experiments need judicious application, as specific designs apply to particular types of evaluation problems. The designs discussed are considered to approximate the effects of randomized trials (Schneider *et al.*, 2007; West *et al.*, 2000). A main assumption is that variables defining the evaluand, outcomes, covariates, and matching variables are all well specified and properly measured. A further assumption is that all alternative hypotheses explaining outcomes are systematically ruled out. Covariate-based regression procedures assume that there is no interaction between the treatment and covariates – an assumption that needs testing.

There are several threats to quasi-experiments that mirror those listed for randomized experiments. Some common internal and external validity issues include the following: persistent group selection biases; poorly measured or selected covariates, matching variables, or outcomes; subject attrition resulting in nonequivalent samples; reduced statistical power due to loss of subjects or limited sample sizes; external factors influencing the outcomes during the course of the study (e.g., environmental, history or maturation of sample); lack of attention to nonlinear relationships; regression toward the

mean; weakened generalizability due to poor sampling of relevant units; and lack of attention to hierarchical, nested structures where applicable.

Observational (nonexperimental) designs

In this design category, we consider three overlapping approaches: survey research, secondary analysis of large databases, and retrospective case control designs. At a basic level, observational methods are useful in quantitatively describing the status or trends in a population on selected characteristics. When comparative experimentation is impossible, these approaches help establish associations (or covariations) among independent and dependent variables under less controlled and more natural conditions. The methods are so called because there is no direct manipulation of an experimental variable. Data from such studies permit descriptive, correlational, predictive, or explanatory analyses.

Large-scale education evaluations using survey methods, both cross-sectional and longitudinal, are widely used today. For example, the National Center for Educational Statistics in the United States (U.S.) publishes periodic reports called *The Condition of Education*, based on sample survey research – a nonexperimental approach. In the developing world, India's National Sample Survey Organization conducts similar nationwide surveys to monitor population trends vis-à-vis national policy changes. Bangladesh's *Education Watch* reports published by the Campaign for Popular Education since 2002, are another international evaluation relying on nonexperimental methodology.

Most large-scale surveys employ probability sampling procedures, with mail-out, web-based, telephone, or interview-based surveys of subjects conducted by trained field researchers. Survey databases can be used to generate a series of subsequent and ongoing studies. A distinction, thus, is made between a primary analysis of an original survey, and a secondary analysis of the same database by other researchers.

With the development of newer statistical methods, some degree of causal inferences are possible with these data sets when supported with appropriate and theoretically grounded causal models, statistical controls, and variable measures (Schneider *et al.*, 2007). Although there is debate, some researchers recommend confirmatory evaluations using covariance structure models, incorporating causal inferences.

Survey research involves the design of self-report questionnaires that tap variables and domains of interest, such as public opinions, perceptions, and attitudes towards teachers, and schools. Researchers should gather the necessary evidentiary support to claim validity and reliability of survey-based indices. Target populations for education surveys may include students, teachers, parents, or administrators.

To see how a retrospective, case control design might be designed, let us consider a study investigating the

correlates of high school dropout status. To begin, cases are selected that are known to belong in two conditions (e.g., school dropouts vs. completers). Next, researchers go backwards in time to collect data on potential predictors and background characteristics of the groups. Predictor selection may be based on existing knowledge or social science theory. Cases in the two groups may be matched or statistically controlled on selected background characteristics, and an analysis ensues to identify variables maximally predicting the propensity of students to drop out or stay in school.

Strengths and limitations

Many evaluative questions are best answered with observational designs. Needs assessments (e.g., identifying incidence of smoking in schools), process evaluations (e.g., monitoring instructional delivery practices), trend studies (e.g., comparing achievement trends in different groups in education systems) call for some combination of descriptive, longitudinal, or correlational approaches that rely on surveys or large database analyses.

Some variables relevant for particular policy evaluations, such as gender, simply cannot be experimentally manipulated. For example, monitoring male versus female outcomes is necessary for in global education evaluations examining gender equity of initiatives such as the United Nations' Millennium Development Goals and Education for All. With carefully selected probability samples, surveys make it possible to extrapolate from sample statistics to population parameters with estimates of error. Further, survey methods are relatively easy and practical to administer to school populations; statistical procedures are, likewise, well developed and tested.

Simultaneously, survey questionnaires and data retrieved from existing databases place a measurement burden on researchers. Common sources of error include low response rates, missing data, low validity and reliability of survey indices due to poorly constructed items or data collection instruments, acquiescence bias and faking by respondents, and variabilities caused by irregular survey administration or data collection procedures. In addition, errors can be introduced through other breakdowns in the sampling procedures and fieldwork, threatening representativeness and external validity of findings. Causal-comparative inferences with observational data are, at best, tentative without addressing all the statistical issues that apply to experimental methods, such as covariate selection, control of subject selection biases, and appropriate modeling of moderators and mediators.

Qualitative Design Options

Qualitative research methods arise from a phenomenological philosophy of inquiry (Creswell, 2003). Here, the interest is in understanding and interpreting the essence

of a phenomenon through direct lived experience. Several discipline-based traditions to qualitative inquiry exist, including ethnography (from anthropology), phenomenology (from philosophy), hermeneutics (from theology, philosophy, and literary criticism), heuristics (humanistic psychology), and ethnomethodology (from sociology).

Common themes in these approaches are immersion of the researcher in the details of occurrences through direct induction; unobtrusive, unmanipulated, naturalistic study of real-world phenomena; personal contact, narration, and subjective insights; attention to processes and process dynamics; sensitivity to context and context dynamics; holistic approaches to interpreting and understanding phenomena; unique case orientation; and emergent rather than fixed, predetermined designs (Ryan and Bernard, 2000).

Qualitative data sources include running text, video or audio data from interviews, field notes of external observers, participant observations, and documents and artifacts. Focus group interviewing is another popular method used in evaluations. Although some methods of data reduction and categorization might yield counts and frequencies (such as classical content analysis rooted in linguistics), rich, thick description is a primary characteristic of qualitative methodology. Themes are extracted from data gathered from natural environments and organized to tell a story. By design, the researcher becomes an instrument in the processes of data collection, analysis, and interpretation.

Qualitative methods are useful in answering ‘why’ and ‘how’ things happen as they do; the approach emphasizes interpretation and use of insights and personal experiences of both the researchers and participants to deepen understandings. The purpose of one kind of qualitative inquiry is description, narration, and interpretation (e.g., content analysis and historiography). Researchers collect data through direct participation and observation; then, they record, code, and construct meanings from themes and patterns that emerge.

The aim of another kind of qualitative inquiry is in rendering expert, subjective criticism or value-based insights (e.g., literary criticism and critical review).

Specific aims vary with individual studies. For example, a case study may be more descriptive in purpose, employed to examine bounded social units and how they function. An ethnography may be critically interpretive, aiming to both describe and compare cultures from a value-based position.

There are techniques that add rigor to qualitative inquiry. These include triangulation, cross-validation, internal and external criticism, use of formal arguments, and justification of findings with constant comparison methods to cross-corroborate findings.

Strengths and limitations

Qualitative methods provide techniques and tools to document processes and contextual factors holistically and under natural conditions. They give evaluation

researchers insights into questions on how and why particular programs work, and the meaning and nature of effects found in authentic settings. They offer useful tools for conducting evaluability assessments, context evaluations, input and process evaluations, as well as in implementing systemic evaluation designs.

Qualitative methods, at present, are not as formally developed and well tested as the quantitative methodologies discussed in earlier sections. There are, thus, high levels of variability in both researcher training and applications of these methods in education and the larger field of evaluation.

The subjectivity of interpretations and confounding of researchers’ values and personal factors with the data may be viewed as a limitation in evaluation contexts. The more open-ended and flexible format of inquiry (as opposed to fixed, hypothesis-driven research) can lead to lack of closure and large volumes of hard-to-decipher and unwieldy data. Researchers must thus be careful in keeping their focus and utilizing defensible methods of data reduction and coding that are consistent with the goals of evaluation research.

Mixed-Method Design Options

The last category of evaluation methods involves mixed-method designs (see Caracelli and Greene, 1993). Although typologies have been proposed, there is no single way to do mixed-methods research. Depending on research purposes, it is possible for researchers to mix quantitative designs (e.g., surveys with comparative experiments), to combine qualitative methods (e.g., ethnography with focus group interviews), or align qualitative–quantitative designs (field observations, surveys, with comparative experiments). The preceding sections suggest that such approaches may be useful for either exploratory or confirmatory studies. An example of a mixed-method evaluation design intended for making generalizable, causal inferences, follows.

As the fundamental assumptions of comparative experimentation are violated or severely tested in field settings where most programs operate, broader design options are often necessary. Drawing on a body of historical work, Chatterji (2005; 2007; 2009) proposed the extended-term mixed-method design (ETMM). The ETMM approach offers several strategies to enhance the grade of evidence on the effects and workings of complex education programs in their natural settings. The design strategies include the use of:

1. expanded and layered questions, guided by logic models;
2. multiphase designs incorporating exploratory (formative) and confirmatory (summative) phases;
3. comprehensive evidence-gathering approaches with multiple research methods;

4. delayed use of comparative experiments, when applicable, to gauge effects; and
5. contextualized inference-making on program effects using both qualitative and quantitative evidence (Chatterji, 2005: 19–21).

Several ETMM design elements are found in the global research framework for the Strategic Impact Inquiry (SII) studies of CARE international's women's education and empowerment program, which has a highly complex configuration. CARE's SII studies focus on international agency collaborations that offer multiplicity of services to women in developing nations, including programs in basic literacy, health and nutrition education. To gauge the impact, the SII studies employ multiple methods and tools, including secondary analysis of quantitative databases, site-based interviews, surveys, and qualitative participant-oriented methods. The multiphase studies are conducted over a few years, using a learning-process approach that mimics the formative–summative model in ETMM. Researchers could not experimentally manipulate CARE's program due to logistical barriers; however, they applied a more systemic and contextually based mixed-method design to shed light on causal connections and make generalizations about the impact of a socially complex program.

Strengths and limitations

Mixed-method tools allow for more flexible evaluation design options, with a possibility of combining evidence in various ways, as dictated by the purposes of an investigation and object of inquiry. The advantages and disadvantages of mixed-method designs stem from the properties and limitations of particular quantitative or qualitative approaches. Trade-offs must be weighed. For example, well-executed sampling techniques focusing on persons, treatments, time points, and settings would give researchers several ways to increase generalizability and ecological validity of findings. On the other hand, qualitative tools will facilitate a more detailed study of context, changing processes, with attention to particular and unique cases. Causal inferences would be best made with experimental designs, scaffolded with descriptive and qualitative methods. However, when experiments are impossible to mount, observational designs can also be effectively combined with other methods to permit some degree of causal inferences. With multilevel interventions, analytic models accounting for nested-ness of data and longitudinal change designs would allow for better testing of sustained effects.

Other Issues in Evaluation Research

Interdependence of Methods, Use, and Values

When conducting evaluations, social research methods must be balanced against the social and public utility of

evaluation results, as well as the values of stakeholder groups and, in some cases, the values of evaluators themselves. The use of research methods generates data. However, the methods are mute with respect to whether the results are good or bad for society. Values are a necessary part of the evaluation research process and influence how the findings are viewed, prioritized, and used by stakeholders. Likewise, methods alone cannot solve the problem of evaluation utility. As evaluations aspire toward social betterment, the research is wasted if stakeholders do not use the findings (an unfortunate but common occurrence). There are, thus, three interdependent components to sound evaluative inquiry that run parallel to the roots of the evaluation enterprise: research methods, use, and values (Alkin, 2004).

To maximize evaluation use, formulation of evaluation questions should begin by identifying the information needs of relevant stakeholders. The evaluation issues examined should be given priority based on the identified stakeholder needs. How methods are selected, deployed, and resourced in evaluations, are affected by priorities set (see American Evaluation Association's *Guiding Principles for Evaluators*). Evaluation approaches and standards are inevitably value based, and can involve evaluator judgments to different degrees. In the connoisseurship model (Eisner, 1994), the evaluator serves as the expert, outside judge. In other approaches, selected stakeholder groups make judgments about results through the application of some systematic procedures, often facilitated by trained evaluators. Standard-setting methods for large-scale testing and educational assessment programs, for example, follow the latter procedures.

Evaluator–Stakeholder Roles and Relationships

Methodological decisions in an evaluation study are influenced by roles, responsibilities, and relationships among evaluators, participants, and other stakeholders. The role played by the evaluation researcher, and relationships developed among evaluators, sponsors, and stakeholders can vary widely depending on the type of evaluation study and the timing of the evaluation with respect to the evaluand (see Fitzpatrick *et al.*, (2003) for a classification of models attending to this criterion). Here again, professional standards and guidelines on ethics and propriety can be of great assistance to evaluation researchers (The Joint Committee On Standards for Educational Evaluation, 1994).

Some evaluations involve external evaluators, who maintain a clinical distance from both the entity and local stakeholders, controlling the design and implementation of a study. Other investigations call for more participatory approaches; here, evaluators may be internal or external to the community or organization, with program participants involved in the evaluative exercise to different degrees.

Methods appropriate for one form of evaluation may not be appropriate for another. Different types and levels of training, experience, and rigor may be required for a thorough implementation of different approaches. Typically, it is the evaluation researchers who contribute to the methodological expertise.

The Evidence Debate and Methodological Hierarchies

Internationally, the advent of policies pushing for evidence-based education (EBE) has given educational evaluation a new and different focus (see, e.g., the Evidence for Policy and Practice Information and Co-ordinating Centre in the United Kingdom; the Iterative Best Evidence Synthesis Programme in New Zealand; and the What Works Clearinghouse in the US). EBE is based on the principle that interventions, tools, and materials used to educate or provide services should be scientifically tested and proven to work. Borrowing from the Cochrane Collaboration's advocacy for evidence-based medicine in the US, these organizations have established standards for synthesizing evidence on what works in education from published research and evaluation studies. Schools in the US are now asked to use research-based practices.

A widely published position among policymakers worldwide calling for EBE, is that some research designs are better than others in yielding impact evidence on education programs. This policy position, called the evidence hierarchy, places randomized controlled experiments that are replicated on a large scale at the topmost rung of the methodological ladder for generating the best evidence on the causal effects of education interventions. Quasi-experiments occupy the next rung in the evidence hierarchy. The hierarchy rejects all other research methods as useful in generating sound impact evidence.

Evidence hierarchies have resulted in heated debates in the educational research and evaluation community. As is obvious from the discussion in this article, no single method is foolproof, particular methods are best suited for particular purposes, and all of them can be implemented poorly or well. Evidence-based policies place a responsibility on the research and evaluation community for using appropriate methods with rigor and integrity.

Globalization and Large-Scale Assessments

Nations now compete in a global marketplace. Governments are, thus, paying attention to the performance of their educational systems and outcomes of education. Global policy circumstances have serious implications for the proper use of tests, assessments, and evaluation methodology. They also influence the roles and responsibilities borne by assessment and evaluation specialists.

Evaluation Reporting and Communicating

R T Torres, Torres Consulting Group, New Orleans, LA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Audiences – Those who receive information about the evaluation and its findings. Audiences include, but are not limited to stakeholders – for example, staff from other programs who would benefit from information about a particular program.

Evaluand – The object of an evaluation; the program, project, process, organization, product, or issue that is the subject of an evaluation.

Formative evaluation – Evaluation that provides information about how a program or organization operates and how to improve it. Typical audiences for formative evaluation are program staff and managers.

Stakeholders – Those individuals, groups, or organizations who may be affected by the planning, activities, and/or findings of an evaluation. For instance, program staff are stakeholders. Stakeholders might also include groups such as parents of students in a particular school program. They do not directly participate in a program, but do have a vested interest in it.

Summative evaluation – Evaluation that provides information about the overall effectiveness, impact, and/or outcomes of a program. Summative evaluation serves accountability purposes. Typical audiences for summative evaluation are funders, sponsors, and/or organizational leaders.

Introduction

Evaluation tends to emphasize one of two purposes and sometimes both: accountability or summative evaluation; improvement or formative evaluation. The following definitions focus on summative evaluation, the process of determining the evaluand's merit or worth:

Evaluation: The systematic investigation of the worth of an object. (Joint Committee on Standards for Educational Evaluation, 1994: 3)

Program evaluation is... a process dedicated to making, generating, or feeding judgments about the worth or significance of a program. (Mathison, 2004: 334)

Evaluation refers to the process of determining the merit, worth, or value of something, or the product of that process. Terms used to refer to this process or part of it include appraise, analyze, assess, critique, examine, grade, inspect, judge, rate, rank, review, study, test. (Scriven, 1991: 139)

Typically, merit or worth is assessed in relationship to some criteria or standards.

Evaluation is defined as the “periodic assessment of the relevance, performance, efficiency and impact (both expected and unexpected) of the project in relation to stated objectives.” (Fort *et al.*, 2001: 1)

Evaluation is the comparison of the condition or performance of something to one or more standards. (Stake, 2004: 4)

The evaluation process normally involves some identification of relevant standards of merit, worth, or value; some investigation of the performance of evaluands on these standards; and some integration or synthesis of the results to achieve an overall evaluation or set of associated evaluations. (Scriven, 1991: 139)

Other definitions emphasize evaluation in service of program improvement:

Program evaluation is the systematic collection of information about the activities, characteristics, and outcomes of programs to make judgments about the program, improve program effectiveness, and/or inform decisions about future programming. (Patton, 1997: 28)

Program evaluation is the use of social research methods to systematically investigate the effectiveness of social intervention programs in ways that are adapted to their political and organizational environments and are designed to inform social action to improve social conditions. (Rossi *et al.*, 2004: 16)

Program evaluation examines programs to determine their worth and to make recommendations for programmatic refinement and success. (Spaulding, 2008: 5)

Most evaluators agree that evaluation communicating and reporting is the central activity through which evaluation serves its intended purpose, regardless of the specific focus of that purpose. Almost 30 years ago, Lee J. Cronbach positioned evaluation as fundamentally a learning process:

The proper function of evaluation is to speed up the learning process by communicating what might otherwise

be overlooked or wrongly perceived Success is to be judged by . . . success in communication Payoff comes from the insight that the evaluator's work generates in others. (Cronbach, 1982: 8)

The value of an evaluation is no greater than the effectiveness of its reporting in, meaningfully conveying the evaluation's findings. In the author's view, this perspective rightfully burdens the reporting and communicating process with maximizing the possibility that the evaluation audience will assimilate and learn from the evaluation findings. It contrasts sharply with historically traditional views which held that the evaluation's job was done once a comprehensive, valid, and credible evaluation report had been written and delivered to the evaluation's primary stakeholders (i.e., typically those who funded and/or requested the evaluation).

This view has shifted gradually but solidly toward a more integrative, participatory, and learning approach to evaluation (see, e.g., Patton, 2008; Preskill and Torres, 1999; Russ-Eft and Preskill, 2009), which engages stakeholders in all phases of the evaluation in an effort to maximize the credibility of the evaluation process and the use of its findings. The nature of the reporting effort and indeed the communication that takes place throughout the evaluation is crucial to meeting this goal. While a final evaluation report is the most commonly used means of conveying findings, the degree to which it is accepted, seen as credible, and ultimately used in most cases is largely mediated by the communication that takes place during the evaluation between the evaluator(s) and audiences for the report. This communication includes not only written interim reports that may be delivered to stakeholders, but also the verbal and written interaction that occurs during the evaluation. In a participatory approach to evaluation, the evaluator(s) and the intended evaluation users (see Patton, 1997, 2008) collaborate throughout all phases of the evaluation, from its design to follow-up activities specifically supporting the use of the findings. The more meaningful this engagement with stakeholders is, the more likely they are to use the final evaluation report.

The remainder of this article overviews the purposes of communicating and reporting, and then focuses on the final evaluation report and ways to increase its use. Further, additional strategies for increasing the effectiveness of communications and reports are covered: (1) adding visual appeal to evaluation products, (2) using highly interactive formats, (3) maintaining communication, (4) engaging audiences with creative formats, and (5) introducing cross-cultural considerations. The article concludes with the development of a communicating and reporting plan, designed to address all considerations of the endeavor: audiences, purposes, formats/strategies, timing, and resources.

Purposes of Communicating and Reporting

In general, the purposes of evaluation communicating and reporting are to convey information, build understanding and create meaning, and/or support decision making. Specifically, during the evaluation communicating and reporting serves to (1) include stakeholders in decision making about evaluation design and activities; and (2) inform them about (i) specific upcoming evaluation activities, (ii) overall progress of the evaluation, and (iii) interim findings. After the evaluation, it serves to (1) inform about a program and its evaluation to create awareness/support, (2) communicate final findings to support change and improvement (formative evaluation), and/or (3) communicate final findings to show results and demonstrate accountability (summative evaluation). These purposes can best be met by making information in the communications and reports accessible and easy to assimilate, and by facilitating interaction wherever possible and appropriate.

The Final Evaluation Report

As mentioned above, the final evaluation report is the most commonly expected and used format for communicating evaluation processes and results. Yet, evaluators continually experience frustration with hours spent on writing reports that are seldom read, or shared with others. This frustration is especially apparent when learning and evaluation use is an expected goal of the evaluation. Typically, the contents of a comprehensive, final evaluation report are modeled after a social science research report (see **Table 1**). This academic focus has its origins in the notion that sufficient information about methodology, findings, and conclusions so that (1) readers can understand how claims for an evaluation's validity are justified, and/or (2) another researcher/evaluator could replicate the study.

There are ways, however, in which these researcher-focused purposes can be served, and evaluation reports also can be more readable, accessible, and useful for audiences who are primarily concerned with the substance of the evaluation findings (especially in cases of participatory evaluation when stakeholders have been involved in decision making about the evaluation methods; see **Table 2**).

Adding Visual Appeal to Evaluation Products

Making evaluation products visually appealing is a fundamental means of increasing their accessibility to users, specifically aiding in the assimilation of text-based documents. Text-based formats can be made more readable, visually appealing, and instructive, with features of layout and design and the inclusion of photographs. Visual appeal can be maximized with the use of video to convey evaluation findings.

Given the wide variety of visually appealing material all readers and audiences are exposed to in everyday life, there is an increasing expectation for easy access and readability in professional documents and products.

Table 1 Typical sections and contents of comprehensive written evaluation reports

Introduction

Purpose of the evaluation, including evaluation approach
Brief description of the program
Evaluation stakeholders/audiences
Relationship between/among organizations involved and those serving in evaluator roles
Overview of contents of the report

Program description

Program history, background, development
Program goals/objectives
Program participants and activities

Evaluation design and methods

Evaluation questions
Data collection methods (including participants and schedule) used to address each question
Analysis methods for each type of data collected

Findings/results

Description of how the findings are organized (i.e., by evaluation questions, logic model components, themes/issues, etc.)
Results of analyses of quantitative and/or qualitative data collected (usually represented in tables, charts, graphs, illustrations, and text)

Conclusions and recommendations

Conclusions drawn about the evaluation results
Recommendations for action based on these conclusions
Suggestions for further study, if applicable

Design, graphics, and layout

With the advances in technology, the sophistication of today's print media is ever growing, increasing expectations of lay and professional audience for readability and easy access to information. Therefore, it goes with evaluation. Text-based evaluation reports and other communications (e.g., executive summaries, newsletters, or brochures) can be made more readable, visually appealing, and instructive through the use of:

- variation in headings with different typefaces;
- bulleted lists;
- boxed text, charts, graphs, tables, figures, and graphic images; and
- variations in color from shades of gray to the full color spectrum.

The technology for producing evaluation products using these features is readily available in software applications accessible to most computer users. Many evaluation organizations are opting for professional design and layout of their reports, producing reports similar to those of annual reports from foundations and government agencies.

Photography

Still photographs can be added to evaluation reports and other text-based products to:

- illustrate the context and the realities of program participants;
- convey various perspectives; and
- show program activities.

Table 2 Strategies for increasing the relevance and utility of final evaluation reports

1. Maximize the accessibility of findings, conclusions and recommendations:
 - Describe the methodology briefly in an introductory section, and present it fully within an appendix
 - Organize the report by the evaluation questions (or other questions that guide the reader or main topic areas). Immediately after each question, describe the data that addresses the question, and then present a summary of the findings and recommendations. Detailed presentations of methods and findings can be included in appendices
 - Organize the report by the main body of the recommendations. For each recommendation, present conclusions and evidence (evaluation findings) to support it
 - In the case of numerous tables or graphs, put them in an appendix and reference the specific appendix pages throughout the earlier sections in the report that describes these findings
 - Provide a reader's guide or description of the report structure in the front inside cover of the report.
2. Select an organizing framework for the presentation of findings that is most salient for the primary report audiences:
 - The evaluation questions
 - The program's logic model or theory of action
 - Decision-making processes with the life cycle of the program
 - Emergent themes or categories that tell the program's story.
3. Get feedback from primary audiences about the style and focus of the final report.
4. Develop shorter versions of the final report in language and design/layout appropriate for different audiences.
5. Maximize dissemination of the final report as well as shorter renditions by:
 - Posting them on websites accessible to various audiences
 - Using e-mails, newsletters, staff meetings, and/or latest news sections of websites accessed by stakeholders to announce the availability of evaluation findings and where different versions of the report can be found.
6. Design and facilitate interactive working sessions with primary stakeholders (and others as appropriate):
 - To present findings and provide an opportunity for stakeholder input on the interpretation of findings and development of recommendations
 - To answer questions and carry out action planning based on findings and recommendations developed by the evaluator(s).

Photography is particularly useful when language or cultural barriers may inhibit participants' ability to easily assimilate information in written reports. It can also be used as a data-collection device to count, measure, compare, qualify, or track artifacts or information that can be captured visually. Further, when evaluation findings are presented through photographs, they can stimulate audiences' participation in interpreting important events and experiences, and engage them in dialog about the meaning and implications of findings.

Video

Video is an enhancement to still photography with motion and sound. In evaluation, it is particularly useful for:

- conveying information about new or innovative programs;
- disseminating findings to broader audiences than those directly involved with a program;
- providing findings to groups with limited time, and/or to those not accustomed to reading reports;
- projecting multisite evaluations to depict events and activities at different sites; and
- documenting evaluation processes.

Evaluation videos have the advantage of easy dissemination (depending on length) as electronic files: attached to e-mails, included within electronic versions of text-based reports, or PowerPoint presentations, and/or posted on websites. Longer videos can be disseminated on digital versatile discs (DVDs) that are mailed or delivered to evaluation audiences.

Using Highly Interactive Formats

Participatory evaluation is based on significant degrees of interaction and opportunities for learning that occur between the evaluator(s) and the evaluation user(s). Providing social contexts for decision making about evaluation activities and the interpretation of findings is one example of how group learning can support evaluation use. This section explores two highly interactive formats, working sessions and web conferences.

Working sessions

Evaluation working sessions typically engage stakeholders in some aspect of the evaluation. They are similar to meetings, but are usually planned and facilitated by the evaluator(s) to realize specific objectives. That is, they can be used throughout the evaluation, for:

- identifying concerns about the study;
- establishing buy-in;
- making decisions regarding the evaluation's implementation and/or use of the findings;

Table 3 Steps for carrying out evaluation working session

1. Assess and refine your skills for facilitating working sessions.
2. Build support for participation in working sessions by explaining the purposes and benefits to stakeholders.
3. Specifically tailor each working session for your participants and carefully plan it to achieve clear objectives.
4. Do your best to get key stakeholders at the table.
5. Determine what information or documents participants should receive ahead of time.
6. Consider conducting working sessions as part of other regularly scheduled meetings.
7. Provide sufficient background information at the beginning, and close session with a clear outline of what is to follow.
8. Reach common understandings at the outset about basic issues/information regarding the evaluand.
9. Use worksheets to organize activities.
10. Develop ground rules about confidentiality.
11. Follow up with stakeholders who may not have been able to attend.

- obtaining input about evaluation design, data-collection methods, and procedures; and
- engaging stakeholders in interpreting findings and developing recommendations and action plans.

Evaluators must draw on group process skills to successfully carry out working sessions with stakeholders (see **Table 3**). In addition, they require careful planning with consideration of purpose and specific objectives, participants, group dynamics, need for follow-up sessions, processes, and activities to engage participants, length of session, and materials preparation.

Web conferences

Web conferences allow participants to exchange messages in real time without being in each other's physical presence. They are meetings of two or more individuals conducted over the Internet with features of audio and visual communication, simultaneous viewing of electronic files including PowerPoint presentations. In evaluation, they are generally set up as working sessions (described above) and are used when face-to-face meetings are impractical or impossible. However, Web conferences:

- can lead to more timely dissemination of findings and subsequent decision making;
- can provide opportunities to include stakeholders who might not otherwise be able or available to travel to a meeting; and
- can be used for any phase of the evaluation work, but are best after some face-to-face meetings have occurred.

Computer programs for conducting Web conferences are available as part of many software applications and/or operating systems, and through Web-based service providers. Web conferences should be planned with the same

care as face-to-face working sessions, with the additional burden of making sure that all participants can successfully access the necessary computer and Internet technology.

Maintaining Communication

In addition to regular meetings that evaluators typically have with those stakeholders directly involved in the evaluation, communication can be maintained with e-mail and postcards and online collaborative tools, as well as newsletters and brochures.

E-mail and postcards

E-mail is the mainstay of most communication among those involved in professional activities, including evaluation. It provides for easy reading and assimilation of information at the beginning of the evaluation (e.g., regarding evaluation purpose and activities), throughout the evaluation (e.g., regarding data-collection activities, feedback from stakeholders, interim findings), and at the end of the evaluation (e.g., regarding final findings and next steps).

Postcards are an alternative to e-mail for short communications. They can be used to maintain contact and build interest in the evaluation, invite stakeholders to and/or remind them of data-collection events, and solicit reactions to preliminary findings. In this age of e-mail overload, evaluators can use postcards with color and graphic illustrations that accompany text to gain attention, pique interest, and solicit engagement of stakeholders.

Online collaborative tools

Many online collaborative tools are in use today that provide ongoing communication and/or project management functions for teams of individuals working on the same project. Programs available at the time of writing this article include Base Camp, Central Desktop, and Google Groups. Their features useful for evaluators are summarized in **Table 4**. Some orientation and training is likely necessary for fully utilizing the different features. These programs are probably the most useful for stakeholders involved in carrying out the evaluation.

Newsletters and brochures

Newsletters and brochures that contain evaluation information are typically created and disseminated by organizations that house the evaluand, house the evaluator(s), fund the evaluand or the evaluation, support the evaluand, and/or support the development of the evaluation profession (including capacity building). They provide another means of maintaining contact with evaluation audiences, and:

- can be disseminated to publicize program information, upcoming evaluation activities, and/or evaluation findings;

Table 4 Features and evaluation uses of online collaborative tools

<i>Feature</i>	<i>Evaluation use</i>
Email/ message boards	Share evaluation updates, ask questions, have others respond; keep message exchanges in one place
Milestones/ to-do lists	Establish milestones and create lists of tasks for specific upcoming evaluation activities
Calendar	Make aware of scheduling of activities for carrying out the evaluation
Wikis/whiteboards	Collaborate to write documents
Blogs	Provide access to continuous stream of information about evaluation events, findings, etc.
Document posting and retrieval	Share evaluation documents in progress as well as final reports

- can be distributed after evaluation activities to publicize evaluation findings or actions taken based on the findings;
- provide opportunities to reach broad groups of people;
- can be mailed and/or posted on the web;
- allow for presentation of text and graphics;
- are typically 1–4 pages in length; and
- typically provide contact information from where further information about the evaluation can be obtained.

Newsletters take many shapes and forms. A newsletter may be devoted solely to communicating evaluation findings from one study; or, articles about the evaluation activities and/or findings may be included in existing internal or external newsletters, which have a broader purpose. A newsletter can be a single page containing key findings, or it can be several pages created in a newspaper format describing particular elements of the evaluation and its findings.

Brochures typically are intended to generate interest and some follow-up on the part of readers. This might be to find out more about a program, an organization, or an evaluation. Brochures are sometimes used to disseminate and provide easy access to evaluation findings. Today's inexpensive desktop publishing software has dramatically increased the ease with which newsletters and brochures can be created. Word-processing software often contains design templates. Alternatively, evaluators may choose to engage professional services for design, layout, content development, and publishing.

Engaging Audiences with Creative Formats

The nontraditional, but creative formats of cartoons, poetry, and drama are gaining use among evaluators, particularly those who want to facilitate personalized representation and interpretation of evaluation findings.

Poetry, and drama, in particular, can “honor participants’ complex lives and highlight the emotion, drama, and subtleties of [their] stories” (Goodyear, 2007: 38). These formats are particularly good at capturing multiple voices including those of the evaluator whose perspectives are represented through their data analyses and presentations of the findings (often developed in collaboration with stakeholders). Each person who then views the cartoons, reads the poems, or participates as an audience member of a dramatic performance creates his/her own meaning and interpretations. For evaluation communicating and reporting purposes these creative formats share a number of commonalities; they:

- invoke creatively inspired individual interpretations and tend to engage audiences emotionally;
- increase the accessibility of evaluation information for particular audiences (see **Table 5**);
- may be more culturally or audience-appropriate in some cases than in others;
- are most typically used for conveying findings based on qualitative data-collection methods (e.g., interviews, observations, document analysis, etc.);
- are particularly powerful when used as a basis for interaction with program participants and stakeholders to interpret and discuss their meaning;
- warrant special efforts to communicate the methods used for their creation and to obtain stakeholder feedback prior to dissemination;

Table 5 Some suggested audiences for creative formats in evaluation communicating and reporting

Cartoons

- Program administrators and staff involved in the program’s design and implementation
- Youth
- Parents, guardians, caregivers, and teachers of participants
- Stakeholders with low-level reading ability
- Funders who have in depth experience with the context of the program and its participants

Poetry

- Program participants, administrators, and staff, especially those who have participated in case studies or provided qualitative data such as interviews
- Stakeholders of programs related to education, social services, arts and culture
- Audiences whose cultural/social traditions value verbal communications

Drama

- Program administrators and staff involved in the program’s design and implementation
- Other stakeholders who have experiences related to the program’s focus/purposes
- Youth
- Stakeholders of evaluands related to education, social services, arts and culture
- Stakeholders and other audiences who are available to attend a performance

- add costs in terms of time and budget to a typical evaluation endeavor; and
- are best used in conjunction with traditional formats (e.g., written reports and summaries).

Cartoons

In addition to the strategies described earlier in this article, cartoons are another way of adding visual appeal to evaluation reports. They:

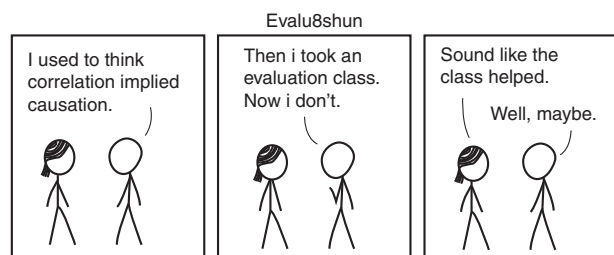

- can illustrate simple or symbolically complex issues in an accessible and concise format;
- may be used to convey information to children and those with low reading levels;
- can provide audiences with an informal, visually oriented understanding of program impact; and
- may be useful when language or cultural barriers inhibit participants’ ability to assimilate information from written reports.

One method for using cartoons in an evaluation (Chin, 2002) involved asking teachers, parents, and students exposed to an elementary reading program what amusing sidelights or funny incidents they had experienced in the program. Their responses reflected benefits, critical issues, and challenges associated with the program and also evidenced in other data sources. The evaluator created four cartoons from the interview findings and classroom observations to reflect major themes, and included them in the annual report. Feedback from stakeholders revealed that the cartoons (1) provided a visual picture of the program, (2) helped them remember the findings, (3) were helpful for those who did not read the entire report, and (4) were amusing and allowed the reader to feel the attitudes of participants.

Cartoons are often used to teach about evaluation to other evaluators and/or evaluation clients and stakeholders. The purpose is typically to engage the audience through humor (see **Figure 1**).

Poetry

As a means of communicating and reporting, poetry can illuminate the emotions, contradictions, and complexities

Adapted by kistler kreatives with permission from xkcd.com

Figure 1 Cartoon created to engage evaluation audiences with humor.

of evaluation contexts, and can be used to integrate the experiences and perspectives of multiple stakeholders (program staff, participants, funders, evaluators, etc.) into a collective voice. It is especially suited for communicating the tacit and the implicit, and making evaluation results more accessible by using participants' language and avoiding evaluation or other academic jargon. It can be developed from evaluation findings using key words, excerpts, and phrases that appear particularly poignant, insightful, and compelling.

For the evaluation of a mental health peer support center, MacNeil (2000) created the poem shown in **Figure 2**. It addressed the evaluation question, "What are the unique qualities a peer professional has to offer?" and was based upon responses from a staff focus group. The poem was created from a transcript of the focus group, reproduced on a large poster, and hung in the center's main meeting room. It served to report evaluation findings, remind staff of the evaluation question, and sustain attention on the evaluation. Occasionally, it has been used in orientations to the center, showing viewers that the center is a place that promotes a different way of thinking, and talking about mental health and peer support.

Insider knowledge and heart gladdening:
What peers have to offer

Art
Music
Poetry
Writing
Journaling
Inspiration
Rejuvenation
Survivor skills
Bringing light
A lot of courage
Capacity seeking
Important purpose
Listening to stories
Antidote to urgency
Releases from isolation
Knack for interviewing
Honoring of spirituality
Appreciation of animals
Retriever of better times
Getting off to a new start
Willingness to love oneself
A campground atmosphere
Finding that something special
Bringing people in from the cold
A common bond beyond mental illness
A different way of being in conversation
Understanding what people give value to
Rescuing the sparkling tellings from the told
Responding that honors ones lived experience
Helping people stand back from traumatic memories

Figure 2 Poem created to convey evaluation findings. From MacNeil, C. (2000). The prose and cons of poetic representation in evaluation reporting. *American Journal of Evaluation* 21, 359–367.

Drama

Drama is a more complex form of communicating and reporting. It can be used to recreate the lived experiences of program participants, combining realism, fiction, and poetic genres. Like poetry, it can help create a balanced representation of the perspective of multiple stakeholders and is particularly powerful when used as a basis for interaction with program participants and stakeholders. **Table 6** shows three formats for dramatic presentations of evaluation findings based on the work of the University of Michigan's Center for Research on Learning and Teaching.

Evaluators can develop options for creating the script of a dramatic performance based on evaluation findings through consideration of the following questions:

- should the performance be a verbatim conversation from interview or focus group transcripts or a dialog created by arranging excerpted quotes?
- how many of the participants in the data collection/evaluation should be represented in the performance?
- what criteria will I use to choose whom to represent in the performance? By stakeholder group? By level of involvement in the program? To show a variety of impacts of the program? To represent positive and negative aspects of the program?

Table 6 Summary of theatrical formats for communicating and reporting evaluation findings

Traditional sketch

- Used to evoke assumptions, motivations, feelings, experiences, themes or metaphors related to evaluation findings
- Developed from original evaluation data (especially focus groups and interviews)
- Performers can be characters or represent abstract themes/metaphors
- Facilitator guides discussion following performance

Interactive sketch

- Uses provocative vignettes from findings to engage audience members
- Typically portrays complexities, challenges of an issue/theme
- Following performance, audience dialogs with the actors who stay in character
- Facilitator guides discussion
- Actors repeat performance incorporating outcomes of discussion

Forum theater workshop

- Used to promote and extend discussions (e.g., action planning) related to findings
- Facilitator presents findings/topic
- Participants serve as both actors and audience members
- Participants create mini-scenes of situations, contexts, scenarios; exchange roles as actors/audience to explore/expand the topic
- Facilitator elicits discussion and reflections about performances

Adapted from <http://www.crlt.umich.edu/theatre/performances-workshops/kinds.php>.

- if the script will be a dialog created from excerpted quotes, should those quotes be attributed only to the individual who said them, or should I create composite characters?
- should the performance highlight the most significant or dramatic aspects of participants' experiences, or should it cover the range of experiences during the entire time frame of the data collection?
- should I develop the sketch as a typical conversation that took place during the interviews or focus groups, or should I include information gathered through observations, surveys, and document review (including quantitative statistics and demographic information)?
- should I include myself as a character in the performance? If so, should I fictionalize my dialog or take it verbatim from transcripts?

Cross-Cultural Considerations

From the standpoint of communicating and reporting, evaluators must design their communications and reports to maximize stakeholders' participation as contributors to

evaluation activities and users of evaluation findings. Participation and use should not be limited by communications and reports that stakeholders do not understand (due to diversity in age, language, educational levels, etc.), or reject because the communications and reports are insensitive to their cultural orientations. Evaluators can increase the cultural sensitivity of their communications and reports by:

- using a fully participatory approach with diverse evaluation stakeholders;
- forming teams of evaluators to include those from multiple cultural contexts;
- providing all communications and reports in the dominant language(s) of evaluation stakeholders;
- using language appropriate for diverse participants and reflective of their voices;
- avoiding primarily relying on written communications; and
- selecting photographs and video footage that are representative of stakeholder's race/ethnicity, socio-economic status, age, and gender.

Table 7 Importance of various evaluation audience characteristics to communicating and reporting

<i>Audience characteristic</i>	<i>Description</i>	<i>Example implication for communicating and reporting</i>
How accessible is this audience, and through what venues?	Audiences may be more or less accessible based on a number of factors: physical/geographical distance, access to use of the Internet, availability in terms of time, etc.	For less-accessible audiences, additional time and effort will be needed to strategize access and select appropriate formats, e.g., for busy executives
How familiar with the evaluand is this audience?	Different audiences are likely to vary in their familiarity with an evaluand; e.g., most funders will know less about the details of the program than program managers	More basic information about the evaluand is necessary for audiences who do not have regular contact with it
What attitude toward or interest level in the evaluand does this audience have?	Audiences may vary in their attitude toward (positive, negative, and indifferent) or interest level (low, medium, and high) with any given evaluand	Additional efforts may be necessary to get participation in presentations of evaluation findings to audiences who are disinterested in a particular program
What role in decision making about the evaluand or the evaluation does this audience have?	Role in decision making is often closely aligned with interest level and can vary from no role at all with respect to a particular evaluand to a significant role regarding a very similar evaluand	The greater the role in decision making, the more detailed that information about the findings the audience is likely to want
How generally familiar with research and evaluation is this audience?	Different audiences for any one evaluation likely vary on this dimension based on their prior experiences with research and evaluation	Those unfamiliar with research evaluation will need explanations of statistical terms and/or other aspects of methodology
What attitude toward or interest level in the evaluation does this audience have?	As audiences vary in their interest level or attitude in the evaluand, so may they vary with respect to the evaluation	Audiences hostile toward the evaluation may require more interaction and personal contact, with the evaluator adopting an educative role about the benefits of the evaluation
What experience using evaluation findings does this audience have?	Some audiences have never had any occasion to read about or use evaluation findings	Audiences with little prior experience using evaluation findings might need an explanation of the purpose and benefits of participating in a working session to interpret findings, for example
What is this audience's reading level and primary language?	Not all audiences have the same reading level and primary language as the evaluators who typically write evaluation reports	Audiences at lower reading levels might be successfully engaged with visually appealing and/or more creative formats such as cartoons or drama

Indeed, as addressed in the next section, evaluators have long been encouraged to match their communications and reports to audience characteristics and needs.

Creating a Communicating and Reporting Plan

Choices among the strategies and formats presented in this article must be based on a comprehensive set of considerations: audiences and their characteristics, purposes and timing, and resources. After addressing each of these, this article concludes with suggested formats for creating a communicating and reporting plan.

Audiences

Evaluation audiences are typically identified with the following questions. Which individuals or groups:

- were mentioned when the rationale for the evaluation was established?
- will be asked to provide data for the evaluation?
- should be involved in planning or carrying out the evaluation?
- might use the findings for program development or improvement?

- might use the findings for making funding or resource decisions?
- might be interested in the findings but are not in a decision-making position relative to the program?
- within the public at large should know about the evaluation's findings?

Audiences are typically categorized or prioritized into three groups. Primary audiences requesting the evaluation are the major decision makers for the evaluand, and include program staff, supervisors, senior managers, and/or funders. Secondary audiences are usually involved with the evaluand, but may have little or no daily contact with them; they include program participants, their supervisors or managers, and others impacted by the evaluand. Tertiary audiences usually are more distant, but may possibly be interested in the evaluation findings; they can include future program participants, general public, and members of same/related professions. It is important to note that use of these categories is arbitrary, relative to each other, and specific to any given evaluation. That is, a type of group that is considered a primary audience in one evaluation, might be considered a secondary audience in another. The most effective communications and reports are designed to

Step 1: List a single audience below: (individual or group) ①	② Audience characteristics							
	How accessible?	Reading level?	Familiarity with program or evaluand?	Attitude toward/ interest level in program?	Role in decision making about program or evaluation?	Familiarity with R&E in general?	Attitude toward/ interest level in this evaluation?	Experience using evaluation findings
Step 2: For each characteristic to the right, circle the response that best describes this audience.	Easily With some effort With substantial effort Don't know	High level Low level Non-reader Don't know	Very familiar Somewhat Familiar Not familiar Don't know	Positive/high +/– Negative/low Don't know	Crucial important minor no role don't know	Very Familiar Somewhat Familiar Not familiar Don't know	Positive/high +/– Negative/low Don't know	Substantial Some None Don't know
Step 3: Check the purposes for communicating with this audience.	③ Communicating/reporting purpose		④ Priority	⑤ Ideas about content	⑥ Format(s) to use	⑦ Dates	⑧ Resources needed	
	<input type="checkbox"/> Include in decision making about evaluation design & implementation		HI MED LO					
Step 4: Considering the audience and the purpose, prioritize each communicating and reporting task.	<input type="checkbox"/> Inform about specific upcoming evaluation activities		HI MED LO					
	<input type="checkbox"/> Keep informed about overall progress of the evaluation		HI MED LO					
	<input type="checkbox"/> Communicate Interim findings		HI MED LO					
Step 5: Note the implications that the characteristics of this audience may have for contents of communication/report.	<input type="checkbox"/> Inform about program and evaluation to build awareness, and/or support		HI MED LO					
	<input type="checkbox"/> Communicate final findings to support change and improvement		HI MED LO					
	<input type="checkbox"/> Communicate final findings to show results, demonstrate accountability		HI MED LO					
Step 6: Indicate appropriate formats to use.								
Step 7: Indicate date for communication/ report.								
Step 8: Indicate resources needed.	<input type="checkbox"/> Other:		HI MED LO					

Figure 3 Detailed evaluation communicating and reporting plan for each audience.

match the audience characteristics described in **Table 7**. Although the answers to these questions about each audience may be obvious, it is important to systematically consider each question for each audience because addressing their communicating and reporting needs may take additional planning and resources.

Purposes and timing

As explained in the section above on “Purposes of Communicating and Reporting,” timing is a key factor in considering what purposes are to be served by the evaluation’s communications and reports. To review, during the evaluation communications and reports typically are for the purpose of (1) including stakeholders in decision making about evaluation design and activities, and/or (2) informing them about specific upcoming evaluation activities, the overall progress of the evaluation, and/or interim findings. After the evaluation, communications and reports typically inform audiences about the program and its evaluation to create awareness/support, or communicate final findings to support change and improvement and/or to show results, to demonstrate accountability.

Planning for communications and reports that takes place during the evaluation is particularly important at its outset, especially for participatory evaluations designed to substantively engage stakeholders and facilitate the ownership of evaluation products that are produced once data collection and analysis is complete. Planning for post-evaluation communications and reports is especially important because they tend to be the more resource-intensive (see below) and require significant lead time to complete.

Strategies/formats and resources

At this point in the planning process for communicating and reporting, it is appropriate to consider the following questions for each audience:

- what strategies and formats are the best to use, given the audience and their characteristics, purpose, and timing of the communication?
- what resources (including time) will be needed for desired strategies/formats?
- what alternatives might be used if sufficient resources are not available?

① List audiences below:	② Describe any implications based on audience characteristics:*	③ Check the communicating and reporting purpose(s) for each audience:	④ List appropriate format(s) for each purpose**	⑤ Indicate date needed for each format:	⑥ Resources needed for each format:
		<input type="checkbox"/> Change, improvement			
		<input type="checkbox"/> Show results, accountability			
		<input type="checkbox"/> Build awareness/support			
		<input type="checkbox"/> Change, improvement			
		<input type="checkbox"/> Show results, accountability			
		<input type="checkbox"/> Build awareness/support			
		<input type="checkbox"/> Change, improvement			
		<input type="checkbox"/> Show results, accountability			
		<input type="checkbox"/> Build awareness/support			
		<input type="checkbox"/> Change, improvement			
		<input type="checkbox"/> Show results, accountability			
		<input type="checkbox"/> Build awareness/support			
		<input type="checkbox"/> Change, improvement			
		<input type="checkbox"/> Show results, accountability			
		<input type="checkbox"/> Build awareness/support			

*Relevant audience characteristics include accessibility; familiarity with evaluand, with research and evaluation; attitude toward/interest level in the evaluand, in the evaluation; role in decision making about the evaluand, about the evaluation; experience using evaluation findings, reading level.

**Note that a single format may serve more than one purpose.

Figure 4 Plan for post-evaluation communicating and reporting.

The communicating and reporting plan

A plan for evaluation communicating and reporting can vary in its detail and complexity. **Figure 3** shows a detailed plan that can be completed for each differently identified audience. It accounts for audience characteristics, the communicating and reporting purposes and their priorities, implications for content based on the audience characteristics, formats/strategies, dates, and resources needed.

An alternative to this plan focuses on post-evaluation reporting only (see **Figure 4**); it accounts for more than one audience on the same page and accounts for audience characteristics, communicating and reporting purposes, formats/strategies, dates, and resources.

Longitudinal Evaluation Designs

X Ma, University of Kentucky, Lexington, KY, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Cohort design – A type of research design in which data are collected repeatedly from a group of individuals who possess a common trait, share a common condition, or receive a common intervention, often accompanied by a different group of normal individuals.

Cross-lagged model – A statistical model to determine cause–effect relationships in data that are obtained from nonexperimental, longitudinal research designs. In such a model, each variable is predicted (as effect) by all variables that precede it in time (as causes).

Cross-sectional design – A type of research design in which data are collected from a number of distinct age groups of individuals at a single point in time.

Multilevel growth model – A multilevel model to analyze data that are obtained from longitudinal research designs. Such a model typically estimates the trajectory of change over a period of time and identifies variables at different levels that contribute to variation in rate of change.

Multilevel model – An extension of the standard multiple regression technique from single level to multilevel. With simultaneous multiple regressions at different levels, such a model accounts for correlated responses at levels where dependencies of observations (or clustering effects) occur.

Panel design – A type of research design in which a group of individuals is surveyed or measured repeatedly over a period of time.

Structural equation model – A statistical technique to test and estimate cause–effect relationships based on both quantitative data and qualitative (causal) assumptions.

Time-invariant variables – Variables in longitudinal research designs whose values are constant over a period of time (e.g., race-ethnicity).

Time series design – A type of research design in which data are collected from a group of individuals on a small number of variables across a large number of points in time.

Time-varying variables – Variables in longitudinal research designs that take on different values at different points in time (e.g., achievement in mathematics).

Trend design – A type of research design in which a different sample of individuals is drawn from a clearly defined population at more than one point in time.

In a longitudinal evaluation, one or more clearly defined outcome measures are assessed repeatedly on a sample of subjects (e.g., students) over a period of time. Longitudinal data can be collected in the form of survey and experiment and can be analyzed for the examination of change and causality. In particular, longitudinal design is essential to study causality in nonexperimental conditions. In educational research and evaluation, longitudinal design has been gaining great momentum for a couple of decades because “the very notion of learning implies growth and change” (Willett, 1988: 346). Research questions under longitudinal design can be reasonably classified into two categories: (1) whether change has occurred and (2) when change has occurred. For example, an evaluation examining mathematics achievement over the entire secondary school (i.e., grades 7–12) is about whether change (i.e., growth) in mathematics achievement has occurred over time (see Ma, 1999), whereas an evaluation examining student avoidance of (i.e., dropout from) mathematics courses during the entire secondary school is about when change (i.e., dropping out of mathematics courses) has occurred over time (see Ma, 1997). With these general longitudinal research questions in mind, this article serves as a latest survey on methods to collect and analyze longitudinal data in educational evaluation.

Research Designs for Collecting Longitudinal Data

Researchers have employed a variety of research designs to collect longitudinal data with different degrees of threats to the validity of the resulting statistical inferences. A research design is truly longitudinal if, and only if, the same sample of subjects (e.g., students) is followed and evaluated repeatedly over time. However, researchers often settle into some sorts of quasi longitudinal design because a true longitudinal design requires considerable commitment of time, labor, and resource, especially when multiple waves of data are planned. This section reviews common strategies to collect longitudinal data.

Cross-Sectional Design

In a cross-sectional design, researchers work with a number of distinct age groups of students at a single point in time. For example, elementary students from grades 1 to 6 are surveyed at the end of a school year, resulting in data describing six groups of elementary students. Obviously, this is not a true longitudinal design. By comparing students from different grade levels or age groups, however, a sense of development emerges. Some researchers distinguish between standard cross-sectional design and simultaneous cross-sectional design. These two designs differ only in terms of how age is intended for data analysis. The former uses age as a control variable (i.e., to remove the impact of age or maturity), whereas the latter uses age as a chief variable (i.e., to study change due to age or maturity).

A cross-sectional design is easy to plan and implement, requiring the least amount of time, labor, and resource. However, threats to the validity of statistical inferences are serious. Obviously, this type of design lacks the ability to control different historical events that students of different ages have experienced, assuming that historical conditions do not attribute to differences across the grade levels. Even with a survey questionnaire that collects historical conditions unique to students at different grade levels as statistical adjustments, it is still impossible to overcome the fundamental difficulty that age effects are confounded with change effects because both come from the same variable – age.

Trend Design

In a trend design, a sample is drawn from a clearly defined population at more than one point in time. In most cases, a different sample is obtained at a different point in time (from the same population), and samples do not need to have the same size. For example, a sample of teachers is drawn from the population of teachers in a certain state to survey their support for the state-run testing system. One year later, another sample of teachers is drawn from the same population regarding the same issue. A comparison of data indicates change among teachers in terms of their support for the testing system. Obviously, this is not a true longitudinal design, unless the same sample is used at different points in time.

A trend design does not require a large investment of time, labor, and resource. It is a good choice for researchers who are concerned about change at the group level rather than at the individual level. A trend design opens the doors for a secondary data analysis of the state, national, or international database to evaluate change over time at the state, national, or international level. As different samples are used across time, it is impossible to identify how many individuals have experienced change. Comparability of data from different samples is always the

key issue. A trend design requires highly valid instruments to ensure that instruments do not discriminate against certain samples. If an instrument has not been psychometrically tested, there is a risk that the same instrument may function differently for different samples. When this happens, data from a trend design become incomparable.

Cohort Design

In a cohort design, cohorts are formed. A cohort is a group of persons who possess a common trait, share a common condition, or receive a common intervention, often accompanied by a different cohort of normal persons. Data are collected repeatedly from cohorts over a period of time and compared to examine whether change comes from age or maturity (which can often be observed across cohorts) or whether cohorts demonstrate differential outcomes of interest. For example, age at entry (into schooling) is often used as a cohort variable (i.e., cohorts of students who enter schooling at an age earlier or later than normal age) to examine whether early (late) entry promotes optimal learning.

A cohort design can be applied to data from both survey and experiment to separate age effects from change effects. It is also a good alternative to randomized experimental design. In fact, there are situations where a cohort design is the only appropriate research and evaluation approach. For example, to examine the impact of school violence (e.g., school bullying) on schooling outcomes of students, researchers cannot apply randomization to subject a group of students to school violence. Instead, a cohort of victims of school violence is followed, accompanied by a cohort of students who have not experienced school violence. Unfortunately, the main threat to validity, as inherited in a cohort design, also comes from the lack of randomization. Without randomization, confounding factors may come into play so that cohort differences may not be due to trait, condition, or intervention but some factors over which researchers do not have control.

Panel Design

In a panel design, a group of persons is surveyed or measured repeatedly (e.g., by means of a common questionnaire) over a period of time. Some panel designs collect data on a regular basis; others on an on-demand basis. For example, the Longitudinal Study of American Youth (LSAY) followed a national probability sample of some 3000 students from grades 6 to 12, collecting achievement and questionnaire data on a yearly basis (see Miller *et al.*, 2000).

As the same sample is used at different points in time, a panel design greatly advances over a trend design, allowing analysis of change at both individual and group levels. With an appropriate number of points in time, a panel

design is highly effective in investigating the pattern of change (i.e., characteristics of trajectory) over time. As a result, it is able to make a credible prediction of long-term change and the cumulative effects of change. A panel design is particularly popular in survey studies because it represents the best opportunity to collect a large quantity of detailed longitudinal data which allow not only the examination of change but also the identification of agents of change. Furthermore, a panel design is perhaps the best (nonlaboratory) approach to examine causality when a random sample is obtained and multiple waves of data are collected.

For a panel design, the main threat to validity stems from the continuous use of a common instrument at different points in time. The repeated use of a common test, for example, creates carryover effects (i.e., students become familiar with the test or even memorize certain items on the test). When parallel (equated) tests are hard to develop, carryover effects pose a serious threat to validity in that improvement in performance is contaminated by an increasing familiarity with the test. Like all other field-oriented (as opposed to laboratory-oriented) research and evaluation designs, a panel design is incapable of control over confounding factors. For example, in survey studies, such as the LSAY, if some clusters of students receive special performance-related treatments at a certain grade level as, say, a state education reform program, an artificial peak in the growth trajectory may occur among those students. Obviously, it is improper to relate this change (caused by an uncollected variable) in any causal manner with collected variables.

Time-Series Design

A panel design, as discussed above, often tends to focus on a large number of variables (measures) across a small number of points in time. In this sense, the power of a panel design resides in its ability to collect information on a huge number of variables, hopefully from which salient agents of change can be identified. The opposite of a panel design is a time-series design that tends to focus on a small number of variables across a large number of points in time. Because of this, a time-series design is particularly effective to examine the developmental characteristics of intraperson change. The large number of points in time produces data that are very sensitive to local change at the person level and allows the intraperson change curve to take on various mathematical functions (e.g., a cubic function) for optimal mathematical representation of change.

The following two examples help differentiate a panel design and a time-series design. A researcher who wants to identify the key causes dropping out of school, is likely to adopt a panel design to focus on the senior high school years (i.e., grades 10–12) and include a large number of student-level and school-level variables as potential candidates

for key characteristics of school dropouts. On the other hand, a researcher who wants to explore how the intention to drop out of school develops into action, is likely to adopt a time-series design that may begin to follow students right after elementary school (i.e., grades 6–12). Furthermore, instead of collecting data once or twice each year as likely in the panel design above, this researcher may interact with students every 2 or 3 months each year. With such a frequent interaction with students, this researcher will strive to minimize the disruption of learning on sampled students by asking them only a few questions (i.e., collecting data on a very small number of variables).

Often, a time-series design involves different age groups of persons so that intraperson change can be compared across age or maturity. Given that a time-series design and a panel design belong to the same family of research design, a time-series design also inherits threats to validity associated with its counterpart. When multiple age groups are involved in a time-series design, the potential issue of differential instrument functioning for different age groups also emerges (e.g., there is a need for a test to be psychometrically equated for use by persons of different ages so that cross-age comparisons can be made).

Statistical Techniques for Analyzing Longitudinal Data

To a large extent, longitudinal design is a modern concept, representing a considerable progress over the conventional conception that views individual change as an increment from before to after (e.g., the typical pre- and post-design is a good reflection of this conception). Willett *et al.* (1998) made a classical argument against this conception, stating that

Individual change takes place continuously over time, and comparison of each person's "before" and "after" status is not the most subtle, nor the most effective, way to reveal the features of that trajectory. To measure individual change well, a truly longitudinal perspective must be adopted – a sample of people must be followed over time allowing the research to collect multiple waves of data at sensibly spaced intervals. (p. 397)

This argument can be viewed as the very research condition that allows a meaningful statistical analysis of longitudinal data to address the two research questions posed at the beginning of this article. In this section, three general analytical frameworks are introduced: (1) multilevel growth model (to analyze whether change has occurred), (2) survival model (to analyze when change has occurred), and (3) cross-lagged model (via structural equation modeling, to specifically address the issue of causality in longitudinal research and evaluation).

The survival model and the cross-lagged model are more restricted than the multilevel growth model on data requirement in that both models require a true longitudinal design that follows one or more groups of persons repeatedly over a period of time. As a result, the survival and the cross-lagged models are appropriate analytical techniques for cohort design, panel design, and time-series design. The multilevel growth model, on the other hand, is quite flexible, and with an appropriate specification of the model, it can be applied to the cross-sectional design and trend design (apart from cohort design, panel design, and time-series design) (see Ma and Ma, 2007). This section focuses on the analysis of data that are obtained from true longitudinal designs (i.e., cohort design, panel design, and time-series design).

Multilevel Growth Model

Many research and evaluation studies in education have data that possess a multilevel or hierarchical structure (e.g., students nested within classes, classes nested within schools, and schools nested within districts). Because of these clustering effects, students are no longer independent in data analyzes (i.e., their responses are correlated, resulting in the loss of independence among observations) (e.g., Hox, 2002; Raudenbush and Bryk, 2002). Consequently, instead of traditional statistical techniques, multilevel modeling or hierarchical linear modeling (HLM) needs to be used to analyze education data (see Rasbash *et al.*, 2000; Raudenbush and Bryk, 2002). Multilevel modeling is an extension of the standard multiple regression technique. With simultaneous multiple regressions at different levels, multilevel analysis specifically accounts for correlated responses at levels where dependencies of observations (or clustering effects) occur; hence, it overcomes the difficulty in analyzing hierarchical data, as the assumption of independence of observations is relaxed. When the multilevel nature of educational data is coupled with the longitudinal perspective, the multilevel growth model is the most effective statistical technique.

Ma (1999) represents a typical multilevel growth model in the form of a three-level HLM (see Raudenbush and Bryk, 2002). Using longitudinal data from LSAY discussed earlier, Ma (1999) examined (among other issues) whether there was a statistically significant growth in mathematics achievement among American students when they progressed through secondary schooling. The first level of the model is a set of separate linear regression models, one for each student. These regression equations model students' outcome scores (dependent variable) on their grade levels (time variable):

$$Y_{ijt} = \pi_{0ij} + \pi_{1ij}(\text{grade})_{ijt} + R_{ijt}$$

where Y_{ijt} is the mathematics achievement score for student i in school j is in at occasion t , $(\text{grade})_{ijt}$ is the grade

that student i in school j is in at the testing time t , and R_{ijt} is an error term, assumed to be independent and normally distributed with a common variance of σ^2 . The parameters π_{0ij} and π_{1ij} represent, respectively, the initial status (referring to grade 7 in this case) and the rate of growth in mathematics achievement for student i in school j .

The second level of the model contains two between-student regression equations modeling the initial status and rate of growth based on student background covariates (student-level independent variables), including age, socioeconomic status (SES), the number of parents (numpar), and the number of siblings (numsib):

$$\begin{aligned}\pi_{0ij} &= \beta_{00j} + \beta_{10j}(\text{age})_{ij} + \beta_{20j}(\text{SES})_{ij} + \beta_{30j}(\text{numpar})_{ij} \\ &\quad + \beta_{40j}(\text{numsib})_{ij} + u_{0ij} \\ \pi_{1ij} &= \beta_{01j} + \beta_{11j}(\text{age})_{ij} + \beta_{21j}(\text{SES})_{ij} + \beta_{31j}(\text{numpar})_{ij} \\ &\quad + \beta_{41j}(\text{numsib})_{ij} + u_{1ij}\end{aligned}$$

where β 's are parameters for student-level covariates, representing the relationships of initial status and rate of growth to student-level covariates, and u_{0ij} and u_{1ij} are student-level error terms. If student-level covariates are centered around their grand means, then β_{00j} and β_{01j} represent the initial status and the rate of growth for what is often referred to as a typical student (with average age, SES, number of siblings, and who attends a school that has the same proportion of single parents as in the sample of students).

The third level of the model has two between-school equations, which regress the average initial status and the average rate of growth on school background covariates (school-level independent variables), including school size, school location represented by suburban (vs. urban) schools and rural (vs. urban) schools, and school mean (average) SES:

$$\begin{aligned}\beta_{00j} &= \phi_{000} + \phi_{001}(\text{size})_j + \phi_{002}(\text{suburban})_j + \phi_{003}(\text{rural})_j \\ &\quad + \phi_{004}(\text{meanSES})_j + v_{00j} \\ \beta_{01j} &= \phi_{010} + \phi_{011}(\text{size})_j + \phi_{012}(\text{suburban})_j + \phi_{013}(\text{rural})_j \\ &\quad + \phi_{014}(\text{meanSES})_j + v_{01j}\end{aligned}$$

In these equations, the average initial status and the average rate of growth are represented as an average value (ϕ_{000} or ϕ_{010} , i.e., grand mean), an error term (v_{00j} or v_{01j}), and the contribution of each school-level covariate.

Statistical analysis is often completed in two steps. First, a simple multilevel growth model is estimated without between-student and between-school covariates. In this simple model, the initial status and the rate of growth are described as an average value (fixed effect) plus a variation (random effect). This provides an opportunity to examine not only the average values of the initial status and the rate of growth but also their variances and covariances.

The second step of analysis introduces between-student and between-school covariates, establishing a complex multilevel growth model. The purpose is to use those covariates to explain variation between students within schools and between schools regarding both the initial status and the rate of growth. Adopted and modified from Ma (1999), **Table 1** presents the analytical results from the above (complex) multilevel growth model that estimates the rate of growth in mathematics achievement across secondary schooling and identifies variables that predict such a growth.

Survival Model

Unlike the multilevel growth model that typically deals with the trajectory of change, another category of longitudinal research and evaluation typically deals with the occurrence of an event of interest. Traditionally, researchers tend to ask whether an event occurs before the end of a certain period. Willett and Singer (1991) argued that, rather than asking whether, researchers should ask when an event occurs during a certain period:

Although logically intertwined, these two types of questions are also conceptually distinct, the “When?” question being far more general than the “Whether?” In fact, . . . by asking when events occur, a researcher learns not only

whether these events occur by each of several points in time but much much more. (p. 408)

To some extent, researchers’ asking ‘whether’ instead of ‘when’ is due to the fact that traditional educational statistics are inappropriate to address the ‘when’ question. Willett and Singer (1991) stated that traditional statistical techniques, such as regression analysis or analysis of variance, are not capable of handling censored event times:

No matter when data collection begins and no matter how long any subsequent follow-up, some study participants do not experience the target event while the researcher watches – some students do not drop out; some children do not leave day care; some teachers do not quit. These people have censored event times. What value of the outcome should they be assigned? Will they experience the event soon after the end of data collection, or will some of them never undergo the transition of interest? (p. 408)

Researchers cannot answer these questions on the basis of traditional statistical techniques. Survival analysis is the most effective statistical approach to work with censored data (Willett and Singer, 1991).

Unlike traditional statistical techniques for longitudinal data analysis, the survival model is capable of incorporating time-varying (independent) variables (i.e., variables that take on different values at different points in time). Willett and Singer (1991) argued that “traditional analytic methods offer few mechanisms for including predictors whose values vary over time or for permitting the effects of predictors to fluctuate over time” (p. 426). As a result, researchers tend to use “values corresponding to a single point in time, the average of values over time, or the rate of change in values over time” in their analyses (p. 426). In doing so, “traditional methods force researchers into building static models of dynamic processes; survival methods [on the other hand] allow researchers to model dynamic process dynamically” (p. 427).

Using data from LSAY, Ma and Willms (1999) developed a survival model to examine participation of American students in mathematics coursework across secondary schooling (i.e., dropping out of mathematics courses). As events, such as dropout, are dichotomous (e.g., 1 = drop and 0 = stay), the nature of data analysis is often logistic regression. There is special treatment for time-varying variables – “for each unit of time that each individual is known to be at risk, a separate observational record is created” (Allison, 1984: 18). Hazard probability (the proportion of persons available at the beginning of a certain period who experience the event during the period) is an important part of any survival model. It is often assumed that hazard probability varies across points in time (e.g., different across the 5 years in the study of dropping out of mathematics courses). To assume varying hazard probability, a set of dummy variables is created, one for each of the later points in

Table 1 Results of multilevel growth model explaining variation in mathematics achievement between students and schools in grade 7 status and rate of growth

	<i>Females</i>		<i>Males</i>	
	<i>Effect</i>	<i>(SE)</i>	<i>Effect</i>	<i>(SE)</i>
<i>Average within-student model</i>				
Grade 7 status	59.79*	(1.35)	59.89*	(1.39)
Rate of growth	3.75*	(0.49)	4.19*	(0.64)
<i>Effects of between-student covariates on grade 7 status</i>				
Age	−3.30*	(0.56)	−4.07*	(0.48)
Socioeconomic status (SES)	2.62*	(0.36)	3.06*	(0.35)
Number of parents	1.74*	(0.71)	2.29*	(0.78)
Number of siblings	0.09	(0.27)	0.37	(0.26)
<i>Effects of between-student covariates on rate of growth</i>				
Age	−0.64*	(0.21)	−0.80*	(0.20)
SES	0.56*	(0.13)	0.45*	(0.13)
Number of parents	0.50	(0.26)	0.45	(0.31)
Number of siblings	0.13	(0.10)	0.19	(0.10)
<i>Effects of between-school covariates on grade 7 status</i>				
School size	−0.01	(0.00)	−0.00	(0.00)
School mean SES	4.75*	(1.72)	6.56*	(1.65)
Suburban	1.38	(1.28)	−1.43	(1.32)
Rural	1.09	(1.30)	−0.68	(1.32)
<i>Effects of between-school covariates on rate of growth</i>				
School size	−0.00	(0.00)	−0.00	(0.00)
School mean SES	−0.33	(0.65)	0.42	(0.76)
Suburban	1.21*	(0.47)	0.34	(0.61)
Rural	1.17*	(0.47)	0.15	(0.61)

* $p < 0.05$.

time, with the first point in time as the reference (see Allison, 1984). In Ma and Willms (1999), one dummy variable was created for each of the last 5 years (grades 8–12), with grade 7 as the base for comparison. The probability of dropping out of mathematics courses is measured as:

$$P(u = 1) = \frac{1}{1 + e^{-Z}}$$

where $P(u = 1)$ denotes the probability that event u (dropping out of mathematics courses) occurs and Z is a linear composite of independent variables. In Ma and Willms (1999), the probability of dropping out of mathematics courses was predicted by students' gender, SES, prior achievement in mathematics (PAIM), and prior attitude toward mathematics (PATM); that is:

$$Z = \sum_{i=1}^5 \beta_i(G_j) + \beta_6(\text{gender}) + \beta_7(\text{SES}) + \beta_8(\text{PAIM})(t) + \beta_9(\text{PATM})(t)$$

where $j = 8, 9, 10, 11, 12$, and $\beta_i (i = 1, 2, 3, 4, 5)$ represents the time-varying hazard probability. For example, $\beta_1(G_8)$ represents the hazard probability in grade 8. Time-varying variables denoted by t may have different effects on the probability of dropping out of mathematics courses at different points in time, which can be modeled by interaction terms between grade-level dummies (G_8 to G_{12}) and independent (time-constant or time-varying) variables. For example, gender differences in dropping out of mathematics courses is expected to occur mainly in the last year of high school (grade 12).

$$Z = \sum_{i=1}^5 \beta_i(G_j) + \beta_6(\text{gender}) + \beta_7(\text{SES}) + \beta_8(\text{PAIM})(t) + \beta_9(\text{PATM})(t) + \beta_{10}(\text{gender} \times G_{12})$$

Adopted and modified from Ma and Willms (1999), **Table 2** presents the analytical results from the above survival model that estimates time-varying hazard probabilities and identifies student background variables that have constant effects (see SES and PAIM) or time-varying effects (see gender and PATM) on dropping out of mathematics courses.

Cross-Lagged Model

Cross-lagged panel design is an effective way to determine the cause–effect relationship between two variables of interest (see Marsh, 1990). Using data from LSAY, Ma and Xu (2004) developed a cross-lagged model via structural equation model (SEM) with latent variables to analyze longitudinal data on attitude toward mathematics (ATM) and achievement in mathematics (AIM) for the purpose of determining the causal ordering between ATM and AIM. The simplest cross-lagged model contains two waves of data, even though Willett *et al.* (1998) have argued against designs producing only before and after data. The cross-lagged model in Ma and Xu (2004) contains six waves of data (grades 7–12). The cross-lagged model via SEM (with latent variables) has a huge advantage of integrating a structural model with a measurement model. This is desirable in that structural relationships can be directly adjusted for measurement qualities. The development of the cross-lagged model is usually achieved in two stages.

In Ma and Xu (2004), the first stage includes specification of measurement models. There are three attitude items:

1. mathematics is useful in everyday problems,
2. mathematics helps a person think logically, and
3. I will use mathematics in many ways as an adult.

Table 2 Results of survival model explaining variation in mathematics participation from grade 8 to 12

Time effect	Effect	SE	Proportion
Grade 8 (D)	3.83*	(0.07)	0.98
Grade 9 (D)	2.55*	(0.05)	0.93
Grade 10 (D)	2.57*	(0.03)	0.93
Grade 11 (D)	2.15*	(0.10)	0.90
Grade 12 (D)	0.71*	(0.11)	0.67
Variable effect	Effect	SE	Exp
Female (D)	0.09*	(0.04)	1.09
Socioeconomic status (SES)	0.14*	(0.02)	1.15
Prior mathematics achievement (T)	0.27*	(0.03)	1.31
Prior attitude toward mathematics (T)	0.11*	(0.02)	1.12
Female \times grade 12	−0.45*	(0.13)	[0.70]
Prior attitude toward mathematics \times grade 11	0.27*	(0.06)	[1.46]
Prior attitude toward mathematics \times grade 12	0.32*	(0.06)	[1.54]

* $p < 0.05$.

Effects in parentheses are calculated by e raised to the power of the sum of interaction effect and base-line effect. For example, the effect of prior attitude toward mathematics in grade 11 is $\text{Exp}(0.27 + 0.11) = 1.46$. D denotes dummy variables; T denotes time-varying variables; SE denotes standard errors; Exp denotes the regression results in terms of e raised to the power of each effect; grades 8–12 (D) represent hazard probabilities in grades 8–12.

They are specified as indicators of the latent variable, ATM, in a measurement model (see **Figure 1**). Specified also in this measurement model are the stability effects of ATM from one year to the next across grades 7–12 (see unidirectional paths in **Figure 1**). Obviously, such a model specification yields estimates of the stability effects that are free from random measurement errors and the effects of a person's unique responses specific to each item over time.

AIM is measured in four mathematics subjects: (1) basic skills, (2) algebra, (3) geometry, and (4) quantitative literacy. The measurement model for AIM is developed in the same way as shown in **Figure 2**. The relationship between two non-neighboring latent variables is completely mediated by latent variable(s) in-between them in these models (**Figures 1 and 2**). These measurement models include sound common statistical practices when analyzing longitudinal data: (1) allowing measurement errors (not shown in the figure for simplicity) to correlate across different points in time for each observed indicator and (2) allowing measurement errors among various indicators to covary at each point in time.

Structural models can then be developed to connect with measurement models by adding cross-lagged effects. In Ma and Xu (2004), cross-lagged effects between ATM and

AIM are specified (see **Figure 3**). Such a cross-lagged model with all possible stability effects and cross-lagged effects, is an ideal approach to investigate the causal relationship between ATM and AIM. With all specifications about measurement errors as discussed in the measurement models maintaining the same, the latent variables of ATM and AIM can now be specified to correlate at each point in time. All of this specification process until now establishes a complete cross-lagged model. There are variations of this cross-lagged model for analytical purposes. A cross-lagged model without paths being specified as equal is unconstrained, often serving as the baseline model. This unconstrained model can then be compared with models that specify stationarity (invariance of factor loadings across measurement waves) and tau equivalence (invariance of factor loadings within measurement waves) to modify the unconstrained model for the causal relationship between ATM and AIM (see Pitts *et al.*, 1996). Model comparisons for goodness of fit can be achieved with common indices such as the chi-square index, the criterion fit index (CFI), the Tucker–Lewis index (TLI), and the standardized root mean square residual (SRMR). **Figure 3** summarizes the causal analysis reported in Ma and Xu (2004) that AIM demonstrates causal predominance over ATM across secondary schooling.

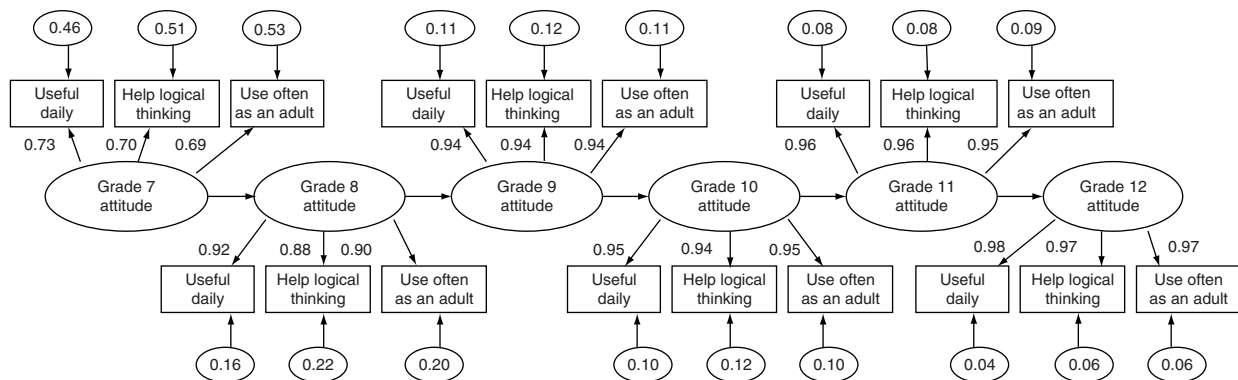

Figure 1 Measurement models of attitude toward mathematics across grades 7–12.

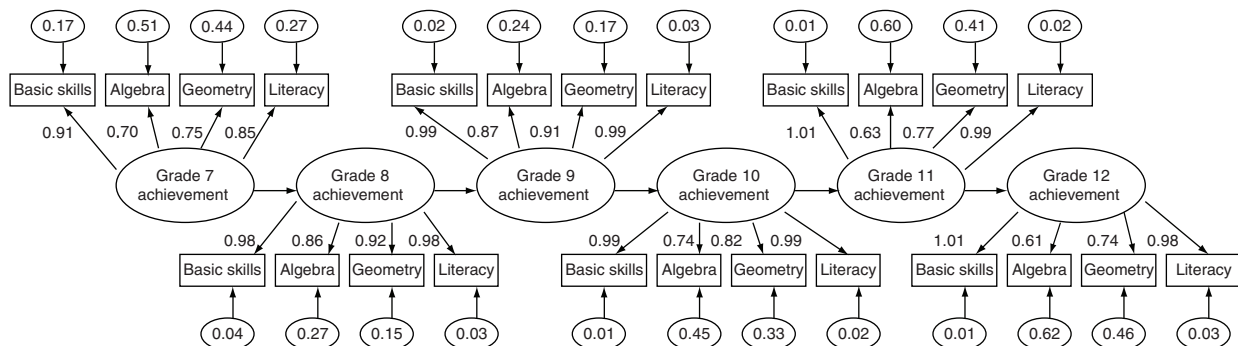

Figure 2 Measurement models of achievement in mathematics across grades 7–12.

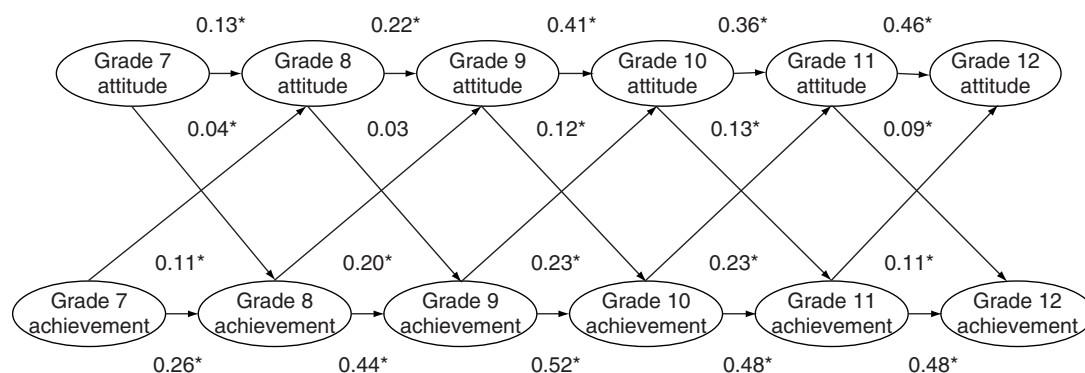

Figure 3 Results of cross-lagged model estimating the causal relationship between attitude toward mathematics and achievement in mathematics across grades 7–12. * $p < 0.05$. Large ovals represent latent factors and unidirectional arrows represent causal links. All parameter estimates for unidirectional paths are standardized.

Meta-evaluation: Purpose, Prescription, and Practice

L A Wingate, Western Michigan University, Kalamazoo, MI, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Evaluation client – The individual or group that requested and/or paid for an evaluation.

Evaluation consumer – Anyone who uses information produced by an evaluation.

Evaluation practitioner – An individual who provides evaluation services.

Evaluation stakeholder – Anyone who is affected by or has a vested interest in an evaluation.

Formative evaluation – The systematic assessment of an object to determine ways in which it can be improved as it is being developed or implemented.

Meta-analysis – The aggregation and analysis of the quantitative results from multiple studies that investigated the same phenomena.

Meta-evaluation – The formative or summative assessment of the merit and worth of an evaluation, group of evaluations, or evaluation system.

Summative evaluation – The systematic determination of the merit and worth of an object (e.g., program, policy).

The term metaevaluation was introduced by Michael Scriven in 1969. In defining it, he explained that metaevaluation has both a theoretical function and a practical one. The former, he said, is “the methodological assessment of the role of evaluation.” The latter “is concerned with the evaluation of specific evaluative performances” (Scriven, 1969: 36). A few years later, Scriven (1975) noted that metaevaluation may seem like an opaque neologism to some (p. 16). It may well have been an opaque neologism in 1975, but it is no longer. Metaevaluation has taken a firm hold in evaluation theory since then. But it is the latter function – that of evaluating particular evaluations – that has taken root, and metaevaluation is commonly understood as the evaluation of an evaluation. Metaevaluation may focus on a single evaluation, a set of evaluations, or an evaluation system. It is applicable to any type of evaluation, such as program, personnel, student, product, and policy. This article focuses on metaevaluation as applied to program evaluations.

Many books, presentations, and websites that provide a general orientation to evaluation start with the issue of why programs should be evaluated. Given that program stakeholders often need convincing about why they should embrace evaluation and expend resources on it,

it is likely that the value of metaevaluation is even less obvious to many. It is for that reason, then, that this article begins with an overview of the various purposes for which metaevaluation may be conducted and the benefits that may be reaped from it. Next, we discuss what has been prescribed by the evaluation profession’s strongest metaevaluation advocates with regard to how metaevaluation should be performed. Then, departing from theoretical and methodological considerations, we turn to issues regarding real-world metaevaluation practice.

Purpose

All the reasons that may be invoked for why programs should be evaluated also apply to why evaluations should be evaluated, such as to provide guidance for improvement, ensure that resources have been expended wisely, ensure that stakeholders have been properly engaged and respected, verify that outcomes were worthwhile and met needs, and learn about what works and does not in particular evaluation contexts.

The range of purposes that metaevaluation serves may be grouped into four categories: formative evaluation, summative evaluation, synthesis, and research. These purposes are not mutually exclusive, and a single metaevaluation may serve multiple purposes. We discuss them independently not because there are unique approaches or criteria associated with them, but to better illuminate the various purposes for and uses of metaevaluation. This article focuses on formal metaevaluation performed by another evaluator, whether internal or external to the primary evaluation. However, evaluations are frequently subject to scrutiny and assessment through means that are not officially labeled as metaevaluation. Such means include review and commentary by project advisory panels, clients, school boards, and organizational boards of directors. Evaluators may also self-metaevaluate by reflecting on their practice in terms of how well it meets the standards and guidelines set forth by the profession. These activities serve similar functions, albeit in a less overt and systematic way.

Formative Evaluation

Formative metaevaluation takes place while an evaluation is underway in order to provide guidance for improvement. Draft evaluation work products, such as evaluation plans, instruments, protocols, and reports, may be subject to review

and feedback by a metaevaluator prior their finalization, implementation, or dissemination. Less tangible aspects of an evaluation may also be assessed in formative metaevaluation, such as data collection, verification, and analysis procedures; competence of the evaluation personnel; and responsiveness to stakeholders' information needs.

The same arguments that are made for formative evaluation of programs can be made for formative metaevaluation. For example, it helps ensure that wise choices are made with regard to how to focus the study, expend resources, perform analyses, and so on. Another important reason that formative metaevaluations are conducted is to reduce bias in evaluation (Fitzpatrick *et al.*, 2004; Scriven, 1975). The mere presence of a metaevaluator has the potential to reduce bias and increase rigor as an evaluation is being implemented (Scriven, 1975), simply because the evaluator knows his or her performance is being scrutinized, not just by the evaluation client, but by someone else with evaluation expertise.

The greatest benefit of formative metaevaluation is that it can reveal deficiencies in the primary evaluation at a point in time when they can still be addressed, thus preventing the determination and dissemination of invalid conclusions and increasing the primary evaluation's utility and cost-effectiveness (Fitzpatrick *et al.*, 2004; Joint Committee on Standards for Educational Evaluation, 1994; Stufflebeam and Shinkfield, 2007).

Summative Evaluation

A summative metaevaluation assesses the quality of a completed evaluation – the appropriateness of its processes and validity of its conclusions. A summative metaevaluation may examine, for example, the extent to which evaluators delivered what was promised, used resources efficiently, and acted ethically. In addition to informing such accountability issues, a summative metaevaluation may serve a verification purpose, that is to confirm (or disconfirm) that an evaluation's conclusions (and recommendations, if present) were sound and justified. Summative metaevaluation that checks the veracity of findings and appropriateness of the methods is especially important for evaluations where stakes are high and important decisions hinge on the results (Patton, 2008; Stufflebeam and Shinkfield, 2007).

When a summative metaevaluation validates a primary evaluation, it adds credibility to it and enhances users' confidence in using the evaluation findings to inform decisions to expand, modify, or cancel programs. When a summative metaevaluation finds serious flaws in a primary evaluation, it can prevent decision makers from taking actions based on faulty information. Evaluation consumers, clients, and practitioners can use summative metaevaluations in a formative manner by taking what was learned in the summative metaevaluation and applying those lessons in their subsequent evaluation experiences.

Synthesis

Metaevaluation may also be performed as a precursor to synthesizing findings across evaluations of a particular program or set of programs (Cooksy and Caracelli, 2005; Scott-Little *et al.*, 2002; Stufflebeam and Shinkfield, 2007). Such syntheses are undertaken to achieve a deeper understanding of the effectiveness of a certain type of intervention or program. In this case, metaevaluation is a means to an end in that it is a tool for determining which evaluations are of sufficient quality to be included in a synthesis of findings to address research questions that are about program – not evaluation – quality or effectiveness. Metaevaluation is a critical step in such syntheses, whether qualitative or quantitative (i.e., meta-analytic), so that methodologically weak evaluations (Cooksy and Caracelli, 2005) or those with incorrect conclusions may be appropriately excluded.

Research

Metaevaluation is a useful vehicle for conducting research on evaluation (Fitzpatrick *et al.*, 2004; Stufflebeam and Shinkfield, 2007). Here, the focus is on addressing questions about the practice and/or use of evaluation. Stufflebeam and Shinkfield (2007) advocate for more empirical research on evaluation that will facilitate the development of “research-based principles for conducting program evaluation” (p. 73). The evaluation theories that prevail today are mostly prescriptions for practice and have not been systematically examined in empirical studies. Stufflebeam and Shinkfield identify numerous hypotheses about evaluation that have been proffered in the literature and could be subject to empirical investigation, and several of these – such as the ones listed here – could be addressed through metaevaluation:

- Appropriate application of evaluation and standards and principles enhances an evaluation's quality and resolution of ethical problems;
- Stakeholder involvement enhances use of evaluation findings;
- Participatory and collaborative approaches used for capacity building enhance program effectiveness and increase evaluation use; and
- Effectiveness of employment of a variety of reporting strategies beyond the written report, applied differentially to audiences, increases their use of findings (pp. 71–73).

In order to test these hypotheses, researchers must be able to discern evaluation quality, effectiveness, usefulness, ethicality, cost-effectiveness, etc. Making judgments about these aspects of evaluations is the domain of metaevaluation.

Prescription

Evaluation theories are essentially prescriptive theories – recommendations about how to go about the business of evaluation – that are informed by both scholarship and practice. Such theories address the focus and function of evaluation, role of evaluation stakeholders, evaluation design and implementation, sources of criteria for determining quality, and use of evaluation results. Although almost any theoretical orientation to or model for evaluation – for example, CIPP, utilization-focused, deliberative-democratic, empowerment – could be applied in metaevaluation, those who advocate for evaluation at the meta level typically do not prescribe the use of a particular model. (Metaevaluation is sometimes confused with meta-analysis, but they are very different endeavors, with meta-analysis being the aggregation and analysis of the quantitative results from multiple studies that investigated the same phenomena. However, a legitimate focus of a metaevaluation may be the extent to which an evaluation adhered to a particular evaluation model, in which case issues related to evaluation models would come into play, but not so much with regard to how the metaevaluation itself is implemented.) Rather, they tend to focus on the central issues of questions and criteria, which illuminate the issues on which metaevaluation should focus, and methodological approaches, that is, how metaevaluations should be implemented.

Questions and Criteria

By nature, metaevaluation focuses on questions about an evaluation's merit and worth. Stufflebeam and Shinkfield (2007) articulate the fundamental question of merit as "how well [the evaluation] meets the requirements of a sound evaluation" and the fundamental question of worth as "the extent to which it meets the audiences' needs for evaluative information" (p. 667). Patton (2008) suggests some basic metaevaluation questions that focus on evaluation processes: "To what extent was the [evaluation] implemented as designed? What adaptations occurred during implementation and what are the implications of those adaptations for intended and unintended outcomes?" (p. 570). The Joint Committee on Standards for Educational Evaluation (1994) identifies the following questions among those that might be addressed in a metaevaluation:

- Were the findings for the program evaluation clear?
- Were the design and implementation of the design appropriate for the study?
- Were the conclusions justified by the data?
- Were the results adequately disseminated? Were they used? (Joint Committee on Standards for Educational Evaluation, 1994: 186)

Questions define the scope of inquiry in a metaevaluation and criteria provide the basis for arriving at judgments in relation to those questions. As in any type of evaluation, the criteria and questions that drive a metaevaluation should be negotiated in advance with the evaluation client and other stakeholders to ensure their information needs are met.

However, metaevaluators should strive to ground their assessments of evaluations in commonly accepted criteria or standards for evaluation. This is important not only for individual metaevaluations, but also for advancing the relatively young evaluation profession by invoking and promoting a common understanding of what constitutes sound evaluation practice – not just among evaluation practitioners and scholars, but also evaluation participants, clients, consumers, and managers. Unlike well-established professions such as accounting, medicine, law, psychology, and the construction trades (to name just a few), there are no regulated certification or licensure processes to verify that individuals are qualified to practice evaluation or call themselves evaluators (although the Canadian Evaluation Society's Professional Designations Project, which started in 2007, is working toward that end –). In the absence of such regulations, it is incumbent on evaluation practitioners, clients, managers, and consumers to educate themselves about and use established criteria and standards to facilitate consistency and professionalization in evaluation practice. Some of evaluation's most distinguished scholars and practitioners, including Patton (2008), Scriven (2007), and Stufflebeam (2001) identify *The Program Evaluation Standards* (Joint Committee on Standards for Educational Evaluation, 1994) as one of the most important sources of criteria for assessing evaluation quality, if not the most. Grounding metaevaluation in the Standards promotes consistency in practice and diminishes the potential for evaluations to be judged on idiosyncratic criteria that do little to advance the profession or educate evaluation consumers about what constitutes sound evaluation. Judgments about the quality of evaluations should not hinge on methodological or theoretical preferences, personal opinion, or arbitrary criteria, but on recognized requirements for sound and credible evaluation, such as *The Program Evaluation Standards*, which are summarized in **Table 1**.

The subtitle of *The Program Evaluation Standards* (Joint Committee on Standards for Educational Evaluation, 1994) book, *How to Assess Evaluations of Educational Programs*, reveals why these standards figure so prominently in discussions of metaevaluation. But they were developed specifically for application to educational evaluations in North America. As someone entrenched in educational program evaluation in the American context, it follows that these are the standards that dominate the author's own evaluation practice and scholarship. However, other standards may be more appropriate – either in

Table 1 The Program Evaluation Standards (Joint Committee 1994)

<i>Utility standards : The utility standards are intended to ensure that an evaluation will serve the information needs of intended users.</i>	
<i>U1 stakeholder identification</i>	Persons involved in or affected by the evaluation should be identified, so that their needs can be addressed.
<i>U2 evaluator credibility</i>	The persons conducting the evaluation should be both trustworthy and competent to perform the evaluation, so that the evaluation findings achieve maximum credibility and acceptance.
<i>U3 information scope and selection</i>	Information collected should be broadly selected to address pertinent questions about the program and be responsive to the needs and interests of clients and other specified stakeholders.
<i>U4 values identification</i>	The perspectives, procedures, and rationale used to interpret the findings should be carefully described, so that the bases for value judgments are clear.
<i>U5 report clarity</i>	Evaluation reports should clearly describe the program being evaluated, including its context, and the purposes, procedures, and findings of the evaluation, so that essential information is provided and easily understood.
<i>U6 report timeliness and dissemination</i>	Significant interim findings and evaluation reports should be disseminated to intended users, so that they can be used in a timely fashion.
<i>U7 evaluation impact</i>	Evaluations should be planned, conducted, and reported in ways that encourage follow-through by stakeholders, so that the likelihood that the evaluation will be used is increased.
<i>Feasibility standards: The feasibility standards are intended to ensure that an evaluation will be realistic, prudent, diplomatic, and frugal.</i>	
<i>F1 practical procedures</i>	The evaluation procedures should be practical, to keep disruption to a minimum while needed information is obtained.
<i>F2 political viability</i>	The evaluation should be planned and conducted with anticipation of the different positions of various interest groups, so that their cooperation may be obtained, and so that possible attempts by any of these groups to curtail evaluation operations, or to bias or misapply the results can be averted or counteracted.
<i>F3 cost-effectiveness</i>	The evaluation should be efficient and produce information of sufficient value, so that the resources expended can be justified.
<i>Propriety standards: The propriety standards are intended to ensure that an evaluation will be conducted legally, ethically, and with due regard for the welfare of those involved in the evaluation, as well as those affected by its results.</i>	
<i>P1 service orientation</i>	Evaluations should be designed to assist organizations to address and effectively serve the needs of the full range of targeted participants.
<i>P2 formal agreements</i>	Obligations of the formal parties to an evaluation (what is to be done, how, by whom, when) should be agreed to in writing, so that these parties are obligated to adhere to all conditions of the agreement or formally to renegotiate it.
<i>P3 rights of human subjects</i>	Evaluations should be designed and conducted to respect and protect the rights and welfare of human subjects.
<i>P4 human interactions</i>	Evaluators should respect human dignity and worth in their interactions with other persons associated with an evaluation, so that participants are not threatened or harmed.
<i>P5 complete and fair assessment</i>	The evaluation should be complete and fair in its examination and recording of strengths and weaknesses of the program being evaluated, so that strengths can be built upon and problem areas addressed.
<i>P6 disclosure of findings</i>	The formal parties to an evaluation should ensure that the full set of evaluation findings along with pertinent limitations are made accessible to the persons affected by the evaluation and any others with expressed legal rights to receive the results.
<i>P7 conflict of interest</i>	Conflict of interest should be dealt with openly and honestly, so that it does not compromise the evaluation processes and results.
<i>P8 fiscal responsibility</i>	The evaluator's allocation and expenditure of resources should reflect sound accountability procedures and otherwise be prudent and ethically responsible, so that expenditures are accounted for and appropriate.
<i>Accuracy standards: The accuracy standards are intended to ensure that an evaluation will reveal and convey technically adequate information about the features that determine worth or merit of the program being evaluated.</i>	
<i>A1 program documentation</i>	The program being evaluated should be described and documented clearly and accurately, so that the program is clearly identified.
<i>A2 context analysis</i>	The context in which the program exists should be examined in enough detail, so that its likely influences on the program can be identified.
<i>A3 described purposes and procedures</i>	The purposes and procedures of the evaluation should be monitored and described in enough detail, so that they can be identified and assessed.
<i>A4 defensible information sources</i>	The sources of information used in a program evaluation should be described in enough detail, so that the adequacy of the information can be assessed.
<i>A5 valid information</i>	The information-gathering procedures should be chosen or developed and then implemented so that they will assure that the interpretation arrived at is valid for the intended use.
<i>A6 reliable information</i>	The information-gathering procedures should be chosen or developed and then implemented so that they will assure that the information obtained is sufficiently reliable for the intended use.

Continued

Table 1 Continued

<i>A7 systematic information</i>	The information collected, processed, and reported in an evaluation should be systematically reviewed, and any errors found should be corrected.
<i>A8 analysis of quantitative information</i>	Quantitative information in an evaluation should be appropriately and systematically analyzed so that evaluation questions are effectively answered.
<i>A9 analysis of qualitative information</i>	Qualitative information in an evaluation should be appropriately and systematically analyzed so that evaluation questions are effectively answered.
<i>A10 justified conclusions</i>	The conclusions reached in an evaluation should be explicitly justified, so that stakeholders can assess them.
<i>A11 impartial reporting</i>	Reporting procedures should guard against distortion caused by personal feelings and biases of any party to the evaluation, so that evaluation reports fairly reflect the evaluation findings.
<i>A12 metaevaluation</i>	The evaluation itself should be formatively and summatively evaluated against these and other pertinent standards, so that its conduct is appropriately guided and, on completion, stakeholders can closely examine its strengths and weaknesses.

Note: In *The Program Evaluation Standards* book, each standard is supported by an overview, guidelines, common errors, illustrative cases, and references to supporting documentation.
Reprinted from the Joint Committee on Standards for Educational Evaluation.

conjunction with or in lieu of *The Program Evaluation Standards* – depending on the subject matter and context. In addition to standards for program evaluations, the Joint Committee has issued standards for educational personnel evaluation (Joint Committee on Standards for Educational Evaluation, 2008) and student evaluation (Joint Committee on Standards for Educational Evaluation, 2002). The United States Government Accountability Office's (2007) *Government Auditing Standards* include standards for evaluations (referred to as performance audits in that document) conducted by and for U.S. federal agencies. The American Evaluation Association's *Guiding Principles for Evaluators* provide general guidance for how professional evaluators should conduct themselves. Some organizations have developed their own criteria for assessing evaluations. For example, ALNAP, the Active Learning Network for Accountability and Performance in Humanitarian Action, has developed a tool for rating evaluations of humanitarian interventions, which is available from its website. In this volume's article on moral and ethical issues in evaluation, Michael Morris directs readers to standards and principles for use in an array of international contexts and provides the website addresses for many of these. Evaluators, metaevaluators, and evaluation clients, consumers, and other stakeholders should make themselves aware of the standards that are most pertinent for their contexts and apply them accordingly.

The increasing attention to the development and use of standards for professional evaluation in these diverse contexts is an indicator of the maturation of the evaluation profession. Use of such established and widely respected standards for metaevaluation purposes further promotes indoctrination of practitioners and scholars from diverse backgrounds into the global community of professional evaluators.

Individuals who request a metaevaluation may have special interests or concerns with regard to a particular evaluation, and their information needs should be respected

and addressed as the criteria and questions for a metaevaluation are negotiated.

Methodological Approaches

Stufflebeam has prescribed a practical, generic approach to metaevaluation that involves eleven tasks, which parallel the tasks in primary evaluation (Stufflebeam, 2001; Stufflebeam and Shinkfield, 2007):

1. Staff the metaevaluation team with one or more qualified evaluators.
2. Identify and arrange to interact with the metaevaluation's stakeholders.
3. Define the metaevaluation questions.
4. Agree on standards, principles, or criteria to judge the evaluation system or particular evaluation.
5. Issue a memo of understanding or negotiate a formal metaevaluation contract.
6. Collect and review pertinent available information.
7. Collect new information as needed.
8. Analyze and synthesize the findings.
9. Judge the evaluation's adherence to appropriate standards, principles, and/or criteria.
10. Convey the metaevaluation findings through reports, correspondence, oral presentations, and other ways.
11. As appropriate, help the client and other stakeholders interpret and apply the findings. (Stufflebeam and Shinkfield, 2007: 663)

The options for data collection methods and analytic techniques for metaevaluation include all of those that are used in primary evaluation. Metaevaluations, whether formative or summative, should almost always examine evaluation documents, such as plans, meeting minutes, instruments, protocols, and reports – that is, pertinent available information, noted in Task 6 above. Such documents, however, cannot tell the full story about an

evaluation, which is why Task 7, which calls for the acquisition of additional information, is often warranted. Additional information may be collected through a variety of means, such as interviews, focus groups, surveys, observations, and advocate–adversary techniques. Methodological choices should be keyed to the metaevaluation questions and criteria and, just as importantly, must consider the scope of the metaevaluation.

Cook and Gruder's (1978) typology of metaevaluation approaches provides a different way to conceptualize how to approach the task of metaevaluation. For them, key considerations are whether the metaevaluation takes place after the primary evaluation or concurrently, whether data collected for the primary evaluation are manipulated, and whether there are one or multiple data sets. They organize the possible options into seven basic approaches for metaevaluation:

1. Essay review of an evaluation report;
2. Review of the literature about a specific program;
3. Empirical reevaluation of an evaluation or program;
4. Empirical reevaluation of multiple data sets about the same program;
5. Consultant metaevaluation;
6. Simultaneous secondary analysis of raw data; and
7. Multiple independent replications (p. 17).

Cook and Gruder's (1978) metaevaluation typology was an influential contribution to early conceptualizations of metaevaluation and a must-read for anyone interested in the topic, but is somewhat dated in light of developments in evaluation that have occurred over the past 30 years. For example, since it was published prior to the issuance of the first edition of *The Program Evaluation Standards* in 1981, it lacks references to standards for judging evaluations. Although the formative/summative functions of metaevaluation are implicit in the dichotomy of whether metaevaluations are conducted subsequent to or simultaneous with primary evaluations, the formative/summative terminology, which has become so entrenched in how evaluators think and talk about evaluation, is absent. Nonetheless, the range of options suggested by Cook and Gruder is broader than what is offered by more contemporary writings on metaevaluation, and persons interested or engaged in metaevaluation would be well served by revisiting this seminal work.

Scriven (2005, 2007) suggests three options that overlap Cook and Gruder's (1978) typology substantially:

- Replicate evaluation using same methodology and compare results;
- Evaluate same evaluand using different methodology and compare results; and
- Apply Scriven's (2007) Key Evaluation Checklist, *The Program Evaluation Standards* (Joint Committee on Standards for Educational Evaluation, 1994; Stufflebeam,

1999), or United States Government Accountability Office (2007) standards to the evaluation.

The first two approaches above and their correlates in Cook and Gruder's typology are applicable to summative metaevaluations that check on the accuracy of a primary evaluation's findings. Scriven (1975) recommends a procedure for reaching convergence when independent evaluations are conducted of the same evaluation, whereby the involved evaluators critique each other's reports, then modifies their own based on the feedback. This process is critical for achieving metaevaluative objectives – otherwise the client just has two evaluations of the same program, which may or not agree. The application of standards or criteria, indicated by the last option above, can address accuracy, but also facilitates a focus on evaluation processes.

Guidance is available for how to apply the criteria embodied in *The Program Evaluation Standards* (Joint Committee on Standards for Educational Evaluation, 1994) to reach judgments about evaluation quality. The Standards book includes a chapter on applying the standards, which recommends that metaevaluators rate an evaluation on each standard in terms of whether the standard was addressed, partially addressed, not addressed, or not applicable. Fitzpatrick *et al.*, (2004) illustrate how a checklist could be developed for evaluating specific aspects of an evaluation, with specific subcriteria to support each standard, and they provide an example of a checklist designed to assess evaluation reports and designs. Stufflebeam (1999) designed an elaborate checklist for evaluating evaluations based on *The Program Evaluation Standards*. His checklist includes subcriteria for each standard and a scoring system to facilitate interpretations of quality. Use of this checklist is also suggested by other prominent advocates of metaevaluation (e.g., Fitzpatrick *et al.*, 2004; Patton, 2008; Scriven, 2007).

Regardless of the criteria, approach, or tools one uses in metaevaluation, it is almost a necessity that there be a connoisseurial (Eisner, 1983) element to it, or what Datta (1999) calls the “I know it when I see it” (p. 346) approach to metaevaluation. Rigorous and extensive data collection is not typically practical in the metaevaluation context, and in the absence of such data, metaevaluators must bring to bear their expert knowledge in evaluation, in combination with what they learn about the particular evaluation through additional means. Primary evaluators can facilitate metaevaluation by keeping thorough records of evaluation processes and decisions, thereby minimizing, albeit not eliminating, the need for additional data collection.

Practice

It is difficult to determine the frequency with which metaevaluation is actually practiced. An evaluation that

the author has been involved with at The Evaluation Center at Western Michigan University has been subject to five separate metaevaluations over the course of 9 years. But this may be an exception and not the rule in evaluation practice, due largely to the lead evaluator's deep commitment to the tenets of The Program Evaluation Standards.

In a recent search of the peer-reviewed literature, the author located 18 examples of metaevaluations. Concurrently and independently of my effort, Cooksy and Caracelli (2009) conducted a search for examples of metaevaluation and also located 18. Cooksy and Caracelli did not limit their search to the peer-reviewed literature, but did restrict it to metaevaluations of single evaluations for formative or summative purposes (excluding metaevaluations of multiple evaluations and those conducted for theory development purposes). Collectively, our two searches yielded just 34 examples of formal metaevaluation (two of these metaevaluations were identified by both searches), suggesting that only a tiny proportion of the evaluations that are conducted are subject to systematic metaevaluation. Although this conclusion may seem to have been reached by rather unsystematic means, it is common perception (Fitzpatrick *et al.*, 2004; Henry and Mark, 2003). It is also noteworthy that 17 of the 18 metaevaluations located by Cooksy and Caracelli were produced by just 3 entities – the Center for Instructional Research and Curriculum Evaluation at the University of Illinois, The Evaluation Center at Western Michigan University, and Cornell University's graduate program in evaluation. There are tentative indications, however, that the practice is may be growing in frequency – of the 34 metaevaluation examples located by both searches, 15 of them were issued in 2000 or later; 10 were published in the 1990s, and the remaining 9 were put forth in the 1980s. Neither search specified any parameters regarding years of publication.

Although formal metaevaluation may be practiced on a relatively limited basis, informal metaevaluation happens all the time. For example, evaluations are often subject to review and feedback by project advisory panels, clients, and organizational boards of directors. Potential clients and competitors may also be paying attention to quality of an evaluator's performance. Any evaluator who uses The Program Evaluation Standards or other evaluation guidelines or principles to keep his or her work on track and/or to inform decisions about how to conduct an evaluation is engaged in metaevaluation.

Examples of metaevaluation in the literature are relatively rare, but Stufflebeam and Shinkfield (2007) and Cook and Gruder (1978) describe several cases of metaevaluation, with clear descriptions of what various approaches to metaevaluation look like in practice and insights that only such seasoned evaluators and metaevaluators can provide. Based on the author's own experience as an evaluator who has conducted internal and external

metaevaluations and who has had her own work subject to metaevaluation, she has identified some evaluation practice issues that are specific to metaevaluation. The author cautions readers that these observations are based on her own experience, although many are substantiated in the literature on metaevaluation, and likely do not represent the full range of issues that are uniquely metaevaluative.

The Program Evaluation Standards were previously discussed in terms of their use as criteria in assessing evaluation quality. However, they are also a guide to evaluation practice. In thinking about the Standards as a guide to practice, it is the author's opinion that some of them manifest slightly differently in metaevaluation than in primary evaluation. These standards and their special considerations in the context of metaevaluation are highlighted as follows: (refer to **Table 1** for the standards' summary statements).

Evaluator Credibility

This utility standard is concerned with the evaluators' trustworthiness and competence. In any evaluation context, it is crucial that stakeholders have confidence in evaluators so that they will trust and use the evaluation findings. As metaevaluation is an unfamiliar concept outside of the evaluation world, it is possible that clients and other primary evaluation stakeholders may think that the presence of a third party checking on the work of the primary evaluator means they should be concerned about his or her competence. Metaevaluators and those who engage them should take care to protect the credibility of primary evaluators. As evaluation consumers and practitioners alike become more knowledgeable of the guidelines for professional evaluation practice, they should come to understand that metaevaluation is part and parcel of sound evaluation practice and is not intended to detract from or discredit a primary evaluation, but rather to enhance its utility and/or credibility.

Values Identification

This utility standard states that evaluators should be upfront about the values they use to interpret findings so that bases for judgments are clear. As noted repeatedly throughout this article, judgments about evaluation quality should be grounded in recognized and widely accepted criteria for sound and credible evaluation. In addition to contributing to the professionalization of evaluation, this focus on common standards also aids in educating evaluation consumers about what they can and should expect from evaluation, providing the metaevaluation results are disseminated (see section titled 'Disclosure of findings' below).

Practical Procedures

This feasibility standard advises evaluators to keep disruption to a minimum (Joint Committee on Standards for Educational Evaluation, 1994: 65) during data collection. Metaevaluators need to be cognizant that primary evaluation stakeholders may have already been called upon to give time or other resources to the primary evaluation. Calling upon them again to provide information for the metaevaluation may contribute to an unfavorable opinion of the evaluation enterprise, especially if they did not value or obtain benefit from their contribution to the primary evaluation. An overzealous metaevaluation effort could also threaten the primary evaluation by burdening the primary evaluators with time-consuming requests (Cook and Gruder, 1978). Cook and Gruder (1978) advise metaevaluators to “be very sensitive to the trade-offs between the needs of busy evaluation staffs for helpful and supportive feedback and the... requirements to monitor quality and discover problems before they become salient” (p. 37).

In addition, metaevaluation budgets are typically fairly small. Stufflebeam and Shinkfield (2007) have observed that is common for metaevaluation budgets to be less than 2% of the primary evaluation’s budget, which means it is especially important to ensure that procedures are realistic.

Political Viability

Evaluation is often a politically charged endeavor. The feasibility standard on political viability calls on evaluators to anticipate the different and possibly competing interests of evaluation stakeholders to avoid derailment of the evaluation process, bias, or misuse of results. Metaevaluation efforts that require the acquisition of anything other than publicly available documents must achieve buy-in from the affected/involved parties. For example, when the focus of a metaevaluation is on evaluations across multiple projects, metaevaluators are dependent on the cooperation of project directors, who may be reticent to relinquish evaluation reports, especially if they were intended as internal project documents, to a third party for review. Metaevaluators should expect to spend a fair amount of time explaining the nature of the work and ensuring the confidentiality of the information provided.

In addition, as much as evaluators may believe in practicing what they preach, they are not accustomed to having their work evaluated and may be reluctant to cooperate with external metaevaluators. As Fitzpatrick *et al.*, (2004) have astutely observed, “Evaluators are human and are no more ecstatic about having their work evaluated than are professionals in other areas of endeavor” (p. 455).

Cost Effectiveness

The feasibility standard on cost-effectiveness states that evaluators should use resources efficiently and produce

valuable information so that evaluation costs are justified. To primary evaluation clients, metaevaluation may seem redundant with the initial evaluation and therefore not worth the expense – either to them or to their evaluators. Care must be taken to explain the value of metaevaluation to primary evaluation clients. Moreover, metaevaluators should be frugal in their efforts to ensure that their work brings value to the evaluation endeavor. This has implications for the selection of methods to perform the metaevaluation. Also important to consider are the stakes involved. High-profile, controversial evaluations warrant greater expense and rigor than internal metaevaluations conducted primarily for improvement purposes (Patton, 2008; Stufflebeam and Shinkfield, 2007).

Human Interaction

The propriety standard on human interaction is about respecting the human dignity and worth (Joint Committee on Standards for Educational Evaluation, 1994: 99) of the persons involved in an evaluation. “A *sin qua non* of metaevaluation,” said Cook and Gruder (1978: 36), “is tact.” In their discussion of consultant metaevaluation (what is essentially now considered formative evaluation), they emphasize the importance of a collegial relationship between the metaevaluator and primary evaluator; without a collaborative and cooperative working relationship, the metaevaluator will find it difficult to do his or her job. Of course, one has to balance such collaborative arrangements with potential threats to credibility and objectivity. Indeed, nonformative metaevaluations would not require any interaction at all between the primary evaluator and metaevaluator.

Disclosure of Findings

This propriety standard advises evaluators to ensure that evaluation findings are disseminated to the individuals impacted by the evaluation. It is especially important for evaluators whose work has been evaluated to share metaevaluation results to demonstrate they practice what they preach, that they are willing to expose their work to criticism and are not shy about sharing them with others. As suggested throughout this article, the practice of metaevaluation can contribute to the advancement of the evaluation discipline, but for this to happen, metaevaluation the findings need to be made available to others who can benefit and learn from them. Broader dissemination of metaevaluations serves to educate both evaluation practitioners and consumers about what should be emulated and what should be avoided in evaluation practice.

Conflict of Interest

The point of this propriety standard is not necessarily to create conditions in which there are no conflicts of

interest present in an evaluation, but instead to deal with such conflicts openly and honestly so that the evaluation's validity and credibility are not jeopardized. Since the community of professional evaluators is fairly small, evaluators and their clients must take care to engage critical friends instead of friendly critics as metaevaluators. Thinking about this issue in opposite terms, it is possible that unscrupulous evaluators could use metaevaluation as an opportunity to discredit the primary evaluator in order to obtain future evaluation contracts for themselves. In short, evaluators evaluating other evaluators create situations in which different types of conflicts of interest exists than in typical program evaluation contexts.

Metaevaluation. The final standard in The Program Evaluation Standards is the Accuracy standard on metaevaluation. It calls on evaluators to subject their work to systematic formative and summative evaluation. This is the one standard that does not transfer well to metaevaluation practice. That is, metaevaluations usually are not subject to metaevaluation – one must consider the point of diminishing returns. That said, Scriven (2009) recommends that metaevaluators have their work independently critiqued by another evaluator. His suggestion that the compensation for this work would be a good dinner implies that meta-metaevaluation would not involve much more than a careful review of metaevaluation plans or reports and/or an in-depth conversation about the process.

Conclusion

Metaevaluation serves several important functions for a wide range of evaluation stakeholders. Formative metaevaluation helps evaluators ensure their services are relevant and technically sound. Summative metaevaluation adds credibility to primary evaluations and helps evaluation audiences gauge how much confidence they should place in the findings. Metaevaluation performed for synthesis purposes ensures that only evaluations that are methodologically sound will be used to extend knowledge about the effectiveness of a given type of intervention, which has implications for policymakers. Metaevaluation as a vehicle for research on evaluation aids in the evaluation discipline's self-knowledge and in the development of more sophisticated models and tools for evaluation. Independently, each type of metaevaluation represents what Scriven (1969) referred to as the practical role of metaevaluation – to evaluate “specific evaluative performances” (p. 36). Collectively, these metaevaluation efforts contribute to our knowledge about what constitutes sound evaluation practice, where evaluation discipline falls short of what it strives to accomplish, evaluation's role in contributing to the betterment of society, and how to advance the discipline. This is what Scriven described as the theoretical function of metaevaluation, which goes beyond

looking at particular evaluations to “the evaluation of the very function and practice of evaluation itself” (Fitzpatrick *et al.*, 2004: 443).

The third edition of The Program Evaluation Standards, forthcoming in 2010, will give metaevaluation a higher profile than in previous editions. A fifth domain of standards called evaluation accountability will join utility, feasibility, propriety, and accuracy, and encompass matters pertaining to metaevaluation. The increased prominence of metaevaluation in The Program Evaluation Standards is consistent with the growing interest and attention to metaevaluation within the profession.

Glossary

Anti-criteriological approaches – Views of quality based on the belief that no list of quality criteria exhaust what quality might mean under specific situational circumstances.

COM-list – A list of Criteria of Merit that can be used as evaluation criteria.

Criteriological approaches – Views of quality based on the belief that quality can be defined on the basis of a definitive list of quality criteria.

Evaluation – A systematic, methodological, value-based assessment of some activity, program, or product, having in mind some practical decision-making or learning related to that activity, program, or product or to other activities, programs, or products.

Evaluation theory – Fairly rational and general assumptions about how an understanding of values, knowledge, evaluands, and the use of evaluation, can guide better evaluation practice.

Maximum standards – Ideal standards from which one may deviate if there are good reasons to do so.

Minimum standards – Standards which must be met under all circumstances.

The issue of quality in evaluation is of continuing and increasing relevance for at least three reasons. First, controversies about any particular evaluation often take a starting point in a discussion of whether that evaluation is good or good enough. Low-quality evaluations may hurt human beings in unethical ways, and may be discarded as bases for decision making.

Second, the reputation of evaluation in society is likely to depend to some extent on its perceived quality. To the extent that management tools and political steering mechanisms such as documentation, benchmarking, and quality assurance are perceived as forms of evaluation, their legitimacy may be in jeopardy if their quality is perceived as low.

Third, if evaluation as a field is to consolidate itself and perhaps move toward increased professionalization of evaluators, a vision of what quality of evaluation might mean for the field should be related to how evaluators define the mission of evaluation for society. Low quality is thus a problem for users of evaluation, for evaluators, and for society.

However, it is not easy to define quality. Except that quality is almost exclusively positive, the meaning of quality is ambiguous, and the term relates to esthetic, epistemological, ethical, organizational, managerial, and statistical domains of meaning. Therefore, it is difficult to keep a fixed idea of quality.

While some argue that quality in evaluation can be defined according to particular criteria (although several sets of criteria may be possible), others argue that quality should be appreciated and enhanced through ongoing dialog, education, and reflexivity instead of fixed criteria. Evaluation takes place in many different situations. These situations call for different approaches and models of evaluation. While some quality criteria are specific to each of these models, not all quality criteria may be generally applied to all evaluations.

The first section of this article gives a definition of evaluation, which helps clarify fundamental dimensions in all evaluations. The next short section looks at special issues in educational evaluation. Third, different sets of

criteria for quality of evaluation are discussed. Four such sets of criteria will be considered under the headlines of product-oriented, process-oriented, and user-oriented, and utility-oriented approaches. Fourth, anti-criteriological approaches to quality are considered. In the fifth and final section, various tools and initiatives to enhance quality in evaluation are discussed.

Definition of Evaluation

Evaluation is a systematic, methodological value-based assessment of some activity, program, or product, having in mind some practical decision making or learning related to that activity, program, or product or to other activities, programs, or products. The definition includes many activities or aspects of activities which are usually not called evaluation in daily life, such as benchmarking, quality assurance, audit, accreditation, assessment, etc. Discussions of the quality of evaluation therefore also apply to these other activities and processes.

Based on the above definition, evaluation includes four fundamental dimensions: one has to do with method and systematic knowledge; a second has to do with values; a third has to do with an understanding of the evaluand (object of evaluation); and the fourth has to do with the intent to use the evaluation. A good theory of evaluation describes how evaluators would design a good evaluation as a result of sound reasoning in all four dimensions. Most evaluators agree, however, that evaluation in practice is complicated, and evaluations are not exhaustively designed through logical algorithms. There is more than one good theory in each dimension of evaluation.

Particularly, the value dimension is controversial. Although, say, ethical theory and democratic theory may help clarify value choices, there continues to be an element of choice in selecting values on which evaluation criteria depend. Furthermore, in a given situation, not all factors in all four dimensions point in the same direction. For example, a concern for immediate use may be in conflict with a concern for in-depth analysis. In addition, most evaluators hold explicit or implicit views about their favorite values, methods, evaluands, and types of intended use. Two experienced evaluators do not approach the same situation in exactly the same way. A good evaluation is therefore a more or less thought-through interpretation of a situation rather than a mechanical response to factors in that situation.

Issues in Educational Evaluation

Although all evaluation may be controversial, educational evaluation involves especially complicated issues in all four of the above dimensions. In the value dimension, different

pedagogical views represent different value systems, and the ultimate purposes of education seem to hinge on different interpretations of what constitutes a good life, not only for the pupil or the student, but for the adult as a member of our civilization. In the knowledge-and-method dimension, a pressing question is how closely educational evaluation should attempt to identify causal relationships between teaching and its outcomes. Some critics of the causal view argue that educational situations are existential meetings which cannot be understood instrumentally, or that educational activities have value in themselves. Others argue that situational and human factors make causal links in various educational situations too complicated to map, and that methods oriented toward causal analysis (such as randomized experiments) are unethical or reductionist. At the same time, there is continuous public pressure on modern education systems to demonstrate the outcome of their activities. In the evaluand dimension, people hold fundamentally different views about the nature of teaching, learning, schooling, and education. In the use dimension, a central conflict has to do with the relation between two major purposes of evaluation, learning, and accountability. Some argue that the two are mutually exclusive. If evaluation is to enhance continuous learning among students and teachers, daily evaluation in schools should be protected against external accountability. According to another view, learning and accountability, or, if you will, the formative and the summative function of evaluation, are both possible, even in the same evaluation. The actual use of an evaluation is only determined by the actual users in the actual moment of use, so pupils, teachers, and school principals can take different actions based on the same evaluation. Finally, some argue that in the broader social arena, learning and accountability are both relevant and necessary functions of evaluation. The practical implication of this view is that even though schools work hard to learn internally from evaluation, the societal need for documentation of performance of schools is not likely to disappear.

Criteriological Approaches to Quality

Common for criteriological approaches is their assumption that quality can be exhaustively defined by means of a list of quality criteria. Some of the approaches are discussed below.

Product-Oriented Approaches

These fundamentally view the written product (such as an evaluation report) as the crux of evaluation. Thus, they define quality in evaluation in terms of how well an evaluation report (or a similar product) scores on various questions such as the following: Is the main question clearly stated? Is the report conceptually clear and theoretically

informed? Is the evaluation model well chosen and well explained? Is the method for data collection transparent and well chosen based on the question which needs to be answered? Are the data convincing? Is the analysis systematic? Are recommendations logically flowing from the analysis?

Since these dimensions of quality are methodological, conceptual, and analytical, they are often held in high regard by readers of evaluation reports who have an academic inclination and who see more similarities than differences between evaluation and research. However, product-oriented criteria for quality in evaluation may also include credibility, relevance, timeliness, communication quality (whether the report is well written and easy to read), and documentation quality (whether it provides proper documentation about the evaluator, the evaluation, and the costs of evaluation).

An obvious problem with product-oriented approaches is that they exaggerate the parallel between a tangible product and evaluation as a service. The latter is an interactive process. If the evaluator has played an important role as consultative, facilitative, enabling, or change agent, it is reductionist to gauge the quality of evaluation based solely on an evaluation report. Some evaluation reports are merely a summary of the most important learning points from the whole evaluation process. In some evaluations, innovative and creative communication formats are developed which render a classical evaluation report nonessential or redundant.

Process-Oriented Approaches

These, instead, define quality in terms of key events throughout the evaluation as a social process. Quality is thus something which happens as this process unfolds. Quality has to do with the management of the evaluation process which includes the following phases: focusing the evaluation, designing the evaluation, collecting information, analyzing and interpreting information, reporting information, managing the evaluation, and evaluating the evaluation.

In a narrow interpretation of process-oriented quality, the evaluation process conforms to a flow-chart-like algorithm. Evaluation is seen as sets of activities in each of the above phases, each of which include quality check points, and potential corrective measures if necessary. Critics of this view argue that evaluation services are not so well defined, controllable, and repetitive. In a broader interpretation, process-oriented quality is defined by good behavioral principles for evaluators, and by the interaction and communication between the evaluator, the commissioner, and other relevant stakeholders. More specifically, how well do the commissioner and the evaluator understand each other? How clear is their communication? Are all relevant stakeholders involved appropriately in the

evaluation process? Is the purpose of the evaluation clear to all? Does the evaluator behave ethically? Does the evaluator select the right method and implement it competently? Is the evaluator culturally competent and does he or she respect the values and views of diverse stakeholders? Are evaluation results communicated to all relevant stakeholders? Does the evaluator balance the concerns of the commissioner with the broader concerns for general welfare in society?

Although a process-oriented view of quality of evaluation has many advocates, it does not provide any guarantee for good evaluation without an authority which establishes standards for good evaluation practice and monitors how well evaluators comply with these standards. Furthermore, since the evaluation process includes interaction between evaluators, commissioners, and other stakeholders, principles for the behavior of evaluators alone cannot guarantee the quality of the overall process.

User-Oriented Approaches

These define quality in evaluation from a client's or commissioner's perspective. Criteria for good evaluation are deduced from how well the evaluation responds to their needs and wants. In other words, if the client is satisfied, it is a good evaluation. Although this view sounds evident, it implies a number of problems. One is that clients may be inconsistent. They may change their views several times during an evaluation. They may regret an otherwise good evaluation when they see the results. Second, they may not have the expertise that allows them to specify the type of evaluation that serves their needs. They may therefore demand an evaluation which is methodologically inferior, and be dissatisfied unless it is delivered. Third, client satisfaction may hinge on superficial characteristics of the evaluation or the evaluator. Among the most problematic of such characteristics is that the evaluation is harmless. Faced with managerial or political obstacles or with ideological tunnel vision, clients may sometimes be satisfied with evaluations which support status quo or which have low utility. User-oriented approaches are therefore not always promoting use of evaluation, and neither do they guarantee anything more than one subjective view of the quality of evaluation. For these reasons, clients' views on good evaluation are difficult to synthesize into a philosophically coherent perspective on evaluation quality, but this does not mean that their views or their role in the utilization of evaluations are generally irrelevant for initiatives to improve evaluation quality.

Utility-Oriented Approaches

These define quality in evaluation on the basis of the actual use of evaluations or at least utility (potential for use). Use or utility may in the long run be much broader

than what immediate clients or commissioners may have in mind.

Over the years, the field of evaluation has identified lack of use of evaluation as a major problem. Evaluators have developed different strategies to overcome the problem, and new categories of use have been identified.

Some evaluators develop strategies to maximize the likelihood of only intended use by intended users. These strategies include maintaining a fruitful dialog throughout the evaluation process, understanding the needs of clients, building personal relationships, sharing information about the pros and cons of all choices in the evaluation process, delivering a timely and well-communicated evaluation product, and not leaving the scene until the evaluation has been utilized.

Critics of this view argue that if evaluators focus too much on immediate use, evaluation will tend to focus on minor problems which are easy to repair. Pragmatic, managerial concerns will reign over larger policy decisions, which are more difficult to change. Evaluators may adopt a clientilistic view, where client satisfaction is enhanced at the expense of broader societal concerns.

Others have developed alternative categories of use, such as enlightenment. In this type of use, evaluations may make little difference here and now. However, evaluation can be useful even when it contradicts the views of clients and other decision makers. Evaluations may help challenge conventional practices, develop new ideas, inspire critical thinking, and facilitate policy change in the long run. If evaluations are carried out rigorously, and become publicly known, their overall broad use may be much more beneficial for society than the sum of the intended uses for intended users of a given number of evaluations. What Weiss called enlightenment through evaluation may transgress or contradict what clients or commissioners expect from the evaluation.

Acknowledging that evaluation takes place in political contexts, there may also be strategic or tactical uses of evaluation. Strategic use refers to the use of evaluation results as political ammunition. Tactical use refers to the use of the evaluation process to divert attention from an issue or delay a decision.

In recent years, a number of additional categories of use have been identified. These include process use, which is a reflexive type of thinking that flows not from evaluation results, but from participation in the evaluation process. Symbolic use has to do with the status flowing from evaluation as a fashionable thing to do. Constitutive effects of evaluation capture how human beings respond to having their activities measured, whether or not these responses enhance the quality of services. In education, teaching to the test is one such effect.

Since the categories of use are multiple, and since it is not easy to distinguish clearly between use and misuse of evaluation (one man's use may be another man's misuse),

it is complicated to gauge the quality of evaluation solely on the basis of the use. Use or utility is decided by a number of factors in the social and political context around evaluation. Due to political interests or ideological barriers, a good evaluation can be ignored and a bad one used. It would therefore be unfair to regard use or utility as dimensions in the quality of the evaluation itself.

Situational and Anti-Criteriological Approaches

According to an anti-criteriological view, no fixed set of criteria can be used to determine the quality of a complex situational and relational practice. The choice of the term practice is significant. While evaluation looks at complex, situationally embedded practices such as teaching and social work, it is also not merely a methodological tool, but itself a practice, too. Referring to Aristotle's view of *phronesis*, or practical wisdom, good practice takes into account factors too numerous to count. Practice is embedded in tradition and in social institutions. Practice is situational, and takes into account circumstantial and even personal factors. Practice is also relational, and often carried out in a community of practice. More often than not, complex and sometimes conflicting moral concerns are tightly woven into practical actions so that the instrumental and the moral are inseparable. A good evaluator exercising practical wisdom will begin not by measuring a practice according to standards, but by seeking to understand the practice at hand. The evaluator will then seek to find out what quality might mean in that particular context. Based on responsiveness and participation, the evaluator will then engage in a dialog with people in the evaluated field. The evaluator plays the role of a critical friend, a teacher, or partner rather than a methodological technician. A central issue for the evaluator is the conflicting moral concerns related to explicit or implicit evaluation criteria both from an external perspective and from an internal perspective in the practice under evaluation. Another critical issue is the degree to which people in the field can tolerate critique of their practice. This depends partly on the relation which the evaluator has built with these people. Finally, the evaluator would understand the evaluated practice in the light of broader institutional and political issues in society. Based on this view, what might constitute quality in evaluation is as contextual as in any other practice, although of course the evaluator would be prudent in consulting methodological expertise, ethical guidelines, other respectable evaluators, and his or her own sense of good practice.

Therefore, contextual quality does not imply a relativistic or nihilistic view. Quality in a particular evaluation can be understood by people in the field as well as by educated evaluators who engage in a serious attempt to

understand how the evaluation has responded to the particular situational challenges at hand. Views from methodological specialists, managers, patients, pupils, or other stakeholders, etc. are also relevant, although no fixed set of criteria would exhaust the total meaning of quality in evaluation.

Initiatives to Enhance Quality in Evaluation

The field of evaluation is dynamic, and its borders are loosely defined. People go in and out of evaluation either in the same job function or over a whole career. Many actors in society buy, sell, or commission evaluation in fairly unregulated ways. The demand for evaluation seems to be increasing, and so are attempts to do it quickly. No authority has a high degree of control of the field.

For these reasons, quality in evaluation is more difficult to control than say, medical or legal practice. Under these circumstances, attempts to enhance quality in evaluation have included the following.

Checklists

An evaluation checklist is a list of factors, tasks, dimensions, or criteria, etc. which need to be taken into consideration when performing a particular evaluation. Checklists are of various types, ranging from simple to-do lists to elaborate criteria of merit (COM)-lists which include all relevant criteria to be used in an evaluation. A checklist is usually expressed in less-sophisticated ways than a formal methodology or theory. Yet, a checklist may be useful if it summarizes earlier experiences with a particular form of evaluation or evaluand. To illustrate the usefulness of a checklist, one might think of the pilot's checklist before take off, which hopefully expresses the total sum of relevant systematized knowledge from earlier events that went wrong with that type of airplane. Some experienced evaluators would argue that evaluation is a more situational, relational, and contingent practice than a mechanical checklist would suggest. Checklists at best support the exercise of practical wisdom in evaluation, but do not replace it. Checklists are often specific to particular evaluation models or approaches. A number of checklists for various evaluation approaches can be found below.

Standards and Guidelines

Many evaluation associations have voluntarily adopted a set of guidelines or standards which describe good evaluation practice. When developing guidelines, evaluators discuss questions such as: Should guidelines be minimum (mandatory) standards or maximum ideals (which should not be met in all situations)? If guidelines cannot be met in

a particular situation, may it still not be better to do evaluation than not do it? How should evaluator's guidelines relate to professional guidelines such as those of psychologists, etc.? How should guidelines in one country relate to potential international guidelines (a pressing question in e.g., Europe)? Should the behavior of commissioners, too, be described in the guidelines? Is it possible to develop guidelines which do not favor one evaluation methodology over another? How and how often should guidelines be revised? What is the meaning of guidelines, if sanctions cannot be imposed on those who break them? Finally, if guidelines are to cover all evaluation situations, and they should be backed by consensus, will they not just be broad, self-evident principles?

Among the more notorious ones are American Evaluation Association's guiding principles, which include systematic inquiry, competence, integrity/honesty, respect for people, and responsibilities for general and public welfare. These principles are not prioritized. Each principle, as well as the history of the guiding principles, is explained at the AEA website, see below. Although most evaluators find these guiding principles fairly evident at first glance, interesting debates often occur when the meaning of a specific principle is unfolded in a particular case, or when a balance between several principles must be struck. Respected evaluators may disagree in those situations about how to best respect the guiding principles. Guiding principles may thus be useful not because they directly control the behavior of evaluators, but because they help raise the awareness among evaluators about ethical issues and quality in evaluation. Evaluators meet the guiding principles regularly in teaching, at conferences, on websites, in folders, and in collegial discussions.

Evaluation Culture, Evaluation Capacity, and Evaluation Policy

Over the years, the field of evaluation has learned that evaluations done on an ad-hoc basis run the risk of having little organizational impact. Therefore an interest has developed in a more holistic and integrated system for the use of evaluative information. Evaluation capacity building is an integrated set of activities which aims at increasing the organizational potential for sustaining continuous and effective evaluation. Evaluation capacity building includes structural, cognitive, and communicative features which support evaluation (offices, staff, training, managerial support, organizational communication, etc.). Evaluation culture is a term which describes the norms, values, and practices related to evaluation in an organization. Some believe that evaluation is only effective if an evaluation culture is developed to support it. Evaluation policy is a term used to describe the deliberate and official strategy toward evaluation which is adopted by management. Some believe that without an evaluation

policy, evaluation activities tend to remain sporadic, fragmented, and unsystematic. A common idea in evaluation culture, capacity building, and evaluation policy is thus the ambition to plan how continuous evaluation fits into a larger organizational picture. The principles for evaluation embedded in these attempts of course affect the quality of evaluation carried out. Although many believe in the advantages of a systematization of evaluation, some fear that evaluation will be reduced to a management information system, and that truly innovative and provocative findings will rarely come from managerially approved evaluation systems.

Education

Some believe that evaluation is too complex for checklists, guidelines, and managerial policies to be of more than limited value. Instead, evaluators should be so thoroughly educated that they have both sufficient competences, a strong sense of quality in evaluation, and an ability to reflect upon their own practice. Some universities therefore offer programs in evaluation. However, many evaluators only do evaluation as a part of their total job function, and some discover the need for training in evaluation only after they already have taken on a full-time job. Most evaluators and commissioners of evaluation have no formal education in evaluation, and some have only a limited amount of short-term training.

Professionalization

Some believe that the quality of evaluation can only be enhanced substantially through professionalization. This includes some sort of education or training plus official control mechanisms regarding who call themselves evaluators. Credentialing includes a set of courses one must go through. Certification includes the assessment of an external body of a person's skills, competencies, and credentials. Licensing involves the approval by some authority of that person's ability to actually carry out the practice. Accreditation is a mechanism whereby the program or institution offering courses is examined and approved by an external body. All these mechanisms involve decisions about what constitutes a good or acceptable evaluator, and they involve decisions about who has the authority to make those decisions. None of these decisions are evident. Few countries have gone very far in the direction of professionalization of evaluators.

Internal and External Evaluation

D Nevo, Tel Aviv University, Tel Aviv, Israel

© 2010 Elsevier Ltd. All rights reserved.

Internal evaluation and external evaluation have long been under discussion in the evaluation literature (Scriven, 1967, 1991; Stufflebeam *et al.*, 1971; Love, 1991; Mathison, 1991; Sonnichsen, 2000). Scriven (1991) gave the following definitions for internal and external evaluation in the context of program evaluation:

Internal evaluators (or evaluations) are those done by project staff, even if they are special evaluation staff – that is, even if they are external to the production/writing/service part of the project. (p. 197)

An external evaluator is someone who is at least not on the project or program's staff, or someone – in the case of personnel evaluation – other than the individual being evaluated, or their family or staff. . . . It is best to regard externality as a continuum along which one tries to score as high as possible. . . . (p. 159)

At the school level, internal evaluation can be performed by a teacher or a group of teachers, by other members of the school's professional personnel, by the principal or other school administrators, or by a special staff member designated by the school to serve as a school evaluator. An external evaluation of the school can be performed by the school district, the state department of education, or a ministry of education using professional evaluators, regional inspectors, or a district/state/national evaluation department. An external evaluation of the school could also be conducted by an independent evaluation consultant or evaluation firm, commissioned by the school itself or its governing board.

External Evaluation

For many years and in many countries, school evaluation was tantamount to external evaluation (Nevo, 2006). In some countries, it was done mainly by inspectors (e.g., in the UK or other European countries), and, in some others (e.g., in the USA), it was done by means of state or district assessment programs. Many educational systems combined both student assessment programs and overall school reviews, some of them conducted in a very systematic way by central units in the educational system (e.g., OFSTED in the UK or OER in New Zealand). The idea of accountability, which has been around for over a quarter century, and relatively newer ideas of setting standards and benchmarks as major means for school improvement,

can all be traced back to this long tradition of controlling schools by means of external evaluation.

Even before the term accountability was used, there was a clear demand by politicians, administrators, parents, and the public at large that schools be evaluated externally to find out if they were fulfilling their duties. There was also a hope that such external evaluations would motivate teachers and school principals to work harder to improve their schools. This was true for democratic and nondemocratic societies, as well as for centralized and decentralized educational systems alike. The demand never ceased, even when external evaluation was highly criticized by innovative educators and when internal evaluation was encouraged by way of an alternative.

Internal Evaluation

Parallel to the almost-universal phenomenon of external school evaluation, many countries have more recently tended to apply newly developed evaluation methods at the school level in the form of internal evaluation or self-evaluation. Participatory evaluation (Cousins and Whitmore, 1998), empowerment evaluation (Fetterman *et al.*, 1996), total quality management (TQM), and Action Research are some attempts made to apply internal evaluation methods at the school level. These seem to be in line with other prevailing ideas such as reflection (Schon, 1983) and professionalization of teachers (Darling-Hamond, 1992) and educational administrators/leaders. Reflection is, in a way, one kind of self-evaluation, although its proponents do not sufficiently stress the important role of systematic data collection as a basis for reflection. A professional perception of teaching regards teaching as a complex undertaking, suggesting that teachers should identify needs, analyze goals, choose instructional strategies, and plan and monitor their work. Evaluation becomes an integral part of the teaching profession, relevant to various aspects of teachers' responsibilities, and no longer narrowly limited to evaluating student achievements.

Internal evaluation is also a very important component of schools in decentralized or decentralizing educational systems, which are following models of school-based management or autonomous schools (Nevo, 1997). Autonomous schools are urged to define their own educational aims, be in charge of the educational process, and to evaluate their actions. With the expansion of school authority, schools are also expected to take greater responsibility

and to be accountable for their deeds. These demands have emphasized the importance of internal self-evaluation not only to support improvement but also to respond to the school accountability requirement.

Internal evaluation becomes a major tool for school-based management, serving decision making at various administrative levels. The improvement of decision-making processes is especially important within the broader context of ongoing decentralization and school empowerment, mentioned above. Schools are granted significant authority and are, in return, expected to make decisions autonomously. Internal self-evaluation is highly salient in such situations: it can provide schools with means to improve decision-making processes and make them more effective. An internal evaluator is usually better acquainted with the local context of the evaluation and less threatening to those being evaluated. He or she knows the local problems, communicates better with the local people, and remains on site to facilitate the implementation of the evaluation recommendations. Developing an internal evaluation mechanism in a school is also an investment in an enduring resource for serving the information needs of the school by means of data pools and school portfolios.

Internal evaluation is also an expression of school empowerment and transfer of authority from the center to the periphery, that is, from the central government to the local community. Participation in the evaluation process may contribute to the empowerment of an organization as a whole, as it acquires the ability to monitor itself in a more systematic way and by gaining greater confidence in its educational direction. Participation in the evaluation process can furthermore empower individuals in the organization by providing them with evaluation skills, which they can later apply in various contexts. The principals and the teachers participating in evaluation activities can apply the newly acquired evaluation skills and knowledge in other areas of their work. For example, teachers can use their knowledge of research methodology to teach pupils to perform investigative tasks as part of their schoolwork.

Another benefit of participation in evaluation activities is that it may increase teachers' involvement in decision-making processes outside the classroom; it may foster collegiality and collaboration among the teachers and serve as a means of promoting reflection. All these are central to development of teacher professionalization (Darling-Hammond, 1992).

However, pointing out the importance of internal evaluation or self-evaluation and its relevancy to professional teachers and autonomous schools should not lead us to ignore external evaluation. Control and accountability requirements and the right of the public to know in democratic societies have also to be kept in mind.

Although internal evaluation, by providing information to parents and the community at large, can also enhance accountability, the credibility of its findings might be limited without external evaluation.

Mutual Benefits

If internal and external evaluation are both important, we need both of them and they might even benefit from each other.

Internal evaluation can benefit from external evaluation in at least three ways. External evaluation can stimulate internal evaluation, expand its scope, and it can legitimize its validity. A more detailed discussion of these three ways is given below.

Stimulating Internal Evaluation

Evaluation is a demanding undertaking whose benefits are yet to be proved. It requires a significant amount of resources, such as funds, time, and skilled personnel. We evaluators believe in its potential usefulness, but our research on evaluation utilization has so far yielded only meager support to our beliefs, and mainly in relation to conceptual use of evaluation (Cousins and Leithwood, 1986; Cousins and Shulha, 2006). The common wisdom is that evaluation is a required activity and hopefully a useful one.

It would be difficult to argue that doing self-evaluation comes naturally to teachers and schools, even less so – being evaluated by others. Schools will surrender with or without protest to inevitable external evaluation requirements, imposed on them by the educational system. In some cases, they might opt for internal self-evaluation if they believe that this will release them from external evaluation. Experience shows that schools might be motivated to engage in self-evaluation if faced with an external evaluation requirement, even when internal evaluation is not suggested as an alternative to external evaluation but only as a prior condition and counterpart. Some schools will tend to do internal evaluation to help them confront the external evaluation. Others believe, as mentioned earlier, that they might be released from the burden of external evaluation if they do internal evaluation or just establish an internal evaluation team. Sometimes it is difficult to avoid the notion that the most important function of external evaluation is to motivate people and organizations to do internal evaluation.

Expanding the Scope of Internal Evaluation

Although internal evaluation usually has the advantage of being more sensitive to the local context of schools and

their unique characteristics, it might suffer from a narrow perspective on their overall qualities. External evaluation can add commonalities to the uniqueness of the school as well as provide a basis to judge its qualities. School inspectors can provide useful observations from their inspection region. Other external evaluators, such as professional state evaluation teams, may be able to supply the school with relevant information available at the central office.

External evaluation can also provide the school with information on national standards or benchmarks or comparative data from other schools (e.g., student achievements) that might help the school interpret its own data and assess its quality. Local standards might be narrow in their scope or not available at all. For example, a national evaluation that has focused on school violence prevention projects, can provide schools engaged in internal evaluations of school climate not only with national comparative data on mean rates of violence, but also with a more comprehensive definition of school violence and its measurement.

Legitimizing the Validity of the Internal Evaluation

Although internal evaluation should exist in its own right, it is always suspected of being biased and subjective. External evaluation can be as biased too, but the accusation of subjectiveness tends to be directed more toward internal evaluation. Being blamed for lack of objectivity is not only a treat to the credibility of internal evaluation, but it also jeopardizes its existence. An evaluation that is not trustworthy might have difficulties in obtaining the resources necessary for its existence. Why should the public waste money on such activity? Why should teachers spend their precious time on an internal evaluation which nobody trusts?

External evaluation can help legitimize internal evaluation – not by providing a formal stamp of approval but by respecting its existence as an important ingredient of school evaluation. External evaluation can engage in a dialog with internal evaluation on equal grounds and with mutual respect, sharing the common cause of gaining a better understanding of the school and its problems. External evaluators do not have to agree with all the findings of the internal evaluation, but they have to perceive them as good enough to argue with.

External evaluation can benefit from internal evaluation in many ways and not less than how it can contribute to internal evaluation. Internal evaluation can deepen the scope of external evaluation by increasing its awareness of local issues; it can improve the interpretation of external findings by making them more sensitive to local needs; and it can also improve the utilization of external evaluation

by diminishing resistance to it and increasing evaluation mindedness (Glasman and Nevo, 1988).

Expanding the Scope of External Evaluation

External evaluation is too often criticized for its narrow scope and its tendency to focus on commonalities rather than the uniqueness. In its attempt to seek comparability and generalization, external evaluation is forced in many cases to address the lowest common denominator, which might be either trivial or insensitive (or both) to local needs and priorities. Our own experience in evaluating the Thirty Townships Project (Nevo and Friedman, 1999) is a case in point. This project was initiated and implemented by the Israeli Ministry of Education, with the aim of improving local education systems of 30 townships suffering from low levels of student achievement, high dropout rates, and low community self-image. Although the main goal of the project was the same for all townships, various intervention agencies implemented the project, together with each township, developing unique intervention programs to meet local needs and in line with the educational perspectives of the intervention agency. The result was 30 different intervention programs. The Ministry of Education commissioned an external evaluation to focus on project outcomes and to be used mainly for accountability. The external evaluation was expected to supply information about the overall impact of the project and thus used an overall set of indicators, which affected its capability of supplying in-depth portrayals of specific interventions. Internal evaluation could, in this case, extend the scope of the external evaluation by pointing out the relevancy of additional data reflecting the unique character of a particular school and local educational system.

Improving Interpretation of Findings

The external evaluation usually has the advantage of allowing to interpret findings regarding the quality of a specific school by comparing them to other schools or national standards and benchmarks. While such interpretations are usually important and legitimate, they might also overlook the local perspective, reflecting the special needs and opportunities of the school. It is the internal evaluation that can add on that local perspective of school and community. The above-mentioned Thirty Townships Project, is a good example of the limited ability of external evaluation to interpret specific findings regarding local perspectives, needs, and constraints.

Moreover, as societies become increasingly diverse and multicultural, it is not only important that external evaluation be complemented by locally specific data, but also important that local perspectives and values be considered in interpreting evaluation findings.

Increasing Evaluation Utilization

Schools that have internal evaluation teams, for whom evaluation is part of their pedagogical and administrative life, have a better chance of understanding the meaning of evaluation and its significance in education. Such schools also have a better chance of appreciating the potential usefulness of external evaluation to the lives of their schools rather than opposing it defensively.

Schools that practice evaluation, by establishing internal evaluation teams or other evaluation mechanisms, increase their institutional evaluation literacy. They have a better grasp of the significance of educational evaluation and can speak its language. They gain technical skills to understand external evaluation reports and argue with their findings, if necessary, rather than opposing them.

A school that engages in self-evaluation, and collects information on its pedagogical and administrative activities for that purpose, might increase its self-confidence and be less defensive when confronted with negative findings from an external evaluation; thus trying to make use of evaluation rather than opposing it.

A school engaged in internal evaluation will tend to develop a commitment to evaluation, which has been found in various evaluation utilization studies (Cousins and Leithwood, 1986; Cousins and Shulha, 2006) as an important factor affecting the use of evaluation.

Terms of Coexistence

If internal and external evaluations are both important and can also benefit from each other, then the remaining question is: How can they coexist? Nevo suggests that they can coexist in a constructive way if an appropriate ground can be created for a dialog between the two (Nevo, 1995, 2001).

We all love the concept of dialog and not many people would dare to argue against it. However, dialog cannot flourish on all grounds and in all climates. Some terms of existence have to be provided to create an appropriate habitat for constructive dialog. These terms are not self-evident and sometimes quite difficult – although not impossible – to achieve. They relate to three aspects of dialog evaluation: conception, methodology, and communication.

On the conceptual level, evaluation has to be perceived as a means for understanding rather than judgment, providing quality profiles rather than composite scores.

On the methodological level, dialog evaluation should be practiced as a process and not as a one-shot activity. The interaction between internal and external evaluators should be based on a two-way flow of information in a process of mutual learning, and evaluation should focus on relevant issues and pertinent data.

On the communication level, there must be mutual respect and trust between the parties. Both have to believe that each has a genuine interest in understanding what is

at stake and can make a significant contribution to such an understanding; evaluation has to be fair to both parties involved in the dialog and both parties should take some responsibility for handling the consequences of the evaluation.

Conclusion

In many educational systems, everybody seems to hate external evaluation while nobody trusts internal evaluation. This article contends that both types of evaluation are needed as they both have important roles in the life of schools, teachers, and educational systems. The article also suggested some conditions that have to be met to establish a constructive dialog between internal and external evaluation as a basis for their coexistence.

Thus, those of us who are proponents of external evaluation should find ways to empower schools and teachers to participate as equal partners in the evaluation process and make use of it; and those of us who believe in internal evaluation as a means for school autonomy and teacher professionalization must admit the legitimacy of accountability and the right of the public to know. They, in their turn, should seek external evaluation as a partner for dialog rather than an object for rejection.

The leaders in many countries and the public at large usually believe in external evaluation and are ready to spend a lot of money on implementing grandiose national school evaluation systems, but have a hard time to waste money on internal evaluation, which nobody trusts anyhow. They must realize that if they can overcome the resistance of teacher and other educators to external evaluation and if they think that it is also useful and being used, they should not waste any money on internal evaluation. However, deep in their hearts they know that this is not the case.

On the other side, school teachers and other professional educators have to agree with external evaluation requirements and waste time on its implementation. They must realize that if they will not respect the authority and responsibility of the ministry of education and the right of parents to know about the schools their children go to, they cannot expect them to respect their right for autonomy and reflection and trust their judgment as professional teachers.

Needs Assessment in Education

J W Altschuld and T L Lepicki, The Ohio State University, Columbus, OH, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Causal analysis – Examining needs in terms of their potential causes particularly in regard to identifying those that can be changed by the school (district) and those that are not under its aegis.

Need – The measured discrepancy between the current (or present) situation and the desired (ought to be) one.

Needs assessment (NA) – A formal process to obtain information on the two states (current vs. desired); identify gaps between them; and arrive at needs-based priorities for actions.

Needs Assessment Committee (NAC) – A group that oversees the conduct of all aspects of an NA, including the development of plans for resolving needs. (The NAC may also be involved in the implementation of NA procedures and resultant solution strategies.)

Introduction

We probably have a sense of what a need is and may have participated in or led a needs assessment (NA). However, after thinking about things a few more questions arise:

- What really are these things – needs and NA?
- How do we organize for and conduct assessments?
- Why should we do an NA now – what is motivating it?
- Who or what groups are pushing for it?
- What kinds of data might be collected?
- Would any individuals or groups not want to provide input into the NA?
- How will we analyze what we find and what good will come from it?
- If identified needs lead to new directions, are teachers, school staff, administrators, and communities ready and motivated to act?
- Who is going to work on resolving needs?
- What sacred cows in school systems might pose obstacles for the assessment or be encountered when implementing activities to resolve needs?

A seemingly straightforward idea is not so simple after all. In this respect, it has been noted that if assessments are viewed just as methods (planning, asking, analyzing, etc.),

the likelihood of success is sharply reduced (Altschuld, 2004). Methods are important, but an NA should be a blueprint for organizational improvement, learning, and change – a perception essential for maximum effect.

To explain what NA is, definitions followed by descriptions of a generic process for making assessments and methods often employed for looking at needs are given here. Suggestions are then offered as to typical uses of NA and when it might be done as shown by brief examples from the literature.

Defining Key Terms

What Is a Need?

A need is the measured discrepancy between the current (or present) situation and the desired (ought to be) one. Without data about both states and the ability to contrast them, it is not possible to have a defined need. Surprisingly, until recently, many NAs did not investigate the two conditions. The focus was more on solutions to problems rather than on probing into and understanding them. Needs indicate the size and direction of gaps, and when compared and prioritized they serve as input for actions to alleviate underlying concerns. While the definition implies quantification ($x - y = z$), most assessors promote the use of mixed methods (including qualitative ones) for full comprehension of needs.

Examples of needs (several pertaining to education) are given in **Table 1** with many subtle features embedded in them. One is that the desired condition may be stated in different ways with implications arising from how they are framed. For example, it could be worded as what is minimally expected (as in minimal competency standards) or what is ideally expected. Such wordings indicate that there are multiple perspectives about needs. Another feature is that needs might be narrowly or globally assessed (see the last entry in **Table 1**) or have more of a future orientation, whereas others are in the near term. Finally, note that the row about wealth illustrates a want not a need. It is a discrepancy, but it would be considered by most to be a want (not a need).

Are There Levels of Needs?

Yes, there are. Witkin and Altschuld (1995) wrote about the three levels of needs:

- Level 1 – receivers of goods and services (students in schools, patients in hospitals, consumers or purchasers of products, those in need of guidance counseling, etc.).

Table 1 Examples of the “What is,” “What ideally should be,” and “What is likely” states

Area	What is	What ideally should be	What is likely
Health	30% of US is overweight	100% at or near a reasonable weight for age, height, gender, and body build	75% will reach the standard within a 5-year period
Mathematics	62.8% of district students achieve the state standard for the fourth-grade mathematics test	100% reach the standard or 75% reach the standard to remove the district from possible state sanctions	65% or more achieve the standard by this time next year
Reading	75% of eighth-grade students read and understand the instructions on an aspirin bottle or on a bottle of patent medicine	100% should be able to do the task	85% are able to do the task 2 years from now after exposure to improved reading instruction
Youth recreation	A community does not have a recreation center and adequate recreation activities for youth	A recreation center will be built and open 5 years from now Within 1 year a recreation program will be started in the community	The recreation center will be a reality 10 years from now A small recreation program will start in 2 years and gradually expand
Immunization	The inoculation rate for preschool children in a particular state is currently at approximately 70–75%	A rate of 90–95% will be achieved, thus greatly reducing the likelihood of increasing the incidence (spread of certain diseases)	Rate of inoculation will gradually increase to 80% over a 5-year period Rate will remain the same without understanding the causes of the problem
Wealth	An individual is currently worth \$1 000 000	With inflation and worries about job stability, the individual would prefer to be at \$2 000 000 to feel more secure	\$1 500 000 would be likely in light of the general growth of investments within a 10-year period
Overall education system	Current state standards for courses and areas required for a high school degree	Given possible changes in knowledge and the world of work, what standards should we develop for children now entering the educational system and who graduate in 13 years	What are reasonable expectations for change in complex multidimensional systems like education

Adapted from Altschuld, J. W. and Kumar, D. D. (2009). *Needs Assessment: An Overview (Book 1)*. Thousand Oaks, CA: Sage.

- Level 2 – providers of services and goods for level 1 (teachers, health care workers, company trainers who keep staff up to date with the latest technologies, etc.).
- Level 3 – the management, administration, and support necessary to enable work by making available finances and other similar entities. It is the structure or system that makes it possible for level 2 to serve level 1.

What frequently happens in NAs is that by identifying the needs of level 1 those of levels 2 and 3 become obvious. On the other hand, misguided NAs place too much stress on the training of level 2 (teachers) or looking at organizational problems at the expense of level 1, thus subverting the systematic approach required for the best NAs. After all, the function of education is to make certain it attends to level 1 (students) and that what levels 2 and 3 do should positively impact on the needs of the ultimate recipients of goods and services. That is the *raison d'être*.

What Is NA?

As a guide to decisions and actions, NA is a formal process to obtain information on the two states (current vs. desired); identify gaps between them; and arrive at needs-based

priorities for actions. Causal analyses of needs (why is the need occurring) are often part of the endeavor. NAs begin when a school or educational group feels that it has problems that must be explored in depth. This perception leads to a study that deduces the priorities and plans for change and/or new directions.

Going back to **Table 1** it is clear that the wording of the ‘what should be’ condition has a major impact on what the organization does for identified needs. Resolution of a realistic or a short-term slight gap is a far cry from resolution of one that is long term and major in nature. It is much more difficult to muster support and enthusiasm for the latter.

Models for Assessing Needs

Numerous models, frameworks, and approaches from a variety of fields are available for assessing needs. While an extensive examination of these is beyond the scope of this article, the reader is recommended to the overview developed by Watkins and the website on which he lists many of them.

Here, we describe two well-known and widely used (complementary) models. One is a model of Kaufman and the other

a version of a three-phase model recently updated by Altschuld and Kumar (2009). In the Kaufman approach (Watkins and Wedman, 2003), needs are discrepancies between desired (what should be) accomplishments and current (what is) achievements. Gaps in such results can occur at any point along a continuum that goes from the mega- to the micro-levels, which are linked together in a systems type of way:

- Mega-level – results (and needs therein) for which the primary client and beneficiary is society as a whole.
- Macro-level – results (and needs therein) for which the primary client and beneficiary is the organization.
- Micro-level – results (and needs therein) for which the primary client and beneficiary are individuals and groups within the organizations.

Kaufman's thinking and usage of the model are prevalent in training in business and industry settings. The system dimension in his writings aligns closely with the three phases of NA underlying the second framework where the emphasis is on the process and procedures for conducting the NA. Its main steps are given below.

1. *Phase 1.* Pre-assessment focuses on the NA and deals almost entirely with existing data and information relative to the needs area, to:
 - a. develop the focus for the assessment;
 - b. establish a Needs Assessment Committee (NAC) responsible for the remainder of the activities within this phase;
 - c. sort out the values driving the assessment;
 - d. identify and locate existing resources and information for the need area; and
 - e. arrive at a consensus regarding recommendations for the organization and its decision makers.
2. *Phase 2.* Assessment is based on the premise that if phase 1 does not produce enough information, new data must be collected; that is:
 - a. identify discrepancies at levels 1, 2, and 3, which can be done by a variety of data-collection methods (see **Table 2**) with multiple methods usually being part of the landscape;
 - b. prioritize discrepancies;
 - c. conduct causal analysis of needs; and
 - d. identify preliminary solution criteria and possible solution strategies.
3. *Phase 3.* Post-assessment is when there is compelling evidence for high-priority needs and we prepare action plans to tackle the problems and the causes underlying them, such as:
 - a. make final decisions to resolve needs and select solution strategies;
 - b. develop action plans for solutions, communicate, and build support for them;

- c. implement and monitor plans; and
- d. evaluate the overall NA endeavor (document with an eye to revisit and reuse).

A number of things are important to highlight. In the early activities of the two approaches (especially in phase 1), stress is placed on using existing sources of data. To the extent this occurs, the costs of conducting an assessment are substantially reduced.

For the health status of children, there are reams of easily accessible data in the National Health and Nutrition Examination Survey (NHANES). From this database, current health can be looked at in terms of health standards to ascertain discrepancies. In education, local and state educational systems have volumes of relevant data and information. Every state has massive archives of information from accountability systems and tests conducted on a yearly basis. Results can be contrasted to norms for tests. Since the data are collected over time, it is possible to study trends and look at emerging needs and then to establish policies and programs for rectifying problems that are uncovered. Sources such as the two just given should be studied before collecting any new data and incurring attendant expenses.

In conducting NAs it is recommended that an NAC be formed (the second step in phase 1) to guide the process. In general, such groups consist of 8–12 individuals chosen on criteria such as being: respected in the school or organization for their opinions and accomplishments; open to new ideas and ways of considering what the organization is doing and what it might be doing in the future; willing to express their views honestly and frankly even if they differ from those of others; respectful of the perceptions of others with an appreciation for how committees work and get things done; and committed to the endeavor by pitching in to get the necessary work completed.

The committee is responsible for looking at the general questions, focusing them down, establishing what should be explored, and locating and analyzing pertinent information. Eventually, the NAC comes to one of three decisions:

1. there is not much of a need and it is not fruitful to go further;
2. more information is desired, and we must move into phase 2; and
3. enough has been learned about the problem and it is clear, hence we should move on to phase 3 and action planning.

NACs are mostly facilitated by an external person with NA experience and knowledge of what is involved in a successful effort. As the assessment progresses into the third phase of an NA, it may be desirable to have the leadership become more internal in nature. This is because the translation of needs into action plans are to be undertaken by staff and organizational personnel. Having a well-chosen

Table 2 An Overview of needs assessment methods

<i>Data type</i>	<i>Comments/description</i>	<i>Information generated</i>
<i>Archival</i>		
Records/logs	Data exist usually in databases or records	Mostly quantitative data about the current (what is) status of target groups
Social indicators	In some instances, it may be possible to initiate new record keeping	Sources may reveal ideas about causes contributing to needs
Census data	Existing data may not exactly match the intent of the needs in question	Some databases/records include comments necessitating qualitative analyses and interpretation
Epidemiological studies		
Test data		
Information derived from databases		
Other existing sources		
<i>Communicative–noninteractive</i>		
Written questionnaires	Methods rely primarily on structured instruments or forms	While some of the data may be quantitative in nature, they come from values, judgments, and opinions of those providing responses and perspectives
Critical incident technique		
Mailed Delphi surveys	Surveys mostly have scaled questions with perhaps a few open-ended ones	
Web-based surveys		
Observations	Observations may follow detailed protocols or permit more freedom in describing phenomena	
<i>Communicative–interactive</i>		
Public hearings	Procedures involve the use of small or large groups with varying degrees of interaction	Highly qualitative data that are summarized into themes and recurring concepts
Community group forums	Group leadership is especially critical to the success of the procedures and the results produced	Data will be about perceptions, opinions, judgments, and values
Nominal group techniques (NGTs)		Information might be about consensus on goals, courses of action, causes, priorities, and the like
Focus group interviews (FGIs)		
Cyber or virtual FGIs		
Key informant interviews		
DACUM process		
Scenario discussions		
<i>Analytic</i>		
Fishbone diagrams	Processes that examine solution strategies and causes or risks associated with needs and/or ways to resolve them	Problems that might lead to the failure of a solution strategy
Cause and consequence analysis		Guidance in choosing a strategy with a high likelihood of resolving a need (with other information from NA, makes for a more comprehensive understanding of needs)
Quality function deployment (QFD)		
Fault tree analysis (FTA)	Results might be shown in graphs or diagrams emanating from the analytic process	
Success mapping		
Task analysis		
Risk assessment		
Trend analysis		
Cross-impact analysis		
Force-field analysis		

Adapted from Altschuld, J. W. and Kumar, D. D. (2009). *Needs Assessment: An Overview (Book 1)*. Thousand Oaks, CA: Sage.

NAC can be very helpful for identifying what is available and for obtaining existing data sources.

Phase 2 requires the creation of instruments and data-collection techniques. Interviews and surveys have to be developed and then implemented. Systematic observations are undertaken. Various group procedures (hearings, community group forums, etc.) are planned and conducted to provide more information and insights into needs. All such activities take additional money and time, so only enter the phase if absolutely necessary. Factor in that as more data are obtained from multiple and different sources the complexity of data analysis and integration escalates dramatically. This is not to say that multiple sources are not useful and should not be pursued but that the situation is a bit more complicated when they are part of the equation of NA.

Some of the methods in phase 3 are different in that they are analytical and employed on the assumption that

needs have been delineated and prioritized. The focus is on probing into what might be causing the needs and if those variables can be determined, then it becomes somewhat easier to think about solution strategies. They also may push us into thinking about what might happen if nothing was done about needs (could they lessen or abate over time) and what might be the risks in attending to or not attending to them. New data are not, for the most part, necessary here; rather, what has been found is subjected to procedures like cause and consequence analysis, fault tree analysis, and fishbone diagrams to see what may be influential in producing problems.

Once the causes are determined, we should be better able to devise solution strategies and to see how effective they would be in resolving the problem. This leads to an action plan for rectification, and since the problem is understood in greater depth, we should have a better grasp of key variables to evaluate as programs are implemented to reduce

needs. If problems are not resolved, the entire process may be thought of as unsuccessful. Therefore, the third phase entails evaluation of not only the solution strategy but also the NA itself. Evaluation is part of the other phases as well but becomes particularly prominent in this phase.

The methods of NA are quite diverse with some more appropriate for one part of the process than another (see **Table 2**). Detailed explanation of the methods in **Table 2** can be found in the work of Witkin and Altschuld (1995), and Altschuld and Kumar (2009). As noted, experienced needs assessors recommend using a combination of quantitative and qualitative methods to understand needs that might be quite complex (such as what is the underlying nature of the problem in the first row of **Table 1**). Quantitative outcomes indicate the size and direction of discrepancies between the two conditions but cannot get into what they mean for the individuals in need. For example,

- Can numbers fully portray a person's feelings about being homeless, foreclosed out of a home, or losing a job?
- What are the feelings of students who are in jeopardy of not passing tests mandatory for graduation from high school?
- How might raising or lowering the passing scores on tests be perceived by students, teachers, and the general public?
- Even if we know that schools in the US are below other countries in mathematics and the sciences, can we find out why from just the test scores or does the situation require other kinds of studies?

The value of qualitative data is apparent for digging beneath numeric information. The juxtaposition of the two creates a more powerful sense of meaning and sensitivity to issues. The practice of NA suggests that the combination of methods is the way to go.

Across all phases, results and progress should routinely be communicated to the organization, its key personnel and decision makers, and stakeholding groups. There is no set schedule; judgment of the NAC and its facilitator should determine when it seems best. Why is this critical?

NA is oriented toward improvement of an organization and is a frank and realistic way of delving into problems with which it must deal. Action plans might change habitual ways of doing work and/or might require shifting resources or emphasis from one department to another. If not handled well and tactfully, this can lead to acrimony and loss of morale and trust. Communication is essential for establishing the right kind of social climate, and the process generally will not work without attention to it.

Now that the foundation has been built, how does the NA get off the ground and when does it occur? What follows is an approximation of how NAs start and trigger events that typically set the process in motion. Every situation is unique and other concerns and foci may be the active ingredients elsewhere.

For What Situations and When Might NA Be Used in Education

NA can be used for an array of educational concerns (lower-than-desired achievement in mathematics and science, school dropout rates, violence in and around schools, problems related to the education of children from broken homes who are in foster care, the guidance and counseling needs of elementary through high school students, problems arising from alcohol and substance abuse, and so on). It goes without saying that almost any area is a possibility for an assessment, but at the same time that does not mean that all needs will be investigated.

Therefore, when would you do an assessment and how do you narrow the focus so that it is meaningful and the probability of findings getting used are increased? NAs are often thought about at the point administrators or involved stakeholders (teachers, parents, or community groups) become concerned about problems. Examples might be: "Our students aren't doing as well academically as we would like," "We feel that there is an emerging drug and alcohol problem in this area," and "We are seeing less minority student enrollment and retention in math and science disciplines." People sense that their concerns merit a closer look and seek a mechanism for making this happen.

NA occurs early in the process of change as opposed to evaluation which is about how well a program is implemented and the degree to which it is resulting in the outcomes and impacts it was intended to achieve. NA and evaluation overlap, but they are done at different times and have unique functions.

General Applications in Education

One interesting application is the Trends in International Mathematics and Science Study (TIMSS), which consists of standardized tests to measure and compare the progress of students in relevant areas. The US did not perform as well as expected in relation to many other countries. Follow-up investigations as to what might be causing this situation indicated that the curriculum might be a factor contributing to lower achievement. In the US, it was characterized as being a mile wide and an inch deep (featuring many topics but not going into them in much depth) in comparison to what is done elsewhere. This observation along with others has led to much introspection about mathematics and science education in the US – its structure and the instructional strategies used (Schmidt and Wang, 2002).

In essence, testing programs and educational accountability systems have all the elements of NA. The test helps get at the 'what is' condition or state, and then the scores are looked at either for individuals or groups in terms of

standards or expected condition status – what ought to be. When the discrepancy between them is too great (outside of a reasonable range of tolerance), school systems will consider what actions they could take to reduce the deficits. Testing programs and school accountability are not ordinarily posed as NA, but indeed they are.

Hunt *et al.* (2002) employed the technique in a school system to explore the nature of violence and ways to resolve and/or reduce such incidents. They studied the problem for over a year through mixed methods to obtain the perspectives of students, teachers, staff, parents, and community members. By means of the prolonged involvement on site with stakeholders, the needs assessors felt that they were able to get more buy-in to solutions to the problem.

An NA was incorporated into an evaluation of a state-wide university consortium dealing with the retention of minority students in the fields of science, technology, engineering, and mathematics (STEM). Students and faculty/administrators were surveyed with similar but slightly different versions of scaled questions. In general, the two groups were in agreement but when they were not, a second survey was sent to them asking them in open-ended format to explain why the groups differed. By this means, the subtle and underlying complexity of quantitative needs was uncovered (Lee *et al.*, 2007a, b).

Chauvin and Anderson (2003) looked at the potential training needs of public health workers. They developed a sophisticated questionnaire asking various levels of stakeholders about the frequency of key tasks, the competency of workers to perform them, and the motivation to have further training for them. They then contrasted different groups of respondents on the three distinct questions and pinpointed where it might be most beneficial to offer training and where it would tend to be well received. The three areas of the questions were rated on a five-point scale. While the scaling technique was somewhat intricate, it was offset by the amount of information generated, the in-depth understanding of needs, and by the possibility of implementing better and more meaningful training for the public health workforce.

Observations from the four NAs described above underscore key, important aspects of NA. It was apparent across all cases that the process helped to illuminate subtle, under-the-surface dimensions of problems. Another aspect was the influence, in some instances, on how actions plans were developed and/or implemented. Third and, perhaps the most notable, was that the data changed the nature of the discourse related to thinking about policies. Even if there was not much in the way of tangible change, decision makers became more thoughtful and attentive to implications of policies and possible directions to be pursued. This is to us the most valuable outcome and emphasises our bottom line that NA is well worth the effort.

The Purpose of Educational Evaluation

S Mathison, University of British Columbia, Vancouver, BC, Canada

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Accountability – Demonstrating that some predetermined level of performance has been achieved with the understanding that meeting expectations results in rewards while not meeting expectations results in sanctions.

Amelioration – Making something better.

Formative – Evaluation done for the purpose of improvement focusing on implementation and process, and which is conducted while the evaluand is ongoing or in the development stage.

Summative – Evaluation done for the purpose of accountability focusing on outcomes and effects, and which is conducted when the evaluand is completed or in its final form.

- States/governments are accountable for providing adequate and equitably distributed resources for education, and certification and other processes to insure educators are properly prepared.
- School districts/units are accountable for their policies, the fair distribution of resources, and for being responsive to their constituents.
- Schools or universities are accountable for a fair internal distribution of resources, promoting continual improvement, and being responsive to their constituents.
- Teachers are accountable for identifying and meeting the needs of students.

The nature of evaluation of accountability can be understood by looking at three contexts: learning, interventions, and organizations.

Two Main Purposes of Educational Evaluation

In education, evaluation serves two primary purposes: accountability and amelioration; the latter purpose is sometimes divided into development and knowledge generation. Both of these purposes are relevant at multiple levels in education, from individual learning to programs to complete educational systems.

Accountability

While accountability can mean more than evaluation, evaluation is always necessary for accountability. In education, individuals, learners, teachers, administrators, specific interventions, organizations, and states may be held to account by someone for demonstrating that something has been accomplished in an explicitly specified way. Evaluation as accountability typically implies there are rewards or sanctions depending on whether the level of performance has met preset standards, although there is considerable variation in whether rewards and sanctions are direct and severe (withdrawal of funding) or indirect and modest (public embarrassment). Accountability is most often associated with summative evaluation, or evaluation that focuses on outcomes and effects, and which is conducted when the evaluand is completed or in its final form.

At different levels the foci for evaluation change and are often expressed as follows:

Learning

Often referred to as summative assessment or assessment of learning, this is evaluation that occurs at the end of a period of instruction and often results in a grade that summarizes what a learner knows. The period of instruction may be a unit of study, a project or paper, a complete course, or even a larger timeframe like fourth grade. Evaluation of learning in this context might take the form of quizzes, chapter tests, end of term examinations, or government mandated standardized tests. Evaluations of learning done for accountability purposes do not play a role in learning or teaching as they occur after the completion of educational interventions and are meant to label the level of performance or achievement.

Performance measurement is the term that typically captures a more general accountability for learning, the sort of broad assessments of educational attainment such as international tests of achievement like the Program for International Student Assessment (PISA) or the US National Assessment of Educational Progress (NAEP). These evaluations are meant to provide information on student outcomes to make judgments about the quality of education at local, national, and international levels. In addition, these evaluations often draw attention to differential effects, such as the achievement gap between social classes or racial groups.

While evaluations of learning that are done for accountability purposes are often equated with summative evaluation, this is accurate only for the specific learning context and participants. Such evaluations can be used for formative

purposes, but only in the sense of the improvement of similar, but future teaching and learning events (Figure 1).

Interventions

Evaluations of interventions may focus on accountability of different kinds – accountability for implementation, process, and long-term outcomes.

Educational interventions (such as curriculum, pedagogical strategies, or processes) are often developed with the expectation that an educational problem will be resolved with a prescribe set of activities implemented under certain conditions. These prescribed activities and conditions are based on a theoretical or logical understanding of needs and effective means for reaching outcomes. But for those outcomes to occur, there is a presumption that the educational intervention must be implemented with fidelity, that is, as it is prescribed. Evaluation that focuses on the degree of implementation is one form of accountability. This is sometimes referred to as quality assurance.

Accountability evaluation may also focus on process, what is often referred to as the black box of interventions, the ways in which resources come together with teaching and learning activities and create an educational process. A process evaluation focuses on more than implementation fidelity and includes a description of how the intervention was implemented, who was involved and received educational services, and examines internal and external factors that have an impact on the intervention. A process evaluation often focuses on untangling differential implementation and effects, such as what components of an intervention work effectively for subgroups of students.

Interventions often have long-term intended outcomes that evaluation may focus on discerning. An outcome evaluation is intended to determine the extent to which

outcomes occur and to establish that the changes are significantly attributable to the intervention. Outcomes are typically attitudes, knowledge, behaviors, or skills that programs aim to positively influence. Examples of typical educational outcomes are academic achievement, school completion, conflict resolution, employment, civic leadership, social development, and so on. An outcome evaluation of a peer mediation program in elementary schools, for example, might focus on determining the extent to which elementary age students are able to resolve conflict for themselves and that it was participation in the peer mediation program that contributed significantly to those conflict resolution skills. Another example is an evaluation of the extent to which a simulation-driven first-year college biology class leads to greater student control of learning and tolerance of uncertainty. While many interventions have such intentions, the multiplicity of intervening factors that may effect outcomes make this kind of accountability focused evaluation challenging (Table 1).

Organizations

Educational evaluation may focus on accountability at an organizational level, that is, a school, school district, college, or any organization with an educational mission. Such accountability may take the individual as the level of data collection, but focuses on the aggregate. Currently in the United States the requirements of the No Child Left Behind legislation require the testing of all children in third through eighth grades, and accountability occurs at a number of levels, but ultimately it is schools that are judged to be successful or in need of improvement. In both K-12 and postsecondary education, accreditation is an example of accountability evaluation at the organizational level. Educational institutions and individual programs are required to demonstrate they have met standards set by recognized external professional bodies. Successful accreditation may directly effect getting operational funding and attracting students, while being unsuccessful might mean loss of funding, inability to recruit students, and/or an inability to attract research grants. This sort of accountability evaluation requires a demonstration of and justification of performance to external audiences, and indeed is often required by external authorities such as inspectorates and professional accrediting agencies. It is evaluation that can be described as top-down and is often motivated by political agendas, at the local, national, and international levels (Table 2).

Amelioration

Evaluation can also play a significant role in planning and development and is manifest in evaluation that focuses on needs assessment, improvement, learning and appreciation, building self-evaluation capabilities, determining fidelity of

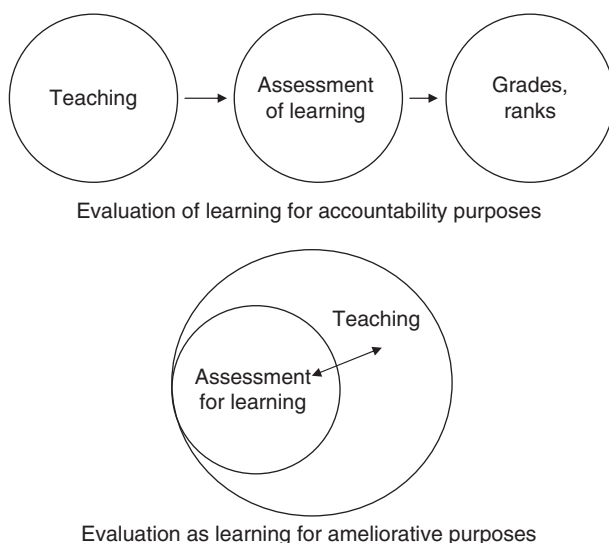

Figure 1 Relationship between evaluating learning for accountability and ameliorative purposes.

Table 1 Purposes of evaluation in education by level of evaluand

	<i>Amelioration</i>	<i>Accountability</i>
Learning	Occur during the teaching learning process Focus on identifying the need for remediation Example Teacher analysis of error patterns in student work to identify topics for reteaching	Occur at the end of a teaching–learning event Focus on identifying knowledge, skills, or attitudes acquired Example End of course grades
Intervention	Support planning and implementation of specific educational interventions or components Focus on implementation, process, and short-term outcomes Example Improve mathematics achievement by creating relevant learning activities	Support resource allocation or selection decisions about educational interventions Focus on outcomes and effects Example Full-scale adoption of a reading program that has been pilot tested
Organization	Support organizational improvement Focus on strategy planning, organizational learning, process, short-term outcomes Example Identify strategies for improving human resource development in the use of technology	Demonstrate financial responsibility and mission accomplishment Focus on outcomes and effects Example Accreditation of a university

Table 2 Characteristics of evaluation for amelioration and accountability

	<i>Amelioration</i>	<i>Accountability</i>
Purpose	To improve, to learn, to generate insight about educational issues, to promote ongoing evaluation, to strength programs and organizations	To provide judgments about outcomes, effectiveness, value, to determine costs, to assess efficiency
Character of evaluation	Internal, formative, diagnostic	External, summative
Audience	Teachers, learners, curriculum developers, parents, policy shaping community	Policy makers, educational administrators, funders, public
Role of evaluator	Often internal to organizations; collaborative, evaluator as critical friend	Often external, distant, independent
Reporting	Informal	Formal

implementation, making informed decisions, and contributing to enlightened discussions. Most ameliorative evaluation efforts give precedence to finding solutions and making improvements in specific contexts and in the short term. Ameliorative evaluation speaks most often to internal audiences such as administrators, educational planners, and teachers or other education professionals.

Often, evaluation that is ameliorative is equated with formative evaluation, that is, evaluation done for the purpose of improvement focusing on implementation and

process, and which is conducted while the evaluand is ongoing or in the development stage. Some evaluation theorists, for example, Eleanor Chelimsky and William Shadish, separate this ameliorative purpose into development and knowledge generation.

Needs assessment

Needs assessment is a key strategy in evaluation that aims to set priorities for improvement and allocation of resources. It is a strategy to identify issues and to develop plans for change by systematically analyzing what is and considering what should be. Evaluation is used to identify gaps between what is desirable or expected and what is actually happening, prioritizing which gaps to be bridged through a determination of where inevitably limited resources should be expended. In educational contexts, a school district might do a needs assessment to determine what is expected of schools by its largely immigrant, English as a second language community, or a statewide university system might use needs assessment to identify community goals and make resource allocations in order to meet those goals.

Improvement and learning

In the context of learning, this type of evaluation is sometimes referred to as assessment for learning or formative assessment. Evaluations of learning that are meant to ameliorate occur during the learning process and provide information that cycles back into the teaching–learning connection so that both the quality of teaching and learning can be enhanced. The idea is that assessment for learning will increase learners' motivation by genuinely engaging them in making judgments about their knowledge and skills. Typical evaluation strategies include questioning,

feedback by comments, peer assessment, self-assessment, and analysis of errors. **Figure 1** illustrates that evaluation in this ameliorative sense is embedded within the teaching and learning activity rather than being separate from and following the teaching/learning activity.

Evaluations are meant to support improvement and learning at programmatic and organizational levels. During the development, planning and piloting of programs and interventions evaluation is a means for providing information about implementation, inputs, processes, and short-term outcomes that feeds back into a planning and development cycle. Such evaluation may be formal or informal, and evaluators and program developers work closely to monitor what is happening and make adjustments as the program is ongoing. Evaluation for this purpose is often a bottom-up enterprise in which educational programs, organizations, and systems are motivated by a desire to identify areas in need of improvement and the strategies for improvement.

The school self-evaluation movement in Europe is a good example of ameliorative evaluation that focuses on improvement and learning at an organizational level. While school self-evaluation focuses on the same elements as other evaluations (outcomes, process, and context), the definition of what the evaluation will focus on and the use of the results is local and specifically targeted to judging how that school is doing with an eye to improving something in that school. Responsibility for doing evaluation is vested in school evaluation teams, which may include students, parents, teachers, school administrators, and other community members. School self-evaluation is a particular case of evaluation capacity building.

Formative evaluations focused on improvement and learning may, however, also serve accountability purposes in evaluation, such as in the case of accreditation where the self-evaluation is largely prescribed by an external agency and will ultimately be reviewed by external evaluators or inspectors.

Evaluation capacity building

Evaluation capacity building (ECB) intends not just to do evaluation for others but instead to build a system of knowledge, process, and practice within an organization so that quality evaluation becomes ordinary and ongoing. Emphasizing ECB means evaluators support the development and sustaining mechanisms for those within an organization to learn about and do evaluation for themselves. For example, ECB within a college or university might focus on the implementation of changes to a student rating of teaching survey, distribution of information about evaluation-related professional development opportunities for academic department heads, reviewing academic department self-reviews, and so on.

Contributing to deliberation about educational problems

Evaluation also serves a more general ameliorative purpose of creating and contributing to public discourse about education, what Lee Cronbach called the policy-shaping community. Cronbach highlighted the contribution evaluation makes by enriching discussions within the polity about important social and educational problems. Evaluations help in clarifying what the issues are, in analyzing programmatic assumptions, and in revealing the political, social, and organizational contexts that influence both problem definition and solution. In this way, evaluations contribute to a broad deliberative discourse about how to solve problems and improve educational and social outcomes.

A useful illustration of this idea is the cumulative evaluative effort of the widely adopted Drug Abuse Resistance Education (DARE) program. Because the DARE program is so ubiquitous, in virtually all schools in the United States and Canada as well as many other countries, many evaluations of the program have been conducted. The evaluation results are mixed – early evaluations of DARE concluded it was effective but more recent evaluations suggest the program does little to decrease the incidence of drug use. Over time and with the investment of considerable programmatic and evaluative resources, evaluations of DARE have resulted in any significant changes in the program. Evaluations have contributed in a broad sense to the public discourse about why and how to discourage youth from drug use.

Evaluation Within Socio-Political Contexts

Accountability and amelioration co-occur as reasons for doing evaluation in education, but often the contemporary socio-political context gives precedence to one or the other. Since the early 1980s, educational evaluation has been preoccupied with the accountability purpose, but in a particular way. Before the current era, which emphasizes regulatory accountability, professional accountability was common and considered trustworthy. However, accountability in education, much like in other domains of public and private life, became too important to leave to educators, and local, state, and sometimes multi-state authorities have assumed a more significant role.

Public confidence in institutions to meet individual and collective needs has been eroded. While once there was confidence that professionals (e.g., teachers, doctors, and accountants) and leaders (e.g., politicians and ministers) had deeply held and ethical commitments to doing the right thing, too many transgressions have led to public skepticism. This skepticism has ushered in what has been called the era of new public management.

Until the late 1970s and early 1980s, accountability was more an expectation than a process. In general, what is referred to as professional accountability prevailed – the expectation that professional judgment and action was informed by good reasons and an acceptance of the authority of those providing the reasons. Professional accountability is self-regulation by a group of professionals. In the past, educators experienced more autonomy in determining how much learning had occurred, what quality teaching was, if schools were doing a good job, and whether organizational missions were appropriately being met.

While scandals are often cited as the reason for a shift away from professional accountability, in fact, there are examples of what are now commonly and widely held senses of inadequate or inappropriate professional knowledge. Historically, both disagreements about whether the public good has been served by professional accountability and incidences of professional misconduct, including but not limited to malfeasance, have led to a disintegration of professional accountability and the rise of a regulatory accountability. Regulations begin to take the place of educators' professional judgment.

Regulatory accountability is a shift to determinations about what professionals should do that is external to the institutions within which they work, rather than being decided by the professionals working within those institutions. This form of accountability vests authority in governments, but not by simply putting the government in charge. Rather, governments are agents that support free markets by creating the conditions that allow markets to operate to maximize effectiveness, profits, and efficiency. Government regulations are the primary means for creating these conditions. Regulatory accountability is facilitated by a global neoliberalism that conceptualized education less as process and more as products or outcomes, a shift in emphasis on competing purposes of education. Vocationalism and democratic citizenship have long competed as the main purpose of education. Taylorism came to US schools early in the twentieth century, an approach that emphasized efficiency of production but developed alongside progressivism's focus on the effectiveness of schools to promote democratic principles. Education has always been conceived as an institution that serves the public interest by preparing young people for work and citizenship, promoting a common culture (especially in nations of immigrants), and reducing race, ethnic, and class inequalities. What is different about these purposes is whether they are conceived in the interest of individuals or the collective, public interest. The current emphasis is on the private and economic benefits (vocational purpose or schooling for the market that serves individual and corporate economic interests), rather than the public benefits (schooling for democratic citizenship with attention to mediating special interests for the common good).

Neoliberal values currently capture the public attention regarding the purpose of schooling and, consequently, how education is evaluated. As politicians, corporate CEOs, and free marketers continue to dominate the public rhetoric about quality in education, so too will the strategies for educational evaluation reflect those values.

The Future Purposes of Evaluation

The fundamental purposes of evaluation will not change; educational evaluation will continue to provide the means for accountability and amelioration through development and knowledge generation. The current era of regulatory accountability emphasizes the accountability purpose in a particular way, but educational evaluators are developing alternate views of accountability that combine both purposes of evaluation. Broadly, these approaches to educational evaluation might be called pluralistic democratic accountability.

Pluralistic democratic accountability is an approach that asks educational stakeholders to enter a compact of mutual, collective responsibility for education and schooling. Such an approach to accountability places far greater emphasis on local context and internal accountability, that is, mutual responsibility within contexts and communities where social actors can and do know each other, and in which there is real participation in education. It is an approach that focuses on learning and improvement, rather than blaming and punishing.

The accountability and ameliorative purposes of evaluation may be perceived as antithetical to each other, but there is no logical reason for this. Indeed, evaluation that is done to improve can be used for accountability and accountability-oriented evaluation can be used to make plans for improvement. Pluralist democratic accountability makes the complementarity of these purposes explicit by promoting evaluation that guides improvement of education (through involvement of multiple stakeholders, school self-reviews, and local analysis of student achievement data) and demonstrates accountability to various publics (through organizational report cards and reporting to a broad range of education's constituencies).

Understanding Approaches to Evaluation

A J Love, Independent Evaluation Consultant, Toronto, ON, Canada

Introduction

During the last two decades policymakers, grant-making bodies, educators, and the public around the globe increasingly have turned to educational evaluation to achieve higher levels of school and teacher effectiveness, guide the reform of education systems, and foster greater accountability. To achieve these aims, a seemingly endless stream of evaluations is taking place at all levels in the education sector. There are extensive in-depth evaluations of national programs and materials, such as the Student Mentoring Program and the Even Start Family Literacy Programs in the United States, and Early Reading First initiatives in England. There are evaluations of student achievement at the state and provincial level, for example, the Illinois Standards Achievement Test and the work of the Education Quality and Accountability Office in Ontario, Canada. There are evaluations of student performance at the national level, such as the US National Assessment of Educational Progress (NAEP) and Australia's National Assessment Program, and at the international level, for example, the Organization for Economic Cooperation and Development (OECD)'s Program for International Student Assessment (PISA). There are also comparative evaluations of the effectiveness of school systems across several regions, such as those conducted across Europe and in the Asia-Pacific region.

In addition, school administrators and teachers worldwide are using internal evaluations (self-evaluations) to drive school improvements and create innovative learning environments. Spurred by greater awareness of the importance of factors outside of the classroom in achieving student and school success, grant-making organizations are demanding evaluations of the relative contributions of the diverse support programs they fund, such as the Healthy Minds School Breakfast Program and Homework Clubs Programs.

These examples reveal a wide variety purposes for educational evaluation. As a partial list, the purposes for educational evaluation include assessing the quality and effectiveness of educational curricula, programs, and materials; accrediting schools and ensuring that they meet minimum standards; assisting parents and students in selecting schools; improving accountability by monitoring student performance at local, state/provincial, and national levels; assessing the effectiveness of school systems across countries and regions; guiding school-reform efforts; and empowering school administrators and teachers to learn

from evaluation as a way of improving their teaching effectiveness and school performance.

If educational evaluation had only a single purpose, then perhaps a single approach to evaluation would be possible. But this is not the situation. Educational evaluation is an applied activity that takes place in the turbulent environments of real-world settings. Evaluators commonly encounter multiple and competing purposes for an evaluation, numerous stakeholders with contradictory information needs, limited time and budget for evaluation, and conflicting views about evaluation methodology. The following section presents several conceptual frameworks that evaluators use to manage the complexity of the evaluation field, select relevant evaluation approaches, and successfully conduct evaluations in challenging practice settings.

Selected Frameworks for Understanding Approaches to Evaluation

In the evaluation field, the term model is used broadly to denote a conceptual perspective or structure, rather than more narrowly in the sense of a scientific or theoretical model. Many evaluators prefer the term approach, however, because it denotes a way of viewing evaluation, its values and purposes, the roles of evaluators, and the recommended steps for designing and implementing the evaluations. In turn, most approaches to evaluation identify relevant methods of data collection and analysis, such as needs assessment or cost-effectiveness analysis. In general, an evaluation approach imparts coherence to the evaluation process and serves as a guide for evaluation training and practice. Given the diversity of purposes for educational evaluation and its varied social and political contexts, literally dozens – if not hundreds – of approaches to evaluation exist today that reflect the views of thoughtful evaluators about the theory and practice of evaluation. To navigate through this labyrinth and manage its complexity, this article concentrates on four major frameworks for organizing and understanding the multiplicity of approaches in the evaluation field.

These four frameworks meet the following criteria: (1) the developers of each framework are highly experienced educational evaluators, even though their frameworks apply beyond the confines of the education field; (2) the developers refined and tested their frameworks over a period of decades and their frameworks have stood

the test of both time and peer scrutiny; (3) the frameworks relate to the entire evaluation field rather than one single approach or methodology; (4) there are widely available books, articles, and reference materials available for each framework that can supply the interested reader with the detailed information not possible within the limitations of this article; and (5) universities and training programs use these four frameworks, alone or in combination, to educate professional program evaluators, graduate students, and teachers about program evaluation and give reliable direction to seasoned evaluators striving to improve their evaluation practice. The four frameworks presented here are:

- chronological framework;
- alternative approaches framework;
- evaluation forms and approaches framework; and
- framework based on a meta-evaluation of evaluation approaches.

In terms of the organizing principles of each framework and ease of comprehension by novice evaluators and those new to the evaluation field, these four frameworks follow a general progression from the simpler to the more complex.

Chronological Framework

The chronological framework is arguably one of the most commonly used frameworks for training novice evaluators in the fundamentals of program evaluation and in selecting appropriate evaluation approaches and methods. The chronological framework is based on the notion that the sequence of events (i.e., chronology) during the developmental life cycle of a program strongly influences the primary purposes for an evaluation, the focus of the specific evaluation questions addressed by the evaluation, and the choice of evaluation approaches and methods required for answering those evaluation questions. The chronological framework also reinforces the idea that program evaluation should be used throughout the program life cycle and not just at the end.

Although elements of the chronological framework appeared in the late 1970s, it received closer attention after its description in the evaluation primer, *Thinking about Program Evaluation* (Berk and Rossi, 1998), and its integration into successive editions of the widely adopted evaluation text, *Evaluation: A Systematic Approach* (Rossi et al., 2004). In addition to the university courses that use *Evaluation: A Systematic Approach*, the chronological framework has made an important contribution to the structure of several national training programs in evaluation, such as those supplied by the Canadian Evaluation Society, the Japan Evaluation Society (Nagao et al., 2005), and the basic course in program evaluation offered by The Evaluators' Institute. The chronological framework is also congruent

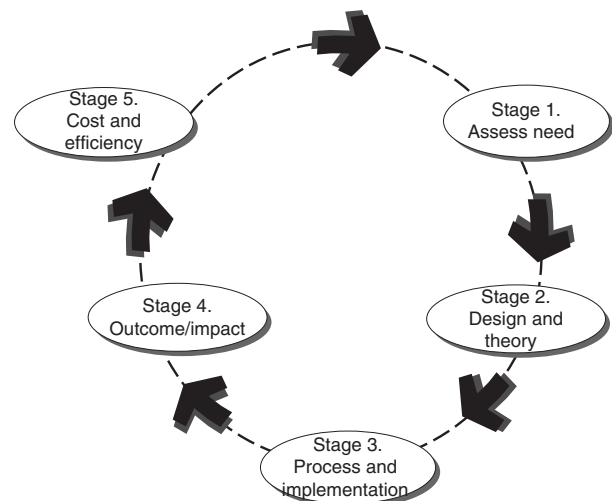

Figure 1 Sequence of events in program life cycle.

with the standards developed by the Joint Committee on Standards for Educational Evaluation (1994).

For a better understanding of the chronological framework, **Figure 1** portrays the major sequence of events in the program life cycle, arranged in the fashion of a clock. **Figure 1** shows that stage 1 in the program life cycle is assessing the need for the program; stage 2 is planning the program design and clarifying the program theory; stage 3 is establishing the processes of program delivery and implementing the program; stage 4 is the generation of outcomes by a fully implemented program; and stage 5 is weighing the cost and benefits of the program.

As most programs follow a similar developmental sequence, the chronological framework is intuitive and readily understood by managers (administrators) and staff (teachers and other staff). With assistance from an evaluator, managers and staff can quickly pinpoint their program's location in the program life cycle. Knowing the location in the program life cycle helps clarify the purposes for evaluation and identifies the relevant evaluation questions. For example, a typical purpose for evaluating a program at stage 3 (implementation stage) is to assess the strengths and weaknesses of the program with an eye to improving its operations. Relevant questions at stage 3 include those about the process of program delivery, whereas a program at stage 4 usually raises questions about program outcomes. In short, applying the chronological framework allows an evaluator to rapidly focus the evaluation by using this shortcut to confirm its purpose and identify the key evaluation questions.

The chronological framework points not only to specific evaluation questions but also suggests appropriate evaluation approaches for each stage. For example, programs at stages 1 through 3 in the program life cycle frequently require a formative approach aimed at adjusting the program theory to the local context and fine

Table 1 Stage of program life cycle matched to major evaluation methods

Stage of program life cycle	Evaluation methods
Stage 1. Need for program	Need identification Needs assessment
Stage 2. Design and theory	Evaluability assessment Logic modeling Describing and assessing program theory
Stage 3. Process and implementation	Program process monitoring (service utilization and organizational functions) Program process evaluation
Stage 4. Outcome/Impact	Identifying intended and unintended outcomes Measuring/monitoring program outcomes Impact assessment Meta-analysis
Stage 5. Cost and efficiency	Efficiency analysis Cost-benefit analysis Cost-effectiveness analysis

From Rossi, P., Freeman, H., and Lipsey, M. (2004). *Evaluation: A Systematic Approach*, 7th edn. Thousand Oaks, CA: Sage.

tuning the program implementation, whereas programs at stages 4 and 5 call for a summative approach that assesses the outcomes and cost effectiveness of the program. The chronological framework also suggests relevant evaluation methods. For example, a program at stage 2 (design and planning stage) usually benefits from specific methods such as evaluability assessment or clarification of the program logic. **Table 1** illustrates the relationship between program stage and choice of evaluation methods.

In short, the chronological framework has clear advantages: it portrays evaluation holistically throughout the stages of program development; introduces novice evaluators to important terms and concepts; and the model provides clear direction about major evaluation questions, appropriate evaluation approaches, and relevant data-collection methods. On the other hand, a central limitation of the chronological framework is that it tends to oversimplify the process of program development and evaluation. The framework implies a systematic or step-by-step process that may not reflect the realities of real-world settings. As evaluators gain experience and gain the capacity to deal with complex and nonlinear evaluations, they may find that one of the other evaluation frameworks described in the following sections more adequately meets their needs.

Alternative-Approaches Framework

The alternative-approaches framework, as described in *Program Evaluation: Alternative Approaches and Practical*

Guidelines (Worthen *et al.*, 2004), imparts order to complex evaluation situations by clustering a selection of the more popular and influential evaluation approaches into five alternative approaches to evaluation:

- Objectives-oriented approaches;
- Management-oriented approaches;
- Expertise-oriented approaches;
- Consumer-oriented approaches; and
- Naturalistic and participant-oriented approaches.

The alternative-approaches framework takes the position that there are many approaches to evaluation and each can be useful depending on the purpose of the evaluation and other factors, such as the organizational context. In developing the five categories of alternative evaluation approaches, this framework considers several important dimensions of the alternative-evaluation approaches, such as epistemological differences (objectivism vs. subjectivism), value differences (utilitarian vs. intuitionist-pluralist), and methodological differences (quantitative vs. qualitative).

The resulting five categories of evaluation approaches are loosely ranged across these dimensions. The categories reflect both the major questions addressed by the approach and its key features. For example, an objectives-oriented approach to school achievement is likely to address questions on the attainment of learning objectives and assess attainment using standardized tests. In contrast, a naturalistic and participant-oriented approach is more prone to evaluate school achievement in terms of questions identified jointly by teachers and students and assess the achievement using qualitative methods, such as portfolios. The following sections describe each alternative approach briefly; and **Table 2** summarizes the major purposes and chief characteristics of the five alternative approaches.

Objectives-oriented approaches

The essence of the objectives-oriented approaches is specifying the goals and objectives of a program and then assessing how well program participants attain them. One of the earliest approaches to educational evaluation assessed student behaviors against the intended educational objectives by using impartial and systematic measures. The differences between the intended and the actual achievement of objectives were used to improve program performance. There are several objectives-based approaches, for example, discrepancy evaluation that measures the discrepancy or difference between program standards and actual program performance. Critics of the objectives-based approaches contend that they promote an inflexible approach to evaluation and lack clear criteria to judge the worth of a program. One reaction to the limitations of objectives-based evaluation is goal-free evaluation, that is, evaluation that focuses on the actual outcomes of a program and unanticipated results, rather than the intended goals/objectives alone.

Table 2 Purposes and characteristics of alternative approaches

<i>Approaches</i>	<i>Major purposes</i>	<i>Major characteristics</i>
Objectives-oriented	Measure extent goals and objectives are achieved	Measurable goals and objectives; assess gaps; apply scientific tools
Management-oriented	Supply useful information for decision making	Support data-based decision making; employ systems analysis; evaluate all stages of program development
Consumer-oriented	Aid decisions about products or purposes	Product testing; apply checklists; render judgments using established criteria
Expertise-oriented	Render professional judgments of quality and achievement of standards	Professional expertise and judgment; apply consensus standards; use of formal and informal review panels
Participant-oriented	Respond to stakeholder information needs; describe program activities and processes	Involve evaluation users; apply naturalistic and mixed methods; portray multiple perspectives of program realities

From Worthen, B., Sanders, J., and Fitzpatrick, J. (2004). *Program Evaluation: Alternative Approaches and Practical Guidelines*, 3rd edn. New York: Pearson Education.

Management-oriented approaches

Rather than assessing goals and objectives, management-oriented approaches concentrate on identifying and meeting the evaluation-information needs of program managers or administrators. The context, input, process, and product (CIPP) approach is an example of an important management-oriented approach to program evaluation in the education field. In these approaches, the evaluator works closely with program managers to identify key decisions and then selects the appropriate evaluation methods to inform those decisions. The management-oriented approaches place primacy on the role of program managers and the importance of a systems approach that values both program context (e.g., classroom environment) and processes (e.g., following lesson plans) in generating program outcomes. Management-oriented approaches also view program managers and program evaluators as having complementary roles and working cooperatively to overcome obstacles to program success.

Some strengths of management-oriented approaches include a clear focus on evaluation questions relevant to managers, application of evaluation throughout all phases of program planning and implementation, and increased use of evaluation information for both learning and accountability. On the other hand, management-oriented approaches experience limitations unless there is strong management commitment to the evaluation process, acceptance of the evaluation interests of managers over the evaluation needs and concerns of other stakeholders, clear formulation of decision alternatives and relevant evaluation questions during the evaluation planning process, and specific mechanisms for ensuring that evaluation findings inform decision making and action planning.

Consumer-oriented approaches

Every year billions of dollars are spent worldwide on educational products and services – all without adequate information about their effectiveness. Consumer-oriented

approaches to evaluation focus on providing consumers (e.g., governments, school authorities, and the public) with dependable evaluation information about competing products and services offered in the education marketplace. Some examples include independent evaluation of learning programs (e.g., tutoring, summer programs abroad), educational products (e.g., literacy instructional materials, technology equipment, and software), and educational services (e.g., in-service training, workshops).

The strengths of the consumer-oriented approach include well-established criteria and checklists for evaluating educational products and services. For nearly half a century, the use of these tools has greatly improved the knowledge of consumers and spurred greater accountability for the effectiveness of educational goods and services. Potential disadvantages of the consumer-oriented approaches include the cost and time to collect credible evaluation information, as well as discourage local solutions because of the effort involved to assess their performance.

Expertise-oriented approaches

These approaches place emphasis on the judgment of experts in rendering an evaluative judgment about the program. Evaluators with the requisite professional expertise collect information about a program through a variety of methods, such as reviews of documents, curricula, student projects, and classroom observation. Then they apply their expertise to make an evaluative judgment about the performance of the program.

Expertise-oriented approaches may be formal or informal. Formal expertise-oriented approaches include professional review systems, such as the national and regional accreditation reviews of school systems and teacher training programs (e.g., National Council for the Accreditation of Teacher Education) that have published standards agreed upon by the profession, clear criteria for rating each standard, site review by experts to validate the attainment of the standards, review of the site-review

report by a distinguished accreditation committee, an appeal procedure, and a final accreditation decision by the accrediting organization. Informal expertise-oriented approaches include *ad hoc* panel reviews, funding-agency-review panels, and blue-ribbon panels (e.g., Rosenberg Commission in Maryland and the Wessell Commission in New York) with members selected for their experience, expertise, and credibility.

The strength of the expertise-oriented approaches is that they draw upon the years of training, wisdom, and insight of professionals to examine a program with the depth and discernment not available through other approaches. On the other hand, this is also seen as the weakness of these approaches – the subjective and possibly narrow judgment of experts is not a substitute for objective criteria and the application of systematic analysis. Furthermore, without a strong mandate and formal structure, critics of these approaches contend that is relatively easy to ignore the findings of expertise-oriented evaluations.

Participant-oriented approaches

In general, participant-oriented approaches invite the involvement of a broad range of stakeholders to identify evaluation questions, select data sources and data-collection tools, and in some approaches, assist in the interpretation of the findings. These approaches view the program managers, staff, and participants as important stakeholders and seek to meet their evaluation needs, as well as the needs of stakeholders external to the program (e.g., government departments or community partners). The primary task for the evaluator is to balance the values and perspectives of the various stakeholders and to protect the pluralism of views when gathering data and reporting evaluation findings. In practice, this means that participant-oriented evaluations are more likely to draw data from multiple sources, employ both qualitative and quantitative data-collection methods, and report evaluation findings in ways that give voice to multiple viewpoints, such as oral briefings, multimedia presentations, and public meetings.

A wide variety of participant-oriented approaches have been influential in educational evaluation, such as the stakeholder-based and responsive-evaluation approaches that urge program evaluators to respond to the participants' concerns and need for evaluation information; the utilization-focused evaluation approach that stresses that an evaluation must be useful for its audiences; participatory evaluation approaches that involve program managers and staff directly in the evaluation process; the empowerment evaluation approaches that give program participants the tools to evaluate their programs and learn from their experiences; and the deliberative democratic evaluation approaches that support transparency and democratic discussion about programs and their outcomes.

Critics of participant-oriented approaches argue that involving multiple stakeholders in the process of designing, implementing, and interpreting the evaluation findings tends to make the evaluation too complex and can present a bewildering array of contradictory viewpoints. The net result is a murky description of the program rather than a clear evaluative judgment about its worth and merit.

In summary, the alternative-approaches framework acknowledges the diversity of approaches to evaluation and the importance of considering differences in values, philosophy, and methodology when selecting an evaluation approach within a specific organizational context. While the chronological framework adopts a sequential viewpoint that matches evaluation approaches and methods to specific stages in the program life cycle, the alternative-approaches framework arranges evaluation approaches along a continuum that reflects their similarities and differences. Although this strategy reflects more accurately the range of evaluation approaches, to apply the alternative-approaches framework well in different settings requires a firm grounding in the theories of evaluation, assessing the evaluation setting, and an understanding of a broad range of evaluation approaches.

Forms-and-Approaches Framework

John M. Owen, who served as director of the Centre for Program Evaluation at the University of Melbourne's Faculty of Education, developed the forms-and-approaches framework. The latest edition of *Program Evaluation: Forms and Approaches* (Owen, 2007), presents an up to date and comprehensive framework for designing program evaluations. The forms-and-approaches framework depends on an analysis of the evaluation situation, rather than arranging evaluation approaches sequentially according to program life cycle, as portrayed in the chronological framework, or clustering approaches according to common characteristics, as found in the alternative-approaches framework. The analysis of the evaluation situation allows the evaluator to apply a framework based on five evaluation forms that provide the conceptual mechanism for organizing different approaches to program evaluation.

Evaluation forms

The five evaluation forms are the proactive form, clarificative form, interactive form, monitoring form, and impact form. Each evaluation form relates to a specific evaluation purpose and focuses on a common set of issues. Here is a brief description of the five evaluation forms:

- the proactive form provides input to decisions about how to design and develop a program before the program enters the planning stage;

- the clarificative form clarifies the theory or logic of the program to assess program feasibility, identify design problems, and strengthen its design;
- the interactive form supplies information about delivery or implementation of a new or rapidly changing program to strengthen the program;
- the monitoring form offers regular feedback about the ongoing performance of well-established programs, often using performance indicators; and
- the impact form determines the extent and level of long-term attainment of outcomes and results.

Evaluation approaches linked to evaluation forms

As noted earlier, each evaluation form links to a specific set of evaluation approaches. In turn, the evaluation approaches for a given evaluation form link to a specific set of evaluation methods. In this way, identifying the underlying evaluation form helps the evaluator select appropriate evaluation approaches and methods.

As the use of the concept of evaluation forms is new for many evaluators, the forms-and-approaches framework

presents the details of each evaluation form in depth. It presents the rationale and focus of each evaluation form, defines the major evaluation approaches related to that evaluation form, and outlines the major methods for data collection that are linked to those approaches. Many detailed examples give life and substance to these discussions and the vast majority of the examples come from the education field. **Table 3** summarizes the major evaluation approaches and the evaluation methods that are linked to each evaluation form.

For example, the interactive form of evaluation suits situations that raise questions about program delivery and the desire to improve decision making by using evaluation to learn more about program implementation. To continue this example, according to the forms-and-approaches framework, the major approaches linked to the interactive form of evaluation include responsive evaluation, action research, quality reviews, developmental evaluation, and empowerment evaluation. In turn, these approaches use specific methods to obtain the desired evaluative information and translate it into action. These methods are the core methods shared in common among the evaluation

Table 3 Major approaches and methods linked to each evaluation form

<i>Evaluation form</i>	<i>Major evaluation approaches</i>	<i>Major evaluation methods</i>
Proactive form	Needs assessment and needs analysis Research review and evidence-based synthesis Review of best practices Benchmarking	Review documents and databases Site visits Interviews Focus groups Nominal groups Delphi method
Clarificative form	Logic modeling Evaluability assessment Accreditation	Document analysis Interviews Site visits Direct observation
Interactive form	Responsive evaluation Action research Quality review (institutional self-study) Developmental evaluation Empowerment evaluation	Intensive onsite studies Direct observation Depth interviews Self-studies
Monitoring form	Component analysis Performance measurement Systems analysis	Program Records Client and management Information systems Performance indicators Client feedback via interviews, focus groups, and/or surveys Key informant interviews
Impact form	Goal-based evaluation and Objectives-based evaluation Process-outcomes studies Needs-based evaluation Goal-free evaluation Performance audit of effectiveness and efficiency with financial and nonfinancial measures Realistic evaluation	Experimental or quasi-experimental designs Standardized tests Direct observation Qualitative exploratory and investigative inquiry

From Owen, J. (2007). *Program Evaluation: Forms and Approaches*, 3rd edn. New York: Guilford Press.

approaches included in the interactive form. The methods for the interactive form are intensive onsite studies, direct observation, depth interviews, and self-studies. The specific mix of core methods and the addition of supplementary methods (e.g., databases and focus groups) vary according to each evaluation situation.

The forms-and-approaches framework has several advantages. It provides a flexible framework that covers a wide range of purposes for educational evaluation and links them to contemporary evaluation approaches (e.g., developmental evaluation, and realistic evaluation) and methods (e.g., performance indicators, qualitative exploratory and investigative inquiry), as well as traditional ones, in a balanced and coherent manner. The forms-and-approaches framework also provides a structure for conversations about the application of evaluation approaches in hotly contested and high-stakes areas of the educational evaluation field, such as outcomes indicators, standardized testing, evidence-based practice, and the use of randomized control studies as the gold standard for impact analysis.

On the other hand, the forms-and-approaches framework requires an accurate appraisal of the evaluation situation before the evaluator can select the appropriate evaluation form that, in turn, guides the choice of evaluation approaches and methods. Assessing the situational complexities of an evaluation can be challenging for novice evaluators. For this reason, the forms-and-approaches framework is arguably more suitable for evaluators, school administrators, and teachers who already have a good working knowledge of evaluation fundamental and also grounding in basic approaches to evaluation. In such cases, the forms-and-approaches framework provides a pathway to develop a deeper understanding of the evaluation situation and to select evaluation approaches and methods that generate useful evaluative information.

Framework Based on a Meta-Evaluation of Evaluation Approaches

The final framework follows a different way of categorizing evaluation approaches than found in the other evaluation frameworks in this article. To develop their framework, Stufflebeam and Shrinkfield (2007) used a meta-evaluation (evaluation-of-evaluations) process for identifying and rigorously assessing the most frequently used approaches for program evaluation before presenting their findings in the book *Evaluation Theory, Models, and Applications*. The credibility of a framework based on a meta-evaluation depends largely on the expertise of the developers and their ability to rigorously apply extensive criteria in their analyses. Both developers are well qualified for the task: Stufflebeam led the work of the Joint Committee for Educational Evaluation Standards in developing the Program Evaluation Standards and for

nearly half a century, he served as director of the Evaluation Centers at Ohio State University and then at Western Michigan University; and Shrinkfield was both headmaster of a college and an evaluator for independent schools and universities in Australia.

The framework that emerged from this exhaustive meta-evaluation identified 26 approaches to evaluation. These were sorted into three major categories according to a set of descriptors: pseudoevaluations, quasi-evaluations, and true evaluations. In turn, quasi-evaluations are divided into two subcategories: questions-oriented and methods-oriented quasi-evaluations; and true evaluations are separated into three sub-categories: improvement/accountability true evaluations, social agenda/advocacy true evaluations, and eclectic true evaluations. **Table 4** outlines these categories and identifies the evaluation approaches associated with each one.

Pseudoevaluations

The authors identify pseudoevaluations as the first category. Pseudoevaluations are studies that masquerade as valid evaluations, but conceal, distort, or falsify the evaluation findings. The motivation behind pseudoevaluations is usually the desire to promote a program or political aims. The five types of pseudoevaluations include public relations studies that present program strengths but conceal weaknesses; politically controlled studies that deceive and mislead through selective and biased evaluation, pandering evaluations, evaluation-by-pretext studies, and empowerment under the guise of evaluation, that is, studies fully controlled by a program but done under the name and status of an evaluator to gain credibility. The discussion of pseudoevaluations makes a unique contribution by clearly flagging those approaches an evaluator should avoid and by demonstrating the importance of ethics as a central consideration throughout the evaluation process.

Quasi-evaluations

The second category includes approaches that legitimately evaluate programs, but have some deficiencies. Stufflebeam and Shrinkfield classify 14 approaches as quasi-evaluations because they narrow the scope of the evaluation and thereby do not provide a complete assessment of a program's merit or worth. The first two quasi-evaluation approaches are objectives-based studies and accountability studies, especially payment-by-results studies. The authors call them questions-oriented approaches because they tend to focus on a limited set of questions related to a program's objectives or the accountability requirements of a funding body.

Table 4 shows that the other 12 quasi-evaluation approaches include the success case method, objective testing programs, outcome evaluation as value-added assessment, performance testing, experimental studies, management information systems, benefit-cost analysis, clarification hearings, case study evaluations, criticism

Table 4 Approaches by categories as identified by meta-evaluation

Categories	Approaches
Pseudoevaluations	1. Public relations-inspired studies 2. Politically controlled studies 3. Pandering evaluations 4. Evaluation by pretext 5. Empowerment under guise of evaluation 6. Objectives-based studies
Quasi-evaluations: Questions-oriented evaluation approaches	7. Accountability studies, particularly payment-by-results studies 8. Success case method
Quasi-evaluations: Methods-oriented evaluation approaches	9. Objective testing programs 10. Outcome evaluation as value-added assessment 11. Performance testing 12. Experimental studies 13. Management information systems 14. Benefit–cost analysis 15. Clarification hearing 16. Case-study evaluations 17. Criticism and connoisseurship 18. Program-theory-based evaluation 19. Mixed-methods studies
True evaluations: Improvement/accountability-oriented evaluation approaches	20. Decision/accountability-oriented studies 21. Consumer-oriented studies 22. Accreditation/certification approach
True evaluations: Social agenda/advocacy evaluation approaches	23. Client-centered studies or responsive evaluation 24. Constructivist evaluation 25. Deliberative democratic evaluation
True evaluations: Eclectic evaluation approaches	26. Utilization-focused evaluation

From Stufflebeam, D. L. and Shrinkfield, A. J. (2007). *Evaluation Theory, Models, and Applications*. San Francisco, CA: Jossey-Bass.

and connoisseurship, program theory-based studies, and mixed-methods approaches. Stufflebeam and Shrinkfield call these methods-oriented approaches because they prescribe the application of a specific method (e.g., literacy test, success case method) or set of methods (e.g., use of both quantitative and qualitative methods, whether appropriate or not). Since many of the shibboleths of the evaluation field fall into the quasi-evaluations category, this categorization is both controversial and thought provoking.

True evaluations

The authors reserve the term true evaluations for those approaches that assess a program's merit and worth in a comprehensive manner. True evaluations also foster program improvement by supplying information to program decision makers and assist consumers with relevant information about program options and competing programs.

The authors cluster true-evaluation approaches into three groups. The first group is the improvement and accountability oriented evaluation approaches that include decision and accountability oriented studies, consumer-oriented approaches, and accreditation and certification approaches. Decision and accountability oriented

approaches encourage evaluators to interact with stakeholders and supply useful information that contributes to program improvement, rather than rendering a judgment about outcomes of a program alone. Both consumer-oriented and accreditation and certification approaches strive to assist and protect consumers and the public.

The second group is the social agenda and advocacy evaluation approaches that support equity and social justice. These approaches include client-centered studies or responsive evaluation, constructivist evaluation, and deliberative democratic evaluation approaches. A key aspect of these approaches is the inclusion of safeguards that eliminate the biases and distortions that characterize pseudoevaluations.

The third group is called eclectic evaluation approaches but it contains only one approach – the utilization-focused evaluation approach developed by Patton (1997). Utilization-focused evaluation focuses on designing evaluations so they are useful and developing evaluation questions that provide important information to a range of stakeholders. This approach views evaluators working collaboratively with program managers, staff, and clients throughout the process of program development. As the program develops, it also evolves; therefore, the evaluation questions and the specific evaluation methods change as

well. Stufflebeam and Shrinkfield acknowledged that it was difficult to classify utilization-focused evaluation because although it shares common elements with other approaches, such as involvement with stakeholders and a concern for program improvement, it also has characteristics that set it apart.

It is worth noting that checklists for a number of the highest-rated approaches are available to the public for download from the website of The Evaluation Center at Western Michigan University. The checklists were developed by experts in particular evaluation approaches to capture lessons learned from practice and to remind evaluators what they are supposed to check, observe, and do during an evaluation.

A major contribution of this framework based on meta-evaluation is the application of a clear set of criteria to assess the comparative strengths and weaknesses of a wide variety of approaches to evaluation. The recognition of the pitfalls leading to pseudoevaluations is a particularly valuable feature of this framework, especially those new to the evaluation field. Another contribution is the acknowledgment that all evaluation approaches have weaknesses as well as strengths. Knowing the strengths and weaknesses of the evaluation approaches during the design process allows evaluators to reduce potential biases and overcome practical obstacles in the application of different approaches.

One of the limitations of this framework is that the meta-evaluation is based on the judgments of only two developers, even though these evaluation experts applied detailed checklists and drew on their many decades of experience in the evaluation field to make those judgments. Another consideration is that the range and amount of detail contained in the descriptions of the individual evaluation approaches can be overwhelming even for knowledgeable and experienced evaluators. Novice evaluators will likely require extensive period of time to study, master, and apply this framework in real-world situations. An additional factor is that complex educational-evaluation environments may require the application of more than one approach or a hybrid approach during an evaluation, but Stufflebeam and Shrinkfield's framework tends to emphasize the use of one approach alone.

Summary

Educational evaluation has grown rapidly during the last two decades. As the boundaries of educational evaluation continue to widen, the purposes for evaluation are expanding also. Evaluation is being used to measure student progress, reform education systems, and enhance accountability for outcomes. School administrators and teachers alike are conducting evaluations of their own to improve school performance and foster creative spaces for learning. This

proliferation of the purposes for evaluation has brought with it a greater appreciation of the demand for evaluators to understand the evaluation needs of stakeholders, recognize the importance of contextual factors (e.g., normative, political, ethical, and organizational) in the evaluation enterprise, and select an evaluation approach that is responsive and supplies useful information to specific audiences.

The contextualizing of evaluation has fundamentally changed the way evaluations are designed. Instead of consistently applying one approach or set of methods to all evaluation situations, evaluators are aware that the choice of evaluation approaches and methods for data collection and analyses must be matched to the unique purposes of an evaluation within a unique evaluation setting. In response to these new realities, literally dozens of approaches to evaluation have emerged. Essentially, the approaches to evaluation define the content of the evaluation field.

The challenge in this article was finding a way to make sense of this complexity while acknowledging the enormous range and diversity of evaluation approaches. The overall strategy made use of four major frameworks developed by highly experienced educational evaluators. These frameworks have proved their value as lenses for viewing more clearly the realities of contemporary evaluation and as a guide to evaluation practice. The use of four frameworks gives insight into alternative characterizations of the evaluation field and portrays the evaluation process in a less linear fashion than by examining one framework alone.

The presentation of these four evaluation frameworks is intended as a point of departure, because the number and range of evaluation approaches are likely to increase in the years ahead. Although at one time educational evaluation was influenced primarily by the social and behavioral sciences, contemporary evaluation is considered by many to be a trans-discipline (Scriven, 2003) that has its roots in many distinct disciplines. As evaluation continues to be influenced by new and emerging disciplines, our frameworks and approaches to program evaluation are likely to evolve regarding their basic assumptions, purposes, processes and tools, roles of evaluators, and modes of disseminating and using evaluation information (Love, 2001).

PREFACE

A preface usually provides a brief introduction to a work, intended to set the stage, provide some background insight, and whet the appetite of the reader. In our case, however, this preface has to address a fundamental question, one that was in our minds at the time we were recruited as Editors-in-Chief for the International Encyclopedia of Education. The question was “Why do we need an Encyclopedia? Its subtext was inspired by the ever-growing, ever-popular Internet. We believe that *this* Encyclopedia is desperately needed and will become a valued resource in education and associated social sciences and arts. The reasons are intellectual and procedural. Anyone with a modicum of knowledge knows that finding and trusting information gleaned from the Internet are two separate actions. The reliance on browsers to help discover references and comments result in resources based on popularity not quality. Pithy titles catch the eye and references rise in the ranks of browser searchers. Related to this is the “editing” in the Internet realm of populist efforts at encyclopedia, references, and other compilations. Once again, after removing offensive material, the accuracy, completeness, lack of bias, and other provenance for entries simply do not exist. Experienced researchers in education can sort through and make intelligent choices. Novices and many journeyman, or practitioners, parents, and policy makers cannot. Contrast how this Encyclopedia was built. Key domains of educational research were identified, and a tentative list of sub-domains or useful applied areas was posited. Then the Editors-in-Chief (apologies for the awkwardness of the term) identified the leading researcher in a particular domain, and with surprisingly little effort, recruited them to participate. They in turn identified the two best researchers in a sub-domain, such as formative assessment or the training of pre-school teachers. The authors of the sections of the Encyclopedia do not represent a collective group of friends and acquaintances, although friendships have been made. Rather they embody a deep and broad scholarly community. The difference from compiled Internet resources is the built-expertise and intellectual engagement of the authors. The summary of the developments and futures in their personal areas of scholarship have been filtered through their years of experience, both as scholars and communicators. Quality, then, is endemic to each piece, developed through this top-down identification of expertise, and made indelible by the bottom-up application of high standards from people leading the sub-domains – the authors, and the domains themselves, the section editors.

On a procedural level, the publishers early committed to the notion that this Encyclopedia would also be an online resource, and access would be available through print, for those with strong bookcases and the persisting love of turning real pages. The Internet version will allow multiple prisms through which the reader may access articles and provide, as it were, an emulation of the Internet in our field, albeit bounded by expertise and high quality.

What must be underscored in the assessment of this effort are the Editors-in-Chief and the publishers’ commitment to find excellence worldwide. We tried very hard to persuade notable scholars from all parts of the world to make contributions. Less than to fulfill the title of “International,” we were on the hunt for perspectives that would enrich the scope and depth of the sections. Our section editors put in enormous time attempting to find the best in the field, wherever they resided. Yet, not everyone is in the volume. Some were overcommitted. Many were not fully confident of their English, and the automated translation software has not yet met standards for technical writing. We believe that such writing and editing tools will make the outreach to an even broader International group of scholars possible in future revisions, or online updates. Furthermore, the birth of the World Educational Research Association (in 2009) will provide a better set of interlocking networks to find and evaluate scholarship from any place on the globe.

Finally, the scope of the effort must be acknowledged: 28 section editors, 926 articles were commissioned, drafted, reviewed, redrafted, edited, and put together in the space of four years. The publishers underwent some internal changes, and alterations in management. We as Editors-in-Chief, changed roles, moved, and also had to keep our own research and development enterprises afloat. Deadlines wobbled; authors dropped from view and had to be replaced.

Yet, at times frustrating as all development is, we find the final product exhilarating. We are enthusiastic not simply because it came into being at all, but because the collective light of the minds that wrote have left a bright resource for the future, one that will impact the way our colleagues understand and experience the educational knowledge, improvement, and impact in the future.

HOW TO USE THE ENCYCLOPEDIA

The International Encyclopedia of Education is intended for use by students, research professionals, and interested others. Articles have been chosen to reflect major disciplines in the study of education and common topics of research by academics in this domain. Each article serves as a comprehensive overview of a given area, providing both breadth of coverage for students, and depth of coverage for research professionals. We have designed the encyclopedia with the following features for maximum accessibility for all readers.

The contents of the encyclopedia are arranged alphabetically by section, and within sections, alphabetically by article. The Subject Index is located in Volume 8. Some topics are covered in a multitude of articles from differing perspectives, while other topics may have only one entry. We encourage use of the index for access to a subject area, rather than use of the Contents list alone, so that a reader has a full notion of the coverage of that topic.

The articles include cross-references to other related encyclopedia articles, suggested further readings where applicable, and many contain relevant websites for additional information. We encourage readers to use the cross-references to locate other encyclopedia articles that will provide more detailed information about a subject.

The Further Reading sections include recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research articles that are considered of primary importance to the understanding of a given subject area are also listed. These suggested further readings are not intended to provide a full reference listing of all material covered in the context of a given article, but are provided as next steps for a reader looking for additional information.

- Parent Support in Early Childhood – Approaches and Outcomes *K S Howard, K A Beckmann, and J Brooks-Gunn* 126

Early Childhood Education and Care Research

- Development and Implementation of Early Learning Standards in the United States *C Scott-Little* 132
- Global Status of Early Learning and Development Standards *P R Britto and S L Kagan* 138
- Rethinking Early Childhood Education and Care: Implications for Research and Evaluation *K Thorpe, D Cloney, and C Tayler* 144

Early Childhood Education and Care Theory

- Child Rearing and Early Education: Parents and Professionals: Theoretical and Historical Influences *H Penn* 151

Early Childhood Education and Care Workforce

- Early Childhood Education and Care Professional Profiles in the United Kingdom: Multiagency Teamwork and Transdisciplinary Challenges *A Anning and P Calder* 157
- Early Childhood Education and Care Staff Support: Mentoring and Professional Development in Finland *P Lindberg* 162

Economics of Education

- Education and Health *P Muennig* 169
- Data *M Perez and M Socias* 178
- Empirical Research Methods in the Economics of Education *P J McEwan* 187
- Theoretical Concepts in the Economics of Education *D J Brewer, G C Hentschke, and E R Eide* 193

Economics of Education – Costs and Financing of Schooling

- Cost–Benefit Analysis and Cost–Effectiveness Analysis *C Belfield and H M Levin* 199
- Economic Approaches to Adequacy *J Imazeki* 204
- Economic Approaches to School Efficiency *L L Taylor* 210
- School Finance Reform *T Downes* 216
- School Finance: An Overview *J K Rice, D H Monk, and J Zhang* 222
- The Economics of Tuition and Fees in Higher Education *R G Ehrenberg* 229

Economics of Education – External Benefits of Schooling

- Education and Civic Engagement *T S Dee* 235
- Education and Crime *L Lochner* 239
- Education and Economic Growth *E A Hanushek and L Wößmann* 245
- Parental Socioeconomic Status, Child Health, and Human Capital *J Currie and J Goodman* 253
- The External Benefits of Education *W W McMahon* 260

Economics of Education – Labor Markets, Education and Earnings

- Education and Inequality *J Blanden and S Machin* 272
- Human Capital *E R Eide and M H Showalter* 282
- Race Earnings Differentials *M Carnoy* 288
- Returns to Education in Developed Countries *M Gunderson and P Oreopoulos* 298
- Returns to Education in Developing Countries *H A Patrinos and G Psacharopoulos* 305
- School Quality and Earnings *J R Betts* 313
- Signaling in the Labor Market *M E Page* 321
- The Economics of High School Dropouts *R W Rumberger* 325

Economics of Education – Markets, Incentives and School Choice

- Competition and Student Performance *A A Payne* 331
- Educational Privatization *C Belfield and H M Levin* 337

Student Incentives	<i>E R Eide and M H Showalter</i>	342
The Economic Role of the State in Education	<i>D N Plank and T E Davis</i>	347
The Economics of Catholic Schools	<i>W Sander and D Cohen-Zada</i>	354
The Economics of Charter Schools	<i>R Zimmer and R Buddin</i>	360
The Economics of Parental Choice	<i>R Chakrabarti and J Roy</i>	367
The Economics of School Accountability	<i>D N Figlio and H F Ladd</i>	374
The Efficacy of Educational Vouchers	<i>R Zimmer and E P Bettinger</i>	380
Tiebout Sorting and Competition	<i>T J Nechyba</i>	388

Economics of Education – Production of Schooling

Desegregation, Academic Achievement and Earnings	<i>S Rivkin</i>	394
Education Production Functions: Concepts	<i>D N Harris</i>	402
Education Production Functions: Developed Country Evidence	<i>E A Hanushek</i>	407
Education Production Functions: Evidence from Developing Countries	<i>P Glewwe and S Lambert</i>	412
Family Environment in the Production of Schooling	<i>R Rothstein</i>	423
Neighborhoods and Peers in the Production of Schooling	<i>J Vigdor and J Ludwig</i>	431
Teacher Quality in Education Production	<i>I Pelayo and D J Brewer</i>	438
The Economics of Class Size	<i>D W Schanzenbach</i>	443
The Economics of Early Childhood Interventions	<i>M Nores</i>	450

Economics of Education – Teaching Labor Markets

An Overview of Teacher Labor Markets	<i>H Lankford and J Wyckoff</i>	456
Compensating Differentials in Teacher Labor Markets	<i>J Chambers</i>	465
Economic Approaches to Teacher Recruitment and Retention	<i>S Loeb and J Myung</i>	473
Teacher Incentives	<i>L Santibañez</i>	481
Teacher Supply	<i>P Dolton</i>	489
Teacher Training and Preparation in the United States	<i>M Podgursky, M G Springer, and R Hutton</i>	498
Teachers in Developing Countries	<i>F H Rogers and E Vegas</i>	504
The Economics of Teachers' Unions in the United States	<i>K Strunk</i>	512

Education of Children with Special Needs

Adapted Physical Activity for Students with Special Needs	<i>S R Hodge</i>	519
Assessment Accommodations for Children with Special Needs	<i>R J Kettler and S N Elliott</i>	530
Assistive Technology and Educational Practice	<i>H P Parette and G R Peterson-Karlan</i>	537
Augmentative–Alternative Communication	<i>C Mason and K M Chinn</i>	544
Community Integration and Employment of Youth with Special Needs	<i>B A Ford and A W Daviso III</i>	550
Cooperative Learning for Children with Special Needs	<i>E A Dooley and K R Kossar</i>	555
Co-Teaching	<i>E D Cramer</i>	560
Cultural and Linguistic Diversity and Children with Special Needs	<i>J M Patton, N Day-Vines, and A McSwain</i>	565
Curriculum-Based Assessment and Students with Special Needs	<i>D J O'Shea and J D Katsafanas</i>	571

Diagnosis and Classification	<i>M Sapp</i>	577
Direct Instruction and the Education of Children with Special Needs	<i>T Mehring</i>	584
Disabilities and Gifted Education	<i>V I Daniels and M J McCollin</i>	588
Early Childhood Special Education: Birth to Eight Years Old	<i>T S Lovelace, R Gardner III, J B Axe, and D M Sainato</i>	594
Early Intervention for Students with Special Needs	<i>P A Grant</i>	608
Early Transition of Children with Special Needs	<i>S A Fowler</i>	613
Educating Children Who are Deaf-Blind	<i>J Wood and K M Chinn</i>	621
Educating Children with Deafness and Hearing Impairments	<i>G M Mukuria and C J Eleweke</i>	628
Educating Children with Other Health Impairments (ADHD)	<i>G M Mukuria and F E Obiakor</i>	634
Educating Children with Physical Disabilities	<i>Z P Nkabinde, F E Obiakor, M T Ofor, and D J Smith</i>	640
Educating Children with Specific Learning Disabilities	<i>P A Grant and P B Grant</i>	646
Educating Children with Speech and Language Disorders	<i>S L Green and C D Qualls</i>	654
Educating Students with Autism and Related Disorders	<i>T T Dyches</i>	661
Educating Students with Cognitive Disabilities	<i>J P Bakken</i>	669
Educating Students with Emotional and Behavioral Disorders	<i>S W Smith and G G Taylor</i>	678
Educating Students with Special Needs: An Overview	<i>F E Obiakor, M K Harris, P Harris-Obiakor, and G M Mukuria</i>	688
Educating Students with Traumatic Brain Injury	<i>S Burkhardt and A Rotatori</i>	695
English Language Learners with Special Needs	<i>R Rueda and G Ragusa</i>	701
Functional Behavioral Assessment	<i>J P Bakken</i>	708
History of Special Education	<i>L M Garrick Duhaney and S J Salend</i>	714
Inclusion of Students with Special Needs in General Education Classrooms	<i>M A Prater</i>	721
Instructional Accommodations for Children with Special Needs in Inclusive Settings	<i>A L Yurick, S Musti-Rao, and G Cartledge</i>	727
Interagency Agreements	<i>L A Owens</i>	733
Interdisciplinary Collaboration in Early Childhood	<i>N File</i>	739
Language Development in Children with Special Needs	<i>M S L Stewart</i>	745
Large Scale Assessment and Accountability and Students with Special Needs	<i>M L Thurlow</i>	752
Literacy Instruction for Students with Special Needs	<i>L H Mason</i>	759
Math Instruction for Children with Special Needs	<i>B A Bottge</i>	767
Overrepresentation of Culturally and Linguistically Diverse Students in Special Education	<i>S C Trent</i>	774
Paraprofessionals in Special Education	<i>B Y Ashbaker, S C Dunn, and J Morgan</i>	780
Parent and Family Involvement in the Education of Children with Special Needs	<i>L P Prater</i>	788
Peer Relations and Socialization of Children and Adolescents with Special Needs	<i>L M Bullock, M Wong-Lo, and R A Gable</i>	794
Peer-Tutoring	<i>L J O'Shea and D J O'Shea</i>	802
Postsecondary Participation of Students with Special Needs	<i>R A Stodden and K D Roberts</i>	808
Prereferral Strategies	<i>C G Simpson and J P Bakken</i>	815

Preventing Antisocial Behavior and Delinquency: A Comprehensive School-wide Approach <i>P R Hallam, K R Young, P Caldarella, D G Wall, and L Christensen</i>	820
Programs and Instructional Strategies for Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	829
Related Services for Children with Special Needs <i>S O Obi</i>	834
Risk and Resilience Frameworks in Understanding Special Education <i>W-Y Hsieh and M L Donahue</i>	840
School Dropout Prevention <i>F E Obiakor</i>	845
School-Based Services for Children with Special Needs <i>S O Obi</i>	850
Self-Determination <i>M L Wehmeyer</i>	857
Social Competence <i>L A Owens and S Johnston-Rodriguez</i>	865
The Identification of Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	870
Transition from School to Adult Life <i>M J McCollin and F E Obiakor</i>	876
Visual Impairment <i>W Sapp</i>	880
Workforce Issues in Special Education <i>E Carlson and B Billingsley</i>	886

VOLUME 3

Education of Professionals

An Overview of Accreditation, Certification, and Licensure Processes <i>J J Norcini and M van Zanten</i>	1
Educating America's Military Officers <i>M H Adamshick</i>	7
Education for Architecture in the United States and Canada <i>S Schreiber</i>	13
Education for Medicine <i>M B Anderson</i>	19
Education for the Legal Profession <i>J W Wegner</i>	25
Education of Clergy <i>D O Aleshire</i>	31
Framing Professions Education <i>P S O'Sullivan</i>	37
Issues in Accounting/Business Education <i>W H Gijsselaers and R G Milter</i>	39
Professions – Engineering <i>J Heywood</i>	45
Professions – Health-Related <i>G M Jensen and C B Royeen</i>	51
Professions – Pharmacy <i>D E Beck</i>	58
Teaching for the Complex Practice of Nursing <i>P Benner and M Sutphen</i>	65
Veterinary Education <i>K M Edmondson</i>	71

Education Research Methodology: Quantitative Methods and Research

Abductive Research Methods <i>B D Haig</i>	77
Field Experimentation in Education <i>M A Constat</i>	83
Internal Validity <i>M H Clark and S C Middleton</i>	90
Methods for Approximating Random Assignment <i>B Schneider and S-K McDonald</i>	97
Methods for Approximating Random Assignment: Regression Discontinuity and Propensity Scores <i>L M Scheier</i>	104

Multitrait–Multimethod Designs	<i>M Bong and S Hong</i>	111
Multivariate Longitudinal Data Analysis	<i>H Liu and L Chang</i>	120
Quasi-Experimentation: Two Group Design	<i>E Hong</i>	128
Regression Discontinuity Designs	<i>A Kelava, S Rohrmann, and V Hodapp</i>	134
Sampling	<i>R S Brown</i>	142
Statistical Conclusion Validity	<i>P L Busk</i>	147
Survey Research Methods	<i>A Fink</i>	152

Educational Assessment

An Overview of Educational Assessment	<i>M James</i>	161
Assessment and the Evaluation of Institutional Effectiveness	<i>S M Thomas</i>	172
Assessment in Schools – Dispositions	<i>R D Crick</i>	181
Assessment in Schools Related To Literacy: Reading	<i>K J Topping</i>	189
Impact of Assessment on Students' Learning Strategies and Implications for Judging Assessment Quality	<i>M Segers, F Dochy, and D Gijbels</i>	196

Educational Assessment – Assessment Activities

Alternative Assessment	<i>G Stobart and C Gipps</i>	202
Classroom Assessment Tasks and Tests	<i>J Phelan and J Phelan</i>	209
Dynamic Assessment	<i>J G Elliott, E L Grigorenko, and W C M Resing</i>	220
Instructional System Provided Feedback	<i>H F O'Neil, S Chuang, and T Huang</i>	226
Peer and Self-assessment	<i>C Harrison</i>	231
Portfolio Assessment	<i>V Klenowski</i>	236
Records of Achievement: Beyond Traditional Tests	<i>P Broadfoot</i>	243

Educational Assessment – Assessment in Domains

Assessment in Higher Education	<i>D R Sadler</i>	249
Assessment in Schools – Affective Domain	<i>M Ventura, R D Roberts, and M Zeidner</i>	256
Assessment in Schools – Creative Subjects	<i>T E Costantino and L Bresler</i>	262
Assessment in Schools – Learning to Learn	<i>A Hautamäki, J Hautamäki, and S Kupiainen</i>	268
Assessment in Schools – Literacy Writing (Extended)	<i>J M Parr and L Earl</i>	273
Assessment in Schools – Mathematics	<i>M Brown and J Hodgen</i>	279
Assessment in Schools – Oracy	<i>A L Bailey</i>	285
Assessment in Schools – Primary Science	<i>W Harlen</i>	293
Assessment in Schools – Secondary Science	<i>J Shemwell, A Fu, M Figueroa, R Davis, and R Shavelson</i>	300
Assessment in Schools – Technology Education and ICT	<i>A Jones, B Cowie, and J Moreland</i>	311
Assessment in the Early Years	<i>M J Drummond</i>	316
Assessment in the History, Civics and Social Studies Domains	<i>P G Avery</i>	323
Assessment in the Workplace of Performance, Developing Expertise and Competence	<i>A J Brown</i>	330
Assessment in Vocational Education	<i>K Ecclestone</i>	337

Educational Assessment – Concepts and Issues

Assessing Group Work	<i>M Galton</i>	342
Assessment and the Regulation of Learning	<i>L Allal</i>	348
Challenges of Developing and Implementing Formative Assessment Practices in Schools	<i>R Sutton</i>	353
Formative Assessment	<i>P Black</i>	359
Formative Assessment and Instructional Planning	<i>B Marshall</i>	365
Progression and Assessment: Developmental Assessment	<i>M Forster and G Masters</i>	369
Students' Rights in Assessment and Evaluation	<i>J Gardner and B Holmes</i>	378
Summative Assessment by Teachers	<i>R Daugherty</i>	384
The Multiple Purposes of Assessment	<i>P E Newton</i>	392
The Relationship between Assessment and the Organization and Practice of Teaching	<i>L B Resnick, D William, R Apodaca, and E S Rangel</i>	397

Educational Assessment – Enhancing Quality and Use

Assessment Conversations: Reading and Writing Conferences with Students and with Parents	<i>M Barrs</i>	403
Assessment: Pre-service and In-service Teacher Education	<i>A Davies</i>	410
Classroom Assessment in Policy Context (Australia)	<i>J J Cumming</i>	417
Classroom Assessment in Policy Context (England and France)	<i>M Osborn and M Raveaud</i>	425
Classroom Assessment in Policy Context (French Sources)	<i>D Laveault</i>	432
Classroom Assessment in Policy Context (Hong Kong)	<i>D Carless</i>	438
Classroom Assessment in Policy Context (New Zealand)	<i>T J Crooks</i>	443
Classroom Assessment in Policy Context (Sub-Saharan Africa)	<i>S J Howie, L Zimmerman, and K Draper</i>	449
Moderation of Student Work by Teachers	<i>G S Maxwell</i>	457
School Policies and Practices to Support Effective Classroom Assessment for Learning	<i>D Pedder</i>	464
Student Assessment: Policy and Practice in Eastern Europe	<i>G Bethell</i>	472

Educational Assessment – Key Relationships

Assessment Practice in Policy Context: Latin American Countries	<i>F M Rizo</i>	479
Impact of Assessment on Learner Groups (Boys/Girls)	<i>J Elwood</i>	486
Impact of Assessment on Learner Groups (Disabilities)	<i>M Rouse</i>	492
Impact of Assessment on Students' Test Anxiety	<i>P Buchwald and C Schwarzer</i>	498
Impact of Assessments on Classroom Practice	<i>J L Herman</i>	506
Social Practices in School Assessment and their Impact on Learner Identities	<i>A Pollard and A Filer</i>	512

Educational Evaluation – Concepts, Practice, and Future Directions

Educational Evaluation: Concepts, Practice, and Future Directions	<i>Y J Ni</i>	518
---	---------------	-----

Educational Evaluation – Contemporary Themes in Evaluation

Evaluating E-Learning	<i>D D Williams and C R Graham</i>	530
Evaluating Schools as Learning Communities	<i>S M Thomas</i>	539
Evaluation of Adult Education and Training Programs	<i>G McNamara, P Joyce, and J O'Hara</i>	548
Evaluation of Integrated Health Programs in School	<i>T M Franke</i>	555

Formative Assessment in Teacher Education and Teacher Professional Development	<i>H Tillema</i>	563
Informal Education and Evaluation	<i>T Jeffs</i>	572
Methods to Evaluate Technology	<i>W L Bewley</i>	578

Educational Evaluation – Contexts of Educational Evaluation

Cost Analysis in Evaluation Studies	<i>J D Fletcher</i>	585
Cultural Issues that Can Affect the Validity of Educational Evaluations	<i>R P Durán</i>	592
Evaluation and Accountability	<i>E Sato and S N Rabinowitz</i>	600
Evaluation Governance and Planning	<i>R Picciotto</i>	607
Evaluation Use	<i>V G Thomas</i>	614
Moral and Ethical Issues in Evaluation	<i>M Morris</i>	622
The Role of Stakeholders in Educational Evaluation	<i>S Taut and M C Alkin</i>	629

Educational Evaluation – Evaluation Domains

Curriculum Evaluation	<i>T Levin</i>	636
Evaluating Education in Three Policy Eras	<i>M A Peters, R Britez, and S M Weber</i>	645
Evaluation of Mathematics Education Programs	<i>J Cai</i>	653
Evaluation of Science Education Programs	<i>G Berberoğlu</i>	660
Evaluation of Social Studies and Civic Education Programs	<i>S G Grant</i>	667
Evaluation of Teacher Quality and Practice	<i>W Robinson and J Campbell</i>	674
International Evaluations	<i>A Schleicher</i>	681
National Assessment Programs: The Example of the U.S. National Assessment of Educational Progress	<i>M Schneider</i>	690
Principal Evaluation: Concepts, Needs and Realities	<i>N S Glasman and L D Glasman</i>	698
Program Evaluation	<i>C A Christie and L A Fierro</i>	706
School Based Evaluation: Purposes, Protocols and Processes	<i>J MacBeath</i>	713
School Inspection/External School Evaluation	<i>C Chapman and P Earley</i>	719
The International System for Teacher Observation and Feedback: A Theoretical Framework for Developing International Instruments	<i>L Kyriakides, B P M Creemers, C Teddlie, and D Muijs</i>	726

Educational Evaluation – Evaluation Methods

Evaluation Methodology	<i>M Chatterji</i>	735
Evaluation Reporting and Communicating	<i>R T Torres</i>	746
Longitudinal Evaluation Designs	<i>X Ma</i>	757
Meta-evaluation: Purpose, Prescription, and Practice	<i>L A Wingate</i>	765

Educational Evaluation – Purposes and Models of Educational Evaluation

Defining Quality in Evaluation	<i>P Dahler-Larsen</i>	775
Internal and External Evaluation	<i>D Nevo</i>	781
Needs Assessment in Education	<i>J W Altschuld and T L Lepicki</i>	786
The Purpose of Educational Evaluation	<i>S Mathison</i>	792
Understanding Approaches to Evaluation	<i>A J Love</i>	798

VOLUME 4**Educational Measurement**

Ability Testing	<i>P B Tymms</i>	1
Admissions Testing	<i>R Zwick</i>	7
Appropriateness Measurement: Person Fit	<i>R R Meijer and A M Weekers</i>	15
Automated Essay Scoring: Writing Assessment and Instruction	<i>M D Shermis, J Burstein, D Higgins, and K Zechner</i>	20
Classical Test Theory Reliability	<i>M D Miller</i>	27
Criterion-Referenced Measurement	<i>S A Shrock and W C Coscarelli</i>	31
Differential Item Functioning	<i>M D Hidalgo and J Gómez-Benito</i>	36
Educational Measurement: Overview	<i>R L Linn</i>	45
Equating and Scaling	<i>A A von Davier</i>	50
Fairness	<i>C Gipps and G Stobart</i>	56
Generalizability Theory	<i>R L Brennan</i>	61
Impact of Assessment on Classroom Practice	<i>J L Herman</i>	69
Intelligent Systems	<i>V J Shute and D Zapata-Rivera</i>	75
Item Response Theory	<i>W J van der Linden</i>	81
National Assessments	<i>T J Crooks</i>	89
Norm-Referenced Measurement	<i>H D Hoover</i>	95
Progress Monitoring	<i>L S Fuchs and D Fuchs</i>	102
Rasch Models	<i>D Andrich</i>	111
Scoring Rubrics	<i>J A Arter</i>	123
Second Language Assessment	<i>L F Bachman</i>	140
Self Adaptive Testing	<i>J Revuelta</i>	148
Student Test Results in School Accountability	<i>L S Hamilton</i>	153
Test Development	<i>S M Downing</i>	159
Test Translation and Adaptation	<i>A Allalouf and P Hanani</i>	166
Testing Creativity	<i>M A Runco</i>	170
Testing in History	<i>S Wineburg and B Fogo</i>	175
Validity	<i>R L Linn</i>	181
Validity of Achievement Gains on High-Stakes Tests	<i>D Koretz</i>	186
Validity of Educational Indicators	<i>B P M Creemers and L Kyriakides</i>	193

G**Globalization of Universities and Institutions**

Globalization, Universities and Medium of Instruction	<i>J Lo Bianco</i>	201
The Washington Accord on Engineering Curriculum	<i>E Ko</i>	209

H

Higher Education

Higher Education: An Overview	<i>P Scott</i>	217
-------------------------------	----------------	-----

Higher Education – Management, Leadership and Governance

Academic Managers – Heads of Departments/Schools	<i>S Marshall</i>	229
Leading and Managing the University – Presidents and their Senior Management Team	<i>R Middlehurst, T Kennie, and S Woodfield</i>	238
Management of and in Higher Education Institutions	<i>B Sporn</i>	245
Managerialism and Collegialism in Higher Education Institutions	<i>M Shattock</i>	251
Strategic Planning in Higher Education	<i>L Zechlin</i>	256
The Changing Role of University Presidents, Vice-Chancellors and Rectors	<i>M F Green and P D Eckel</i>	264
The Changing Roles of University Governing Boards and Councils	<i>J Fielden</i>	273

Higher Education – Research and Scholarship

Funding of University Research	<i>G Harman</i>	279
Mobility of PhD Students and Scientists	<i>S Avveduto</i>	286
National Science Policy and Universities	<i>M Henkel and U Kogan</i>	294
Research Commercialization	<i>S Slaughter</i>	300
Research Quality Assessment	<i>I McNay</i>	307
The Management of University Research	<i>J Kirkland</i>	316
The Training of New Scientists	<i>R Neumann</i>	322

Higher Education – Society

Academic Freedom	<i>S F Macintyre</i>	328
Access and Equity in Higher Education	<i>G Baldwin and R James</i>	334
Boundaries of Institutional Autonomy and their Impact on Higher Education	<i>V L Meek</i>	341
Diversity of Higher Education	<i>U Teichler</i>	347
Employability of University Graduates and Graduate Outcomes	<i>J Brennan</i>	354
Higher Education and the Knowledge Society	<i>J Välimaa</i>	360
Higher Education and the Labor Market	<i>J Enders</i>	365
Higher Education and the Transformation of Society	<i>P Scott</i>	370
Quality Assurance in Higher Education – Practices and Issues	<i>D Dill</i>	377
The Role of Accreditation of Higher Education Institutions	<i>J S Eaton</i>	384
Universities and Regional Development	<i>J Goddard and J Puukka</i>	390
Universities' Engagement with Society	<i>D Watson</i>	398

Higher Education – Teaching and Learning in Higher Education

Distance Education and Open Universities	<i>A Kanwar and J Daniel</i>	404
Education Development in Higher Education	<i>Y Ryan and K Fraser</i>	411
Effective Use of Technology in Teaching and Learning in HE	<i>D Laurillard</i>	419

Facilitating Students' Success – Student Support and Learning Resources in Universities	<i>E Woodberry and C Barnes</i>	427
Faculty Values and Expectations and Their Implications for Teaching, Learning and the Organization of Higher Education Institutions	<i>K Harman</i>	433
Flexible Learning in Higher Education	<i>S Alexander</i>	441
Innovation in Teaching and Curriculum Design	<i>J M Dearn</i>	448
Productivity of University Faculty Staff	<i>S Kyvik</i>	455
Promoting Effective Student Learning in Higher Education	<i>K Trigwell</i>	461
Student Attrition from Higher Education Institutions	<i>M Hayden</i>	467
University Students' Experiences of Higher Education	<i>C McInnis</i>	473
What Do University Students Learn?	<i>G D Kuh and B K Bridges</i>	479

Higher Education – Tertiary Education in a Globalized World

Associations of Universities	<i>G F Moodie</i>	485
Collective Bargaining in Higher Education	<i>C Allport, K McAlpine, and S Roberts</i>	491
Financing of Higher Education	<i>B Chapman and P Tulip</i>	499
Higher Education Crossing Borders	<i>J Knight</i>	507
Higher Education in Post-Conflict Societies	<i>M Daxner</i>	514
Higher Education in the New Economies	<i>J Fielden</i>	520
Human Resource Issues in Higher Education	<i>E El-Khawas</i>	527
International Accreditation in Higher Education	<i>A Stella and D Woodhouse</i>	533
Internationalization of Higher Education	<i>M van der Wende</i>	540
National and International Rankings of Higher Education	<i>S Marginson</i>	546
Steering of Higher Education Systems – The Role of the State	<i>K Yokoyama and V L Meek</i>	554
Student and Faculty Transnational Mobility in Higher Education	<i>U Lanzendorf and B M Kehm</i>	559
The Bologna Process in European Higher Education	<i>D Rich</i>	566
The Economics and Finance of Higher Education	<i>A Wolf</i>	573
The Role of the OECD in the Development of Higher Education in a Globalized World	<i>R Yelland</i>	584
Transforming Higher Education in Developing Countries: The Role of the World Bank	<i>J Salmi and R M Bassett</i>	590
UNESCO's Role in the Development of Higher Education in a Globalized World	<i>S Uvalić-Trumbić</i>	597

Higher Education – The Organization and Financing of Higher Education

Higher Education in Federal Systems	<i>M A M Cortés and U Teichler</i>	603
Pathways and Articulation into Higher Education	<i>G F Moodie</i>	609
Unitary, Binary and other National Systems of Higher Education	<i>L Goedegebuure</i>	616
Viewing Private Higher Education: How Much, Where, Why, and What?	<i>D C Levy</i>	622

I

Immigration

Children of Migrant Populations	<i>M M Suárez-Orozco and C Suárez-Orozco</i>	629
Third Culture Kids	<i>R E Van Reken</i>	636

International Comparisons

IEA Studies in ICT	<i>N Law</i>	644
IEA Studies in Mathematics and Science	<i>F K S Leung</i>	650
IEA Study in Civic Education	<i>J Torney-Purta, J-A Amadeo, and J Schwillie</i>	656
IEA: Globalization and Assessment	<i>H Wagemaker</i>	663

International Organizations in Education

Education and the European Union	<i>S Hegarty</i>	669
National University on Educational Planning and Administration, New Delhi	<i>J B G Tilak</i>	676
On School Management – International Council on School Effectiveness and Improvement, Commonwealth Council on Educational Administration and Management	<i>A Walker and T Townsend</i>	681
UNESCO's International Institute for Educational Planning	<i>S J Hite and M Bray</i>	688

L**Leadership and Management**

Leadership and Management Overview	<i>B Mulford</i>	695
------------------------------------	------------------	-----

Leadership and Management – as a Field of Study

Contexts for Leadership at the Beginning of the 21st Century	<i>M Bottery</i>	704
Educational Leadership: Philosophical Issues	<i>C W Evers</i>	710
Ethical/Moral Issues in Educational Leadership	<i>R J Starratt, L Langlois, and P Duignan</i>	717
History of Educational Leadership/Management	<i>R Bates</i>	724
Educational Leadership as a Field of Study: Professional Journals 1994–2006	<i>A R Thomas</i>	731
Research on Educational Leadership – Approaches/Promising Directions	<i>W A Firestone and V M J Robinson</i>	740

Leadership and Management – Leader Preparation

Leaders for Productive Schools	<i>J Murphy, S N Elliott, E B Goldring, and A C Porter</i>	746
New Approaches in Preparing School Leaders	<i>S G Huber</i>	752
Research for Leaders: The National College for School Leadership	<i>G Southworth</i>	762
School Leadership Standards	<i>L Ingvarson</i>	768

Leadership and Management – Leadership Issues

Effective Leadership in Challenging Schools	<i>A Harris</i>	777
Esthetics, Educational Leadership and Management	<i>R Bates</i>	783
Leader Mistreatment of Teachers	<i>J Blase and J Blase</i>	790
Leadership and Gender	<i>J Blackmore</i>	797
Leadership and Student Voice	<i>C Lanskey and J Rudduck</i>	803
Leadership and Urban Education	<i>K A Riley</i>	809
Leadership for Learning	<i>J MacBeath</i>	817
Leadership in Diverse Cultures	<i>A Walker and P K Yu-kwong</i>	824

Leading Diverse Schools	<i>J Ryan</i>	832
Supervision and Personnel Administration	<i>P D Tucker and D G Pounder</i>	839
The Big Challenge: Leadership for Inclusion	<i>M Ainscow and A Sandill</i>	846
The Educational Leader's New Work	<i>P Gronn</i>	852

VOLUME 5

Leadership and Management – Leadership Types

A Distributed Perspective on School Leadership and Management	<i>J P Spillane</i>	1
Leadership: Authentic	<i>P T Begley</i>	7
Leadership: Democratic	<i>J Møller</i>	12
Leadership: Instructional	<i>P Hallinger, K Leithwood, and R H Heck</i>	18
Leadership: Transformative	<i>C M Shields</i>	26
Strategic Leadership	<i>B Davies and B J Davies</i>	34
Teacher Leadership and Organizational Development	<i>A Harris</i>	40
Understanding How Leadership Influences Student Learning	<i>K Leithwood and B Levin</i>	45

Leadership and Management – Politics and Governance

Equity and Educational Effectiveness	<i>P Sammons</i>	51
Leading/Managing Schools in Communities Made Poor	<i>P Thomson</i>	58
Principals Role in Restructuring Schools	<i>G M Crow and K D Peterson</i>	66
School Reform and Restructuring: Self Managing School	<i>B J Caldwell</i>	72
System Leadership	<i>D Hopkins and R Higham</i>	78

Leadership and Management – School and Community

Educational Leadership and Social Capital	<i>J West-Burnham</i>	85
Networked Learning Communities School-to-School Collaboration as an Essential Component of a System Reform Strategy	<i>D Jackson</i>	92
Networks and Communities of Knowledge	<i>T Schuller and H Theisens</i>	100
School Community Relations	<i>R L Crowson and E B Goldring</i>	106
Social Capital, Educational Institutions and Leadership	<i>S Kilpatrick, S Johns, and B Mulford</i>	113

Leadership and Management – School Effectiveness and Improvement

Leadership and Technology	<i>C F Webber</i>	120
Leadership in the Implementation of Innovations	<i>I E Bogotch, T Townsend, and M Acker-Hocevar</i>	128
Leadership: School Improvement	<i>R H Heck and P Hallinger</i>	135
Organizational Learning in Schools	<i>B Mulford and H Silins</i>	143
Professional Learning Community	<i>L Stoll</i>	151
Transformational School Leadership	<i>K Leithwood</i>	158

Learning and Cognition – Issues and Concepts

Attention in Cognition and Early Learning	<i>M Heimann, T Tjus, and K Strid</i>	165
Concept Learning	<i>S J Unsworth and D L Medin</i>	172
Cooperative Learning	<i>R E Slavin</i>	177
Intelligence	<i>R J Sternberg</i>	184
Learning from Multiple Information Sources	<i>H I Strømsø and I Bråten</i>	191
Memory	<i>S Magnussen and T Brennen</i>	197
Metacognition	<i>L Baker</i>	204
Personal Epistemology in Education: Concepts, Issues, and Implications	<i>I Bråten</i>	211
Piaget: Recent Work	<i>L Smith</i>	218
The Adult Development of Cognition and Learning	<i>E A L Stine-Morrow and J M Parisi</i>	225
Vygotsky and Recent Developments	<i>J V Wertsch</i>	231

Learning and Cognition – Issues and Concepts – Focus on Cognition

Cognition and Emotion	<i>F Pons, M de Rosnay, and F Cuisinier</i>	237
Cognition: Overview and Recent Trends	<i>J Wiley and B D Jee</i>	245
Development of Creativity	<i>M A Runco</i>	251
Knowledge Domains and Domain Learning	<i>L Maggioni and P A Alexander</i>	255
Problem Solving and Human Expertise	<i>T J Nokes, C D Schunn, and M T H Chi</i>	265
Problem Solving and Reasoning	<i>R E Mayer</i>	273
Reasoning, Moral and Social	<i>N S Jampol, C B Richardson, and M Killen</i>	279
Remembering as Social Activity	<i>D Middleton</i>	285

Learning and Cognition – Issues, Concepts, Types

Computer-Supported Collaborative Learning: Basic Concepts, Multiple Perspectives, and Emerging Trends	<i>S R Ludvigsen and A I Mørch</i>	290
Learning as Inquiry	<i>S R Goldman, J Radinsky, S Tozer, and D Wink</i>	297
Learning Through Narrative Socialization	<i>A Fasulo</i>	303
Neuroscience Bases of Learning	<i>M H Immordino-Yang and K W Fischer</i>	310
The Neuroscience of Reading	<i>U Goswami</i>	317

Learning and Cognition – Issues, Concepts, Types – Focus on Learning

Learning Strategies	<i>C E Weinstein, J Jung, and T W Acee</i>	323
Learning Through Play	<i>K Aronsson</i>	330
Situated View of Learning	<i>A Collins and J G Greeno</i>	335
The Neuroscience of Aging and Cognition	<i>W J Hoyer and B Bessette-Symons</i>	340

Learning and Cognition – Language, Literacy and Subject-Related

An Overview of Language and Literacy in Educational Settings	<i>V G Aukrust</i>	345
Bilingualism and Learning	<i>L S Verplaetse and E Schmitt</i>	355
Classroom Discourse and Student Learning	<i>L Hemphill</i>	361
Early Writing	<i>B E Hagtvet</i>	367

First Language Acquisition	<i>N B Ratner</i>	375
Foreign Language Learning	<i>C Kinginger</i>	382
Learning Science	<i>J Leach and P Scott</i>	387
Learning to Read	<i>M S Burns and J K Kidd</i>	394
Mathematics Learning	<i>L Verschaffel, B Greer, and E De Corte</i>	401
Music Learning	<i>S Hallam</i>	407
Reading Comprehension: Reading for Learning	<i>C E Snow</i>	413
Second Language Learning	<i>J S Arnfast, J N Jørgensen, and A Holmen</i>	419
Writing: Advanced	<i>R Andrews</i>	426

Learning and Cognition – Other Issues

Gender and Learning	<i>L Yates and J McLeod</i>	432
Parent–Child Relationships in Early Learning	<i>C P Edwards, S M Sheridan, and L L Knoche</i>	438
Peer Interaction and Learning	<i>S Blum-Kulka and S Dvir-Gvirsman</i>	444

Learning and Cognition – Places of Learning

Learning in a Cross-Cultural Perspective	<i>L-F Zhang and R J Sternberg</i>	450
Learning Outside of School	<i>T Nunes</i>	457
Reasoning and Explanatory Talk: Learning in Everyday Settings	<i>D E Beals</i>	464

Learning and Cognition – Theoretical Perspectives – Learning

Apprenticeship Approach to Learning	<i>K Nielsen</i>	469
Connectionism and Learning	<i>T R Shultz</i>	476
Constructivism and Learning	<i>S Sjøberg</i>	485
Cultural–Historical Activity Theory	<i>A Havnes</i>	491
Learning in a Sociocultural Perspective	<i>R Säljö</i>	498
Self-Regulated Learning and Socio-Cognitive Theory	<i>P H Winne and A F Hadwin</i>	503

N

National Systems of Education

Australia	<i>C N Power</i>	510
Austria	<i>M J Gaertner</i>	517
Bangladesh	<i>R Z Dewan</i>	524
Barbados	<i>R Rudder</i>	534
Bulgaria	<i>A Chavdarova and D Vesselinov</i>	540
England	<i>C Whatford</i>	550
Estonia	<i>M Keränen and J Kõrgesaar</i>	555
Fiji	<i>I Senibulu</i>	563
Finland	<i>J E Tuovinen</i>	569
France	<i>M Sellier</i>	576

Germany	<i>A Hüfner and K Hüfner</i>	582
Ghana	<i>R Palmer</i>	590
Greece	<i>K Toura and A Karagiannis</i>	599
Iceland	<i>M Hardardottir and M Gunnlaugsdóttir</i>	605
Indonesia	<i>A C Alwasilah and Furqon</i>	611
Israel	<i>A Volansky</i>	618
Jamaica	<i>E Hannam</i>	627
Latvia	<i>A Joma</i>	630
Lebanon	<i>N A Mneimneh</i>	636
Lithuania	<i>J Navickaitė, L Paurienė, R Zablackė, A Tijūnelytė, and V Kožemiakina</i>	656
Malawi	<i>F R Mkandawire and D Mulera</i>	666
Malta	<i>C Farrugia</i>	673
Mongolia	<i>B Yembuu</i>	681
Namibia	<i>J Ellis</i>	687
New Zealand	<i>R Baker and C Wylie</i>	692
Niger	<i>A A I Daouda</i>	699

Solomon Islands	<i>D P Malasa</i>	790
South Africa	<i>P Kgobe and J Pampallis</i>	799
Spain	<i>A Tiana</i>	806
Sri Lanka	<i>B M J Balasooriya, M M Wehella, and S U Wijeratne</i>	813
Suriname	<i>H R Ori</i>	826
Taiwan	<i>C-M Lee</i>	834
Tanzania	<i>R Wedgwood</i>	841
Thailand	<i>C Rukspollmuang</i>	847
The Gambia	<i>Y A-M Jobe</i>	858
The Philippines	<i>E A P Valenzuela</i>	865
Uruguay	<i>B Guinovart and C Troncoso</i>	873
USA	<i>B Pusser and M E R Lloyd</i>	888
Zanzibar	<i>I M Hija</i>	896

VOLUME 6**P****Philosophy of Education**

Philosophy of Education: Overview	<i>P Enslin</i>	1
-----------------------------------	-----------------	---

Philosophy of Education – Contemporary Issues

Neoliberalism, the Market and Performativity	<i>M A Peters</i>	11
Parents and Children's Rights	<i>M Clayton</i>	17
Peace Education	<i>I Gur-Ze'ev</i>	22
Philosophy and Educational Research	<i>D Bridges</i>	29
Race, Critical Race Theory and Whiteness	<i>B Applebaum</i>	36
School Choice and the Common School	<i>G Haydon</i>	44

Philosophy of Education – Philosophical Perspective

African Philosophy of Education	<i>K Horsthemke</i>	50
Feminism	<i>L Stone</i>	56
Hermeneutics	<i>C Bingham</i>	63
Islamic Education	<i>Y Waghid</i>	69
Liberalism and Education	<i>W Feinberg</i>	74
Phenomenology and Existentialism	<i>B Levering</i>	80
Pragmatism	<i>B Thayer-Bacon</i>	86
Psychoanalysis and Education	<i>P Smeyers</i>	92
Social and Cultural Capital in Education	<i>M Print</i>	97
The Aims of Education	<i>R Marples</i>	103
The Analytical Tradition	<i>D Carr</i>	108

Philosophy of Education – Philosophical Themes

Adult Learning: Philosophical Issues	<i>D Beckett</i>	114
Autonomy	<i>C A Wringe</i>	121
Bildung	<i>J Masschelein and N Ricken</i>	127
Critical Theory and Pedagogy	<i>M Mason</i>	133
Critical Thinking	<i>H Siegel</i>	141
Environmental Education	<i>M Bonnett</i>	146
Identity	<i>M S Merry</i>	152
Inclusion	<i>R Cigman</i>	158
Justice and Care	<i>M Tjiattas</i>	164
Lifelong Learning	<i>J Halliday</i>	170
Post-Structuralism and Education	<i>M Mason and M Clarke</i>	175
Reason and Rationality	<i>P Hogan</i>	183

Religious and Spiritual Education	<i>J C Conroy and S J McKinney</i>	189
The Capabilities Approach	<i>L Terzi</i>	194

Primary and Secondary Education – Learning and Teaching in School Age Education

Class Size – Arguments and Evidence	<i>P Blatchford and K C Lai</i>	200
Continuing Professional Development of Teachers	<i>P Earley</i>	207
Homeschooling	<i>P Farenga</i>	214
Innovations and Early Intervention in the Teaching of Literacy	<i>R E Slavin</i>	221
Personalized Learning in School Age Education	<i>D Hopkins</i>	227
Perspectives on Schooling in the Middle Years	<i>V J Russell</i>	233
Reform of the School Workforce	<i>H M Gunter and G Forrester</i>	242
Secondary Education in Developing Countries	<i>P Hughes and A Walker</i>	249

Primary and Secondary Education – Social Justice Issues in School Age Education

Community Focused Schools	<i>A Dyson</i>	255
---------------------------	----------------	-----

Primary and Secondary Education – The Effectiveness of School Systems

Reforming the American School System	<i>M Barber</i>	261
School Effectiveness in Developed Societies	<i>D Reynolds</i>	269
School to School Collaboration: Innovation and Improvement	<i>R Higham</i>	274
Studies of School Improvement in Developing Countries	<i>S E Anderson</i>	281
Sustainable Educational Reform	<i>A Hargreaves</i>	289
The Role of the District in Tri Level Reform	<i>M Fullan</i>	295
Whole School Designs for Enhancing Student Achievement	<i>S Stringfield and J Nunnery</i>	303

Q

Qualitative Research

Action Research in Education	<i>E Stringer</i>	311
Classroom Ethnography	<i>F Erickson</i>	320
Computer Assisted Qualitative Data Analysis	<i>C Silver and A Lewins</i>	326
Conversational Analysis	<i>H G Levine</i>	335
Critical Ethnography	<i>D Foley</i>	337
Critical Race Theory	<i>D Gillborn and G Ladson-Billings</i>	341
Critical Theory	<i>J J Ryoo and P McLaren</i>	348
Cultural Studies	<i>R Gaztambide-Fernández and K Cairns</i>	354
Cultural–Historical Activity Theory	<i>Laboratory for Comparative Human Cognition</i>	360
Design Experiments	<i>A Collins</i>	367
Discourse Analysis	<i>P Nikander and S Vehviläinen</i>	373
Document Analysis	<i>T Rapley and K N Jenkins</i>	380
Ethnography	<i>M Hammersley</i>	386

Ethnomethodology in Education Research	<i>D Macbeth</i>	392
Focus Groups	<i>D L Morgan and K Hoffman</i>	401
Grounded Theory	<i>K Charmaz and A Bryant</i>	406
Hermeneutics	<i>J Dyer</i>	413
Interpretive Research	<i>E Rauscher and M E Graue</i>	419
Interviews and Interviewing	<i>A Marvasti</i>	424
Life History	<i>J A Hatch and S K Newsom</i>	430
Narrative Inquiry	<i>D J Clandinin and J Huber</i>	436
Participant Observation	<i>J Schostak</i>	442
Phenomenology	<i>M van Manen and C A Adams</i>	449
Qualitative Case Studies	<i>S B Merriam</i>	456
Qualitative Data Management	<i>C Grbich</i>	463
Semiotics	<i>M Danesi</i>	475
Symbolic Interactionism, Naturalistic Inquiry, and Education	<i>J A Forte</i>	481
The Quality of Evidence in Qualitative Research	<i>S K Biklen</i>	488
Visual Data in Education Research	<i>J Wagner</i>	498

Qualitative Research – Standards of Proof

Validity: Mapping Diverse Perspectives	<i>G B Rossman, S F Rallis, and A M Kuntz</i>	505
--	---	-----

Quantitative and Qualitative Approaches to Research – Integration

Mixed Methods	<i>A Tashakkori and I Newman</i>	514
---------------	----------------------------------	-----

Quantitative Methods and Research Design

External Validity	<i>G E Matt, A Brewer, and M Sklar</i>	521
-------------------	--	-----

R

Role of NGOs in Globalization

NGOs and Globalization of Education	<i>M Ahmed</i>	529
-------------------------------------	----------------	-----

S

Social and Emotional Aspects of Learning

Achievement Goal Theory: Definitions, Correlates, and Unresolved Questions	<i>T Urdan</i>	537
Affect, Mood and Emotions	<i>S Schnall</i>	544
Anxiety	<i>M Zeidner</i>	549
Attribution Theory	<i>B Weiner</i>	558
Children's Friendship	<i>S R Asher and K L McDonald</i>	564
Coping with Stressful Situations: An Important Aspect of Self-Regulation	<i>M Boekaerts</i>	570
Culture in Motivation Research: A Challenging and Enriching Contribution	<i>K Kimmel and S Volet</i>	576
Early Social Development and Schooling	<i>G M van der Aalsvoort</i>	585

Emotion in Educational Contexts	<i>P A Schutz, P D Quijada, S de Vries, and M Lynde</i>	591
Empathy	<i>R Arnold</i>	597
Flow in Education	<i>J A Schmidt</i>	605
Interest	<i>M Ainley</i>	612
Intrinsic and Extrinsic Motivation	<i>C Levesque, K J Copeland, M D Pattie, and E L Deci</i>	618
Motivating Students in Classrooms	<i>J Brophy</i>	624
Motivation Regulation	<i>C A Wolters and S A Mueller</i>	631
Peer Learning in the Classroom	<i>N M Webb</i>	636
Poverty, Effects of on Social and Emotional Development	<i>N Philipsen Hetzner, A D Johnson, and J Brooks-Gunn</i>	643
Seeking Help as an Adaptive Response to Learning Difficulties: Person, Situation, and Developmental Influences	<i>S A Karabenick and R S Newman</i>	653
Self-Concept in Learning: Reciprocal effects model between academic self-concept and academic achievement	<i>H W Marsh and L F Scalas</i>	660
Self-Efficacy Beliefs	<i>D H Schunk and F Pajares</i>	668
Social and Emotional Outcomes of Learning	<i>J Vorhaus</i>	673
Social Aspects of Collaborative Learning	<i>M Arvaja and P Häkkinen</i>	685
Social Development and Schooling	<i>G W Ladd</i>	691
Social Interaction and Learning	<i>K Littleton</i>	698
Social Networks and the Education of Children and Youth	<i>B Schneider, T G Ford, and L Perez-Felkner</i>	705
Sociocultural Issues in Motivation	<i>R A Walker</i>	712
Socioemotional Aspects of Technology-Supported Learning	<i>S Järvelä</i>	718
Volitional Control of Learning	<i>J Husman and L Corno</i>	724
Wellbeing	<i>T Hascher</i>	732

VOLUME 7

Statistics

An Overview of Statistics in Education	<i>S Sinharay</i>	2
Analysis and Interpretation of Multivariate Data	<i>D J Bartholomew</i>	12
Analysis of Covariance	<i>N T Longford</i>	18
Analysis of Extreme Values in Education	<i>J Beirlant, G Dierckx, K Luwel, and P Onghena</i>	25
Analysis of Variance	<i>B M King</i>	32
Bayesian Statistical Analysis	<i>G Kokolakis</i>	37
Bootstrap Method	<i>K Singh and M Xie</i>	46
Canonical Correlation	<i>A Basu and A Mandal</i>	52
Categorical Data Analysis	<i>S E Fienberg and B W Junker</i>	58
Causal Inference	<i>D B Rubin</i>	66
Cluster Analysis: Overview	<i>S Landau and I Chis Ster</i>	72

Cognitive Psychology and Educational Statistics	<i>H S Kim and S Embretson</i>	84
Computational Statistics	<i>J E Gentle</i>	93
Continuous Probability Distributions	<i>S Sinharay</i>	98
Correspondence Analysis	<i>M Greenacre</i>	103
Data Mining	<i>R S J d Baker</i>	112
Decision Theory	<i>M Mendoza and E Gutiérrez-Peña</i>	119
Design of Experiments	<i>C A Albers and T R Kratochwill</i>	125
Discrete Probability Distributions	<i>S Sinharay</i>	132
Discrimination and Classification	<i>R C Neath and M S Johnson</i>	135
Empirical Bayes Methods	<i>E Ip and G Molenberghs</i>	142
Evaluation Research	<i>T Kellaghan</i>	150
Exploratory Data Analysis	<i>A Unwin</i>	156
Factor Analysis: An Overview and Some Contemporary Advances	<i>F A N Alhija</i>	162
Generalized Linear Mixed Models	<i>S Rabe-Hesketh and A Skrondal</i>	171
Generalized Linear Models	<i>J J Faraway</i>	178
Generating Random Numbers	<i>P J Pashley and A Amodeo</i>	184
Goodness-of-Fit Testing	<i>A Maydeu-Olivares and C García-Forero</i>	190
Graphical Models	<i>R G Almond</i>	197
Growth Modeling	<i>I Plewis</i>	203
Hierarchical Linear Models	<i>D Rindskopf</i>	210
Hypothesis Testing and Confidence Intervals	<i>T R Konold and X Fan</i>	216
Instrumental Variables	<i>E P Bettinger</i>	223
Jackknife Methods	<i>S Sinharay</i>	229
Large-sample Statistical Methods	<i>J M Singer and D F Andrade</i>	232
Latent Class Models	<i>J K Vermunt</i>	238
Markov Chain Monte Carlo	<i>A M Johansen</i>	245
Matrix Algebra	<i>H Yanai and H Ishii</i>	253
Measure of Association	<i>G-H Huang</i>	260
Measures of Central Tendency	<i>D Clark-Carter</i>	264
Measures of Dispersion, Skewness and Kurtosis	<i>D Rindskopf and M Shiyko</i>	267
Meta Analysis	<i>J Sánchez-Meca and F Marín-Martínez</i>	274
Missing Data	<i>C A W Glas</i>	283
Model Selection	<i>S J Haberman</i>	289
Monte Carlo Methods	<i>A M Johansen</i>	296
Multidimensional Scaling	<i>Z Zhang and Y Takane</i>	304
Multiple Comparisons	<i>C Lewis</i>	312
Multivariate Analysis of Variance	<i>N T Longford</i>	319
Multivariate Linear Regression	<i>S Ganesh</i>	324
Multivariate Normal Distribution	<i>J Tacq</i>	332

Nonlinear Regression Analysis	<i>H-H Huang, C K Hsiao, and S-Y Huang</i>	339
Nonparametric Statistical Methods	<i>K Sijtsma and W H M Emons</i>	347
Observational Studies	<i>P R Rosenbaum</i>	354
Order Statistics	<i>I Bairamov</i>	360
Point Estimation Methods with Applications to Item Response Theory Models	<i>F Bartolucci and L Scrucca</i>	366
Principal Components Analysis	<i>D J Bartholomew</i>	374
Probability Theory	<i>T Rudas</i>	378
Recursive Partitioning	<i>S Landau and S Barthel</i>	383
Sampling	<i>J Qian</i>	390

Glossary

Bell curve – Also known as the Gaussian distribution and the normal distribution. It refers to a frequency distribution commonly found in social science and specifically in relation to ability tests.

COMBSE – Confidential Measurement Based Self Evaluation. A monitoring project from schools which emphasises the formative use of performance indicators. It is now called ALIS (A-level information system).

Correlation – A numerical indicator of the degree of association between two variables. It can vary from -1 to 1 where 1 indicates a perfect positive association and 0 no association.

Ecological fallacy – An inferential error in which associations found in aggregate statistics are assumed to apply at the individual level.

Factor analysis – A statistical technique designed to simplify a dataset by building on patterns in the data. It involves extracting a small number of factors from information on a large number of items.

Heritability – Variation in observed traits amongst individuals can be due to environmental and genetic factors. Heritability is the proportion of variance attributable to genetic variance in a population.

IQ – Intelligence quotient. The term was first used in its German version by William Stern in 1912.

Item Response Theory – A modern assessment approach which puts testees and items on a single equal interval scale. It can accommodate items of varying difficulty, varying discrimination, and varying susceptibility to guessing.

Rasch – A unique modern approach to assessment which may be seen as a subset of Item Response Theory.

Introduction

Ability has two meanings. One refers to established competence such as the ability to run or do arithmetic and the other involves a prediction that somebody will be able to do something. In common parlance, ability can be taken to be either of these two things, but in the educational/psychological context, ability is taken to mean an indication of the propensity to be able to do something, an underlying trait which shows that someone, given the right opportunities, will demonstrate competence in an area. Some would call this intelligence but, as will be noted later, the word intelligence and its measurement to produce an intelligence quotient (IQ), have acquired negative connotations. Perhaps, as a result of this the word, ability is much more widespread and accepted in educational circles.

Historical Perspective

Much research has gone into the measurement of ability and its different types. It has a long history within education and much can be traced back to Binet's work in the latter part of the nineteenth and the early twentieth centuries in France where he was involved in an effort to try to find those pupils who were educable. Officials wanted a method which would bypass teachers' judgments which, it was felt, might be unduly influenced by the trouble that individuals caused. This led to the development of the Binet–Simon scale which was revised and extended at Stanford to produce the Stanford–Binet intelligence scale. This proved to be enormously popular particularly in the United States and elsewhere as well. It went through several revisions and was widely used by clinical and educational psychologists.

Since then, the interplay between researchers' understanding of the psychological constructs, their meaning,

and etiology have run in parallel with efforts within schools and classrooms to try to use the concept and measures of ability. Some of this research has produced theoretical perspectives such as the distinction proposed by Raymond Cattell between fluid and crystallized intelligence. Fluid ability is the capacity to reason and adapt to new situations whereas crystallized intelligence employs stores of information which have already been acquired and which can be applied or extended. Others have tried to look at component parts of ability and so at the structure of ability. Key workers in this area include Charles Spearman, Philip Vernon, J. P. Guilford, and John Carroll. They all subscribe to a general factor running across all abilities – an idea which originated with Spearman and which has more recently been linked to brain structure. It has been termed 'g' (general ability) and its existence is widely although not universally accepted. Carroll's work is the most extensive in this area. Much of this work has involved a statistical technique known as factor analysis which is not without criticism.

Howard Gardner's idea of multiple intelligences which are proposed to consist of linguistic, musical, logical–mathematical, spatial, bodily kinesthetic, and personal intelligences can be seen as an extension of the more psychometric approaches of Carroll and others but based on hypotheses (ideas which are yet to receive strong empirical backing). An alternative perspective comes from a systems approach taken by Robert Sternberg. It is known as the triarchic theory of successful intelligence. Essentially, the theory brings together the interplay between three systems, the internal working of the mind, the interface between the individual and his or her world (experience) and the external world.

Much of the work noted above comes from differential psychology. Others have concentrated on developmental psychology – the most famous worker in that field being Jean Piaget. A third related area is known as cognitive psychology which is concerned with the flow and processing of information. To a large extent, these three traditions have developed independently but recent serious work by Andreas Demetriou has sought to provide a theoretical basis for the manifestations of abilities that we see and to integrate work from the three areas.

Testing and Measurement

A good deal of research in differential psychology has been devoted to exploring the underlying constructs of ability using assessments (also known as tests) and there has been an interplay between the development of tests and theory as the one informs and influences the other. For the majority of research it has been common practice in measurement to use what is known as classical test theory, in which the results from a sample for testees are used as the norm reference to produce scales with known

means and standard deviations (standard scores). A scale with a mean as 100 and a standard deviation of 15 has been so commonly used in ability testing that it has come to be known as the IQ scale. However, it has always been appreciated that this is not a perfect system and indeed Gene Glass has called the process "... pseudoquantification, a meaningless application of numbers to a question not prepared for quantitative analysis." Various workers including L. L. Thurston, Raymond B. Cattell, and Georg Rasch have tried to put psychometrics onto a more satisfactory basis. This has led to equal interval scales of measurement which require the researcher to focus on a single construct. The testee and the items making up the test are both located on the same unidimensional scale. The simplest approach which has a wide following is known as Rasch measurement but it should be noted that some see Rasch as a subset of Item Response Theory. Purists see Rasch measurement as being a major advance for the social sciences moving it forward by engaging in fundamental measurement. Only with such measurement, it is argued, can social science be put on to a serious scientific base.

These theoretical debates and associated advances in psychometrics have provided the necessary basis for the creation of computer-adaptive assessments rather than traditional pencil-and-paper assessments. Such tests employ algorithms which ensure that the test-taker is efficiently assessed. Responses to items are used to select new items and, as a result less time is spent obtaining the same information than in a test where everyone is required to answer all the questions. A downside of computer-adaptive testing is that it takes enormous time and energy to develop.

Controversy

It is to be regretted that some of the research surrounding ability has resulted in the whole field becoming tainted with accusations of racism. This has largely followed the work on differences between racial groups on measures of IQ by high-profile pieces of research by Arthur Jensen and Hans Eysenck. While reports of the research have often failed to recognize the nuanced views of the authors, an impression has been created. Various studies of heritability have indicated that inheritance has a part to play in explaining measures of IQ. The studies involve looking at IQ scores within and between families, at the scores of siblings and twins (fraternal and identical), at twins reared apart and together, and at adoption studies. There is argument over the precise figures and it is accepted that the figure must be different for different settings or cultures, but estimates vary from 30% to 70%. This is a complex area and not one that should be approached lightly or with little knowledge. Nevertheless, workers such as Jensen and Eysenck and more recently Herrnstein

and Murray have argued that the heritability figures can be used to explain the difference between different racial groups. These studies have created a furore and much condemnation from others within the scientific community. Of particular relevance to the debate have been empirical findings such as the changes in IQ over the years. The IQs of African Americans in the United States now exceed those of Whites when the work identified the difference in the first place. There has also been a decrease in the gap between the two groups.

A general rise in IQ scores, the so-called Flynn effect, has been observed across the Western world. It has been particularly seen in those tests which are apparently the purest measures of *g*, the most famous of which is Ravens progressive matrices. This has led to advances in theoretical explanations of how ability develops through its interaction with the environment. A particularly important theoretical perspective by William Dickens has sought to explain how differences can appear between races because of the way in which society is organized, and yet can still have substantial heritability. It also shows how *g* can appear as a result of personal selection, societal structure, and interaction with the environment.

Developed Ability

The baggage associated with ability testing and IQ scores indicates that there is a problem with the use of ability tests. It produces, in the minds of some, thoughts of innate differences and inherited IQ that cannot be changed and which are linked to race. In reality, ability is the propensity, at a certain point in time, to acquire certain skills, resulting from an individual's decisions, interaction with the environment, opportunities that have presented themselves, and genetic make-up. This developed ability is something which can be altered, albeit slowly, which schooling improves but only over a considerable period of time, and which can be suppressed by a culture and ways in which society operates.

Ability Testing by Psychologists and Teachers

It should be taken as read that the aims of ability testing within education must ultimately be to improve the education of the individuals who are being assessed and that high standards should be maintained. It is important to distinguish between different types of testing. It is rare to find that teachers develop their own measures of ability. They might make judgments of individuals but they rarely create ability tests in the way that they might create tests of geography or mathematics. These implicit judgments are important and probably have long-term consequences

for individuals but the actual tests themselves are left to specialists. Further, there are two types of tests known as open and closed tests. Closed tests are only available to psychologists and open tests, as the phrase implies can be bought and used more readily in schools.

The most famous of closed tests is the Weschler Intelligence Scale for Children (WISC), which has gone through a series of revisions and is now available in its fourth edition strongly influenced by Carroll's work. It is associated with systematic use by educational psychologists either as part of their duties within the schools or in clinical practice. The second stream of ability testing is in schools and districts by teachers and administrators. Sometimes ability testing has been used for the selection of pupils. In England, following the 1944 Education Act, and the creation of a national selective system of secondary schools, those who passed the ability test, the so-called 11+, went to grammar schools and those who did less well went to technical schools, and those lesser than that into secondary modern schools. The psychologist Cyril Burt was influential in devising the policy. Although many state secondary schools in England are now not selective, grammar schools in England continue to exist and continue to select on the basis of ability tests as do some private schools.

The use of IQ tests was widespread in schools in the United States but concern over the tests' validity with subgroups has led to their restriction. This restriction in use has been encouraged by legal action. For example, in 1984 the 9th Circuit Court of appeals ruled that IQ tests should not be used to place students into classes for the mentally retarded. Arguments continue in the courts and outside.

Dyslexia

It may seem natural to assume that students with high ability who find difficulty reading fluently and accurately should be treated differently from students with low ability who have similar problems. Such thinking led to a definition of dyslexia which involved a discrepancy between IQ and reading scores. It also led to policies in which different approaches were used for poor readers with high and low IQ scores. But a series of investigations has found that irrespective of IQ, poor readers are best helped by diagnosing their specific problems and tackling those directly. It is also generally accepted that dyslexia should be defined without reference to ability.

Monitoring

A quite different use of ability tests in schools is linked to monitoring. In England in 1982, the governor of a prestigious school came to the local university and sought out

an assessment expert, Carol Taylor Fitz-Gibbon, and asked her to look at some grades that had been given for preuniversity math tests, which are known in England as Advanced Level exams. The school were expecting Grade As, but they were largely Ds and Es or even unclassified. Fitz-Gibbon looked at the results, and perhaps to the disappointment of the governors, said that on the basis of those grades she could say nothing because she had not seen any indication of the ability of the math students, and she wondered what those students who had chosen mathematics as one of three subjects, thought about mathematics now. Did they enjoy their time doing it? How were they taught? A whole range of questions flooded out, none of which had ready answers. As a result, she set up a project with a group of schools and colleges in the North East of England, which would share the data anonymously, together with information about attitudes and about processes. A key to the project was the development of statistical controls so that like could be compared with like as one school looked at its data in comparison with others. This project was known as Confidential Measurement Based Self Evaluation (COMBSE) project. Since those ideas and since that original development, that project has grown every year until now in 2007, it covers well over half of all A-level provision.

One of the issues that Fitz-Gibbon had to face was what the controls should be. Of course, there were ready variables that could be put into the regression equations such as sex, eligibility to free school meals, and there were even prior achievement measures taken by the students 2 years before their A-level exams. These were leaving exams taken in England. They correlated at the 0.5–0.7 level and acted as good statistical controls for looking at the A-level results, but there was a problem with them – they were dependent on the teaching of the schools which then went on to teach the A levels. So, were a school to be seen as particularly good at teaching for the leaving certificate, they would then be potentially penalized when it came to look at their A-level grades because the controls would show that their progress had been less than expected. She therefore looked for an ability measure to act as a control, the idea being that this would be a cognitive measure which the school had not specifically taught. From Education Testing Services, she obtained the International Test of Developed Abilities (ITDA). It had been created for colleges in the United States in order to select students who had been in different countries and had varied backgrounds. Using that, a school would be able to look at its A-level grades and the gains made against the ITDA, also against the gains made against the national leaving certificate test, or against the gains made simply knowing the home background of the children. This allowed schools to look at the data in very different ways. It did not give an answer which was right and for which people could be held accountable, but rather it provided information for teachers to understand their

own situation and to integrate professional knowledge with quantitative data. Since the success of the COMBSE Project, a whole series of projects for different ages and different countries have been created in its image.

In using these data in schools, it became clear that the communication of the idea of cognitive measures, ability measures, which the schools had not deliberately enhanced was understood and largely well accepted. It was emphasized that ability is not something which is fixed, nor is it something which is entirely dependent on genes, but it is something which develops over time.

Some have tried to monitor school performance by using controls for home background alone. This is not adequate. Measures of the home typically correlate with schools success at about the 0.3 level in the United Kingdom explaining about 10% of the outcome measure. On the other hand, cognitive measures, such as an ability test, correlate at about the 0.7 level explaining about 50% of the variance. The correlations with home background are much increased if the unit of analysis is taken to be the school rather than the students and can get as high as 0.8. But, any suggestion that such correlations can be extrapolated to indicate that home background is a good predictor of school success is to fall foul of the ecological fallacy.

School Effectiveness

A project like COMBSE generates much data which can be examined to develop hypothesis about effective schooling and much research has been carried out into this area. Some of it, particularly in the Netherlands and the United Kingdom, has involved ability testing and an effort to look for associations between gain scores and other school-based factors.

Consequences

What have been the consequences of ability testing in education? Has it helped students? Over the last 100 years, it is clear that mistakes have been made. Many students have been wrongly classified by intelligence tests because of inaccurate measurement but, more worryingly, because of bias in the assessments and sometimes because of unjustified theoretical stances. On the other hand, society and schooling is such that judgments are inevitable. Some schools offer high-level math classes for which pupils must be chosen; some pupils have difficulties and need help with limited resources. Whenever human judgment is required, mistakes abound. We are notoriously biased and persistent in our mistaken homespun theories. If a badly behaved child from a poor background is to be selected then he (*sic*) may have more chance passing an

ability test than being chosen by his teacher, taking us back to the issue presented to Binet at the turn of the nineteenth century. On balance, have more selection mistakes been created or avoided as a result of ability testing? It is impossible to say. What cannot be doubted is that the potential for better decisions to be taken exists if knowledgeable educators have high-quality ability data available to them.

Have the professional monitoring systems with the use of ability tests enhanced education in the way that was originally hoped and envisaged? Is better information through feedback loops actually having an impact? There have been experiments in the area and the evidence has been synthesized by Robert Coe. On balance, feedback has a small positive effect although the evidence is not specifically linked to ability testing. However, the professional monitoring movement has proved to be important in enabling schools to defend themselves against unwarranted attacks on the basis of judgments made on the basis of inadequate controls or inspectors' judgments. Giving teachers the capacity to defend themselves has been very important. It has also provided very good data to look at the relative difficulties of subjects and thus to comment on the comparability of examinations.

Conclusion

Ability testing has been in use for a little over 100 years and it has been used so widely and investigated so thoroughly that more is probably known about the subject than any other area in education. Through that time, ability tests have been used to spot talent and to help to remove bias from judgment using objective measures. Other uses and perspectives have changed dramatically. The simplistic links made to race are now no longer tenable and concerns about bias within the tests themselves are much more clearly understood and widespread. Indeed, the knowledge base generated through research into abilities can now be used to counter racist perceptions. Further, our understanding of how intelligence develops is much stronger than it ever was as is our knowledge about the architecture of the mind and how we think.

There can be little doubt that ability testing has been used in harmful ways – condemning individuals to inappropriate situations. But there can also be little doubt that if used appropriately, ability testing can be used in a positive way to help education.

Glossary

Correlation coefficient (multiple) – A measure of association, ranging from 0 to 1, between a set of (at least two) variables and a single variable. For example, a multiple correlation coefficient could be used to assess the degree to which test scores and high school grades, considered jointly, are associated with college grade-point average.

Correlation coefficient (simple) – A measure of linear association, ranging from – 1 to 1, between two variables (e.g., an admissions test score and a college grade-point average).

Differential item functioning (DIF) –

A phenomenon in which two (or more) groups of test takers (e.g., men and women) tend to perform differently on a test question despite having equal skill in the area that is being tested. One possible cause of DIF is the inclusion in the test question of material that is irrelevant to the proficiency that is intended to be assessed.

Linear regression analysis – A statistical technique used to assess the relationship between a set of predictors (consisting of one or more variables) and a criterion variable. In the admissions context, for example, test scores and high school grades are often used to predict college grade-point average.

Predictive validity – The degree to which a test or other measuring instrument can predict a criterion of interest, typically academic or job performance. In the case of admissions tests, the criterion is typically a grade-point average in a subsequent academic program.

Range restriction – A reduction in the range (distance between maximum and minimum values) of a variable that results from a selection process. For example, the SAT scores of students admitted to college typically have a smaller range than the SAT scores of applicants.

Background

This article provides a brief historical perspective and then describes several aspects of higher education admissions testing in the USA: the main tests used, the role of tests in the admissions process, and the evidence on predictive validity. Following this is a short discussion of test fairness issues. Admissions testing in several other countries is then described.

Accounts of testing history agree that the administration of tests for regulating admissions to universities began in Europe, most likely in the eighteenth century (Webber, 1989: 37), although some reports give an earlier date (e.g., Office of Technology Assessment, 1992; Stewart, 1998). Most descriptions agree that admissions testing had been instituted in Germany and England by the mid-1800s.

Standardized admissions testing first took root in the USA during the early part of the twentieth century, when the leaders of 12 northeastern universities formed the College Entrance Examination Board in 1900. The College Board created a common set of examinations that were administered by member institutions and then shipped back to the Board for scoring. Initially, the Board developed essay tests in several subject areas; it later developed a new exam that contained mostly multiple-choice questions – the SAT. This precursor to today's SAT was first administered in 1926 to about 8000 candidates.

The first SAT consisted of questions similar to those included in the Army Alpha tests, which had been developed for use in selecting and assigning military recruits in World War I. These Army tests, in turn, were directly descended from intelligence quotient (IQ) tests, which had made their first USA appearance in the early 1900s. The SAT gained popularity over the next two decades and, in 1947, Educational Testing Service (ETS), currently the largest USA testing organization, was founded. ETS has had a role in most of the standardized admissions tests used in the USA today.

Higher Education Admissions Testing in the USA

Main Admissions Tests Used in the USA Today

Admissions processes in the USA are largely under the control of individual institutions and instructional programs. These entities decide whether and how to use tests in making admissions decisions. The main admissions tests

* Portions of this article are adapted from *Fair Game? The Use of Standardized Admissions Tests in Higher Education*, RoutledgeFalmer, 2002. Copyright © 2002 by Rebecca Zwick.

used in the USA today are the SAT and ACT, used for college admission; the Graduate Record Examinations (GRE), used for graduate school admission; the Medical College Admission Test (MCAT); the Law School Admission Test (LSAT); and the Graduate Management Admission Test (GMAT), used for admission to business school. As described below, these tests are developed and produced by private organizations. (Tests that are not discussed here include the Test of English as a Foreign Language, which is required of foreign students by some USA colleges or graduate schools and the Miller Analogies Test, which is accepted by a small percent of graduate programs as an alternative to the GRE.)

Today's SAT

The SAT testing program is sponsored by the College Board; the tests are administered by ETS under a contract with the Board. According to the College Board website, the SAT Reasoning Test “measures critical reading, mathematical reasoning, and writing skills that students have developed over time and that they need to be successful in college.” (“SAT” is no longer considered to be an acronym, but the actual name of the test. Originally, it stood for Scholastic Aptitude Test, which was later changed to Scholastic Assessment Test. More recently, the test was known as the SAT I: Reasoning Test.)

The SAT has undergone many changes in content in its eight decades of existence; a history of these changes is provided by Lawrence *et al.* (2004). The most recent revisions occurred in 2005, following a nationwide controversy about the utility and fairness of the SAT. Historically, the SAT had provided math and verbal scores, but the new version of the test consists of three separately scored sections: math, critical reading, and writing. Analogy items were eliminated, and more advanced math content was added. All the critical reading questions and most of the math questions are multiple choice. Each SAT also includes some math questions that require student-produced answers – there are no response choices. The newly added writing section, which is mandatory, includes separately scored multiple-choice and essay sections. An overall writing score is also provided.

In addition to the SAT Reasoning Test, the current SAT program also includes 20 SAT Subject Tests (formerly called the College Board Achievement Tests and later, the SAT II: Subject Tests), which assess the candidates' knowledge in particular areas.

The ACT

In 1959, the SAT program acquired a competitor in the college admissions test market – the American College Testing Program. (Today, the company is ACT, Inc. and the test is simply the ACT. Like ‘SAT’, ‘ACT’ is no longer considered an acronym.) In its early years, the ACT was administered primarily in Midwestern states, but it is now considered interchangeable with the SAT by most institutions.

From the beginning, the ACT was somewhat different from the SAT in terms of underlying philosophy: While the SAT consisted only of verbal and mathematical sections, the ACT was more closely tied to instructional objectives. Today, the content of the test is informed by regular surveys of secondary school teachers and curriculum experts. The ACT consists of four multiple-choice sections: English, mathematics, reading, and science. Students receive a score in each subject area, as well as a composite score. Seven subscores are also reported – two in English, three in mathematics, and two in reading.

In 2002, after the College Board announced that a writing component would be added to the SAT, ACT, Inc. announced that it would add a 30-min essay test to the ACT. Unlike the SAT writing section, however, the ACT writing test, first administered in 2005, is optional. Students who elect to take it along with the ACT receive two additional scores, a writing test score, and a combined English/writing score, as well as comments about their essays.

The GRE

The GRE program of the Carnegie Foundation for the Advancement of Teaching administered its first exam in 1937. In 1948, the GRE program was transferred to the newly formed ETS. Today, the GRE, which is used to evaluate candidates for admission to graduate school, is developed and administered by ETS under the direction of the GRE Board, an independent 34-member organization that is affiliated with the Association of Graduate Schools and the Council of Graduate Schools. The GRE General Test was the first major admissions test to be administered as a computerized adaptive test, beginning in 1993. In a test of this kind, candidates are administered items that are intended to be tailored to their skill levels. The exam is available in test centers around the world.

The GRE has undergone several content changes since its inception. Among the more recent modifications was the incorporation of a writing assessment into the General Test in 2002, replacing the analytical reasoning section. According to the ETS website, today's GRE General Test “measures verbal reasoning, quantitative reasoning, and critical thinking and analytical writing skills that have been acquired over a long period of time and that are not related to any specific field of study.” The verbal and quantitative reasoning items are primarily multiple-choice, although some quantitative items requiring student-produced answers were added in 2007. The analytical writing section consists of two essay tasks, one asking the candidate to take a perspective on an issue, and one requiring the candidate to analyze an argument. Test-takers receive separate scores in quantitative reasoning, verbal reasoning, and writing. In addition to the General Test, eight GRE Subject Tests are available.

The MCAT

The Medical College Admission Test, first given in 1946, is sponsored by the Association of American Medical Colleges, which currently represents about 125 USA medical schools, 17 Canadian medical schools, 400 teaching hospitals, and various academic societies and medical professionals. Since 2007, the MCAT has been administered as a (nonadaptive) computer-based test by Thomson Prometric, a technology-based testing company.

As described in an MCAT bulletin, the test assesses “the skills and knowledge that medical educators and physicians have identified as key prerequisites for success in medical school and the practice of medicine,” including “mastery of basic concepts in biology, general and organic chemistry, and physics, . . . capacity for problem solving and critical thinking as well as general writing skills” (Association of American Medical Colleges, 2007). The test consists of three multiple-choice sections – verbal reasoning, physical sciences, and biological sciences – as well as a writing sample composed of two essay questions. A separate score is reported for each section of the MCAT.

The LSAT

The LSAT was conceived at a 1947 meeting between College Board staff and representatives of an association of nine law schools, the precursor of the Law School Admission Council (LSAC). In 1948, the first LSAT was administered by ETS. Since 1979, the LSAT has been developed by the LSAC itself, which today has more than 200 member institutions in the USA and Canada.

The LSAT is “designed to measure skills that are considered essential for success in law school: the reading and comprehension of complex texts with accuracy and insight; the organization and management of information and the ability to draw reasonable inferences from it; the ability to reason critically; and the analysis and evaluation of the reasoning and argument of others” (Law School Admission Council, 1999). Four sections serve as the basis for a single score: one reading comprehension, one analytical reasoning, and two logical reasoning sections. All LSAT questions are multiple-choice except a writing sample, added in 1982, which is not graded, but is sent to the law schools to which the candidate applies.

The GMAT

In the late 1940s and early 1950s, the GRE was used to screen business school applicants. In 1953, however, representatives of nine graduate schools of business agreed that they needed an admissions test of their own and, just a year later, the precursor to the GMAT was administered (Schmottter, 1993). For five decades, the test was developed and administered by ETS for the Graduate Management Admission Council (GMAC), which includes about 160 governing schools of business and management.

Since 2006, the GMAC has contracted with ACT, Inc. to develop the GMAT and with Pearson VUE, a company specializing in computer-based testing, to administer it.

Today’s GMAT, according to its information bulletin, “measures general verbal, mathematical, and analytical writing skills that are developed over a long period of time . . . The GMAT does not presuppose any specific knowledge of business . . . [and] does not measure achievement in any particular subject areas” (Graduate Management Admission Council, 2000: 5). Since 1997, the GMAT has been a computerized adaptive test, like the GRE.

The test contains verbal and quantitative sections, both of which are multiple choice, and an analytical writing section, which was added in 1994. The writing section requires the test-taker to produce essay responses to two questions, with half an hour allowed for each. Separate scores are reported for each of the three sections of the GMAT; a total score that reflects performance on the verbal and quantitative sections (but is not the total of the verbal and quantitative scores) is also reported.

The Use of Higher Education Admissions Tests in the USA

Use of admissions tests at undergraduate institutions

In the USA, use of admissions tests varies widely across institutions. At open-door colleges, tests play no role in the admissions process: all that is required is to complete an application and, in some cases, show proof of high school graduation. Eight percent of the 957 4-year institutions that responded to a survey conducted in 2000 by ACT, Inc., the Association for Institutional Research, the College Board, Educational Testing Service, and the National Association for College Admission Counseling (referred to hereafter as ‘the joint survey’), came under the open-door category; 80% of the 663 2-year institutions were open-door (see Breland *et al.*, 2002: 15).

According to the joint survey, the percentage of 4-year colleges requiring either the SAT or ACT held steady at slightly over 90% between 1979 and 2000 (Breland *et al.*, 2002). Two major sources of information, the joint survey and the National Association for College Admission Counseling (NACAC) Admission Trends Survey (Hawkins and Lautz, 2005) indicate that test scores are viewed as the second-most important factor, after high school grades, and that the importance attributed to test scores has increased in recent years (Breland *et al.*, 2002: 67; Hawkins and Lautz, 2005: 39). (The watchdog organization FairTest lists 740 schools that “deemphasize the use of standardized tests by making admissions decisions about substantial numbers of applicants who recently graduated from U.S. high schools without using the SAT or ACT.”)

Use of admissions tests at graduate and professional schools

Graduate and professional school programs tend to be smaller, and admissions policies less formalized and less public than at undergraduate institutions. Decisions are typically in the hands of faculty, rather than admissions officers and admission rates tend to be much lower.

Admissions policies and rates vary widely over the hundreds of fields of doctoral study available in the USA. Decisions are typically made at the department level, using very flexible procedures. As a College Board report noted, “published statements about [doctoral] admissions provide ample latitude for almost any decision” (Rigol and Kimmel, 1997: 13). Surveys have shown that standardized admissions tests are widely used in graduate admissions, in combination with undergraduate grades and other factors (Kuncel *et al.*, 2001; Rigol and Kimmel, 1997). The vast majority of USA graduate programs require the GRE General Test (Norcross *et al.*, 1996); some require certain GRE Subject Tests as well. The Miller Analogies Test, developed by The Psychological Corporation, is accepted by a small percentage of graduate programs as an alternative to the GRE.

Use of admissions tests is nearly universal at professional schools. The MCAT is required by nearly all American medical schools. All American and Canadian law schools that belong to the LSAC require the LSAT, and most other law schools do as well. According to its website, the GMAT is used by “thousands of graduate management programs around the world.” Undergraduate grades are also considered very important in professional school admissions, and medical schools place a high value on interviews as well (Johnson and Edwards, 1991).

Predictive Validity of Admissions Tests

Although they differ somewhat in the skills they are alleged to measure, all college, graduate school, and professional school admissions tests share one particular claim – that they are useful for predicting the grades students will receive in the educational programs they enter. Although a comprehensive evaluation of a test’s validity must involve a consideration of the test’s design, development, content, administration, and use, the validity of admissions tests as a selection tool for higher education institutions is, in practice, judged largely by the degree to which test scores can predict students’ grade-point averages in college, graduate school, or professional school (GPAs). Most often, first-year grades are used.

Conducting a predictive validity study requires that the GPAs for the cohort of interest be available so that the predicted GPAs can be compared to the GPAs actually earned by the admitted students. Predictive validity studies are usually conducted within a single institution, although results may later be averaged across institutions.

Linear regression analysis is typically applied to estimate an equation for predicting college, graduate school, or professional school GPA. The predictors are typically admissions test scores and high school grades (in the case of college admissions) or undergraduate grades (in the case of graduate or professional school admissions). The resulting multiple correlation, which can range from 0 to 1, provides an index of the effectiveness of the prediction equation. The regression analysis can then be repeated using prior grades alone as a predictor. Comparing the predictive effectiveness of the two equations gives an estimate of the value added by using admissions test scores. The simple correlations between test scores and subsequent GPAs are often examined as well.

A factor that complicates the interpretation of these correlations, or validity coefficients, is restriction of range: students whose test scores are too low to allow admission to a higher education institution will not have GPAs. Because of this restriction of range (of test scores, and, as a result, of other predictors and of GPAs as well), validity coefficients tend to be smaller for the admitted students than they would be for the entire population of applicants. Statistical corrections are often applied in an attempt to estimate how big the association would have been if the range had not been restricted (see Gulliksen, 1987: 165–166). Except where noted, the correlations reported in this article have not been corrected for range restriction. Typically, the corrected correlations are larger by 0.15 – 0.20.

An examination of large-scale studies (focusing on multi-institution studies and reviews published in 2000 or later) reveals some consistent patterns in the findings on the predictive validity of admissions tests in college, graduate school, and professional school. (See Kuncel and Hezlett (2007) for an excellent overview of graduate and professional school results.) The multiple correlation of the ACT or the SAT with college GPA is typically about 0.3 – 0.4 (ACT, Inc., 2007; Burton and Ramist, 2001; Camara and Echternacht, 2000; Kobrin *et al.*, 2008). In the case of the ACT, these results are based on analyses that use scores on the English, mathematics, reading, and science sections, considered together. In the case of the SAT, results are based on analyses that use math and verbal (or, after 2005, critical reading) scores considered together. The correlation between the admissions test (ACT or SAT) and college GPA is usually found to be slightly lower than the correlation between high school grades and GPA. Considering ACT or SAT scores as predictors along with high school grades yields correlations with GPA that average about 0.5.

A study of the SAT writing test, first administered in 2005, showed that scores were correlated about 0.5 with college GPA (Kobrin *et al.*, 2008). These results supported the predictive validity of the writing test, but also showed that it added only a small amount (0.02) to the validity

coefficient obtained using critical reading and mathematics scores alone. These results paralleled those obtained from an earlier study of a prototype version of the SAT writing test (Norris *et al.*, 2005; see also Mattern *et al.*, 2007). Similarly, research on the ACT writing test (ACT, Inc., 2009) showed that scores were predictive of grades in 'writing-intensive' college courses, but that inclusion of the writing test in the prediction equation increased the validity coefficient by only 0.02 over the value that is obtained using the ACT English test alone.

Most GRE validity research predates the substitution of the writing assessment for the analytical reasoning component in the main part of the test. Results from the GRE Validity Study Service collected between 1986 and 1990, which are based on more than 1000 departments and more than 12 000 test-takers (Educational Testing Service, 2003), as well as on other recent multi-institution studies (Burton and Wang, 2005; Kuncel *et al.*, 2001), show that the predictive validity of the GRE (as formerly constituted) is quite similar to that of the SAT and ACT. GRE scores (verbal, quantitative, and analytical reasoning considered together) typically have a validity coefficient of 0.3 – 0.4, and this is usually similar to the correlation between undergraduate GPA and first-year graduate school GPA. When undergraduate GPA and GRE scores are considered in combination, their correlation with graduate school GPA is 0.4 – 0.5. Including scores on the GRE Subject Tests as predictors usually boosts the correlation to 0.5 – 0.6.

Separate validity analyses of the GRE writing assessment (before it was added to the main assessment) were conducted based on approximately 2000 college juniors, college seniors, and first-year graduate students. Analyses showed that the writing assessment (the combined score on two essays) had correlations of about 0.3 with a GPA based on courses that 'required considerable writing'. Correlations with overall GPA were about 0.2, and correlations with GPA in the students' major field were smaller (Powers *et al.*, 1999: 33).

The association between the GMAT (verbal, quantitative, and analytical writing scores considered together) and business school GPA (evaluated halfway through the business school program) was investigated by Talento-Miller and Rudner (2005), based on results from 273 schools. They found a median multiple correlation of 0.5, substantially larger than the median correlation between undergraduate grades and business school GPA (0.3). (These correlations were adjusted for restriction of range.) According to a recent summary of results from 166 schools, the LSAT typically does a slightly better job of predicting first-year law school GPA than do undergraduate grades, yielding correlations averaging over 0.3 (Stilwell *et al.*, 2007). A study based on two student cohorts at each of 14 medical schools reported that the median correlation between MCAT scores and the average of

first- and second-year medical school GPA exceeded 0.4, higher than the median correlation between undergraduate grades and medical school GPA (Julian, 2005). In the case of the GMAT, LSAT, and MCAT, using test scores and undergraduate grades in combination to predict subsequent GPA was slightly more effective than using test scores alone.

In summary, college admissions test scores tend to be slightly weaker than high school grades as predictors of college GPA. Including test scores in addition to past grades in the prediction equation tends to increase the validity coefficient by about 0.1. In predicting graduate school grades, GRE scores and undergraduate grades tend to be equally effective. Test scores are frequently found to be more effective than undergraduate grades in predicting professional school grades.

Although first-year GPA is the most common criterion variable in admission test validity studies, other criteria have been studied as well. For example, there is considerable evidence that admissions test scores are helpful in predicting grades beyond the first year (Burton and Ramist, 2001; Kuncel and Hezlett, 2007; Zwick, 2006, 2007). The evidence on prediction of degree attainment is mixed (Zwick, 2006, 2007). The SAT appears to be useful for this purpose (Burton and Ramist, 2001; Carnevale and Rose, 2003), while graduate and professional school admission tests are less so (Kuncel and Hezlett, 2007). Some studies have examined prediction of other criteria, such as performance on licensing exams and measures of career success, with inconsistent results (see Zwick (2006) for a summary).

Use of personal characteristics to predict success in higher education

An area of ongoing debate is whether including formal measures of personal characteristics could improve the prediction of success in higher education. In a landmark 1985 study, Warren Willingham identified a characteristic he called 'productive follow-through,' defined as 'persistent and successful extracurricular accomplishment' in high school. Productive follow-through proved to be a poor substitute for high school grades and admissions test scores in predicting which students would be identified as most successful by their colleges, but taking this quality into account along with traditional academic qualifications substantially improved the prediction of success (Willingham, 1985: 184).

A measure of personal characteristics that has often been used for admissions purposes in recent years is the Noncognitive Questionnaire (NCQ) developed by William E. Sedlacek. The NCQ is intended to assess such factors as positive self-concept and preference for long-term goals (Sedlacek, 1998: 11). The NCQ is claimed to be useful for predicting college GPA and college persistence (e.g., Tracey and Sedlacek, 1984). However, a recent

meta-analysis based on over 9000 cases from 47 samples found NCQ scores to be “largely unrelated to college performance as measured by GPA, college persistence, and credits earned” (Thomas *et al.*, 2007: 648).

Although there is widespread agreement that factors such as perseverance, determination, and ability to delay gratification are relevant to success in higher education, measuring these characteristics accurately and without bias is difficult. One problem in using self-reports about these attributes in the admissions context is that the desired answers are often obvious to the respondent. Thus, the use of information from respondents other than the candidates themselves (possibly in the context of a standardized letter of recommendation) may yield more useful data.

Fairness of Admissions Tests to People of Color, Women, and Other Special Populations

Standardized admissions test results often reveal substantial average score differences across ethnic, gender, and socioeconomic groups. Among the general public, these differences are often regarded as sufficient evidence that these tests are biased. From a psychometric perspective, a test’s fairness is inextricably tied to its validity. According to Cole and Moss (1989), test bias occurs (i.e., fairness is violated) “when a test score has meanings or implications for a relevant, definable subgroup of test takers that are different from the meanings or implications” for other test-takers. “. . . [B]ias is differential validity of a given interpretation of a test score . . .” (p. 205).

Psychometric assessment of the fairness of admissions tests typically comprises two broad types of investigations. One type consists of analyses of differential prediction of a criterion, usually a GPA. Two distinct questions are typically addressed: first, are the test scores equally predictive of later grades for all groups? This question is typically investigated by obtaining separate prediction equations for each group and then comparing correlation or regression coefficients across groups. Second, if we obtain a single prediction equation for students as a whole, does this equation produce predicted GPAs that are systematically too high or too low for some groups? (See Zwick, 2002: 117–124, 147–150.)

Another common component of fairness assessment is an examination of item content. Before an item is approved for inclusion in an admissions test, it undergoes a ‘sensitivity review’ to make sure its content is not disturbing to certain student groups or offensive in some other way. Later, after the test is administered, a differential item functioning (DIF) screening is performed to determine whether equally skilled members of different groups (e.g., men and women) have statistically different rates of correct response on some items. The purpose of DIF analysis is to identify test items with content that may

be problematic for some student group. For example, the item may include content that is irrelevant to the construct being assessed, and is more familiar to some student groups than others, such as sports content in a mathematics test. Items found to have DIF are either discarded immediately or flagged for further study.

Zwick (2002, 2006, 2007) summarizes findings on differential prediction of GPAs for key student groups, including people of color, women, people with disabilities, and students with limited English skills (see also Young, 2004), and provides a discussion of DIF findings and fairness issues associated with test coaching.

Higher Education Admissions Testing Around the World

Higher education admissions processes vary internationally in terms of the degree of government oversight, the degree of centralization, and the role, if any, of admissions tests. Some examples follow.

In Europe, the minimum requirement for admission to higher education institutions is a certificate of completion of secondary school or its equivalent. (The certificate itself typically requires passage of exams based on the secondary school curriculum.) Most countries also have additional requirements for university entrance, such as admissions tests or interviews. In the UK, Ireland, and Norway, candidates for university admission apply through central offices, which process applications for multiple institutions (Eurydice, 2007). Turkey also relies on a centralized application system, which it uses in combination with a national university entrance exam, the Student Selection Examination (ÖSS). Scores on the ÖSS, which is intended to measure primarily verbal and quantitative reasoning, are used in combination with candidates’ high school grades (and in some cases, the results of a foreign-language examination) to determine eligibility for higher education programs (Student Selection and Placement Center (ÖSYM), 2006).

In other European countries, such as Sweden, the admissions process is fairly similar to that in the USA. Most Swedish universities require an entrance test, the Swedish Scholastic Aptitude Test (SweSAT), which consists of subtests in vocabulary, data sufficiency, Swedish reading comprehension, interpretation of diagrams, tables, and maps, and English reading comprehension (ERC). The test falls under the authority of the Agency for Higher Education but is developed and administered by the Department of Educational Measurement at Umeå University, with the exception of the ERC subtest, which is constructed at Göteborg University (Stage and Ögren, 2004). Originally developed for members of the work force who were at least 25 years of age and wanted to return to school (Wedman, 1995), the SweSAT is now used widely as a selection tool. Some institutions,

however, use only high school grades in making admissions decisions.

In Israel, admissions procedures closely parallel those in the USA. Universities generally require the Psychometric Entrance Test (PET), which consists of verbal reasoning, quantitative reasoning, and English sections. The PET is developed and administered by the National Institute for Testing and Evaluation, an independent body governed by the leaders of Israel's seven research universities (Beller, 2001). Universities develop their own admissions requirements and typically use a composite of PET scores and secondary school record in admissions decisions. The validity of the PET and of the composite are very similar to their American counterparts, as are the national concerns about the fairness of the PET to various groups and the possible advantages of test coaching.

At least two other countries have taken steps toward American-style college admissions testing: The British government is conducting a 5-year trial of the SAT, sponsored in part by the College Board (Labi, 2005), and Russia began nationwide use of a standardized admissions test similar to the SAT in 2009 (MacWilliams, 2007; Nemtsova, 2009).

Appropriateness Measurement: Person Fit

Glossary

Person-fit analysis – A technique for determining if a person's results on educational or psychological test are valid. The purpose of a person-fit analysis is to detect item-score vectors that are unlikely given a hypothesized test theory model or unlikely compared with the majority of item-score vectors in the sample.

In educational and psychological standardized testing, measurement inaccuracy has received widespread attention. Examples are reliability theory, methods for estimating reliability, and statistics comparing groups with respect to the probability of correctly answering an item (differential item functioning). In this article, we discuss methods for determining the fit of an individual item-score pattern to a test model, that is, we discuss person-fit methods that can be used to investigate the validity of a test score. Validity of test scores may be threatened when factors other than the trait being measured, such as cheating, guessing, or plodding, influence an individual's test score.

In large-scale cognitive assessment, item response theory (IRT) modeling is often used for test construction, analysis, and scoring. Although empirical similarities of tests and questionnaires constructed according to classical test theory and IRT do exist, IRT offers better solutions to many psychometric problems than classical test theory (e.g., Embretson and Reise, 2000). The detection of invalid test scores, often called person-fit or appropriateness measurement, is an interesting and practically useful example (Meijer, 2003). Before we discuss different techniques used in person-fit research and its applications, we explain the basic principles of IRT and the idea of studying individual item-score patterns.

Item Response Theory

In most IRT models, test responses are assumed to be influenced by a single latent trait, denoted by the Greek letter θ . Both IRT models for dichotomous and polytomous item scores have been proposed. For dichotomous (correct/incorrect or true/false) data, the goal of fitting an IRT model is to identify an item response function (IRF) that describes the relation between θ and the probability

of correctly answering an item. In most IRT models, it is assumed that the probability of a correct response should increase as the trait level increases; thus, IRFs are monotonically increasing functions.

More formally, the IRF, denoted $P_g(\theta)$, gives the probability of a correct answer to item g ($g = 1, \dots, k$) as a function of θ . It is the probability of a correct response ($X_g = 1$) among persons with the latent trait value θ . For dichotomous items, $P_g(\theta)$ often is specified using the 1-, 2-, or 3-parameter logistic model (1-, 2-, 3PLM, see Embretson and Reise, 2000). The 3PLM is given by

$$P_g(\theta) = \gamma_g + \frac{(1 - \gamma_g) \exp[\alpha_g(\theta - \delta_g)]}{1 + \exp[\alpha_g(\theta - \delta_g)]}$$

where γ_g is the lower asymptote (γ_g is the probability of a correct score for persons with low θ 's, that is, $\theta \rightarrow -\infty$), α_g is the slope (item discrimination) parameter, and δ_g is the item location parameter.

The 2PLM can be obtained by fixing $\gamma_g = 0$ for all items, and the 1PLM or Rasch model by additionally fixing $\alpha_g = 1$ for all items.

As an alternative to these parametric IRT models, non-parametric IRT models have been proposed that only put order restrictions on the IRFs and do not assume a specific parametric function (e.g., Sijtsma and Meijer, 2007).

For polytomous item scores (more than two answer categories), polytomous IRT models have been proposed. In these models, category response functions specify the relation between endorsing a particular category and the latent trait. In this article, we mainly focus on person-fit statistics for dichotomous IRT models and refer to person-fit statistics for polytomous data and some important work in this area.

Studying Individual Item-Score Patterns

By means of an IRT model it is possible to predict a person's answering behavior when confronted with a particular set of questionnaire items. Let us illustrate this by means of **Figure 1**. For the sake of simplicity, we depicted five IRFs that do not intersect across the latent trait range. These IRFs comply with the Rasch model. Assume that we have an estimate of someone's trait level to be $\theta = 0$, then the probability of answering item 1 correctly equals 0.9 (this is the easiest item) and the probability of answering item 5 correctly equals 0.1 (this is the most difficult

Figure 1 Item response functions that comply to the Rasch model. Meijer RR, Egberink IJL, Emons WHM, et al., (2008). *Journal of Personality Assessment* 90(3), 227–238.

item). Suppose now that the items are ordered to increasing item difficulty and that a person answers three items correctly, then the item-score pattern that has the highest probability of occurrence is 11100 and the item-score pattern with the lowest probability of occurrence is 00111. This second pattern thus is unexpected (misfitting or aberrant) and it may be questioned whether the total score of 3 has the same meaning for both patterns.

Several person-fit statistics and statistical tests have been proposed to identify unexpected item-score patterns (Meijer and Sijtsma, 2001). Most statistics have been proposed for parametric IRT models. We first, however, discuss a statistic that can be used in the context of nonparametric IRT modeling or using classical test theory.

Nonparametric IRT-Based and Group-Based Person-Fit Statistics

Nonparametric IRT-based or group-based person-fit statistics are statistics that compare the score of an individual against score patterns of other persons in the group. An individual's item-score pattern is evaluated given the nonparametric IRT model that can be applied to the group's data.

An often-used and simple person-fit statistic is the number of Guttman (1950) errors found in an individual's item-score pattern. Given that the items are ordered according to increasing difficulty, for dichotomous item scores the number of Guttman errors is simply defined by the number of 0 scores to the left of each 1 score. Thus, for example, the pattern (1110101) contains three Guttman errors (three (0,1) item pairs) (see Emons *et al.* (2005) for an application of this statistic).

For polytomous (e.g., Likert scale) items, the popularity of the item steps can be determined and the item steps

can then be ordered according to decreasing popularity. An item step is the imaginary threshold between adjacent ordered response categories. A Guttman error consists of endorsing a so-called less-popular item step in one item, while not endorsing a more popular item step in another item. To illustrate this, consider a scale that consists of six items with four response alternatives (coded 1 through 4). This implies that there are three item steps per item (from 1–2, 2–3, and 3–4). Thus, there are $6 \times 3 = 18$ item steps for each person. As an example, we consider two score patterns. One observed score pattern is (323322). From this pattern we obtained the item step score pattern 11111001101000000 with item steps ordered to decreasing popularity. These popularities can be obtained from the observed proportion of respondents who endorse a particular response category. This pattern contains seven Guttman errors (seven pairs of 0 before 1 scores). Consider now another pattern (144414) with the corresponding item step pattern 011100111010101111 which contains 45 Guttman errors. This latter pattern can thus be considered more unexpected than the first pattern. The question, however, is when do we classify a pattern as unexpected or misfitting?

In general, let t be the observed value of a person-fit statistic T . Then, the significance probability or probability of exceedance is defined as the probability under the sampling distribution that the value of the test statistic is smaller than the observed value: $p^* = P(T \leq t)$, or larger than the observed value: $p^* = P(T \geq t)$, depending on whether low or high values of the statistic indicate aberrant item-score patterns.

Nonparametric or group-based person-fit statistics, like the number of Guttman errors, are mainly used in a descriptive way and use some rule of thumb to classify a score pattern as misfitting. Sampling distributions that can be used to classify a pattern as fitting or misfitting are unknown. Although it may be argued that this is not a serious problem as long as one is only interested in the use of a person-fit statistic as a descriptive measure, a more serious problem is that the distribution of the numerical values of most group-based statistics is dependent on the total score (e.g., Drasgow *et al.*, 1987). This dependence implies that when one critical value is used across total scores, the probability of classifying a score pattern as aberrant is a function of the total score, which is undesirable.

Parametric IRT-Based Person-Fit Statistics

In parametric IRT-based person-fit, an observed item-score pattern is compared to the predicted item-score pattern under certain restrictions derived from a parametric IRT model. Most person-fit statistics are sensitive to unlikely response behavior and do not test against

specific model violations. For example, Wright and Stone (1979) proposed mean squared residual-based statistics such as U , which is given by

$$U = \sum_{g=1}^k \frac{[X_g - P_g(\theta)]^2}{kP_g(\theta)[1 - P_g(\theta)]}.$$

The nominator contains the difference between observed and expected item scores; the denominator contains the conditional variances of the individual item scores. U can be interpreted as the mean of the squared standardized residuals based on k items.

Perhaps the most popular person-fit statistic in the literature is the log-likelihood function:

$$l_0 = \sum_{g=1}^k \{X_g \ln P_g(\theta) + (1 - X_g) \ln [1 - P_g(\theta)]\}$$

This statistic was first used by Levine and Rubin (1979) and has been further developed and applied by, for example, Drasgow *et al.* (1985). l_0 is determined as the logarithm of the likelihood function evaluated at the maximum likelihood estimate of θ . Two problems occur when using l_0 as a fit statistic. (1) l_0 is not standardized implying that the classification of an item score pattern as model-fitting or misfitting depends on θ . (2) For classifying an item-score pattern as misfitting, a distribution under the null hypothesis of fitting scores is needed. The null distribution is unknown for l_0 . To overcome these problems, Drasgow *et al.* (1985) proposed a standardized version of l_0 that is less confounded with θ and purported to be standard normally distributed.

The standardized version of l_0 is given by

$$l_z = \frac{l_0 - E(l_0)}{[Var(l_0)]^{1/2}},$$

where $E(l_0)$ and $Var(l_0)$ are the expectation and variance of l_0 , respectively:

$$E(l_0) = \sum_{g=1}^k \{P_g(\theta) \ln [P_g(\theta)] + [1 - P_g(\theta)] \ln [1 - P_g(\theta)]\},$$

and

$$Var(l_0) = \sum_{g=1}^k P_g(\theta) [1 - P_g(\theta)] \left[\ln \frac{P_g(\theta)}{1 - P_g(\theta)} \right]^2,$$

Snijders (2001) proposed further refinements accounting for the fact that in practice $\hat{\theta}$ was used instead of θ and Glas and Dagohoy (in press) discussed distributions for polytomous item scores.

In contrast to the person-fit statistics discussed above, Levine and Drasgow (1988) proposed a statistically optimal method for the identification of misfitting item-score patterns against a particular alternative model. No other method can achieve a higher rate of detection at the same type I error rate. A likelihood ratio statistic was proposed

that provides the most powerful test for the null hypothesis that an item-score pattern is model fitting. A model for model-fitting behavior (e.g., 1-, 2-, or 3PLM) and a model for a particular type of misfitting behavior (e.g., a model with violations of local independence) are specified in advance. Other examples for testing against specific model assumptions can be found in Klauer (1995).

An alternative approach was proposed by Trabin and Weiss (1983). They used the person response function (PRF) to identify aberrant item-score patterns. At a fixed θ value, the PRF specifies the probability of a correct response as a function of the item location δ . In IRT, the IRF often is assumed to be a nondecreasing function of θ , whereas the PRF is assumed to be a nonincreasing function of δ . To construct an observed PRF, Trabin and Weiss (1983) ordered items to increasing δ values and then formed subtests of items by grouping items according to $\hat{\delta}$ values. For fixed $\hat{\theta}$, the observed PRF was constructed by determining, in each subtest, the mean probability of a correct response. The expected PRF was constructed by estimating according to the 3PLM, in each subtest, the mean probability of a correct response. A large difference between the expected and observed PRFs was interpreted as an indication of misfitting responses for that examinee. For developments with respect to the PRF, see Sijsma and Meijer (2001) and Ferrando (2007).

Depending on the type of data and the problems envisaged, a researcher may choose a particular statistic; however, not all statistics have equally favorable properties in a statistical sense. For example, for short tests and tests of moderate length (say, 10–60 items) and using the standard normal distribution, due to the use of $\hat{\theta}$ rather than θ for most statistics the nominal type I error rate is not in agreement with the empirical type I error rate. Recently, statistical theory for correcting the bias caused by using the maximum-likelihood estimate $\hat{\theta}$ rather than θ was developed (e.g., Snijders, 2001; Glas and Dagahoy, in press). Sound statistical methods have been derived for the Rasch model, but because this model is rather restrictive to empirical data, the use of these statistics is also restricted.

In general, it may be wise to first investigate possible threats to the fit of individual item-score patterns before using a particular person-fit statistic. As another example, if violations against unidimensionality are expected, one of the methods proposed by Klauer (1995) may be used instead of a general statistic such as the l_z statistic (see also Molenaar and Hoijtink, 1990). Not only are tests against a specific alternative more powerful than general statistics, but also the type of deviance is easier to interpret. Statistics such as l_z statistic are helpful in situations when the researcher has no idea which threats are most realistic. Statistics such as U or the PRF can be used as diagnostic tools to test whether item-score patterns on *a priori* specified subtests fit the IRT model.

Furthermore, research (see, e.g., Meijer and Sijtsma, 2001) has shown that detection rates are highly dependent on: (1) type of misfitting behavior (more unexpected item scores result in more power), (2) θ value (in general, at the extremes, power is lesser than in the middle of the distribution), and (3) test length (longer tests result in more power).

Applications

The literature on person fit is mainly technical in the sense that there are many studies devoted to the psychometric characteristics of the statistics and tests (such as the correct sampling distribution) but there are very few studies that illustrate the usefulness of these statistics in practice (e.g., Meijer and Sijtsma, 2001). There is a gap between the often very sophisticated articles devoted to the psychometric characteristics of several statistical tests and measures, on the one hand, and the articles that describe the practical usefulness of these measures, on the other. Two types of applications can be distinguished: (1) studies on the usefulness of person-fit statistics and their link to the respondents' characteristics and (2) the usefulness of the statistics in new applications such as computer adaptive testing (CAT).

Misfitting Patterns and Person's Characteristics

Several researchers applied person-fit statistics in practice. For example, Lamprianou and Boyle (2004) analyzed data of the National Curriculum tests in mathematics in England and found that pupils having English as an additional language and pupils belonging to ethnic minorities are significantly more likely to generate aberrant response patterns. Furthermore, they concluded that pupils having English as an additional language and pupils belonging to ethnic minorities produce significantly more misfitting patterns than the remainder of pupils by taking the mathematics National Curriculum tests.

Reise and Waller (1993) analyzed 11 unidimensional personality scales that had well-defined content clusters and were therefore able to link unsalability to aberrant responding for specific types of item content. In general, however, one should be careful when interpreting misfitting item-score patterns. Reise and Waller (1993) discussed that interpreting misfitting item-score patterns is difficult. Possible causes may be response faultiness, misreading, or random responding. Thus, person-fit statistics allow the identification of a deviant item-score pattern but not the recovery of the mechanism that created a deviant item-score pattern.

As a researcher usually does not know the cause of an atypical answering behavior, background information

about individual persons needs to be incorporated into the diagnostic process. Depending on the application, such information may come from previous psychological-ability and achievement testing, school performance (tests and teacher's accounts), clinical and health sources (e.g., about dyslexia, and learning and memory problems), or social-economic indicators (e.g., related to language problems at home). Although in many studies it has been suggested that quantitative and qualitative information should be combined, there are few studies where this has been done.

Recently, Meijer *et al.* (in press) integrated psychometric analysis with information from qualitative sources to make judgments about the validity of an individual's test score. More specifically, they (1) explored the usefulness of person-fit statistics to identify invalid test scores using real data from self-concept theory in a sample of children and (2) validated information obtained from IRT using personality theory and qualitative data obtained from observation and interviews. They showed that invalid test scores were the result of a less-developed self-concept in young children. We hope that future research will concentrate more on how person-fit statistics can be used in practice.

Computer Adaptive Testing

A new field of application for person-fit research is CAT (e.g., van der Linden and Glas, 2000). In CAT, the difficulty of the test is adapted to the θ level of the candidate. With the increasing use of CAT, the use of person-fit statistics may be helpful to detect item memorization or to detect examinees who, as a result of continuous test administration from the same item bank, are familiar with some of the items. Research showed that, in CAT, the distributional characteristics of existing person-fit statistics are not in agreement with the expected theoretical distributions (e.g., van Krimpen-Stoop and Meijer, 2001). This may be explained by the modest spread in the item difficulties, which results in an under-dispersion of the assumed null distribution of the person-fit statistics. Consequently, empirical type I errors are too small compared to nominal type I errors. Person-fit statistics that are especially designed for a CAT may be more powerful than conventional person-fit statistics, and the statistical properties of the former statistics should be less susceptible to the characteristics of a CAT. Both Bradlow *et al.* (1998) and van Krimpen-Stoop and Meijer (2001) proposed person-fit statistics that make use of the property of CAT that a fitting item-score pattern will consist of an alternation of correct and incorrect responses, especially at the end of the test when $\hat{\theta}$ comes closer to θ . Item-score patterns that consist of strings of 1 scores or 0 scores are unexpected. Another recent development is the link between response times administered in a CAT and the detection of misfitting response behavior (e.g., Van der

Linden and van Krimpen-Stoop, 2003). Very short response times to difficult items may indicate cheating.

Summary

We discussed methods that can be used to investigate the aberrance of individual item-score patterns under particular IRT models. The methods ranged from statistics for testing whether an item-score pattern is in agreement with the other patterns in the sample (group-based statistics) to methods for investigating whether there are specific violations against model assumptions (parametric IRT-based statistics).

A drawback of some person-fit statistics is that only deviations against the model are tested. This may result in interpretation problems. For example, item-score patterns that do not fit the Rasch model may be described more appropriately by means of the 3PLM. If the Rasch model does not fit the data, other explanations are possible. Because in practice it is often difficult, if not impossible, to substantially distinguish different types of item-score patterns and/or to obtain additional information using background variables, a more fruitful strategy may be to test against specific alternatives.

Automated essay scoring – A measurement technology in which the computer evaluates human written responses.

Introduction

This article documents the advent and rise of automated essay scoring (AES) as a means of both assessment and instruction. The first section discusses what AES is, how it works, and who the major purveyors of the technology are. The second section describes outgrowths of the technology as it applies to ongoing projects in measurement and education.

In 1973, the late Ellis Page and colleagues at the University of Connecticut programmed the first successful AES engine, Project Essay Grade (PEG) (1973). The technology was foretold some 6 years earlier in a landmark *Phi Delta Kappan* article titled, The imminence of grading essays by computer (Page, 1966). At the time the article was provocative and a bit outrageous, though in hindsight, it can only be deemed prophetic. As a former high school English teacher, Page was convinced that students would benefit greatly by having access to technology that would provide quick feedback on their writing. He also realized that the greatest hindrance to having secondary students write more was the requirement that, ultimately, a teacher had to review stacks of papers. While PEG produced impressive results, the technology of the time was too primitive to make it a practical application. Text had to be typed on IBM 80-column punched cards and read into a mainframe computer before it could be evaluated. As a consequence, the technology sat dormant until the early 1990s and was revitalized with the confluence of two technological developments: microcomputers and the Internet. Microcomputers permitted the generation of electronic text from a regular keyboard and the Internet provided a universal platform to submit text for review (Shermis *et al.*, 2001).

AES is a measurement technology in which computers evaluate written work (Shermis and Burstein, 2003). Most of the initial applications have been in English, but past work has been applied to Japanese (Kawate-Mierzejewska, 2003, March), Hebrew (Vantage Learning, 2001), and

Bahasa Malay (Vantage Learning, 2002). Computers do not understand the written text being evaluated. So, for example, the computer would not get the following joke.

Q-When is a door not a door?

A-When it is ajar.

Unlike humans, a computer cannot interpret the play on words, and infer that the predicate in the answer (i.e., ajar) is being cleverly used as a noun (i.e., a jar).

What the computer does in an AES context is to analyze the written text into its observable components. Different AES systems evaluate different numbers of these components. Page and Petersen (1995) referred to these elements as proxies or approximations for underlying traits (i.e., intrinsic characteristics) of writing. It is the observable components that AES engines, identify, computationally, and subsequently use to compute essay scores. AES statistical models are developed by weighting the various observable components as they relate to intrinsic characteristics of writing. For example, a model in the PEG system, might be formed by taking five intrinsic characteristics of writing (content, creativity, style, mechanics, and organization) and linking proxies. An example of a simple proxy is essay length. The empirical evidence suggests that the longer an essay is, the more highly valued it is by a rater. This could be because the writer provides additional details which improves the essay's standing in the eyes of the grader. However, this relationship is not linear, but logarithmic. More specifically, it appears as if essay length is important up to a point, but beyond a certain threshold it carries little additional weight. Where that point is becomes a function of the average essay length. If most essays have 150 words and a candidate essay has 200 words, then the writer has probably already taken advantage of any contribution that essay length would influence in a rater's decision-making.

Again, in the PEG framework, an example of a complex proxy might be a count of the number of times because is used in an essay. Though this counting method is admittedly superficial, it is an indicator of sentence complexity, and is also tied conceptually to the intrinsic characteristic of style. It is useful to note that this one proxy is joined with a number of others to estimate the trait, and would not normally be used as a single indicator for the trait.

How are models formed? There are three general approaches, two of which involve the collection of empirical data, and one that is currently more of a theoretical option.

In the first approach, two samples of essays are collected – one for model building and the other for model evaluation/confirmation – each of which has been rated by multiple raters. For the purpose of creating a model, one might utilize the field distribution of ratings or select a fixed sample size (e.g., 300) with approximately an equal number of essays at each cut point. Using the latter technique if there were six points on the rating rubric that raters used, the model would be most discriminating if there were 50 essays for each point of the scale ($300/6 = 50$). As rating points at the extremes of the scale are more difficult to come by, one may need a pool of more than 500 essays from which to draw the data if using the field distribution of ratings. As alluded to previously, the prox (or prox cluster) variables are regressed against the essay ratings (or in the case where the model is not formulated on an a priori basis, to select the variables and optimize the weights). The validation sample (e.g., 200 cases) is used to evaluate the results from the first set of estimates. Most AES developers use multiple regression to create their models, but one developer uses multiple statistical techniques, and then selects the one that explains the most variance.

In the second approach, the evaluation of content may be accomplished through the specification of vocabulary (i.e., the evaluation of the other aspects of writing is performed as described above). Latent semantic analysis and its variants are employed by some developers to provide estimates as to how close the vocabulary in the candidate answer is to a targeted vocabulary set (Landauer *et al.*, 1998).

The third approach is to develop models that are based on a gold standard formulated by experts. To date, this mechanism for developing models is more theoretical than applied. If normative models can be created for the relevant dimensions of writing (i.e., age and writing genre), then other variables could be tailored on an a priori basis to generate a statistical blueprint for the ideal response. The blueprint may or may not be aligned with human ratings. For example, the guidelines for a few high-stakes writing programs explicitly direct raters to ignore expressions of nonstandard English. However, raters find this a difficult challenge, even when exposed to comprehensive training programs. When presented with an expression of nonstandard English, a typical rater will inevitably undervalue the essay even though an answer may be functionally equivalent to a response given in standard English. AES would have the capacity to overcome this human limitation if the relevant affected variables associated with nonstandard English can be isolated and adjusted.

AES Programs

Presently, there are three major developers of AES. The Educational Testing Service (ETS) has e-rater which is a

component of Criterion, a comprehensive electronic portfolio administration system. E-rater is also used as a scoring application for high- and low-stakes assessments, as well as a number of test-practice applications. Vantage Learning has developed Intellimetric which is also part of an electronic portfolio administration system called My-Access. Finally, Pearson Knowledge Technologies supports the Intelligent Essay Assessor which is used by a variety of proprietary electronic portfolio systems. All of the products have the capacity to receive text via a webpage and return feedback to both a student user and comprehensive database that may be accessed by teachers. In the paragraphs below, a short description is given that illustrate the kinds of factors/dimensions/variables used in building AES scoring models. References are provided for a more comprehensive description of the process.

The construction of e-rater v. 2.0 models is given in detail in Attali and Burstein (2006). (E-rater v.2.0 is the infrastructure for all subsequent version of e-rater. Currently, e-rater v.9.1 has been released. Some of the mathematical transformations implemented in the earlier e-rater v. 2.0 have been modified in more current versions.) It is composed of up to 12 features used by e-rater v.2.0 to score essays. These 12 features are associated with six areas of analysis: errors in grammar, usage, and mechanics (Leacock and Chodorow, 2003); style (Burstein, 2003); identification of organizational segments, such as thesis statement (Burstein *et al.*, 2003); and vocabulary content (Attali and Burstein, 2006).

Eleven of the individual features reflect essential characteristics in essay writing and are aligned with human-scoring criteria. These features included related to: (1) proportion of errors in grammar, (2) proportion of word-usage errors, (3) proportion of mechanical errors, (4) proportion of style comments, (5) number of required discourse elements, (6) average length of discourse elements, (7) score assigned to essays with similar vocabulary, (8) similarity of vocabulary to essays with score 6, (9) number word types divided by number of word tokens, (10) log frequency of least common words, (11) average length of words, and (12) total number of words (Attali and Burstein, 2006). (This feature is not used in the current version of e-rater.) E-rater uses a sample of human-scored essay data for model building purposes. E-rater identifies features and feature weights are assigned using a multiple regression procedure. E-rater models can be built at the topic level, in which case a model is built for a specific essay prompt. However, more often, e-rater models are built at the grade level. So, for instance, a model is built for sixth-grade writers in Criterion. Writers can respond to topics selected by the teacher from the set of Criterion prompts, or the teacher can assign his or her own topic, and the sixth-grade model will be used to score these teacher–topic responses.

A comprehensive specification of the Intellimetric model is given in Elliot (2003). The model selects from 500

component features (i.e., proxies) (and clusters the selected elements into at least five consolidated sets). These sets include content, word variety, grammar, text complexity, and sentence variety. Other dimensions of writing may be used, but these five are common to Intellimetric models. Intellimetric uses word nets based on Latent semantic dimension which is similar in nature to LSA (i.e., it determines how close the candidate response is, in terms of content, to a modeled set of vocabulary). Word variety refers to word complexity or word uniqueness. The grammar composite that evaluates things like subject-verb agreement, and text complexity is similar in nature to ascertaining the reading level of the text. The information gleaned is then used by a series of independent mathematical judges, or mathematical models, to predict the expert human scores and then optimized to produce a final predicted score. Typically, the judge that explains the largest proportion of rater variance will be employed in model development.

The technical details of the Intelligent Essay Assessor (IEA) are highlighted in Landauer *et al.* (2003). IEA is modeled using a two-pronged approach. The content of the essay is assessed by using a combination of external databases and LSA. For example, if the writing prompt had to do with the differentiation among Freud's concepts of superego, ego, and id, the reference database might include the electronic version of an introductory text in psychology. From that database, LSA would determine the likelihood of encountering certain words (e.g., the term conscience as a synonym for superego) given the constellation of vocabulary in the reference text. A candidate essay with more relevant vocabulary will be awarded a higher score. In setting up the models, IEA incorporates a validation procedure to check that LSA scores are aligned with those that might be given by human raters.

In contrast to e-rater and Intellimetric, the noncontent features (e.g., mechanics, style, and organization) of IEA are not fixed, but rather are constructed as a function of the domains assessed in the rating rubric. The weights for prox variables associated with these domains are predicted based on human ratings, and then are combined with the score calculated for content.

Reliability and Validity

As AES models often formed by using more than two raters, studies that have evaluated interrater agreement have usually showed that the agreement coefficients between the computer and human raters is at least as high or higher than among human raters themselves (Elliot, 2003; Landauer *et al.*, 2003; Page and Petersen, 1995). All AES engines have obtained exact agreements with humans as high as the mid-1980s and adjacent agreements in the mid-high 1990s – slightly higher than the

agreement coefficients for trained human raters. Several validity studies have suggested that AES engines tap the same construct as that being evaluated by human raters. Page *et al.* (1995) examined the construct validity of AES, Keith (2003) summarized several discriminant and true-score-validity studies of the technology, and Attali and Burstein (2006) demonstrated the relationship between AES and instructional activities associated with writing.

AES is not without its detractors. Ericsson and Haswell (2006) performed a comprehensive critique of the technology from the perspective of those who teach postsecondary writing. Objections to the technology ranged from a concern about the ethics of using computers rather than humans to teach writing to the lack of synchronicity between how human graders approach the rating task and the process by which AES evaluates a writing sample to failed implementations of AES in university placement-testing programs. Clearly, there are certain types of stylized text writing that AES may never be able to evaluate. Nevertheless, AES is now used as a scoring process for high-stakes tests (e.g., GMAT) and is provided as a common instructional intervention for writing.

AES was a technology trigger that has spawned several related, and new innovative education technologies. In the next section we provide descriptions of emerging technology that, based on AES, has migrated to other measurement domains.

Transformations into New Applications

The success of AES and short-answer scoring (Leacock and Chodorow, 2003) has set the stage for a number of new capabilities developed for text-based analysis for enhanced feedback related to technical and organizational writing quality to help both native and non-native English speakers, and applications that incorporate text-analysis capabilities to provide reading-comprehension support for English-language learners (ELLs). Until now, the majority of AES and related capabilities have focused on text. However, speech-based capabilities are also making their way into commercial applications. In light of this, the second half of this section is focused a discussion of a speech-based, instructional capability currently used for scoring the speech of ELLs.

Criterion Online Essay Evaluation Service

As mentioned above, automated essay-scoring engines are typically combined with electronic portfolio systems to provide a full-spectrum set of services for those involved with writing instruction and assessment. In this section, a description of the Criterion online essay evaluation service is provided. The application is designed to help

teachers in K-12 classrooms, in community college, and university classrooms who typically have a large number of writing assignments to grade. This limits the number of writing assignments that teachers can offer to students. In an effort to offer additional writing practice to students, researchers have sought to develop applications not only for AES, but also for offering more descriptive essay feedback similar to teacher feedback of student writing: indications of grammar, usage, and mechanics errors, stylistic, and organization and development issues. Pioneering work in automated feedback of this kind was initiated in the 1980s with the Writer's Workbench (MacDonald *et al.*, 1982), and continues in applications, including the Criterion online essay evaluation service (Burstein *et al.*, 2004), the AOL Writing Wizard, and Vantage Learning MY Access!®.

The Criterion online essay evaluation service combines e-rater AES, advisories indicating anomalies, such as off-topicality (Higgins *et al.*, 2006), and descriptive feedback. The descriptive feedback is comprised of a suite of programs that evaluate and, subsequently, flag essays for errors in grammar, usage, and mechanics; identify an essay's discourse structure; and recognize undesirable stylistic features. As the population of ELLs grows, researchers are working on enhancements to the grammatical error-detection component to accommodate the kinds of mistakes more common in the ELL population. This kind of feedback includes determiner and preposition errors (Han *et al.*, 2004), and collocation errors (e.g., strong computer instead of powerful computer) (Futagi *et al.*, 2008; Pantel and Lin, 2000; Shei and Pain, 2000).

Criterion offers a prewriting (planning) utility. This emphasis on planning was a logical outgrowth of the process-writing approach that Criterion embodies. Both earlier literature (Elbow, 1973) and more recent research have suggested that making plans can help students produce better-quality writing, just as revising drafts can (Chai, 2004; Goldstein and Carr, 1996). In light of this research, it is advisable to incorporate formal planning activities into writing-instruction applications. The ability to collect student-planning data through formal planning applications provides a new and authentic data source that can be used in writing research. Other computer-based instructional systems also offer a planning tool, including Inspiration Software, Inc., which offers elaborate graphic organizers for writing and research projects, while online writing-instruction applications such as the AOL Writing Wizard, CompassLearning Odyssey Writer, and Vantage Learning MY Access provide onscreen planning tools to aid in the process of composition.

Generally speaking, researchers continue to develop capabilities for online writing instruction programs that are aligned with different populations of students and their respective needs with regard to their becoming more proficient writers.

Text Adaptor: Technology to Support ELLs

Authentic texts for the classroom that are grade-level appropriate and accessible to ELLs are often unavailable, especially in middle school and high school. As a result, the time-consuming practice of manual text adaptation has become a required task for both ESL and content-area teachers. Research suggests that certain kinds of text modifications, specifically vocabulary expansion and elaboration (i.e., providing synonyms and native-language cognates) can facilitate students' comprehension of content in a text (Perez, 1981; Carlo *et al.*, 2004; Fitzgerald, 1995; Hancin-Bhatt and Nagy, 1994; Ihnot, 1997; James and Klein, 1994; Jimenez *et al.*, 1996; Nagy *et al.*, 1993; Oh, 2001; Yano *et al.*, 1994).

Text Adaptor, a web-based tool, was designed as an authoring tool to support K-12 teachers in the text-adaptation practice. While we continue to develop the tool, it currently incorporates several natural language processing (NLP) capabilities to support automated generation suggested text modifications for classroom texts. Tool suggestions are similar to the kinds of adaptations that teachers might implement for ELLs in their content-area classes.

Text Adaptor allows users to import a text or webpage, and subsequently, to generate the following types of adaptations of the imported text: English and Spanish text summaries, vocabulary support, including synonym (Lin, 1998), antonym, and Spanish/English cognate identification (WordNet lexical database). Text Adaptor also identifies complex phrasal and sentence structures, and academic vocabulary, fixed phrases (e.g., phrasal verbs and collocations), and cultural references. Teachers can then modify the text accordingly, given the learning needs of the ELL students in their classrooms. NLP capabilities used to generate these adaptations include, automatic summarization (Marcu, 2000), machine translation (Language Weaver's English-to-Spanish machine-translation system), and synonym and antonym identification. The adaptation capabilities include strategies used by teachers to manually create adaptations, such as summaries and varied vocabulary support, as well as translate a text into another language. Teachers can use Text Adaptor to author any kind of classroom text, including reading texts, activities, and assessments.

As part of this research, a 2008 pilot study was conducted in two online teacher professional development (TPD) for ELL teachers in the United States: one at a large, private university on the west coast, and another at a large, private university on the east coast (Burstein, 2009; Shore *et al.*, 2009). A central purpose of the pilot was to gauge whether Text Adaptor increased teachers' linguistic awareness, resulting in improved text adaptations for ELLs. A pre-post test design was implemented with approximately 70 teachers enrolled in the TPD courses. The pilot activities were integrated into the respective

TPD courses. All participants completed online background surveys about their educational and teaching experiences, and postsurveys that asked the control group about their experience adapting texts in the pilot study, and asked the treatment group about their experiences using Text Adaptor. All participants completed manual (pre-) adaptations to gauge baseline adaptation knowledge and ability. Both completed a mid- and post-adaptation activity. Control teachers completed these activities manually, while treatment teachers were trained to use Text Adaptor and complete their adaptations using the tool. An important outcome indicated that all teachers who participated in this pilot gained knowledge about linguistic features as a result of the TPD training. Teachers were better able to articulate how to modify content to make it accessible to all students. In comparative analyses of the pre- and postadaptations, we found that teachers who used Text Adaptor modified features in texts that were closely associated with best practices in modifying materials for non-native English speakers, and modified the language and content of the text more comprehensively than teachers who did not have access to Text Adaptor. Positive outcomes suggesting teachers' increased knowledge and linguistic awareness around text adaptations when they used the tool has inspired additional research toward developing additional tool features to support authoring of content-area texts for ELLs.

Automated Scoring of Spoken Responses

Automated scoring of speech follows a paradigm similar to that of AES. First, language-related features are extracted, and in a second step a scoring model is used to compute a score based on a combination of these features. The main difference between text and speech is that the word identities are unknown in speech, and additional programming is needed for a speech recognizer to generate word hypotheses from the digitized candidate's speech response to an item prompt. (Another difference from an assessment perspective is that speech testing is generally done for non-native speakers.)

Ordinate, a subsidiary of Harcourt, has been developing language tests since the 1990s where basic language abilities such as reading or repeating are tested (Bernstein, 1999). This is another way of avoiding the high error rate in open-ended speech recognition for spontaneous speech. They showed correlations around 0.80 between their tests and other widely used language tests such as ETS's Test of English as a Foreign Language (TOEFL) (Bernstein *et al.*, 2000).

Cucchiari *et al.* (1997a, 1997b) developed a speech-recognition-based automatic pronunciation scoring system for Dutch by using features such as log likelihood Hidden Markov Model scores, various duration scores, and information on pauses, word stress, syllable structure,

and intonation. They also found good agreement (correlations above 0.70) between machine scores and human ratings of pronunciation.

Stanford Research Institute (SRI) International, similarly, has been developing an automatic pronunciation scoring system, EduSpeak, which measures phone accuracy, speech rate, and duration distributions for non-native speakers who read English texts (Franco *et al.*, 2000). Unlike in Ordinate's test, the texts being read need not be known to the system for prior training.

At ETS, research in automated speech scoring has been conducted since 2002. In 2006, a first speech-scoring system, SpeechRater^M, was successfully deployed to score the speaking section of TOEFL Practice Online (TPO). This is an environment that helps students prepare for the TOEFL. Unlike for the aforementioned predecessors, the goal for developing SpeechRater is to provide scoring for assessments that cover a wide range of speaking proficiency (i.e., not only pronunciation) and to elicit spontaneous and natural speech from the test candidates as opposed to mere reading or repetition (Xi *et al.*, 2006, 2008; Zechner and Bejar, 2006; Zechner *et al.*, 2009).

The tasks scored by SpeechRater are modeled on those used in the speaking section of the TOEFL iBT (Internet-based test). These tasks ask the examinee to provide information or opinions on familiar topics based on their personal experience or background knowledge, as well as to respond to read or audio stimuli related to campus life and academic situations, such as lectures. The speaking time per item is about a minute. They are scored on a scale of 1–4, with a score of zero assigned to responses which do not address the task.

The design of SpeechRater is similar to that of e-rater, which underscores both the influence which the history of work in essay scoring has had on the development of speech-scoring systems, and the fundamental similarities in the two domains. Both systems proceed by first extracting a vector of features to represent a response, and then using a machine-learning system to predict the appropriate score based on those features.

In fact, there is a preliminary step in the case of SpeechRater: the response is first processed by a speech recognizer, the output of which provides a more pliable basis for the construction of scoring features than the raw speech stream. This speech recognizer is adapted to the speech of non-native English speakers from a wide variety of first-language backgrounds, but still manages a word accuracy rate of only around 50%. While this means that, on average, every other word is recognized incorrectly, this is the best that can currently be achieved by state-of-the-art wide-coverage speech-recognition systems on data from nonnative speakers with multiple-language backgrounds and proficiency levels, under variable recording conditions. (Since TPO is web-based,

examinees may record their responses in their own homes, using their own microphones.)

This level of recognizer performance means that the features extracted by SpeechRater must not be highly dependent on recognition accuracy. By the same token, this means that SpeechRater cannot presently be expected to account for the full range of elements mentioned in the TOEFL rubric. The rubric specifies three dimensions of attributes which contribute to the score of a response:

- delivery (low-level technical features of speech production, such as pronunciation and fluency),
- language use (formal cues of linguistic competence, such as grammar and diction), and
- topic development (higher-level semantic, pragmatic, and organizational aspects of the response).

Delivery features can most easily be extracted from the state of the speech-recognition system, while language use is more difficult to address, given the constraints of recognition accuracy. Of course, the appropriate development of the topic is even more challenging to assess without an accurate transcript of the response.

Most of the features actually used in SpeechRater address the delivery aspect of the TOEFL speaking construct in one way or another. A subset of the features do, however, relate to the language-use dimension of the construct as well. The statistical model SpeechRater uses to predict the score on the basis of these features is a multiple linear regression, although promising experiments have been performed using decision trees as well.

Currently, SpeechRater is in operational use to score the TOEFL Practice Online speaking section only. It provides the examinee with a predicted score for the entire section, comprised of six speaking items, and with a range within which their score is expected to fall with a certain probability. In the future, the application's use may be expanded to other testing programs, and work is being conducted to expand the construct coverage of the model, to bring it into closer alignment with the scoring of the operational TOEFL.

Conclusion

As amazing as the invention of television was in the late 1940s, it was clear that the kinescopic pictures and mono-channel sound that reflected the technology of the times was an inadequate substitute for re-creating the real thing. However, over time, improvements were made to the broadcasting enterprise – tape for the kinescope, color, multi-channel sound, and high-definition clarity. In addition, new uses were made for television beyond entertainment (e.g., instruction, security). Do these developments make the experience any more authentic? Maybe. How often have you heard someone say, “I’d rather watch it on TV”?

In a similar vein, AES might still be characterized as an emerging technology. Though it has been demonstrated to replicate human judgments in the grading of essays, over time it will be enhanced to do so with even more proficiency and accuracy. Moreover, it has branched out to perform other roles (instruction) and is now used as a conceptual platform for other applications (language-proficiency ratings). Finally, it has engendered a discussion about what constitutes good writing and how it is best achieved.

Classical Test Theory Reliability

M D Miller, University of Florida, Gainesville, FL, USA

© 2010 Elsevier Ltd. All rights reserved.

Reliability refers to the degree to which test scores are free from errors of measurement. It is not a global property of an assessment. Instead, different types of errors of measurement might be considered for different test uses. For example, a test might provide reliable scoring without being stable over time. Reliability is also a matter of degree. Tests are not generally perfectly reliable or completely unreliable. Instead, a test is reliable to some degree.

Estimates of reliability quantify the amount of measurement error for a particular test use or interpretation for a specified population. Although reliability can be defined broadly in terms of consistency or generalizability, specific statistical indices of reliability will vary depending on the statistical model and the sources of error. The statistical model may be based on classical test theory, generalizability theory, or item response theory. For classical test theory, there are multiple indices of reliability based on different sources of measurement error, including item heterogeneity, equivalence of test forms, stability over time, or consistency of subjective ratings. Different sources of error would be of concern in different contexts. For example, the test score from a student writing an essay will be affected by errors in scoring, while the test score from a student taking a multiple-choice test would be affected by the heterogeneity of the items selected to measure the construct. In addition, a test score can be affected by multiple sources of error simultaneously. A student taking an admissions test would be affected by the heterogeneity of the items, the form of the test, and the subjectivity of the scoring for any open-ended written portion of the test. Thus, there are many types of reliability that vary depending on the sources of error being considered. These varying definitions should be selected based on the particular test use or score interpretation being made and one type of reliability should not be considered interchangeable for another.

Classical Test Theory

Classical test theory is defined such that any observed test score, X , is the sum of a true score, T , and a random error, E . That is,

$$X = T + E$$

This model assumes that the expected value of the random errors are zero and that the random errors are uncorrelated

with the true score, with errors on alternate forms of the test, and with other measures such as another test or grades in school. Validity focuses on the definition (i.e., use and interpretation) of the true score, while reliability focuses on the random error. The error is the sum of all random effects, while the true score is the sum of all consistent effects. Thus, the error is undifferentiated with respect to different sources of randomness unlike in generalizability theory. Broadly, two indices of reliability are commonly reported: the reliability coefficient and the standard error of measurement (SEM).

The reliability coefficient ($\rho_{XX'}$) is defined as the ratio of the true score variance (σ_T^2) to the observed score variance (σ_X^2), or the ratio of the true score variance to the sum of the true score variance and the error variance (σ_E^2). That is,

$$\rho_{XX'} = \sigma_T^2 / \sigma_X^2 = \sigma_T^2 / (\sigma_T^2 + \sigma_E^2)$$

Hence, the value of the reliability coefficient is the proportion of variation in test scores that can be attributed to consistent measurement (i.e., the true score). The reliability coefficient ranges from 0.0 to 1.0 with higher values being preferred. At $\rho_{XX'} = 0.0$, there is no consistency in the measurement procedure and the observed score is equal to the random error ($X = E$). At $\rho_{XX'} = 1.0$, the observed score has no error and the observed score is equal to the true score ($X = T$). In practice, the reliability coefficient will be somewhere between the two extremes.

The SEM is defined as the standard deviation of the errors of measurement, σ_E . The SEM ranges from 0.0 to the standard deviation of the observed scores, σ_X . When the SEM = σ_X , there is no consistency in the measurement procedures, the reliability coefficient is equal to 0.0, and the observed score is equal to the random error. When the SEM = 0.0, there is perfect consistency in the test scores, the observed score is equal to the true score, and the reliability coefficient is equal to 1.0. In practice, the SEM will fall somewhere between the two extremes.

The reliability coefficient is an easily interpreted index of the consistency of the test scores since it is in a standard range for all tests. While the SEM is more difficult to interpret initially, it is in the metric of the test scores which allows for the interpretation of the individual test scores via confidence intervals. Another advantage of the SEM is that it is not based on the true scores and, consequently, its estimation is not influenced by sampling errors. The reliability coefficient will be underestimated when

the sample range of scores is restricted, whereas the SEM will be largely uninfluenced by sampling fluctuations.

Types of Reliability

Within the framework of classical test theory there are several types of reliability coefficients based on the source of the random errors. The types of reliability discussed below are test–retest, alternate form, alternate form test–retest, interrater, split half, and internal consistency.

Test–retest reliability is used to examine the stability of the trait being measured over time. The reliability coefficient is the correlation between test scores for a sample taking the same test on two occasions. Generally, test–retest reliability is higher when the time span between test administrations is shorter. However, the test–retest reliability should be estimated with a time interval that mirrors the actual use of the test rather than trying to maximize the value of the coefficient.

Alternate form reliability is used to measure the equivalence of test scores across two (parallel) forms of a test. The reliability coefficient is the correlation between test scores on the two forms of the test taken by the same sample without a substantial time lag. Usually, half of the sample receives one form first (e.g., form A), while the other half of the sample receives the other form first (e.g., form B) so that there is no order effect. Then, examinees take the form they had not taken yet. Alternate form reliability is higher when care is taken to make sure that the two forms are equivalent in content and statistical properties (i.e., mean, standard deviation, and distribution shape).

Alternate form test–retest reliability follows the same procedure as with the alternate form reliability except that there is a time lag between test administrations. In this case, the errors of measurement include stability over time and equivalence of the forms. In general, this type of reliability will be lower than alternate form or test–retest reliability which targets only one type of random error.

Interrater reliability is used to measure the consistency of ratings from subjective scoring. The reliability coefficient is the correlation between the ratings from two raters on the same sample of writings/essays/performances. Interrater reliability is higher when standardized procedures are used by the raters to score the writings. At a minimum, the standardized procedures should include training of the raters and clearly defined rubrics. Large-scale assessments further standardize the procedures to include the use of benchmarks, monitoring the process, intervening when ratings are discrepant, and other procedures to check the rating process.

Split-half reliability is used to measure the consistency within a single administration of a test by examining

the relationship between two halves of the same test. The procedure for split-half reliability is to administer a single form of the test to a sample. The reliability estimate is then based on the correlation between two halves of the test adjusted for test length. That is, the test is divided into two equivalent halves based on test content and item statistics (often this can be accomplished by using odd- and even-numbered items to form the halves) and the halves are correlated. However, the reliability will be less for half of a test than it is for the full-length test. Consequently, the correlation between the halves is adjusted upward using the Spearman–Brown prophecy formula. Split-half reliability will be higher when the equivalence of the two forms is higher in terms of content and item statistics. However, the matching of the two halves should not be completed on the basis of the sample statistics since random sampling fluctuations could inflate the value of the reliability. Instead, careful matching should be completed based on content and item statistics from a prior data collection. The Spearman–Brown prophecy formula is:

$$\rho_{XX'} = 2\rho_{HH'}/(1 + \rho_{HH'})$$

where $\rho_{XX'}$ is the full-length reliability and $\rho_{HH'}$ the half-length correlation.

Internal consistency is used to measure the consistency of items within a single test form. The procedure for internal consistency is to administer a single form of the test to a sample and estimate the internal consistency using item and test statistics with an internal consistency formula. The formula for internal consistency has many equivalent forms in the literature, including the Kuder–Richardson 20 (KR20) formula for dichotomously scored items and Cronbach's alpha. Internal consistency is also easy to compute with most standard statistical software (e.g., SPSS or SAS). Internal consistency is higher when the items are more homogeneous. The formula for Cronbach's alpha coefficient is

$$\alpha = \frac{n}{n-1} \left(\sigma_X^2 - \sum_{i=1}^n \sigma_i^2 \right) / \sigma_X^2$$

where n is the number of items, σ_X^2 is the total test score variance, and σ_i^2 is the item variance.

Table 1 summarizes the reliability coefficients and their major sources of error that are reported in classical test theory.

Each of the reliability coefficients shown in **Table 1** differs in its data collection procedure, computation, and the major source of error. The appropriate reliability coefficient should match the intended use or interpretation of the test. For example, when subjective measurements are part of the assessment procedure, interrater reliability is needed. When multiple items are being used (which should be the case), internal consistency or

Table 1 The reliability coefficients and their major sources of error

<i>Reliability type</i>	<i>Source of error</i>
Test–retest	Stability over time
Alternate form	Equivalence across forms
Alternate form test–retest	Stability over time and equivalence across forms
Interrater	Consistency of ratings
Split half	Equivalence across halves
Internal consistency	Equivalence and item homogeneity

split-half reliability should be used. In short, the reliability estimate(s) should include all sources of error that will be part of the test use or interpretation. One type of reliability should not substitute for another.

Standard Error of Measurement

The reliability coefficient is used to quantify the precision of an assessment for a particular use or interpretation. The index is simple to interpret since it is always based on the same scale (0.0–1.0). However, the reliability coefficient fails to show the amount of error that might be expected in an individual's test score. The SEM is the standard deviation of the errors of measurement and can be used to create confidence intervals for examinee scores. Assuming a normal distribution, 68% of the observed scores will be within one SEM of their true score; and 95% if the observed scores will be within 1.96 SEMs of their true score. For example, if $SEM = 2.00$ and an examinee's true score was 25, upon repeated measurements, 68% of the scores for that examinee would be between 23 and 27. Note that the confidence interval is around the true score and not the observed score, which leads to the interpretation that 68% of the time that a confidence interval based on one SEM is constructed, it will contain the true score.

As with the reliability coefficient, an SEM can be created for different types of measurement error. In fact, the SEM is calculated using the appropriate reliability coefficient so that the appropriate source of error is being used. Thus, **Table 1** can be used for the SEM or the reliability coefficient so that the SEM can be created with each of the different sources of error.

Magnitude of Reliability

The literature does not provide definitive guidance on acceptable levels of reliability. However, what constitutes an acceptable level of reliability is determined by the use of the test. Uses of the test with higher stakes require higher levels of reliability. For example, reliability for a test being used in theoretical research may not require

the same level of consistency as would be required for high stakes uses of tests such as high-school graduation, certification, or licensure.

How to Increase Reliability

It is important to be able to increase reliability when developing instruments. In general, there are two ways that should always be considered in increasing reliability: greater standardization and increasing the number of items. Test administration and test development procedures should be standardized so that no random errors are introduced. The effect of the standardization will not only globally affect each type of reliability but will also have specific effects on certain types of reliability. Standardization includes methods to create equivalent forms of a test (alternate form), and methods to create homogeneous pools of items (internal consistency), or equivalent halves of tests (split half), as well as it includes methods to create consistency in scoring through the development of rubrics and standardized scoring procedures (interrater).

Another key element to increasing reliability is increasing the length of the test. The Spearman–Brown formula is based on the principle that longer tests are more reliable. Assuming that the conditions of testing do not change with increased length (i.e., fatigue, boredom, or item quality), increasing the number of items always leads to more reliable tests. Thus, short forms of a test or subscores are generally less reliable than the full form.

Reliability and Aggregation

Increasing the number of items will increase the reliability of test scores due to averaging over more data. Similarly, increasing the number of examinees and averaging across their scores will reduce the SEM and increase reliability. That is, the reliability of the mean will generally be higher than the reliability of an examinee. This applies to estimates for the full sample as well as to aggregates such as classrooms, schools, or states. Whether averaging across items or examinees, the estimate becomes more stable. Indeed, the SEM will almost always be lower for group means than it is for individuals. (Note: under some conditions the reliability coefficient could be lower for the group means when the true score variance in the groups is restricted in range. However, even under these conditions, the SEM will typically be lower and the group means will be more stable.)

Reliability and Growth Scores

The reliability of growth or difference scores, defined as posttest minus pretest, has received considerable attention

in the literature. Some have argued that the growth score is unreliable and that growth is negatively correlated with the pretest. That is, growth will be higher for examinees with low pretests. However, other researchers have pointed out that low reliability for the difference scores does not necessarily result in less power for comparisons among groups and the difference score may be the construct of interest. At any rate, caution should be used in interpreting growth scores at the examinee level.

Relationship of Reliability and Validity

Classical test theory assumes that an examinee's test score is the composite of a true score and random error. Validity addresses the true score by examining its uses and interpretations. Thus, any systematic error or bias is part of the true score, while only random errors are addressed in the reliability analysis. However, reliability is a necessary, but not sufficient, condition for validity. This means that there needs to be a true score (with some level of reliability) to examine validity; however, that the existence of a true score does not guarantee the validity of it. That is, the true score may still be a biased estimate of the construct of interest as a result of systematic errors. In addition to this relationship of validity and reliability, there may be a tension between the two psychometric properties of the test. Higher reliability can be attained by standardizing

the testing procedure which has the potential to reduce the breadth of the construct being measured and, thus, to decrease the validity. For example, higher internal consistency is attained by increasing item homogeneity. To the extent that the construct requires heterogeneity of the items, this will create a tension between reliability and validity. As a second example, interrater reliability is increased by standardizing the scoring procedure (e.g., clearly defined rubrics and training). This standardization can limit the definition of good writing by not including some types of writing in the rubric and, as a consequence, limit the breadth of the construct. As a result, it is important to consider the impact of any standardization on the validity of the test as well as the reliability so that the construct is still clearly being measured.

Criterion-Referenced Measurement

S A Shrock and W C Coscarelli, Southern Illinois University, Carbondale, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Conjectural technique – A method of setting the passing score on a criterion-referenced or mastery test that relies on expert estimation of item or assessment task performance at the mastery borderline.

Contrasting groups – A method of setting the passing score on a criterion-referenced or mastery test by examining the performances of test-takers of known competency level.

Criterion-referenced measurement – The measurement of human performance in relation to a well-defined, accepted standard.

Domain-referenced measurement – The measurement of human performance by random sampling from a well-defined population of items or assessment tasks such that the percent correct on the measurement tool implies capability to perform the same percent of the population of items/tasks.

Domain specification – A set of descriptive criteria used to create the items or assessment tasks for a criterion-referenced or domain-referenced measurement tool.

Informed judgment – A method of setting the passing score on a criterion-referenced or mastery test by considering the preferred cutoff scores of all major stakeholders in the assessment.

Mastery testing – The measurement of human performance of specific competencies for the purpose of classifying the performer as a master or nonmaster of the competencies assessed.

Norm-referenced measurement – The measurement of human performance in relation to the performances of others.

Introduction

Criterion-referenced measurement typically refers to measurement of human performance in relation to an accepted, described standard. Performance, as used here, is evidence of a human competency – a demonstration of a skill or mastery of a knowledge base. Criterion-referenced measurement is frequently defined in contrast with norm-referenced measurement – the measurement of human performance in relation to the performances of

others. The two forms of measurement can be thought of usefully as two different ways to interpret test results; however, it is the role of test construction to produce results that allow the alternative interpretations. In other words, one cannot typically discriminate a criterion-referenced test from a norm-referenced one by simply examining the questions. However, the norm-referenced test will have been created to separate the test-takers' performances from one another, that is, to create test score variance, while the criterion-referenced test will have been composed of questions carefully matched to stated objectives or competencies. Norm-referenced measurements are ideal for making comparative, selection decisions among test-takers. Criterion-referenced measurement is useful for determining whether or not individual test-takers have specific competencies.

Criterion-referenced measurement is relatively new compared to norm-referenced measurement. Classical test theory that posits the assumptions and principles that undergird norm-referencing and its statistical indicators of reliability, validity, and error was developed and refined over the past century. Criterion-referencing was conceptualized as an alternative in the 1960s; its initial theory, principles and implementation procedures developed rapidly during the 1970s and 1980s, slowing considerably during the more recent past. On the other hand, the term is used more frequently now in the world of applied measurement than ever before, in school and university contexts as well as in those of government and business. To what extent current usage reflects adherence to the original tenets of the paradigm is a current issue in the field.

Distinctions Within Criterion-Referenced Measurement

The term criterion-referenced seems to be used interchangeably with domain-referenced, competency-based, objectives-based, and mastery testing, in education literature, if not among psychometric professionals. Actually, the terms imply important differences in test construction, as well as in test score interpretation.

Items included on a domain-referenced test are selected through a random or stratified random sampling from a pool of items generated to match a content domain specification. Because the items in the pool constitute essentially a population of tasks, the test-taker's percentage score on the domain-referenced test is taken to represent the percentage

of the total pool of tasks that the test-taker would perform correctly. The technology of domain-referenced testing was pursued aggressively during the 1970s. It presented some major challenges, most notably the need for tightly defined content domains that would ensure the generation of large numbers of comparable test items whose membership in the same population could be defended. This domain specification proved more feasible for some content areas (math and grammar) and cognitive levels (knowledge, comprehension, and application) than others (history, and science at the analysis level); the more complex the required cognition and the more divergent the universe of correct performances became, the harder the underlying premises of the domain-referenced model were to meet.

The terms objectives-based measurement and competency-based measurement suggest that test items are based only on descriptions of desired behaviors, rather than a comprehensive, precise content domain specification. These terms are largely nonspecific regarding test score interpretation.

Mastery testing introduces an alternative means of test score interpretation, that is, a dichotomous decision – master or nonmaster. In doing so, mastery test results open the analysis of test quality – especially reliability and validity indicators – to modifications of the statistical procedures used with norm-referenced tests. The major modification is reliance on the consistency and accuracy of mastery classifications, instead of score correlations, to calculate reliability and validity coefficients.

Criterion-referenced measurement could refer to any of the assessments described above. In this respect it has become an imprecise term and one is well advised to seek clarification of any usage with serious implications or consequences. The term now most often refers to mastery testing, although certainly not to the entire mastery learning model, and only rarely to domain-referenced measurement as it was originally proposed.

Criterion-Referenced Test Development

It is not true that criterion-referenced assessments are limited to tests composed of multiple-choice or other closed-ended questions, although these are the most common referents. Even though the procedures described below are phrased in terms of question-based test construction, a criterion-referenced measurement instrument could take the form of a performance test or other so-called authentic assessment composed of what might be more descriptively called assessment tasks.

Domain Specification

A criterion-referenced test begins with a thorough analysis of the competencies that the test must measure.

The result is a definitive set of behavioral descriptions that focus item creation, content validation, and score interpretation – a content domain specification. Failure at this stage of the process will doom the validity and, therefore, the usefulness of the test that results regardless of the efforts devoted to subsequent steps.

Popham (1978) provides guidelines for constructing content domain specifications. Descriptions of incorrect performance or responses are included in the elaborated objectives that constitute the domain specification.

Item/Assessment Task Writing

Using the guidance provided by the domain specifications and typically the assistance of a test design specialist, item writers draft a pool of items whose correct completion requires the criterion behaviors the test must measure. Instruction in the technical aspects of sound item writing at this draft stage pays great dividends in reduced revision of the items later. Novice item writers can be expected to have greater difficulty writing items that require cognition above the knowledge or memory level. The item-writing activity typically raises questions about the domain specifications; the two activities are actually reciprocal in practice.

The question of how many items should be created is not a simple one. More items should be written than will appear on the test – some would recommend creating twice that number – because during content validation and pilot testing, many flawed items will be discarded. The number also depends upon whether and how many parallel forms of the test are planned; because parallel forms of a test measure the same competencies using different items, additional items are required. Similarly, large numbers of items are needed if the goal is to build a bank from which items will be randomly chosen to form multiple parallel forms of the test. The length of the finished exam can be a function of many factors, perhaps the most important of which is the criticality of the decisions to be made based on the test results; test reliability will be a function partly of test length. Other factors include the breadth of the domain competencies assessed by the test, the number of different domains covered, and pragmatic yet critical factors such as available testing time and budget size.

Content Validation

The content validity of a criterion-referenced test is established by having content experts examine items and verify that they match (or elicit) the criterion behaviors described in the domain specification. If a criterion-referenced test cannot be said to have content validity, it probably does not matter what other kind of validity evidence might be presented in its defense. The resolution of litigation

surrounding these tests has tended to hinge on the content validity question.

At this stage in the test development process, the items should be examined for technical flaws such as cueing, improper reading level, and confusing language or visual images. In addition, the items should be screened for bias against any segment of the test-taker population, including stereotyping that could heighten test anxiety or other negative attitude in test-takers. If content experts are not skilled in detecting these flaws, then measurement specialists should be sought to provide this review. Flawed items must be revised or discarded. Substantial revision of items may mean that the content validation process must be repeated.

Item Analysis and Selection

At this point the test(s) are given to groups representative of the test-takers for whom the test was designed. The major goal of this pilot is the collection of item analysis data. Item statistics serve two major purposes: to detect flawed items for revision or elimination from the item pool and to provide a basis for matching items on difficulty and discrimination power to create parallel forms of the test. Suspected flawed items are those that appear substantially easier or more difficult than other items from the same domain specification, or any item with a negative discrimination coefficient. Numbers of test-takers included in the pilot sample should be larger as the stakes of the implemented test and the diversity of the intended test-takers increase. If the pilot sample is adequate, possible adverse impact of the test on subgroups of test-takers could be detected at this point.

It should be noted here that advocates of domain-referenced testing have argued that item analysis data should not play a role in the selection of items for domain-referenced tests (Millman, 1974). Domain-referenced testing theory posits that all items created to reflect the content domain are eligible for inclusion on the test; selection of the items is necessarily random, and this random selection guarantees the parallelism of all test versions and their fidelity to the criterion behaviors the test is designed to measure.

Standard Setting

After test revision is complete and the test assembled, the fundamental issue of standard setting – establishing the score that separates mastery from nonmastery – must be resolved. (Domain-referenced tests do not require a standard or cutoff score. The score interpretation is the percent of items correct.) Historically, psychometricians have relied on three classes of techniques: informed judgment, conjectural techniques, and contrasting groups. The informed judgment technique relies on a systematic review of the test by stakeholders and their consensus

decision on the standard for mastery. The conjectural approaches use subject-matter experts for review of test items and development of the cut-score. Contrasting groups approaches rely on gathering data of known masters and nonmasters and determining the cut-score based on the distributions of the two groups and the subjective determination of the risk associated with false positives or false negatives in selecting the standard. (An alternative standard setting process is still in use, although it provides no logical basis for mastery determination: “Standards by directive or authority” (Browning *et al.*, 2006) are established by legislative or managerial fiat.)

Current practice in standard setting has seen the ascendancy of conjectural techniques. Perhaps because the informed judgment process is too political and compromises test security, and contrasting groups procedures demand large sample sizes and are unwieldy for rapidly changing content areas, the conjectural approaches represent the mini-max strategy between feasibility and valid judgment. The Angoff technique was one of the first approaches proposed for standard setting; its applicability and ease of use with both closed-ended and open-ended testing approaches likely contribute to its continued popularity. A growing number of conjectural approaches are also being developed and implemented primarily for school accountability assessment, for example, Jaeger-Mills, Bookmark, and Body-of-Work procedures.

In the end, there is no technique in the psychometrician’s armamentarium that will provide a singularly statistical calculation of the correct standard; there is no substitute for professional judgment on the part of the standard setter.

Test Reliability

Establishing reliability for criterion-referenced tests requires a different set of assumptions than those for norm-referenced tests. As norm-referenced tests maximize variance to spread test-takers along a continuum of scores, criterion-referenced tests often result in a lack of variance in scores; for example, when all test-takers master the performance measured by the test. Further, since criterion-referenced tests often measure a series of discrete and independent performances, the assumption of a single unifying ability or construct is not met. Therefore, classic approaches to reliability must be reinterpreted in light of these alternative assumptions.

There are three general approaches to criterion-referenced reliability: decision consistency, single-test administration, and interrater reliability (Shrock and Coscarelli, 2007).

Decision consistency

In this approach, the test-taker is given two tests over a short period of time and the consistency of classification

of mastery is measured. This design can be either a test-retest model using the same form in both administrations or an equivalence model where two parallel forms are used to assess the same competencies. Reliability can be determined using the agreement coefficient (p_o), Cohen's kappa (κ), or phi (ϕ). The p_o is the easiest to conceptualize but provides an estimate inflated by chance; κ and ϕ will often provide similar indices, although κ is not a correlation coefficient and provides different information – the realized proportion of possible improvement in classification above chance level. A reliability estimate of 0.85 or higher is desirable.

Single-test administration

Mainly because of logistical, political, and economic issues, test designers must often accept a reliability estimate based on one test administration. Squared-error loss approaches use the squared distance between a person's score and the cutoff score to establish reliability. Livingston's coefficient kappa (κ^2) which draws on common norm-referenced internal consistency measures is one approach; the Brennan and Kane indexes of dependability $\Phi(\lambda)$ and Φ also provide similar information, although they seem to offer increased precision through a correction for chance. Subkoviak's Z also provides p_o and κ , although it requires support of an adjunct set of tables. Brennan's BB-CLASS software system provides a sophisticated assessment of decision consistency and accuracy. Generalizability (G) theory based on analysis of variance (ANOVA) models and item response theory (IRT) approaches also exist that provide reliability information (Cizek and Bunch, 2007). Livingston's κ^2 is probably more widely used due to its ease of computation and its use of norm-referenced statistics.

Interrater reliability

When mastery judgments of a performance are being made by observers, their reliability must also be determined. Simple percentages of agreement between or among judges should not be viewed as adequate measures of reliability. Both ϕ and κ , as used in the decision consistency approach, can be used to determine consistency among raters of a performance.

Concurrent Validation

Concurrent validation of a criterion-referenced test demonstrates the ability of the test to correctly classify masters and nonmasters. Only one administration of the test is needed for each test-taker and the estimate of validation is typically expressed through a ϕ correlation coefficient.

The concurrent validation process begins with the identification of known masters and nonmasters – a sample of test-takers who are representative of those between

whom the test is designed to distinguish. The potential range of errors includes:

1. introducing nonmasters who are far less competent than those nonmasters who will take the test,
2. choosing superior masters whose skills reside far above the cut-score,
3. choosing a sample of convenience rather than a representative sample,
4. choosing a sample that is too small for meaningful statistical purposes (fewer than 60), and
5. selecting judges who are not competent to make the selection of masters and nonmasters.

Once the test-takers are identified, the test is administered to each person. (Testing need not be done in a single administration time and location for all test-takers.) Phi is then calculated between the two dichotomous variables found in this design: the known status as determined by the judges (master/nonmaster) and the test's classification of each person (master/nonmaster).

Reporting Test Results

The most basic interpretation of criterion-referenced test results is a single decision: master/nonmaster. Currently, there is distinct pressure from test-takers and policy-makers alike to provide test results that reflect degrees of competence. Some seek to provide three outcomes, for example, basic, proficient, and advanced, while others advocate as many as five classifications. These categories are often developed not from a content analysis perspective but from statistical adjustments based, essentially, on the concept of standard error of measurement. Sophisticated approaches to create these psychometrically based classifications often rely on IRT to estimate standard error and provide a basis for creating categories.

At the moment, the confluence of political and personal stakeholders in test reporting, combined with the developing but unsettled issues in standard setting (Cizek and Bunch, 2007) should leave the test designer wary of making refined judgments. Organizations with access to large numbers of test-takers, stable content, and significant computing resources may be able to demonstrate relatively accurate classifications of competence from a single test. Those without such resources would be advised to adhere to the most basic form of criterion-referenced test development.

Application of Criterion-Referenced Measurement

Criterion-referenced tests are currently very widely used to test both adults and children of all ages. The early adopters of criterion-referenced tests seemed to be the

military and professional credentialing bodies. This application is perhaps not surprising for three reasons:

1. the required criterion behavior descriptions were more easily generated in the world of work than in the world of abstract school subjects;
2. the military and the professions had greater urgency to identify incompetent practitioners; and
3. resources to devote to the labor-intensive process of creating criterion-referenced tests were more available in defense departments and through a fee structure to professional credentialing groups than in school budgets.

More recently, businesses, especially large corporations, have sought to create criterion-referenced tests for numerous reasons. In this environment, the term certification testing is often used to describe criterion-referenced determination of masters and nonmasters.

On the other hand, major school accountability legislation passed by the United States federal government has demanded that individual states assess the academic progress of virtually every child in every school. This legislation has created an enormous demand for so-called criterion-referenced tests, aggravated by allowing each of the 50 states to develop unique tests. Whether the tests created in response are truly criterion-referenced is less clear.

Emerging Issues

Future issues in criterion-referenced measurement may well be: the applicability of rapidly developing test creation computer software; the influence of America's huge investment in school accountability testing on accepted practice and psychometric research; and the possible

impact of expanded corporate and school testing on test litigation and legislation. More research-oriented issues include application of IRT and computerized adaptive testing to criterion-referenced measurement; a consensus on selection of cut-score techniques; and Monte Carlo simulations to inform choice of an approach to reliability estimation.

Glossary

Bias – A test or item favors one group to the detriment of another, in other words, there is a disparity in its behavior according to one or more group variables (e.g., race, sex, socio-economic level, cultural background, and linguistic ability) which are, however, not relevant to the trait or variable that the test actually aims to measure.

Dichotomous versus polytomous – A dichotomous item is a categorical variable with two possible response values (Yes/No, Agree/Disagree, Success/Fail). A polytomous item is a categorical variable ordinal or nominal with more than two possible values (e.g. strongly disagree, disagree, agree, strongly agree). Most of the proposed methods have focused on detecting DIF in dichotomous items, more recently, and due to the development of new evaluation instruments in the educational context (portfolio-based assessment, authentic assessment, etc.) techniques for detecting DIF have also been adapted to polytomous items.

Differential item functioning (DIF)/differential test functioning (DTF) – Different probabilities of successfully responding to a given item/test for subjects with the same level of the measured characteristic, depending on the group to which they belong.

DIF amplification vs DIF cancellation – DIF amplification is produced when a subtest of items only shows DIF in one of the groups (e.g., focal group). DIF cancellation occurs when one subset of test items shows DIF in one of the compared groups, while another subset of items cancels out the effect of the second.

Focal and reference group – In DIF studies there are normally two groups, known as focal (in which DIF is assumed to exist) and reference (the majority group). However, some DIF techniques allow multiple focal groups.

Impact – Differences observed in item performance for two different population groups that are real differences in the underlying ability of interest measured by the test.

Non-uniform DIF – The difference between the two groups in terms of the probability of responding

correctly to the item is not the same at all levels of the trait, in other words, there is an interaction effect.

Matching criteria – For the groups to be comparable, they have to be equal with regard to a certain criterion, generally the total test score or an estimate of ability. The fact that the performance on the item is conditional on the ability level is fundamental to distinguish between differences in the functioning of the item and differences in the ability level of the groups.

Purification procedures – The DIF is re-evaluated in a second step (two-stage procedures) or by successive steps (iterative procedures), using as matching criteria only those items which do not present DIF in the previous analysis, the aim of which is to purge the items with DIF so that they do not form part of the matching criterion.

Uniform DIF – The probability of responding correctly to an item is greater for one group than another across all levels of the trait.

Introduction

Standardized tests are nowadays frequently used in the field of education to measure aptitudes, skills, interests, attitudes, and performance. The results they provide serve to guide decision making in areas such as personnel selection, promotion, and the evaluation of ability, and they also offer a framework for conducting cross-cultural studies. Given their extensive use in both educational decision-making processes and transcultural comparisons, the possibility of bias in test items has become a key concern when it comes to evaluating test validity, as is clear from the latest edition of the *Standards for Educational and Psychological Testing* (American Psychological Association *et al.*, 1999).

The existence of bias in educational measurement instruments can undermine the validity of a test, as some of its items may be benefiting certain population groups at the expense of others who are at the same level of the measured characteristic. Thus, conducting evaluations that seek to ensure the equity and validity of the interpretations and decisions made on the basis of a test has become a key feature of good professional practice in the field of

educational measurement. Indeed, it is essential to analyze the degree to which the measurement instruments used are free of bias and able to provide valid and fair assessments for groups of people from different demographic, social, cultural, and linguistic backgrounds. In this context, studies of differential item functioning (DIF) have drawn the attention of researchers and professionals at both the methodological and applied levels.

DIF, Bias, and Impact

Bias in a test or item means that the test or item in question favors one group to the detriment of another; in other words, there is a disparity in its behavior according to one or more group variables (e.g., race, sex, socioeconomic level, cultural background, and linguistic ability) which are, however, not relevant to the trait or variable that the test actually aims to measure. However, the term bias assumes that the reason why a given item behaves differently according to certain variables is known or under investigation, when in fact all that can generally be inferred from subjects' responses is that there are differences in the results obtained by different but equally able subjects.

Therefore, a more technical term to refer to this problem is DIF or differential test functioning (DTF). The precise definition of DIF varies across methods, according to whether binary or polytomous items are being examined. In general, DIF exists if an item's statistical properties vary according to the groups under study when these are matched on the attribute measured by the item. There are normally two groups: the focal group (generally the minority group), in which DIF is assumed to exist, and the reference group (generally the majority group). In dichotomous items, DIF is said to exist when the odds of a correct response to the item vary according to the grouping variable. In the framework of item response theory (IRT), DIF is defined as a difference in the conditional probabilities of item response in two or more groups.

When seeking to detect DIF it is important to distinguish between impact and differential functioning. Thus, item impact is present when the differences observed in item performance for two different population groups are real differences in the characteristic measured by the test; in contrast, DIF exists when subjects with the same level of the measured characteristic have different probabilities of successfully responding to a given item, depending on the group to which they belong.

Types of DIF

In general, two types of DIF can be distinguished: uniform and nonuniform. Previous research has identified both

DIF types in real data sets (Ellis, 1989; Hambleton and Rogers, 1989; Mellenbergh, 1982). DIF is said to be uniform when the probability of responding correctly to an item is greater for one group than another across all levels of the trait. In contrast, DIF is nonuniform when the difference between the two groups in terms of the probability of responding correctly to the item is not the same at all levels of the trait; in other words, there is an interaction effect.

DIF Techniques: A Classification

Although more than 40 years have passed since Cleary and Hilton (1968) first proposed using analysis of variance (ANOVA) to detect items that were biased by race or gender, the identification of such items in educational, psychological, and/or social measurement instruments is an issue that continues to arouse considerable interest. Indeed, many studies, whether from a methodological or an applied perspective, have addressed this controversial topic. Within the methodological field, various statistics have been proposed to detect DIF and the relative efficacy of each one has been analyzed under different applied conditions using simulation studies.

Given the wide range of statistical procedures available for detecting items with DIF, several authors have sought to classify them (Camilli and Shepard, 1994; Hidalgo and Gómez-Benito, 1999; Millsap and Everson, 1993; Potenza and Dorans, 1995). Camilli and Shepard (1994) group the procedures into three categories: (1) classical test theory (CTT) and analysis of variance methods; (2) methods based on IRT; and (3) contingency table methods. **Table 1** shows a classification of DIF detection methods according to the following criteria:

1. type of model: parametric or nonparametric;
2. type of matching variable: observed or latent; and
3. type of item: binary or polytomous.

As can be seen in **Table 1**, all these procedures take the matching variable as continuous and DIF is detected on the basis of the observed score or latent variable. Those methods which use an estimation of the latent variable first specify a measurement model and then check to see if the parameters of this model remain invariable for the different groups (Millsap and Everson, 1993). Although it is not very common to find continuous items, it is possible to detect DIF for them by using, for example, linear regression analysis or confirmatory factor analysis, or the more general framework of structural equation models.

Nonparametric DIF Techniques

The statistical techniques which fall into this category are generally based on contingency tables. Three approaches can be distinguished:

Table 1 Classification of DIF techniques

<i>Item format</i>	<i>Matching variable</i>	<i>Model</i>	<i>DIF technique</i>
Binary	Observed score	Nonparametric	Mantel–Haenszel (MH) binary statistic
		Parametric	Standardization Logistic regression analysis Log-linear models Latent class models
	Latent trait	Nonparametric	SIBTEST CATSIB
		Parametric	IRT log-likelihood ratio Lord chi-squared statistic Area measures IRT-Differential Item Functioning Test (DIFT) Confirmatory factor analysis (CFA) Multiple-indicator multiple-cause (MIMIC)
Polytomous	Observed score	Nonparametric	MH-generalized MH-ordinal Standardization
		Parametric	Multinomial logistic regression Discriminant logistic regression Log-linear models Latent class models
	Latent trait	Nonparametric	POLYSIBTEST
		Parametric	IRT log-likelihood ratio Lord chi-squared statistic Area measures IRT-Differential Item Functioning Test (DIFT) Confirmatory factor analysis (CFA) Multiple-indicator multiple-cause (MIMIC)

1. those which involve testing the hypothesis of equal proportions;
2. those which use a categorical model; and
3. the simultaneous item bias test (SIBTEST) procedure.

The first group includes χ^2 (Scheuneman, 1979), the standardization procedure (Dorans and Kulick, 1986), and the Mantel–Haenszel (MH) statistic (Holland and Thayer, 1988); the second would comprise logit and log-linear models (Mellenbergh, 1982), latent class models (Cohen and Bolt, 2002; De Ayala, *et al.*, 2002), and logistic regression (LR) analysis (Swaminathan and Rogers, 1990); and finally, the third group includes the SIBTEST framework (Shealy and Stout, 1993a, 1993b). Among these techniques, the most commonly used are MH and LR.

The MH procedure (Mantel and Haenszel, 1959) was first used to analyze DIF by Holland and Thayer (1988). It is now the gold standard for detecting items with differential functioning and is used by the Educational Testing Service. The MH procedure compares the item performance of the reference and focal groups, which were previously matched on the ability that the test measures. The observed total test score is normally used as the matching criterion (Holland and Thayer, 1988).

In the standard MH procedure, an item shows uniform DIF if the odds of correctly answering the item are different for the two groups at a given level j of the matching

variable. The MH method provides an estimation of the effect size based on the common odds ratio (α). Holland and Thayer (1988) proposed a logarithmic transformation of α for interpretive purposes, with the aim of obtaining a symmetrical scale in which a zero value indicates an absence of DIF, a negative value indicates that the item favors the reference group over the focal group, and a positive value indicates that the item is easier for the focal group than for the reference group. This transformation is expressed as $\Delta_{\alpha\text{MH}} = -2.35 \ln(\alpha)$. Zwick and Ercikan (1989) proposed the following interpretative rules to evaluate the DIF effect size:

1. type A items/negligible DIF: these are items in which $\Delta_{\alpha\text{MH}} < |1|$;
2. type B items/moderate DIF: items in which $|1| \leq \Delta_{\alpha\text{MH}} \leq |1.5|$ and where MH proved to be statistically significant; and
3. type C items/large DIF: items in which $\Delta_{\alpha\text{MH}} > |1.5|$ and MH proved to be statistically significant.

Zwick and Ercikan (1989) point out that type B items can be used in the test if there are no others to replace them, whereas type C items will only be selected if they are necessary to achieve test specifications.

There are several advantages to this method, the main one being its high power rate of DIF detection (Holland

and Thayer, 1988). Furthermore, the statistic is easy to calculate, includes a measurement of effect size, and can be readily interpreted by professionals without expertise in psychometrics. In addition, its application does not require excessively large sample sizes; for example, Mazor *et al.* (1992) found high power and good control of the type-1 error rate in samples of 200 subjects per group (focal and reference). Finally, it should be noted that the MH statistic can be calculated using easily accessible statistical software, whether that for general use (SPSS, SYSTAT, and SAS) or more specific packages (MHDIF: Fidalgo, 1994; EZDIF: Waller, 1998a; DIFAS: Penfield, 2005). However, there are a number of limitations:

1. it does not test for nonuniform DIF (Rogers and Swaminathan, 1993; Swaminathan and Rogers, 1990; Uttaro and Millsap, 1994), although Clauser *et al.* (1994) did propose a variation that is useful for its detection;
2. it works with different levels of a matching variable, which is somewhat arbitrary and may affect statistical decisions regarding DIF;
3. poor performance in terms of its power in detecting DIF with sample sizes of 100 or fewer per group (Fidalgo *et al.*, 2004; Mazor *et al.*, 1992), although exact nonparametric methods have been proposed for both binary and polytomous items (Meyer *et al.*, 2004; Parshall and Miller, 1995);
4. it works with an observed score metric; and
5. it may need to purify matching scores with a small number of items or in a test with a high percentage of items with differential functioning.

LR analysis (Swaminathan and Rogers, 1990) is a technique for detecting different types of DIF (uniform and nonuniform). It is a more sophisticated and complex procedure than others such as the MH statistic, but has greater power in terms of detecting nonuniform DIF (Clauser *et al.*, 1996; Hidalgo and López, 2004; Narayanan and Swaminathan, 1996; Rogers and Swaminathan, 1993). Moreover, LR analysis provides a general and flexible framework for analyzing and evaluating DIF, for example: different item formats (dichotomous or polytomous), different matching criteria or a combination of other criteria, and grouping variables (gender, race, culture, and language) with two or more levels (Zumbo, 1999). Other advantages of this method are:

1. it offers a statistical test and an effect size statistic (French and Maller, 2007; Gómez-Benito *et al.*, 2009; Hidalgo and López, 2004; Hidalgo and Gómez-Benito, 2006b; Jodoin and Gierl, 2001; Zumbo, 1999);
2. it is useful with relatively small sample sizes (Hidalgo and Gómez-Benito, 2006b, 2009); and
3. it can be calculated using readily available software, whether general statistical packages (SPSS, Systat, and

SAS) or more specific applications (LRDIF: Gómez-Benito *et al.*, 2005; EZDIF: Waller, 1998a).

Its limitations include the fact that its sample size requirements depend on the number of response categories and on the degree of skew, such that for items without skew, lower sample sizes (e.g., 100) may be adequate and both uniform and nonuniform DIF can be detected. Two more limitations are that it works with an observed score metric and it may need to purify matching scores with a small number of items.

The SIBTEST (Shealy and Stout, 1993a, 1993b) is based theoretically on the multidimensional model of IRT. This procedure tests for DIF by using differences in the expected scores that are conditional on ability across groups. The conditional expected scores in each group are estimated by conditioning on a valid subtest free of DIF. The results obtained by this method are similar to those of the MH procedure in terms of the direction and amount of DIF estimated (Nandakumar, 1993; Narayanan and Swaminathan, 1994; Roussos and Stout, 1996; Shealy and Stout, 1993b).

The most important advantages of this method include the fact that it is able to detect both DIF and DTF, and therefore it can explore the effects of DIF amplification and cancellation. Amplification is produced when a subset of items only shows DIF in one of the groups. In contrast, cancellation occurs when one subset of test items shows DIF in one of the compared groups, while another subset does so in the other group; this may mean that the effect of the first subset of items cancels out the effect of the second. The method has been extended in order to estimate DIF in polytomous items (Poly-SIBTEST: Chang, *et al.*, 1996) and to assess nonuniform DIF (Crossing-SIBTEST: Li and Stout, 1996). In addition, Nandakumar and Roussos (2004) have proposed another extension of the procedure (CATSIB), in which the observed total score is replaced by IRT-based estimates.

The main disadvantage of this method is that determining the criteria which will be used to select the valid subtest which does not contain items with DIF is a complex procedure. Furthermore, it may not be powerful with smaller sample sizes (Bolt, 2002). Finally, the detection of nonuniform DIF in polytomous items using Poly-SIBTEST has proved somewhat problematic.

Parametric DIF Techniques

IRT includes a wide range of DIF statistics, for example, parameter comparisons such as the Lord statistic (Cohen *et al.*, 1993; Lord, 1980), model comparisons using the likelihood ratio (Thissen, 2001; Thissen *et al.*, 1988), area measures (Cohen *et al.*, 1993; Kim and Cohen, 1991; Raju, 1988, 1990), and methods based on the differential functioning

of items and tests (DFIT) framework (Flowers *et al.*, 1999; Oshima *et al.*, 1997, 2006; Raju *et al.*, 1995).

The Lord statistic and the likelihood ratio test are based on the comparison of the item parameters obtained in different groups: in the first case, the parameters estimated separately for each group (reference and focal) are compared directly, while the second approach involves comparing models in which it is assumed that the parameters of one or more test items vary between the focal and reference groups. Area measures are also obtained by estimating separately the item parameters of the groups to be compared, but the method calculates the area between the item characteristic curve (ICC) of the reference group and the ICC of the focal group.

DFIT procedures can be used with both dichotomous and polytomous items, as well as with multidimensional tests (Flowers *et al.*, 1999; Oshima *et al.*, 1995, 1997). This procedure estimates the size of the difference between the true score of a subject as a member of the reference group and the true score of the same subject as a member of the focal group. The greater the difference between these scores the greater the DTF.

The main advantage of these methods is that they are based on a well-developed theoretical model, since IRT can examine both uniform and nonuniform DIF. When polytomous items are used, IRT methods can measure the impact of DIF on the total score using a test response function. However, some limitations of this procedure are:

1. its sample size requirements in order to ensure an appropriate estimate of the item parameters;
2. the model must fit the data;
3. the model assumptions must be met;
4. the DFIT method, Lord statistic, and area measures all require specific computer programs;
5. the IRT/log-likelihood method requires intensive computer calculation; and
6. the software is not very user friendly, although Thissen (2001) has developed IRTLRDIF, a software implementation of the model comparison approach, and Waller (1998b) has created LINKDIF, a package which implements area measures.

Structural equation models (SEMs) include several procedures to detect DIF, such as restricted factor analysis (RFA) (Gómez-Benito and Navas-Ara, 2000; Navas-Ara and Gómez-Benito, 2002; Oort, 1992, 1998), multi-group confirmatory factor analysis with latent mean and covariance structure (González-Romá *et al.*, 2006), or the multiple-indicator multiple-cause (MIMIC) model (MacIntosh and Hashim, 2003; Muthén, 1989). The advantage of RFA is that it can detect DIF with respect to various bias factors simultaneously, although it is not able to distinguish between uniform and nonuniform DIF. The multigroup CFA approach is useful for assessing the

presence of uniform and nonuniform DIF, but its main limitation is the need for large sample sizes, especially if more than two groups are to be examined; moreover, it does not enable direct modeling of the relationship between group membership and the latent trait (Finch, 2005). In contrast, the MIMIC approach involves the estimation of both direct and indirect effects for a grouping variable. Thus, this model introduces grouping variables, which are assumed to influence the latent factors and the DIF model is incorporated by adding direct effects from the grouping variables to the observed items unmediated by the latent factors. In addition, it is possible to check for the presence of DIF for more than two groups, and with multiple grouping variables, including both categorical and continuous types (Muthén, 1989). The main disadvantage of this approach is the inflated type-1 error rate for short tests of fewer than 50 items (Finch, 2005). In general, these SEM-based approaches are able to detect DIF in multidimensional models and provide various fit indices at the level of both overall and local models (e.g., in the detection of certain noninvariant items). It should also be noted that these procedures not only enable the assessment of DIF but are also very useful in the evaluation of construct equivalence and the analysis of cross-cultural measurement invariance.

Purification of Matching Variables

The methods currently used to detect DIF use as their matching criterion the total test score or an estimate of ability. However, matching on an internal criterion that involves some DIF items can lead to inaccurate ability estimates and, therefore, inaccurate DIF identification (Clauser *et al.*, 1993; Kim and Cohen, 1992).

To mitigate this problem, what are known as purification procedures have been proposed: in an initial stage, the DIF is evaluated in a standard way, but it is then evaluated again using only those items which do not present DIF in the initial analysis. An estimate of the competence level of subjects is then calculated.

Purification procedures are classified into two types:

- *Iterative.* The items with DIF are reevaluated by successive iterations, the aim of which is to gradually purge these items so that they do not form part of the criterion.
- *Two stage.* First, the DIF is evaluated and then, in a second step, those items which in the first stage were shown to be biased are eliminated from the total test score, before once again calculating the DIF.

The contributions of Marco (1977) and Lord (1980), within the framework of IRT, represent the first steps toward an estimate of the competence level of subjects which is not distorted by DIF items; other proposals can

be found in Park (1988) and Park and Lautenschlager (1990). Different purification procedures have also been used outside the framework of IRT, for example, the iterative logit method (Van der Flier *et al.*, 1984), the two-stage version of the MH method (Holland and Thayer, 1988), the two-stage estimation of multinomial LR (Hidalgo and Gómez-Benito, 2003), and iterative RFA (Navas-Ara and Gómez-Benito, 2002).

All the simulation studies carried out with the different DIF detection methods agree that purification procedures reduce false-positive error rates and/or increase power, and also that iterative procedures always present better results than when DIF is evaluated through just one analysis (Clauser *et al.*, 1993; French and Maller, 2007; Hidalgo and Gómez-Benito, 2003; Hidalgo and López, 2002; Kim and Cohen, 1992; Miller and Oshima, 1992; Navas-Ara and Gómez-Benito, 2002; Park and Lautenschlager, 1990).

Guidelines to Detect DIF

A number of practical statistical guidelines for the correct detection of DIF need to be taken into account. First, it is necessary to select an acceptable DIF detection method on the basis of what has been discussed previously. Second, in an empirical study more than one method for evaluating DIF should be used; for example, Millsap and Everson (1993) recommend that when the Lord statistic is significant it should be combined with an area measure. Third, it is important to use a purification procedure for the matching criteria. Finally, in DIF studies, it is advisable to support statistical results with an effect size statistic that allows a more accurate evaluation to be carried out and, subsequently, enables decisions to be made regarding the presence or absence of DIF in the item. Furthermore, the combination of a statistical test with an effect size measure will help to reduce false identification rates.

However, in DIF analysis, other nonstatistical recommendations also need to be taken into account. First, DIF analysis should be followed by content analysis, and, if it is feasible to identify some possible causes of the DIF, we can consider tentative bias factors as evidence of a threat to test validity. Second, the effect that would occur if the DIF item were removed from the test needs to be explored; for example, some findings indicate that item-level DIF does not necessarily make a difference when the scale is considered as a whole. Third, what would the consequence be of decisions made as a result of the assessment process, that is, consideration must be given to consequential validity.

In general, there has been a poor interrelationship between substantive and statistical analyses and attempts to identify the reasons for this have not evolved at the same pace as statistical procedures; thus, there is a deficit

in this area (Bolt and Stout, 1996; Englehard *et al.*, 1990; Gierl, 2005; Roussos and Stout, 1996; American Psychological Association *et al.*, 1999; Sudweeks and Tolman, 1993). Moreover, Gierl and Khaliq (2001) point out that substantive reviewers have not been successful in predicting which items will contain DIF. To strengthen the interrelationship between the two approaches Roussos and Stout (1996) recommended a two-step procedure. The first step consists in a substantive analysis in which DIF hypotheses are generated, and it is decided whether or not DIF is present as a secondary factor. In this stage, substantive reviewers use different sources for the review process, such as previously published DIF analyses, reviews of contexts present in other similar data, or substantive content considerations. In the second stage, statistical analyses are conducted in order to test the DIF hypothesis. Teresi (2004) presented a set of steps that could be performed in examining DIF:

1. convene focus groups to examine how members of different groups perceive the meaning of the studied construct;
2. conduct in-depth interviews to supplement information gathered in the focus groups;
3. convene a panel of experts to review closed-ended items; and
4. perform cognitive interviews, presenting individuals with closed-ended items followed by open-ended probes.

In sum, nowadays there is clearly a growing trend toward explaining DIF, rather than merely identifying it, and thus its study forms part of the validity framework.

Summary

As was pointed out by Gómez-Benito *et al.* (2005) in their historical review of the field over the last quarter of the twentieth century, more than 80% of publications on DIF appeared during the 1990s, and of these, three-quarters were published in the last 5 years of this decade. Moreover, one of the areas showing the greatest interest in the subject of DIF is education. This growing interest is not surprising if one considers the social and political dimensions of the problem, in which there is increasing concern to ensure equality of opportunity among individuals and social groups. Furthermore, possible bias must also be taken into account in tests used for clinical/educational diagnosis, due to the biopsychosocial and educational consequences of how the results are used.

Although enormous progress has clearly been made in terms of developing statistical methods to identify items that show DIF, whether these are dichotomous or polytomous, a key question which remains is that regarding the choice of a particular method. This will depend on several factors including sample size of focal and reference

groups, type of DIF, item scoring, matching variable, and availability of statistical software. In this regard, it should be noted that greater emphasis is now placed on studying the behavior of these statistical procedures in situations that are common in practice, for example, the identification of DIF in small samples (Fidalgo *et al.*, 2004; Hidalgo and Gómez-Benito, 2006b, 2007; Muñoz *et al.*, 2001) and the study of the advantages and limitations of polytomous procedures (Bolt, 2002; Hidalgo and Gómez-Benito, 2006a). Also noteworthy is the attempt to include effect size measures that complement the information provided by the test of significance, as well as the development of flagging rules and cutoff values in order to make decisions about items with DIF (Lai *et al.*, 2005; Hidalgo and López, 2004; Jodoin and Gierl, 2001; Zumbo and Thomas, 1997). Finally, mention should be made of the development of specific software programs that serve a dual purpose, that is, they offer a more user-friendly application for use by nonexpert professionals and also incorporate the latest developments in the field; examples of such software are DIF/DBF (Stout and Roussos, 1999), IRTLRFID (Thissen, 2001), TESTGRAPH (Ramsay, unpublished), and LRIDF (Gómez-Benito, *et al.*, 2005).

To summarize, although it is true that in recent decades DIF has been the focus of many studies carried out in the field of educational measurement, much work remains to be done. This is the case not only in terms of methodology but also with respect to the applied field, where DIF studies are increasingly being used as a routine step in the process of developing new measurement instruments and evaluating existing ones; furthermore, there is a growing awareness of the need to analyze the potential causes of the differential behavior shown by the items of a given instrument. This problem of bias analysis as a fundamental aspect of measurement instrument validity is a field characterized by much debate but one which, due to its intrinsic difficulty, has yet to be explored in depth. It is clear, therefore, that future efforts must seek to address this issue.

Educational Measurement: Overview

R L Linn, University of Colorado at Boulder, Ouray, CO, USA

© 2010 Elsevier Ltd. All rights reserved.

The purpose of this article is to provide an overview of educational measurement. A more detailed discussion of educational measurement can be found elsewhere in the encyclopedia. We begin with a description of four major functions of educational measurement and then move to a consideration of some characteristics of modern educational measurement.

The most recent edition of *Standards for Educational and Psychological Testing* (American Educational Research Association (AERA), American Psychological Association (APA), and the National Council for Measurement in Education (NCME); AERA, APA, and NCME, 1999) began with high praise for the contributions of testing. "Educational and psychological testing and assessment are among the most important contributions of behavioral science to our society" (AERA, APA, and NCME, 1999: 1). This praise must be balanced against a variety of criticisms on the uses of educational tests. It is also important to recognize that the value of tests depends heavily on the purposes of testing and the uses that are made of test results. Hence, it seems appropriate to begin with a consideration of some of the major functions of educational measurement.

Major Functions of Educational Measurement

Educational tests have long been a part of the educational landscape. In the past 10 or 20 years, however, educational measurement has come to play an increasingly prominent role in education. Educational tests and assessments are used for a wide variety of functions. However, four separate functions are particularly noteworthy. First, educational tests are used to make a variety of decisions about individual students (e.g., placement, grade-to-grade promotion, high school graduation, and admission to college). Second, tests are used to monitor student achievement and progress. Third, tests are used to leverage educational reform by holding schools and teachers accountable for student achievement. Fourth, classroom assessments are used for formative purposes and as an integral component of teaching and learning.

The second and third functions sometimes overlap and so do the school accountability and individual decision-making functions. Although some would like to see greater overlap between the accountability and formative functions, the

characteristics of assessments required for those two functions are substantially different.

Decisions about Students

Tests play an important role in many decisions that are made regarding the education of individual students. Test results are used to make decisions about course placement and they may determine whether or not a student is required to attend summer school or be retained in the same grade for another year. Passing tests may also be a requirement for receiving a high school diploma. Although college admission decisions may depend heavily on the courses students have taken and the grades they have received in high school, standardized tests also have a major influence on admission decisions in many colleges as well as graduate and professional schools. Test results earned in high school may also be used to award college credit and tests are often used to determine placement in remedial courses or more advanced college courses.

Many questions regarding technical adequacy arise when tests are used to make decisions about individual students. Justifying the use requires evidence of validity (see Linn) and reliability (see Brennan; Miller). Is the content coverage of the test adequate for the particular use and interpretations of the test scores? Do scores provide adequate prediction of future performance of students? Measurement error is an unavoidable characteristic of any test, but the question is whether the magnitude of the errors is acceptably small for the use that is made of the test scores. For tests used for college admissions or high school graduation decisions there are often questions about the equivalence of scores that are obtained in different administrations of the test either within or between years. Some of these and other measurement issues are discussed after brief discussions of the other three major functions of educational measurement.

Monitoring Function

There are examples of tests being used to obtain a reading on student achievement that date back to the beginning of the twentieth century. Rice (1897), for example, used achievement test results to compare schools. The results were also used to make judgments about the adequacy

of education. Until the last half of the twentieth century (see Crooks), however, major efforts to monitor achievement at the national level or through international studies did not get underway. The International Association for the Evaluation of Educational Achievement (IEA) was officially organized in 1967, although its roots can be traced back to 1958 (IEA, Mission Statement). In the United States the National Assessment of Educational Progress (NAEP) was first administered in 1969 after nearly 6 years of preparation (see, e.g., Jones, 2004).

In the past 40 years, IEA has sponsored several international assessments, including the Trends in International Mathematics and Science Study (TIMSS) and the Progress in International Reading Literacy Study (PIRLS). A substantial number of countries have participated in those assessments. Reports of results from TIMSS and PIRLS are available online from the TIMSS and PIRLS International Study Center. NAEP has expanded to include state as well as regional results. NAEP results have become increasingly prominent in discussions of student achievement in the United States and several other countries have introduced national assessments.

More recently, a series of international studies of student achievement have also been undertaken under the auspices of the Organization for Economic Cooperation and Development (OECD). OECD developed and arranged for the administration of the Program for International Student Assessment (PISA) in cooperating countries. PISA assesses 15-year-old students in reading, mathematics, and science. The assessments are conducted every 3 years with a focus on one of the three subject areas. For example, the focus was reading literacy in 2000, mathematics literacy in 2003, and science literacy in 2006.

For the monitoring function, there is no need to test every student. Good estimates of the achievement of age or grade cohorts of students can be achieved by assessing samples of students and different subsets of items may be administered to different students. In principle, sampling of students and the administration of different subsets of items to different students might be used for a system designed to hold schools accountable. In practice, however, census testing of all students with the same items is generally used for the accountability function.

Accountability Function

Policymakers have looked to educational test results as key indicators of educational quality and progress (see Hamilton). Lackluster test results have been used to advocate educational reforms. Educational tests and assessments have also been used as a critical educational reform tool. Educational policymakers can implement reforms in some countries by introducing changes in the mandated curriculum. In many countries, however, curricular changes alone

are relatively ineffective without being reinforced by other change mechanisms. As McDonnell (2004) has noted, “elected officials and policymakers have few tools at their disposal [to reform classroom instruction]. Standardized tests are one of the most effective levers they have for influencing what happens in local schools and classrooms” (p. 9).

The large-scale, externally mandated educational tests are used not only to monitor student achievement, but to leverage educational reform as well. The tests used for both the monitoring and the accountability functions are built upon an impressive technological foundation. The ability of these tests to yield reliable scores that are comparable from year to year, and have acceptable levels of validity, depends on the sophisticated use of psychometric techniques and statistics.

Formative Function

The formative function of educational measurement differs from the student decision making, monitoring, and accountability functions in several respects. Tests used for these other three functions are generally administered at a specified time during the school year. Formative assessments, on the other hand, do not occur at a fixed time during the school year. Rather, formative assessments are administered as an integral part of instruction at the moment when the information is needed. Tests serving the student decision making, monitoring, and accountability functions are standardized and considerable attention is given to the technical quality of the tests. In contrast, formative assessments are tailored to the student and the information from the assessment is used to foster student learning. As Shepard (2006) has noted, “For teachers to be effective in supporting student learning, they must constantly be checking for student understanding” (p. 627).

Unlike tests used for the other functions, formative assessments are under the control of classroom teachers. They may not even appear to be a test in the usual sense, but instead may consist of a few oral questions or informal observations. Formative assessment has been defined in several different ways; however, the following definition seems to capture the essence of formative assessment in a way that distinguishes it from tests used for other functions. “Formative assessment is a process used by teachers and students during instruction that provides feedback to adjust ongoing teaching and learning to improve students’ achievement of defined instructional outcomes” (Council of Chief State School Officers, no date). This definition makes it clear that formative assessment is not just a test, but it is a process, one that may use an array of different procedures, both formal and informal, that are selected by the teacher to assess individual students.

Effective formative assessment not only requires feedback, but also needs to help students identify strategies for learning and be tied to achievement standards or learning outcomes (Sadler, 1989; Shepard, 2006). Black and Wiliam's (1998) review provided evidence that well-conceived and well-implemented formative assessment practices can yield large improvements in student learning. Few instructional interventions have effects that are as large as those associated with effective formative assessment practices.

Discussions of ways to improve formative assessments are better integrated into discussions of instruction rather than discussions of measurement. This is so because effective formative assessment practices cannot be divorced from effective instructional practices. Thus, formative assessment is excluded from the discussion below not because it is unimportant, but because it has more to do with good instructional practices than with technical measurement characteristics.

Educational Measurement Theory and Practice

Measurement theory, also known as psychometric theory, provides the foundation for evaluating educational tests and their uses and interpretations. Validity and reliability are the most fundamental measurement theory concepts. Together, validity and reliability provide the primary basis for judging the technical quality and the appropriateness of the uses and interpretations of educational tests results. There is widespread agreement among measurement experts that while reliability is important, validity is the most important consideration in evaluating the uses of and inferences that are made from test results. Other considerations, such as fairness and the comparability of test results for different test takers or from one occasion to another, are also important, but such considerations can be readily subsumed under the more fundamental topics of validity and reliability.

Validity

The Standards for Educational and Psychological Testing (AERA, APA, and NCME, 1999), which provide the most authoritative statements of professional consensus about topics such as validity and reliability, define validity as follows: "Validity refers to the degree to which evidence and theory support the interpretations of test scores entailed in the uses of tests. Validity is, therefore, the most fundamental consideration in developing and evaluating tests" (AERA, APA, and NCME, 1999: 9) (see Linn).

It is not unusual to hear a test referred to as valid or invalid. Such references are in keeping with outdated

conceptions of validity, but not with contemporary conceptualizations. It is the uses and interpretations of test results that are validated, rather than the test itself. A particular use or interpretation may have high validity, while another use or interpretation of the same test has unacceptably low validity. Validity is also a matter of degree rather than an all or non phenomenon, therefore the unqualified claim that a test is valid for a particular use is misleading.

Many types of evidence may be relevant to judging the validity of a particular use or interpretation of test scores. Considerations of content are often of central importance to judging the degree of validity of a claim that a test provides an adequate measure of the achievement of students in a given content domain. Relationships to other variables, such as college grades, may also be relevant for judging other uses of test scores. There is not a single type of evidence that is relevant to every use or interpretation. Rather, the priority that different types of evidence should have depends upon logical reasoning that incorporates the evidence into a justification for a specific use or interpretation of test scores.

Building on the conceptualizations of earlier validity theorists (e.g., Cronbach, 1988; Messick, 1989), Kane (2006) has described validity as an argument. According to this formulation, validation requires the evaluation of the rationale for a proposed use or interpretation of test scores. Proposed interpretations and uses must be clearly specified. The intended interpretations and uses provide the starting point for developing two kinds of argument: an interpretive argument and a validity argument. The interpretive argument needs to include "a clear and fairly complete statement of the claims included in the interpretation and the goals of any proposed test uses" (Kane, 2006: 22). Kane refers to the evaluation of the interpretive argument as the "validity argument."

The evidence that needs to be marshaled in for a validity argument depends on the claims that are made in the interpretive argument. For example, if it is claimed that persons with high test scores will be more likely to obtain high grades in college than persons with low scores, then evidence is needed that test scores are reasonable predictors of future college grades. Conversely, if it is claimed that schools where students have high test scores are more effective than schools with lower test scores, then the validity argument needs to include evidence of school effectiveness that goes beyond the test scores on which the claim is based (e.g., gains in test scores from one year to the next, and independent observations of the schools).

Kane (2006: 24–25) uses the example of placement testing to illustrate interpretive and validity arguments. One of the identified claims in the interpretive argument for placement testing is that people with scores below some identified minimum are unlikely to succeed in an identified course. The validity argument needs to evaluate

this claim, possibly with evidence that students with scores below the identified minimum have a lower likelihood of successful completion of the course than students with scores above the minimum.

Reliability

All test scores are subject to measurement error (see Miller). Because of measurement error scores from alternate forms of a test, from one set of items to another, from one occasion to another, or, in cases where scores depend on human raters, from one rater to another will not be perfectly consistent. In other words, scores on tests lack perfect precision due to the inevitable errors of measurement.

As Feldt and Brennan (1989) have noted, “Historically, the reliability of a measuring instrument of process has been quantified via two indexes: the standard error of measurement and the reliability coefficient” (p. 105). In theory, the standard error of measurement is the standard deviation of a hypothetical set of replications of the measurement procedure for a single individual. According to Feldt and Brennan (1989), “The reliability coefficient quantifies reliability by summarizing the consistency (or inconsistency) among several error prone measurements” (p. 105).

A variety of statistical models and techniques are available for use in quantifying the reliability or consistency of scores or the converse, score inconsistency due to errors of measurement. As Haertel (2006) has noted, these include approaches of classical test theory and generalizability theory as well as estimates of measurement error that are based on item response theory (IRT). (IRT approach is briefly discussed as a separate topic below.) As is true of validity, reliability is a matter of degree rather than an all or none phenomenon and the level of reliability depends on the circumstances of test administration. The level of reliability that is achieved under standardized and carefully controlled test administration conditions can be easily eroded if the test is administered under haphazard, nonstandardized conditions.

In classical test theory, an observed score is assumed to be made up of two independent components: a true score, which is a score that would be obtained if the measurement process could be repeated and infinite number of times, and an error of measurement, which is assumed to be random and unrelated to other variables, such as the true score or scores obtained from other measures. Under the classical test theory assumptions, reliability is simply the ratio of the true score variance to the observed score variance and the standard error of measurement is simply the standard deviation of the errors of measurement.

Generalizability theory (see Brennan) can be viewed as an extension of the classical test theory that allows for the differentiation of multiple sources of measurement error

(Feldt and Brennan, 1989; Haertel, 2006). Generalizability theory provides a structure for identifying different components of measurement error (e.g., error due to item sampling, to raters, or to two-way or three-way interactions among persons, items, and raters). Although generalizability coefficients are used to summarize the overall outcome of a generalizability analysis, the outcomes of primary interest are the components of variance due to various sources (e.g., persons, items, raters, and interactions).

Item Response Theory

IRT (see van der Linden) includes a variety of statistical models of person responses to test items (Yen and Fitzpatrick, 2006). Although it did not come into widespread use in educational testing until the 1980s, when computer programs made it feasible to apply IRT models to large-scale testing programs, IRT has become the statistical approach of choice in many situations. In recent years, IRT models have been employed in tests used in making decisions about individuals, in national and international assessments, and in large-scale accountability testing programs. The popularity of IRT stems in large part from its utility for addressing many measurement problems, such as test design, equating, and estimation of measurement error that is conditional on the proficiency of a test taker. IRT models also have appeal because they provide a means of solving some problems that are intractable under the confines of classical test theory (e.g., the selection of items and scoring of item responses for a computerized adaptive test).

Two IRT models, the Rasch model and the three-parameter logistic model, are in widespread use for dichotomous test items. Under the Rasch model, the probability that a person will answer an item correctly is modeled with a single item parameter (the item’s location or difficulty) and a single person parameter (the person’s ability or proficiency). As the name suggests, the probability of a correct response is modeled with three item parameters (item location of difficulty, item discrimination, and the lower asymptote). In addition, there is a person parameter corresponding to the person’s ability or level of proficiency. Under either the Rasch or three-parameter logistic model the person and item difficulty parameters are located on the same scale.

There are also several IRT models for items with multiple response categories. Partial credit models that have a single person parameter and as many item parameters as there are unique response categories. Thus, the partial credit model is a natural generalization of the Rasch model. More generalized models that treat categories as nominal or as graded and allow for item categories to differ in discrimination as well as location are also available (see, e.g., Yen and Fitzpatrick, 2006).

Testing Technology

Testing and technological developments have been closely linked at least since the development of the first electronic scoring machines. The optical scanners made it possible to score large numbers of answer sheets with great efficiency and made multiple-choice test items the dominant approach to educational testing in the United States and some other countries. However, the current ties between technology and testing run much deeper than simply test scoring. Today, technology plays a role in an ever-expanding number of aspects testing. Drasgow *et al.* (2006) paint a vivid picture of the ways technology can be integrated into test design, item generation, test assembly, test delivery, and scoring of both selected-response and constructed-response test items.

Computer-based testing (CBT) makes it possible to report scores immediately after a test is completed; it also makes it possible to administer the test adaptively so the selection of the next item of set of items to present to a test taker depends on the responses that are made to previously administered items or subsets of items. Computerized adaptive tests make it possible to reduce the length of a test while maintaining a fixed level of measurement precision or it makes it possible to terminate testing when a desired level of precision is achieved for a given decision. Moreover, CBT provides the opportunity to introduce simulations and other types of test problems that are not feasible with paper-and-pencil tests. Automated scoring of essays reduces the need for the assembly and training of human scorers and speeds up the scoring process so that results can be returned sooner than is possible with reliance on human scorers.

Scheduling flexibility of test administration on the Internet and the immediate return of results make CBT appealing as a means of getting interim assessment results that provide early warning for end-of-the-year accountability testing. These features, together with the ability to add items to an electronic item bank and select items for administration from that bank for administration at the time deemed appropriate by a teacher, also have the promise of facilitating formative assessment.

Conclusion

Educational measurement is a critical component of education. Educational tests serve a variety of functions, including their use in making educational decisions about students, monitoring student achievement, schools and system accountability, and formative decision making by classroom teachers. Test theory provides a solid foundation for

the development and evaluation of tests and the uses of test results. Technological advances offer the opportunity to improve the quality and efficiency of educational testing. It remains to be seen, however, whether the improved technology will lead to more effective use of educational test results.

Equating and Scaling

A A von Davier, Educational Testing Service, Princeton, NJ, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The term linking has slightly different meanings in the field of educational assessments and it is used as (1) a general term for denoting a relationship between test forms (at the total score level, at the item parameter level, etc.); (2) as a weaker form of equating; and (3) as a synonym to the process of placing item response theory (IRT) item parameters on the same scale, which sometimes is also called IRT calibration. ("Calibration refers to the process of determining the relation between the output (or response) of a measuring instrument and the value of the input quantity or attribute, a measurement standard. In non-specialized use, calibration is often regarded as including the process of adjusting the output or indication on a measurement instrument to agree with value of the applied standard, within a specified accuracy."— www.wikipedia.org). In this article, we refer to equating as a subclass of linking methods (Holland and Dorans, 2006) and we refer to scaling as a common subsequent procedural step to equating (and to some other classes of linking, such as, for example, vertical linking), where scaling denotes the mapping of the already equated scores onto a reporting scale to aid in communications with test takers and test users. The framework and definitions we use here are common in the literature and aid the focus of the article (see Holland and Dorans (2006) and Kolen and Brennan (2004) for an extensive view of categories of linking methods and for other uses of the word scaling).

Here, we give an overview of the existing methodologies for comparing skills and establishing a common scale in educational assessment programs when the scores are reported at the individual level. Next, equating and scaling methodologies are briefly introduced. In the following section, observed-score and IRT equating methods are presented in detail.

An equating process has basically two components: a data collection design and a statistical method for achieving the desired relationship between two or more of the test forms.

In all equating applications, the outcome variable (i.e., the ability measured by the test forms) must be comparable across time points (i.e., each scale point of the measure must retain an identical meaning over time). The outcome variable must also remain construct-valid for at least the entire period of observation and maybe beyond, if prediction of future success is part of the study. These two requirements speak to the necessity of establishing a common scale for the test forms we use (see Harris *et al.*, 2004; Patz *et al.*, 2003).

Equating

The need for test equating arises when there are two or more test forms that measure the same construct and that can yield different scores for the same examinee. The most common example involves multiple forms of a test within a testing program, as opposed to a single testing instrument. In a testing program, different test forms that are similar in content and format typically contain completely different test questions. As the tests may contain different questions, the tests can vary in difficulty depending on the degree of control available in the test development process. Examinees tested with the more difficult test form will get lower scores than they would get had they been tested with the easier form. As testing programs often require comparability of the scores produced on these different forms, test-equating techniques were developed to adjust for these differences in test difficulty across test forms. The goal of test equating is to allow the scores on different forms of the same test to be used and interpreted interchangeably. Test equating requires some type of control for differential examinee ability, or proficiency, in the assessment of, and adjustment for, differential test difficulty; the differences in abilities are controlled by employing an appropriate data collection design (see next section for more details).

Not all assessments need an equating plan. This decision depends on the use of the tests. Some testing programs give one test a year, and students are ranked on that test for some purpose such as college admissions. If the test is used only to find the top performing students on it for that year, and the scores from one year are not ever compared to those from previous years, then equating the forms given annually may be a unnecessary (and expensive). However, if several test forms are used throughout the testing year for a common purpose and it is important that differences between the relative difficulties of the different test forms not affect the assessment of students taking the different forms, then test equating is necessary.

Equating is the most stringent form of score linking because it claims score interchangeability, not merely comparability, as do concordances and predictions (see Holland and Dorans, 2006, for more details and definitions of types of score linking). Other types of score linking may use the same computations as test equating but do not result in scores that are interchangeable. A linking typically does not qualify as an equating if the test forms are not constructed to the same specifications

or if the test forms measure different constructs. Test equating places several stringent requirements on the content and statistical properties of the test forms and on the samples of test takers involved, and is vulnerable to deviations from these requirements. These deviations may result in scores that are not interchangeable. In these circumstances, the intended test equating simply becomes weak, a form of test linking and the lack of interchangeability of scores can lead to unintended unfairness to some test takers.

So far, no systematic theory of test equating has been laid out. Over the years, methods have been developed in response to the need to create comparable test scores in practical circumstances. In order to evaluate these methods, Dorans and Holland (2000), Holland and Dorans (2006), Kolen and Brennan (2004), and Lord (1950, 1980) have laid out a framework that defines a good equating procedure. This framework is based on the following five requirements on the test forms and on the equating functions: the test forms should measure the same construct, and have equal reliability; and the function used for transforming the scores should be symmetric (i.e., the function for equating the new form, X , to the old form, Y , should be the inverse of the function equating Y to X), population invariant (i.e., the use of different subpopulations should yield the same equating function), and should lead to equity, that is, it should be a matter of indifference to an examinee to be tested by either one of two test forms that have been equated (Holland and Dorans, 2006). Many of these requirements are vague or arguable. In most situations, a failure of any of these requirements is hard to detect using available data. The combination of the lack of a theory and difficulties in detecting whether the equating requirements have been violated in practical settings creates a challenging situation for the practitioner.

Some problems in the equating process also appear when the data requirements for an equating method are not fulfilled; for example, when the samples available for equating are too small, and when large ability differences exist in the groups that take the two test forms to be equated, or when differences in subgroups lead to a linking function that is subgroup dependent (see Dorans and Holland, 2000). In an attempt to address these issues, researchers have developed new strategies to cope with design and data difficulties (equating with small samples, new approaches to anchor test construction, and new equating models) (von Davier, in press).

Scaling

Depending on how a test is scored – number correct, formula-scored, IRT scored – a raw score of an examinee on a test will look and be different. In order to aid the interpretability of the scores when provided to test users and test takers, the raw scores are transformed to scale scores. The scale scores of a test are what are reported to the test users, and therefore, they are the most visible, and

important part of an assessment. The reported scores provide the basis for decisions about whether one passes or fails a test, for comparisons across individuals, across institutions, or for policy decisions. Petersen *et al.* (1989) said that the “usefulness of a primary score scale depends in its fulfilling two important goals: facilitating meaningful inferences and minimizing misinterpretation and unwarranted inferences.” For more details about the scaling process see Kolen and Brennan (2004) or Dorans (2004).

Typically, scaling is established by mapping raw scores from a single test form (administered to a sample that is representative of the population of test takers for which the test is intended) to scale scores. Establishing the scale for reporting scores is a process that is both statistically and policy based and it should support the purpose of the assessment. The reporting scale should (1) have an established mean and variance; (2) allow for a good representation of easier or more difficult subsequent test forms; and (3) avoid (misleading) comparisons with different and already-established assessments, and it might incorporate score precision (such as reflecting a special relationship of the standard error of measurement across the score points, or deciding about the number of score scale points). This mapping, called scaling, can be linear or curvilinear. It is common to talk about equating and scaling as a two-step process. In practice, the scaling of the scores from a new test form is accomplished as follows: raw scores on the new test form are equated back to the raw scores of the previous (old) form for which the scaling has already been established.

Other approaches to establishing reporting scale or scale scores incorporate information about the content of the test, expert knowledge about the claims made about the items and test, and the intended message to the test users. Some of the most familiar approaches that consider the content of the test are: standard setting, scale anchoring, and item mapping, which are described in detail in the literature by Livingston and Zieky (1982), Allen *et al.* (1999), and Beaton and Allen (1992).

The rest of the article focuses on the observed-score equating methods and on the IRT calibration and equating methods. In the class of observed-score equating and linking methods, the traditional methods – equipercentile and linear – and a newly developed method – kernel equating (KE) – are discussed. The observed-score and IRT-based equating methods are the two major classes of statistical methods used for equating and linking tests in educational assessments. Each of them is followed by the scaling process, that is, placing the linked raw-scores onto a reporting scale.

Observed-Score Equating Methods

In this section, we introduce the notation and lay out a framework for a discussion of observed-score equating (see also Kolen and Brennan, 2004 for a related discussion).

There are two test forms to be equated, X and Y , and a target population, T , on which this is to be done. The data are collected in such a way that the differences in the difficulty of the test forms and the differences in the ability of the test takers that take the two forms are not confounded. There are two classes of data collection designs for equating: (1) designs that allow for common people (equivalent groups, single group, and counterbalanced designs) from a single target population of examinees T (see Livingston, 2004, for a slightly different view and definition of a target population); and (2) designs that allow for common items (the nonequivalent groups with an anchor test design or NEAT design, also referred to as the common item or anchor test design) where the tests, X and Y , are given to two samples from two test populations (administrations), P and Q , respectively, and a set of common items, the anchor test, is given to samples from both these populations. As the name implies, in a NEAT design, the samples from P and Q are not assumed to be of equivalent ability. The target population, T for the NEAT design, is assumed to be a weighted average of P and Q where P and Q are given weights that sum to 1. This is denoted by $T = wP + (1 - w)Q$.

Many observed-score equating methods are based on the equipercentile equating function. It is defined on the target population, T , as $e_{Y:T}(x) = G_T^{-1}(F_T(x))$, where $F_T(x)$ and $G_T(y)$ are the cumulative distribution functions (cdfs), of X and Y , respectively, on T . In order for this definition to make sense, and to insure that the inverse equating function exists, it is also assumed that $F_T(x)$ and $G_T(y)$ are strictly increasing and have been made continuous or continuized.

Several important observed-score equating methods may be viewed as only differing in the way the continuization is achieved. The traditional equipercentile equating method (percentile rank method) uses linear interpolation of the discrete distribution to make it piecewise linear and therefore continuous. The KE (von Davier *et al.*, 2004) method uses Gaussian kernel smoothing to approximate the discrete histogram by a continuous density function.

Equipercentile equating leads to linear equating if one assumes that $F_T(x)$ and $G_T(y)$ are continuous and have the same shape while differing in mean and variance. The linear equating function is defined by $\text{Lin}_{Y:T}(x) = \mu_{YT} + \sigma_{YT}((x - \mu_{XT}) / \sigma_{XT})$, where μ_{XT} , μ_{YT} , σ_{XT} , and σ_{YT} are the means and standard deviations of X and Y on T , respectively.

In von Davier *et al.* (2004), it is shown that any equipercentile equating function can be decomposed into the corresponding linear equating function and a nonlinear part.

The Kernel Method of Test Equating

The KE method (von Davier *et al.*, 2004; Holland and Thayer, 1989) is an observed-score equating procedure that unifies several observed-score procedures of test

equating into a single method while, at the same time, providing new statistical information that can be used in the practice of test equating. KE brings the steps of an equating process into an organized whole rather than treating them as disparate parts. KE exploits data pre-smoothing techniques by fitting loglinear models to score data and incorporates the error introduced by the pre-smoothing procedure into the standard errors. KE provides new tools for comparing two or more equating functions and for rationally choosing between them based on newly introduced indices.

KE is an equipercentile equating procedure in which the score distributions to be equated are converted from discrete distributions to continuous distributions by using a normal (Gaussian) kernel as opposed to using linear interpolation, as is done in the traditional equipercentile equating method. By varying the bandwidth values of the Gaussian kernel (see von Davier *et al.*, 2004), KE can approximate the traditional equipercentile and linear equating methods. The process of choosing the optimal bandwidth is fully automatic and involves the minimization of a penalty function. When the bandwidths used are 100 times the standard deviation of the scores or larger (i.e., large bandwidths), the continuized distributions will be nearly normal, in which case the KE functions can be regarded as approximately linear. Thus, linear equating can be regarded as special case of equipercentile equating in the framework of KE. The KE framework also introduces the percent relative error (PRE) that aids the diagnosis of the equating function and introduces the standard error of the difference between two equating functions (the SEED). The SEED can help in making a linear or nonlinear decision.

IRT Linking and Equating

If IRT is used in the equating of the test scores, it is necessary to first use some sort of IRT linking or calibration method to place the IRT parameter estimates on the same scale (see Kolen and Brennan, 2004; von Davier and von Davier, 2004). All IRT models have an intrinsic lack of identifiability of the item and person parameters that is usually addressed by imposing some restrictions on the item or person parameters (there are various ways to implement restrictions, and consequently different software use different approaches). This leads to a need for placing the item parameters on the same scale even in the absence of equating. In other words, even if the same test instrument would have been given to two equivalent groups and if the estimation of the IRT parameters was done separately in the two groups then, the item parameters still need to be placed on the same scale by some sort of linear transformation. This process is usually called

IRT linking, but it is also called IRT scaling or IRT calibration in the literature.

Hence, for equating purposes in a NEAT design and assuming that the IRT model used fits the data well, the two separate parameter estimates of the item parameters from anchor items in the two groups need first to be placed on the same scale.

Once this step is accomplished, then additional methods, such as IRT true- or observed-score equating (Kolen and Brennan, 2004), can be undertaken to establish a relationship at the (raw) score level. Then a third step is employed – scaling – which refers to placing the raw scores onto some reporting scale, as was described in the previous section. However, in many settings the second step is skipped altogether – see also the brief discussion in next subsection.

In this section, we describe the IRT linking or calibration procedures (i.e., procedures for placing the item parameters estimates on the same scale) used for data collection designs that involve common items (NEAT design) since this is the most common data collection design. Then, the IRT true score equating is briefly described.

IRT Linking Methods for the NEAT Design

Here, we describe the usual IRT linking or calibration methods: mean–sigma and mean–mean, concurrent calibration, fixed parameters calibration, the Stocking and Lord characteristic curves approach, and the Haebara characteristic curves approach (see Kolen and Brennan 2004: ch. 6, for a detailed description of these methods).

IRT models express the probability of a response z_{ni} of a given person, n ($n = 1, \dots, N$), to a given item, i ($i = 1, \dots, I$), as a function of the person's competency or ability (which is a latent variable), denoted θ_n and a possibly vector valued item parameter, β_i , that is,

$$P_{ni} = P(X = z_{ni}) = f(z_{ni} | \theta_n, \beta_i)$$

In the case of the well-known three-parameter logistic model (3PL) model (Lord and Novick, 1968) that is used to fit data from dichotomous items, the item parameter vector is three dimensional. Its dimensions are the slope or discrimination that is usually denoted by a , the difficulty b , and the guessing parameter c , respectively, that is, $\beta_i' = (a_i, b_i, c_i)$. However, most results presented here do not depend on the specific choice of the model and apply to models for both dichotomous and polytomous data.

In the NEAT design, X is not observed in population Q , and Y is not observed in population P . To overcome this feature of the NEAT design, all equating methods developed for the NEAT design (both observed-score and IRT methods) must make additional assumptions of a type that does not arise in the other designs. IRT calibration makes the following assumptions.

Estimation Methods

The tests to be equated, X and Y , and the anchor, V , are all unidimensional (i.e., all items measure the same unidimensional construct), carefully constructed tests, in which the local independence assumption holds at the item level (Hambleton *et al.*, 1991); and the chosen IRT model fits the data well.

The methods available for the estimation and calibration purposes are mentioned below. Operationally, the estimates of the item parameters are usually obtained using the marginal maximum likelihood (MML) estimation method for IRT models (Bock and Aitkin, 1981). In the past, the joint maximum likelihood (JML) method has been used as well. Conditional maximum likelihood (CML) methods are used for 1PL IRT models (1PL, Rasch model; see also von Davier, 2001) or for 1PL models with fixed slopes, such as the one-parameter logistic model (OPLM; Verhelst and Glas, 1995), and in some recent developments, Bayesian estimations methods have been used in the framework of Markov chain Monte Carlo (MCMC) estimation (see Patz and Junker, 1999).

Concurrent calibration

The item parameters from X , V (in both populations), and Y can be estimated jointly, in a single estimation run, assuming that the items in V are the same for both populations and coding the items that an examinee did not take as not administered, since these outcomes were unobserved and are missing by design.

Fixed parameters calibration

In this method, common items whose parameters are known (e.g., from a previous administration calibration or a separate calibration) are anchored or fixed to their known estimates during calibration of a particular form of the test. By treating the common item parameters as known and, therefore, not reestimating them, the remaining item parameters from the not common set of items in the two test forms are forced onto the same scale as the items with fixed parameters. This calibration procedure is more restrictive than concurrent calibration.

Mean–mean and mean–var IRT calibrations

If an IRT model fits the data, any linear transformation (with slope A and intercept B) of the theta scale also fits these data, provided that the item parameters are also transformed in the same way (see, e.g., Kolen and Brennan, 2004: ch. 6). The most straightforward way to transform scales when the parameters were estimated separately is to use the means and standard deviations of the item parameter estimates of the common items for computing the slope and the intercept of the linear transformation. Loyd and Hoover (1980) described the mean–mean method and Marco (1977) described the mean–var IRT

calibration (Marco, 1977). Both methods are seldom used in practice and tend to be inadequate if the groups taking the test forms differ in ability.

Stocking–Lord and Haebara linkings

Characteristic curve transformation methods were proposed (Haebara, 1980; Stocking and Lord, 1983) to avoid some issues related to the mean–mean and mean–var approaches, such as the fact that various combinations of the item parameter estimates produce almost identical item characteristic curves over the range of ability at which most examinees score.

The Stocking and Lord IRT method finds parameters for the linear transformation of the item parameters estimates from the anchor set in one population (say Q) that matches the estimated test characteristic function of the anchor set in the reference population (say P). Haebara (1980) expressed the differences between the estimated characteristic curves as the sum of the squared differences between the item characteristic functions for each item over the common items for examinees of a particular ability θ_r . The Haebara method is more restrictive than the Stocking and Lord method because the restrictions take place at the item level (i.e., for each item from the set of common items), while the Stocking and Lord approach poses a global restriction at the anchor test level.

von Davier and von Davier (2004) proposed a new perspective on IRT linking by viewing any linking function or calibration method as a restriction function on the joint log-likelihood function based on all the data. Rewriting any linking as a restriction function and estimating the model parameters under this restriction implies a greater degree of flexibility in the IRT calibration process.

Equating of Scores in the IRT Framework

If equating of scores is desired, different programs and testing companies use different techniques after the calibration process. In some programs, an equating step is performed, where the so-called IRT true-score or observed-score equating methods are used to establish a relationship between the raw scores on the two forms. After that, a third step, scaling, is employed, which refers to placing the raw scores onto some reporting scale, as discussed previously. In other programs, the second step is skipped altogether, and the ability scale is linked directly to the reporting scale (Yen, 1984). This method is used in scoring tests of state assessments and published tests, such as TerraNova (CTB/McGraw-Hill, 2000). Next the IRT true-score equating method is briefly described.

IRT true score equating

A common IRT-based equating process can be described as follows: in a NEAT design with tests with multiple-choice items, an IRT model (e.g., the 3PL model) is

separately fitted to the data from the two populations P and Q . Then, the characteristic curve method (Stocking and Lord, 1983) is used to place the separately estimated item parameters onto a common scale. After all the item and person parameters are on the same scale, they are used to estimate the true-score equating function. The number-correct true score for a given θ is obtained by summing the (conditional) probabilities over the number of items in the test. Then the true-score equating method is used to obtain equivalent scores on X and Y (see Kolen and Brennan, 2004; Petersen *et al.*, 1989; von Davier and Wilson, 2005). According to this method, for a given true score of the new test form X , one finds (via iterative procedures, such as the Newton–Raphson method) the value of competency/ability θ and then computes the true score on the old form Y .

The IRT true score equating requires that many assumptions are met and relies on some *ad hoc* decisions: it requires that the tests are number-right scored, which involves an implicit assumption that there are no omits (see Kolen and Brennan, 2004); if the tests are formula-scored, then some sort of transformation is necessary and usually this transformation will treat the omits as wrong. The IRT true score equating introduces one more assumption: The relationship between the true scores holds also for the observed scores. This assumption has not been theoretically proven, but was confirmed in research studies (Lord and Wingersky, 1984). In IRT true score equating that uses the common 3PL IRT model, the lowest possible true score is the sum of the c_j , the so-called guessing parameters, and not 0. In this case, there is some arbitrariness of the results of the conversion of the observed scores that are outside the range of possible true scores on the new form X (see Kolen and Brennan, 2004, for details).

Discussion

This article reviews the existing methodologies for equating tests that measure the same construct, where interchangeability of the scores is desired.

Nowadays, when more and more standardized testing is used nationally and internationally, we are discovering new challenges in ensuring that the testing process and its results are fair and accurate. For example, some of the challenges to test equating are the construction of the anchor sets, the choice of the reporting scale, and the characteristics of the samples used for establishing the scale, which ideally should be representative for the population of test takers. In addition, psychometricians worry about the maintenance of the reporting scale: how to introduce new forms, how to monitor the scale over time, and how to adjust to changes in the administration mode.

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Bias – A technical term used in test construction for when individuals with equal ability, in the subject being tested, but from different groups, do not have the same probability of success.

DIF (Differential Item Functioning) – DIF occurs when people in different groups perform in substantially different ways on a test question even though they may have very similar scores on a test.

Equality – An essentially quantitative approach to differences between groups.

Equity – The ‘spirit of justice’ which looks at the fairness of a given state of affairs. It is essentially a qualitative judgment.

Introduction

Fairness is a concept for which definitions are important, since it is often interpreted in narrow and technical terms. We set fairness in a social context and look at what this means in relation to different groups and cultures. Similarly, we are using educational assessment in a more inclusive way than is often the case; we include tests, examinations, teachers’ informal judgments, or evaluation (assessment in United Kingdom) of student performance. We then explore bias in measurement as well as the broader concept of equity – which goes beyond the more quantitative concerns of equality. Practical approaches to ensuring fairness are discussed in the subsequent section.

Fairness

How would we tell whether a test is fair for different groups (male/female; socially advantaged/disadvantaged; ethnic groupings)? The dilemma is that different groups will have different qualities and experiences, so fairness in assessment cannot assume equal scores or outcomes. Indeed, equal outcomes could represent bias in favor of a lower-achieving group.

Differences in performance may be due to differing access to learning, or there may appear to be differences as the test is biased in favor of one group. Wood (1987)

describes these different factors as the opportunity to acquire talent (access issues) and the opportunity to show talent to good effect (fairness in the assessment).

In our view, fairness in assessment cannot be considered in isolation from access issues in the curriculum, and the educational opportunities offered to the students: fairness in access opportunities and in what the curriculum offers provide the level playing field which must precede a genuinely fair assessment situation.

The approach we take includes these broader issues and, therefore, owes more to sociocultural theory than to measurement theory. Assessment is, after all, a socially embedded activity which can only be understood by taking account of the cultural, economic, and political contexts within which it operates (Sutherland, 1996; Gipps, 1999).

There is a historical legacy here. Examinations were introduced in order to encourage advancement through talent rather than patronage, an example being the Civil Service examinations in England in the 1850s (although the examination was only open to men, and furthermore only to those men who had had a particular type of schooling).

Of course, one can argue that public tests are important as a means of equalizing opportunities and as a necessary corrective to patronage, while at the same time understanding that tests may be biased in favor of one particular gender, social or ethnic group.

Educational measurement has traditionally presented itself as scientific and objective – providing a true picture of an individual’s performance (unless he or she cheats). It is, in this frame, seen essentially as a fair activity. If access to higher levels of education or to certain professions is determined by the open competition of examination, then this allows society to subscribe to promotion through merit, and unsuccessful individuals to accept their lot, since all have been allowed to compete on an equal basis, in that they took the same examination under similar conditions, to demonstrate their competence.

More recent analyses, however, show a rather different reality. Evidence in the 1950s began to emerge that non-verbal intelligence quotient (IQ) tests, which were viewed as culture free, were not independent of culture. A picture was built up of tests being biased toward the culture of the people who designed them. In the United States and the United Kingdom this meant, at the time, white, male, and middle class. Such tests are therefore unfair for people from other backgrounds, as these individuals do not have

the same chance to do well on the tasks. This was particularly important in relation to IQ tests because of the very powerful role of these tests in determining life chances. In the post-1965 Civil Rights legislation era in the United States, critics of advancement through testing pointed out that opportunities to acquire talent, through access to good schooling, were not equally distributed (Wood, 1987; Orfield and Kornhaber, 2001). In other words, these tests were biased in favor of the dominant social group, partly from the design of the tests, and partly from access issues.

In the case of school examinations and tests, the critique has essentially similar underpinnings. Social class is a significant determinant of school performance. Children from lower social groups are not less intelligent or less academically capable, but children from middle-class homes are better able to do well at school because of the correspondence of cultural factors between home and school.

We are now well aware that the form of assessment can differentially affect results for different groups. In England there has been far more analysis of this in relation to gender than to ethnicity. We know that during compulsory schooling (up to 16 years) girls are likely to outperform boys on tasks which involve open-ended writing, particularly when this involves personal response. Even within multiple-choice tests, traditionally seen as favoring boys, there are differential response patterns. Carlton (2000) has shown that in such tests females perform better than males, matched for ability, on questions in which the content is a narrative or is in a humanities field and when the content deals with human relationships. As the context of an item grows longer, the relative performance of females also improves. Males outperform females on questions relating to science, technical matters, sports, war, or diplomacy. We also know that where examinations have a coursework (or essay) element, the performance of girls is likely to be more consistent, although the effect this has on final grades in English-school-leaving examinations has often been overstated (Elwood, 1995).

We know less about other aspects of the form of assessment, particularly in relation to ethnicity. For example, oral assessment plays little part in the examination system in England outside examining languages. Does the emphasis on written response disadvantage groups who place more emphasis on oral communication in their culture?

Bias

Bias is a technical term used in test construction. In layman's terms a test is biased if "two individuals with equal ability (in the subject being tested) but from different groups do not have the same probability of success" (Shepard *et al.*, 1981).

A main cause of bias in a test would be that it was designed by one cultural group to reflect their own experience,

and thus disadvantage test-takers from other cultural groups, as in the example of IQ tests given above. Thus, bias may be due to the content matter in a test. However, it may also be due to lack of clarity in instructions which leads to differential responses from different groups, or to scoring systems that do not credit appropriate or correct responses that are more typical of one group than another.

The existence of group differences in performances on tests is often taken to imply that the tests are biased, the assumption being that one group is not inherently less able than the other. However, as we have argued, the two groups may well have been subject to different environmental experiences or unequal access to the curriculum. This difference will be reflected in group test scores, but the test is not strictly speaking biased.

There are technical approaches to evaluating bias, which we discuss below.

Equity

Equity is defined in the dictionary as moral justice. Equity does not imply equality of outcome and does not presume identical experiences for all – both of these are seen to be unrealistic, but it asserts that assessment practice and interpretation of results need to be fair and just for all groups.

For example, it is possible to have similar outcomes for two groups and yet to see this as unfair to one of them, which may have been disadvantaged in terms of access to the curriculum. Conversely, it is possible to have unequal group outcomes that may be seen as fair. An example would be where there are group differences in the application to learning and preparation, where each had similar resources and opportunities.

Equity is also a quasi-legal term. The legal meaning of equity is the spirit of justice and building on the work of Secada (1989), we see it as a qualitative concern for what is just. "Equity attempts to look at the justice of a given state of affairs, a justice that goes beyond acting in agreed upon ways and seeks to look at the justice of the arrangements leading up to and resulting from those actions" (p. 81).

The implication is that equity is not the same as equality. Equity represents the judgment about whether equality, be it in the form of opportunity and/or of outcomes, achieves just (fair) results.

Looking for equality requires essentially a quantitative approach to differences between groups, while equity goes beyond this and looks at the justice of the arrangements prior to the testing/examination.

Legal Challenges

Sitting behind these sociocultural and technical approaches to fairness are legal challenges to assessment programs and results. Such legal challenges are more common in the

United States and Australia than in the United Kingdom. According to Cumming and Dickson:

Sources of legal action around the world have different bases. For example, in the USA many education cases have been fought and won on constitutional grounds and individual rights. In countries such as Australia, where individual rights do not have a constitutional basis, legal challenges in this area are usually brought through tort, or negligence, law, or on a statutory basis, under anti-discrimination laws. (Cumming and Dickson, 2006: 4)

Simple examples illustrate how discrimination might arise in an assessment context. Direct discrimination in the administering of a test might happen, for example, if a marker marks a student of a particular race, sex, religion 'harder' than students not of that race, sex or religion. Indirect discrimination might arise in the administering of a test if there were, for example, a requirement that students complete the test in a set time. Students with a disability may not be able to comply with this requirement – they may not be able to write quickly, or they may have a processing disorder. (Cumming and Dickson, 2006: 5)

Legal challenges have been made on the grounds of: opportunity to learn – not having been taught the syllabus being assessed; certification decisions made on the basis of a single instrument (which violates the fairness principle of using a variety of assessment approaches); lack of funding – leading to low performance on national performance measures; incorrect scoring of tests; and incorrect (or absent) assessment of students with learning difficulties resulting in inappropriate placement and/or teaching.

A review of legal cases in the United States indicates the high standard required to establish lack of equity in assessment. These authors similarly identify lack of opportunity to learn and lack of opportunity to demonstrate it to good effect – for various reasons, including insufficient preparation time for a new examination or test – as major themes in legal challenge, and conclude:

In most cases, in hindsight, the matters challenged are preventable. Equitable access to the curriculum to be

assessed, provision of adequate resources and implementation of appropriate assessment regimes are surely public expectations of education.

Approaches to Ensuring Fairness

What we have outlined so far is a complex and contested picture, difficult to engage and move forward with. Yet, much work has been done to address this, which is both sociocultural and technical.

An Equity Approach

Apple (1989) argued that attention in the equity and education debate must be refocused on important curricular questions, to which Gipps and Murphy (1994) linked assessment questions (see **Table 1**). Based on accounts of the difficulties of providing effective education to all in countries such as South Africa (Meier, 2000) and Kenya (Mwachihi and Mbithi, 2000), Stobart has added access and resource questions (Stobart, 2005).

Some aspects of this approach are now reflected in the guidelines for test developers.

Test development approach

The most fully articulated approach comes from test developers. The Standards for Educational and Psychological Testing (1999), which has guided later documents, was published jointly by AERA/APA/NCME (1999) to guide test development, scoring, and administration. It has a whole section on fairness in testing and test use, dealing with many of the issues in this article. Educational Testing Service (ETS), the major American test development agency, has its own standards for quality and fairness (ETS, 2000) to guide test developers. There are eight standards for fairness aimed at ensuring that “construct – irrelevant (i.e. to the skill or concepts being addressed) personal characteristics of test takers have no appreciable effect on test results or their interpretation” (p. 17).

Table 1 Access, curriculum, and assessment questions in relation to equity

<i>Access questions</i>	<i>Curricular questions</i>	<i>Assessment questions</i>
Who gets taught and by whom?	Whose knowledge is taught?	What knowledge is assessed and equated with achievement?
Are there differences in the resources available for different groups?	Why is it taught in a particular way to this particular group?	Are the form, content, and mode of assessment appropriate for different groups and individuals?
What is incorporated from the cultures of those attending? (Stobart, 2005)	How do we enable the histories and cultures of people of color, and of women, to be taught in responsible and responsive ways? (Apple, 1989)	Is this range of cultural knowledge reflected in definitions of achievement? How does cultural knowledge mediate individuals' responses to assessment in ways which alter the construct being assessed? (Gipps and Murphy, 1994)

Table 2 The ETS International Principles for Fairness Review of Assessments (2004)

• Principle 1:	Treat people with respect in test materials
• Principle 2:	Minimize the effects of construct-irrelevant knowledge or skills
• Principle 3:	Avoid material that is unnecessarily controversial, inflammatory, offensive, or upsetting
• Principle 4:	Use appropriate terminology to refer to people
• Principle 5:	Avoid stereotypes
• Principle 6:	Represent diversity in depictions of people

From ETS (2004). *ETS International Principles for Fairness Review of Assessments*. Princeton, NJ: Educational Testing Service.

These have been extended to the ETS International Principles for Fairness Review of Assessments (ETS, 2004). The six principles are presented in **Table 2**.

The requirement is to select assessment content that accurately reflects the construct, even if it produces gender/ethnic group differences, and to avoid content that is not relevant to the construct and could affect such differences. The involvement of those with a minority background is crucial here.

The document outlines the procedures for fairness review, and other fairness actions, one of which is the use of a statistical measure:

A statistical measure related to fairness should be used, whenever sample sizes permit, as an empirical check on the fairness of questions. Statistical measures based on the way matched people in different groups perform on each test question, called differential item functioning or DIF, are preferred. DIF occurs when people in different groups perform in substantially different ways on a test question, even though they have very similar scores on the test. If DIF data are available, tests should be assembled following rules that keep DIF low. (ETS, 2004: 11)

Fifteen years ago, the emphasis was solely on a statistical approach to eliminating bias in test design. The shift in emphasis from statistical manipulation as a major approach to it being just one element of test review is notable, and we would argue, to be welcomed.

An important approach to offering fairness, it is now argued, is to use, within any assessment program, a range of assessment tasks involving a variety of contexts – a range of modes within the assessment and a range of response format and style. This broadening of approach is most likely to offer pupils alternative opportunities to demonstrate achievement if they are disadvantaged by any one particular assessment in the program (Linn, 1992):

Also, if we wish pupils to do well in tests/exams we need to think about assessment which elicits an individual's best performance (after Nuttall, 1987). This involves

tasks that are concrete and within the experience or the pupil (an equal access issue) presented clearly (the pupil must understand what is required of her if she is to perform well) relevant to the current concerns of the pupil (to engender motivation and engagement) and in conditions that are not threatening (to reduce stress and enhance performance). (Gipps, 1994)

Large-Scale Assessment Programs

There are four key areas within large-scale testing/examination systems in which to raise issues of fairness, particularly in relation to multicultural societies. These are:

- The nature and requirements of the assessment system itself, for example, how are cultural and linguistic diversity approached? (For example, in which languages are examinations conducted?)
- How do the assessment methods meet the cultural diversity of the candidates?
- How does the content of the assessment reflect the experiences of different groups? (For example, whose version of history is tested?)
- How effectively is the performance of different groups monitored and how is this fed back into the system? (Stobart, 2005)

Teachers' Informal Evaluations/Assessments

Fairness in assessment in the informal setting of the classroom can be both more difficult – because there are many complex issues for the teacher to consider – and more possible – since a range of assessment approaches is possible.

It is more feasible for the teacher to offer, in the informal assessment setting, a range of assessment tasks and modes, and an approach which supports fairness as we argued above. It is also more feasible to provide the situation that can elicit an individual's best performance, since it is under the teacher's control.

However, teachers' informal assessment is, to a certain extent justifiably, perceived as being unreliable and biased (Harlen, 2004a EPPI-Centre). This is usually to do with lack of clarity, and variability, in standards or criteria. It is possible to improve the consistency of teachers' assessments through: providing clear criteria, training teachers to assess against these, and supporting the process with moderation of judgments via discussion (ARG, 2006).

In relation to the curriculum offered and opportunity to learn, there is another inconvenient fact: teacher expectation can affect the curriculum and learning experiences offered to children. There is clear evidence that teachers offer a different curriculum to children for whom they

hold low and high expectations (Tizard *et al.*, 1988; Troman, 1988; Harlen, 2004b). This is pertinent to the equal access issue.

Conclusion

Fairness is both essential and elusive. It is the appeal to fairness that has made educational measurement a pivotal part of most cultures. We have argued that different groups being allowed to sit, and be judged by, the same test is a simplistic view. Equality of opportunity includes access to similar resources and curricular opportunities. The more familiar, and narrower, discussion of bias is only a small part of this.

We will never achieve fair assessment, but we can make it fairer: The best defense against inequitable assessment is openness. Openness about design, constructs, and scoring will bring out into the open the values and biases of the test design process, offer an opportunity for debate about cultural and social influences, and open up the relationship between assessor and learner. These developments are possible, but they do require political will.

Generalizability Theory

R L Brennan, University of Iowa, Iowa City, IA, USA

© 2010 Elsevier Ltd. All rights reserved.

Generalizability theory offers an extensive conceptual framework and a powerful set of statistical procedures for addressing numerous measurement issues. To an extent, the theory can be viewed as an extension of classical test theory (see, e.g., Feldt and Brennan, 1989, and Haertel, 2006) through an application of certain analysis of variance (ANOVA) procedures to measurement issues. Classical theory postulates that an observed score can be decomposed into a true score, T , and a single undifferentiated random error term, E . As such, any single application of the classical test theory model cannot clearly differentiate among multiple sources of error. Generalizability theory liberalizes classical theory by employing ANOVA methods that allow an investigator to disentangle the multiple sources of error that contribute to the undifferentiated E in classical theory.

The defining treatment of generalizability theory is a monograph by Cronbach *et al.* (1972) entitled *The Dependability of Behavioral Measurements*. A history of the theory is provided by Brennan (1997). Cronbach (1991) described the theory as “a tapestry that interweaves ideas from at least two dozen authors” (p. 394). In particular, Burt (1936), Hoyt (1941), Ebel (1951), and Lindquist (1953, chapter 16) discussed ANOVA approaches to reliability. Indeed, the work by Burt and Lindquist appears to have anticipated the development of generalizability theory.

The essential features of univariate generalizability theory were largely completed with technical reports in 1960–61. These were revised into three journal articles, each with a different first author (Cronbach *et al.* 1963; Rajaratnam *et al.* 1965; Gleser *et al.* 1965). In the mid-1960s, the Cronbach team began their development of multivariate generalizability theory, which is incorporated in their 1972 monograph.

Since the Cronbach *et al.* (1972) monograph, a number of publications have explicated and, in some cases, extended the theory at various levels of detail and complexity. Brennan (1983, 1992a) provides a monograph on generalizability theory that is quite extensive but still less detailed than Cronbach *et al.* (1972). Shavelson and Webb (1991) provide a primer on generalizability theory. Shorter treatments are given by Brennan (1992b, 2001). Allal and Cardinet (1994), Crocker and Algina (1986), Feldt and Brennan (1989), Haertel (2006), Shavelson and Webb (1992), and Webb *et al.* (2007). Cardinet *et al.* (1981) propose some extensions to the theory. Various misconceptions are discussed by Brennan (2000). Brennan (2001a) provides the most extensive current treatment of

generalizability theory. Cardinet and Tourneur (1985) and Yang and Chang (2002) provide books on generalizability theory in French and Chinese, respectively.

Generalizability theory has broad applicability. It has been employed in a vast array of educational testing programs and to a wide range of other types of tests, as well. In addition, generalizability theory has been employed in numerous areas of research in education, business, and medicine.

Framework of Generalizability Theory

Classical test theory and ANOVA can be viewed as the parents of generalizability theory, but the child is both more and less than the simple conjunction of its parents. For example, although generalizability theory liberalizes classical test theory, not all aspects of classical theory are incorporated in generalizability theory. In addition, the ANOVA issues emphasized in generalizability theory are different from those that predominate in many experimental design and ANOVA texts. In particular, generalizability theory concentrates on variance components and their estimation.

Perhaps the most important aspect and unique feature of generalizability theory is its conceptual framework. Among the concepts are universes of admissible observations and G (Generalizability) studies, as well as universes of generalization and D (Decision) studies. The concepts and the methods of univariate generalizability theory are considered next in the context of a specific example. Subsequently, multivariate generalizability theory is introduced using an expanded version of the same example.

Univariate Generalizability Theory

Brennan *et al.* (1995) describe a Listening and Writing assessment that was administered to 50 examinees. (Strictly speaking, there were three forms, each of which was administered to three different groups of 50 examinees. Here, we will simply use results averaged over the three forms.) Each examinee (p) listened to 12 tape-recorded messages (t). Examinees were told to take notes while each message was played. At the conclusion of each message, examinees were told to use their notes to construct a written message. The written messages were scored by three trained raters (r) on a five-point holistic

scale for listening skills (i.e., information accuracy); a different three raters evaluated responses for writing skills. In the discussion here of univariate generalizability theory, we consider the Writing scores, only. Later, in the discussion of multivariate generalizability theory, we consider both the Listening and Writing scores.

Universe of Admissible Observations and G Studies

Assume that the $n_t = 12$ prompts can be viewed as a sample from an indefinitely large (i.e., approaches infinity) universe of potential prompts. Similarly, assume that the $n_r = 3$ raters can be viewed as a sample from an indefinitely large universe of potential raters. We say that prompts and raters are facets in the universe of admissible observations. Assume, as well, that in principle any one of the prompts in the universe of admissible observations could be evaluated by any one of the raters in the universe. If so, we say that the two facets are crossed in the universe of admissible observations ($t \times r$). (Although the example considered here involves only two facets, generalizability theory can accommodate any number of facets.)

Note that in describing the universe of admissible observations, no explicit reference has been made to persons who respond to the prompts. In generalizability theory the word universe is reserved for conditions of measurement (prompts and raters, in this example), while the word population is used for the objects of measurement (persons, in this example). If any person in the population might respond to any prompt in the universe evaluated by any rater in the universe, we say that the population and universe of admissible observations are crossed, which is represented $p \times t \times r$. For this situation, any observable score for a single prompt evaluated by a single rater can be represented as:

$$X_{ptr} = \mu + v_p + v_t + v_r + v_{pt} + v_{pr} + v_{tr} + v_{ptr} \quad [1]$$

where μ is the grand mean in the population and universe and v_α designates an uncorrelated effect for the component α . (Actually, the effect ptr is a residual effect involving the triple interaction and all other sources of error, not explicitly represented in the universe of admissible observations.)

The variance of the scores given by eqn [1], over the population of persons and the conditions in the universe of admissible observations, is

$$\sigma^2(X_{ptr}) = \sigma^2(p) + \sigma^2(t) + \sigma^2(r) + \sigma^2(pt) + \sigma^2(pr) + \sigma^2(tr) + \sigma^2(ptr) \quad [2]$$

That is, the total observed score variance can be decomposed into seven independent parts called variance components. When it is assumed that the population and both

facets in the universe of admissible observations are indefinitely large, the variance components in eqn [2] are called random effects variance components. It is important to note that these variance components are for single person–prompt–rater scores, as opposed to average scores over prompts and/or raters, which fall in the realm of D study considerations.

The above discussion of the population and universe of admissible observations is motivated by the Writing assessment introduced previously, but nothing stated so far actually relates to data from the Writing assessment. A particular type of analysis of the actual data constitutes a G study. The purpose of a G study is to estimate the variance components for the population and universe of admissible observations. This is usually accomplished using mean squares (see, e.g., Brennan, 2001a, especially section 3.4 and appendix B). The resulting estimates are for a random effects model, since we are assuming here that both facets and the objects-of-measurement facet are indefinitely large.

For the Writing assessment, the estimated variance components are:

$$\left. \begin{aligned} \sigma^2(p) &= 0.691, & \sigma^2(t) &= 0.025, & \sigma^2(r) &= 0.010 \\ \sigma^2(pt) &= 0.159, & \sigma^2(pr) &= 0.047, & \sigma^2(tr) &= 0.008 \\ \text{and } \sigma^2(ptr) &= 0.218. \end{aligned} \right\} \quad [3]$$

These are estimates of the actual variances (parameters) in eqn [2]. For example, $\hat{\sigma}^2(p)$ is an estimate of the variance component $\sigma^2(p)$, which can be interpreted roughly in the following manner. Suppose that, for each person in the population, the person's mean score (technically, expected score) was obtained over all essay prompts and all raters in the universe of admissible observations. The variance of these mean scores (over the population of persons) is $\sigma^2(p)$. The other main effect variance components for the prompt and rater facets can be interpreted in a similar manner. Note that for the Brennan *et al.* (1995) universe of admissible observations, the estimated variance attributable to essay prompts, $\hat{\sigma}^2(t) = 0.025$, is over twice as large as the estimated variance attributable to raters, $\hat{\sigma}^2(r) = 0.010$. This suggests that prompts differ much more in average difficulty than raters differ in average stringency.

Interaction variance components are more difficult to describe verbally, but approximate statements can be made. For example, $\hat{\sigma}^2(pt)$ estimates the extent to which the relative ordering of persons differs by prompt, and $\hat{\sigma}^2(pr)$ estimates the extent to which persons are rank-ordered differently by different raters. It is especially important to note that $\hat{\sigma}^2(pt) = 0.159$ is over three times larger than $\hat{\sigma}^2(pr) = 0.047$. This fact, combined with the previous observation that $\hat{\sigma}^2(t)$ is over twice as large as $\hat{\sigma}^2(r)$, suggests that prompts are a considerably greater source of variability in persons' scores than

are raters. The implication and importance of these facts will become evident in what follows.

Infinite Universe of Generalization and D Studies

The G study estimated variance components can be used to design efficient measurement procedures for operational use and to provide information for making substantive decisions about objects of measurement (i.e., persons in this example) in various D (Decision) studies. Broadly speaking, D studies emphasize the estimation, use, and interpretation of variance components for decision-making with well-specified measurement procedures.

Perhaps the most important D study consideration is the specification of a universe of generalization, which is the universe to which a decision maker wants to generalize based on the results of a particular measurement procedure. For the Writing assessment, suppose the universe of generalization contains all the prompts and raters in the universe of admissible observations. Since both facets are assumed to be infinite, the universe of generalization would be called infinite as well. This implies that the investigator wants to generalize persons' observed scores based on the specific prompts and raters in the measurement procedure to their scores for a universe of generalization that involves all of the infinite number of prompts and raters. In analysis of variance terminology, such a model is described as random.

The universe of generalization is closely related to potential replications of the measurement procedure. Suppose that the measurement procedure has each person responding to n'_t prompts, with each response to every prompt evaluated by the same n'_r raters. Furthermore, suppose that decisions about a person are based on his or her mean score over the $n'_t n'_r$ observations associated with the person. This is a verbal description of a D study $p \times T \times R$ design. It is much like the $p \times t \times r$ design, but there are two important differences.

First, the sample sizes for the D study (n'_t and n'_r) need not be the same as the sample sizes for the G study (n_t and n_r). This distinction is highlighted by the use of primes with D study sample sizes. Second, for the D study, interest focuses on mean scores for persons, rather than single person–prompt–rater scores that are the focus of G study estimated variance components. This emphasis on mean scores in a D study is highlighted by the use of uppercase letters for the facets in the D study $p \times T \times R$ design.

Under the conceptualization presented above a replication of the measurement procedure would involve a different sample of n'_t essay prompts and a different sample of n'_r raters. Such measurement procedures are described as randomly parallel. These randomly parallel replications span the entire universe of generalization, in the sense that the replications exhaust all conditions in the universe.

Universe scores

In principle, for any person, one can conceive of obtaining the person's mean score for every replication of the measurement procedure in the universe of generalization. For any such person, the expected value of these mean scores is defined as the person's universe score. The variance of universe scores over all persons in the population is called universe score variance. It has conceptual similarities with true score variance in classical test theory.

D study variance components

For the D study $p \times T \times R$ design, the linear model for an observable mean score over n'_t essay prompts and n'_r raters can be represented as

$$X_{pTR} = \mu + v_p + v_T + v_R + v_{pT} + v_{pR} + v_{TR} + v_{pTR} \quad [4]$$

The variances of the score effects in eqn [4] are called D study variance components. When it is assumed that the population and all facets in the universe of generalization are infinite, these variance components are random effects variance components. They can be estimated using the G study estimated variance components in eqns [3].

For example, consider using sample sizes $n'_t = 6$ and $n'_r = 2$ for the Writing assessment. In this case, the estimated D study random effects variance components are

$$\left. \begin{aligned} \hat{\sigma}^2(p) &= 0.691, & \hat{\sigma}^2(T) &= 0.004, & \hat{\sigma}^2(R) &= 0.005 \\ \hat{\sigma}^2(pT) &= 0.027, & \hat{\sigma}^2(pR) &= 0.024, & \hat{\sigma}^2(TR) &= 0.001 \\ & \text{and } \hat{\sigma}^2(pTR) &= 0.018. \end{aligned} \right\} [5]$$

These estimated variance components are for person mean scores over $n'_t = 6$ prompts and $n'_r = 2$ raters. Obtaining these results is simple, as indicated by the formulas in the first column in Table 1. These formulas are based on one of the fundamental results in statistics: the variance of a mean is the variance of the individual elements divided by the sample size. For example,

$$\hat{\sigma}^2(pT) = \hat{\sigma}^2(pt)/n'_t = 0.159/6 = 0.027$$

Table 1 Random effects variance components that enter $\sigma^2(\tau)$, $\sigma^2(\delta)$, and $\sigma^2(\Delta)$ for the $p \times T \times R$ design and different universes of generalization

	D studies ^a	
	T, R random	T fixed
$\sigma^2(p)$	τ	τ
$\sigma^2(T) = \sigma^2(t)/n'_t$	Δ	
$\sigma^2(R) = \sigma^2(r)/n'_r$	Δ	Δ
$\sigma^2(pT) = \sigma^2(pt)/n'_t$	Δ, δ	τ
$\sigma^2(pR) = \sigma^2(pr)/n'_r$	Δ, δ	Δ, δ
$\sigma^2(TR) = \sigma^2(tr)/n'_t n'_r$	Δ	Δ
$\sigma^2(pTR) = \sigma^2(ptr)/n'_t n'_r$	Δ, δ	Δ, δ

^a τ is universe score.

Note that the division-by-sample-size rule does not apply to the objects of measurement facet p . In particular, for this random effects example, $\hat{\sigma}^2(p) = 0.25$ is unchanged from its G study estimate, and it is the estimated universe score variance for the Writing assessment. An examinee's universe score is simply the expected value of that examinee's observed scores for all potential replications of the measurement procedure involving the same universe of generalization, the same D study design, and the same D study sample sizes. Universe score variance is denoted generically $\sigma^2(\tau)$, which is simply $\sigma^2(p)$, here.

Error variances

Under the random model, variance components other than $\sigma^2(p)$ contribute to one or more different types of error variance. Considered next are absolute and relative error variances.

Absolute error variance, $\sigma^2(\Delta)$. Absolute error is simply the difference between a person's observed and universe scores:

$$\Delta_p \equiv X_{pTR} - \mu_p \quad [6]$$

For the Writing assessment design,

$$\Delta_p = v_T + v_R + v_{pT} + v_{pR} + v_{TR} + v_{pTR} \quad [7]$$

Consequently, the variance of the absolute errors, $\sigma^2(\Delta)$, is the sum of all the variance components except $\sigma^2(p)$. This result is also provided in Table 1 under the column headed 'T, R random'.

Given the estimated D study variance components in eqns [5], the estimate of $\sigma^2(\Delta)$ for three prompts and two raters is

$$\begin{aligned} \hat{\sigma}^2(\Delta) &= 0.004 + 0.005 + 0.027 + 0.024 + 0.001 \\ &\quad + 0.018 = 0.079 \end{aligned}$$

and its square root is $\hat{\sigma}(\Delta) = 0.28$, which is interpretable as an estimate of the absolute standard error of measurement (SEM).

The sample sizes of $n'_t = 6$ and/or $n'_r = 2$ were chosen here for illustrative purposes, only. The same procedures and equations could be applied to any pair of sample sizes. For example, the left-hand panel of Figure 1 illustrates results for n'_t ranging from 1 to 12 and for n'_r ranging from 1 to 3. It is evident from Figure 1 that increasing n'_t and/or n'_r leads to a decrease in $\hat{\sigma}(\Delta)$. This result is sensible, since averaging over more conditions of measurement should reduce error. Figure 1 also suggests that using more than two raters leads to only a very slight reduction in $\hat{\sigma}(\Delta)$. Consequently, it would probably be unnecessary to use more than two raters for an actual measurement procedure. Further, Figure 1 indicates that using additional prompts decreases $\hat{\sigma}(\Delta)$ quicker than using additional raters. This is a direct result of the fact that $\hat{\sigma}^2(t) = 0.025$ is larger than $\hat{\sigma}^2(r) = 0.010$, and $\hat{\sigma}^2(pr) = 0.159$ is larger than $\hat{\sigma}^2(pr) = 0.047$. Finally, it does not appear that having more than about 10 prompts makes an appreciable difference in the magnitude of $\hat{\sigma}(\Delta)$; an investigator might even conclude that about six prompts is enough.

Relative error variance, $\sigma^2(\delta)$. Relative error is defined as the difference between a person's observed deviation score and his or her universe deviation score:

$$\delta_p \equiv (X_{pTR} - \mu_{TR}) - (\mu_p - \mu) \quad [8]$$

where μ_{TR} is the expected value over persons of the observed scores, X_{pTR} , for the $p \times T \times R$ design and an infinite universe of generalization. For the random model $p \times T \times R$ design, it can be shown that

$$\delta_p = v_{pT} + v_{pR} + v_{pTR} \quad [9]$$

and the variance of these relative errors is the sum of the variance components for the three effects in eqn [9].

Figure 1 $\hat{\sigma}(\Delta)$ and $E\hat{\rho}^2$ for the $p \times T \times R$ design and an infinite universe of generalization.

This result is also given in **Table 1**, under the column headed '*T, R* random'. Relative error variance is similar to error variance in classical theory.

For the Writing assessment with $n'_t = 6$ and $n'_r = 2$,

$$\hat{\sigma}^2(\delta) = 0.027 + 0.024 + 0.018 = 0.069$$

and its square root is $\hat{\sigma}(\delta) = 0.26$, which is interpretable as an estimate of the relative SEM. Note that this value of $\hat{\sigma}(\delta)$ is smaller than $\hat{\sigma}(\Delta) = 0.28$ for the same pair of sample sizes. In general, $\hat{\sigma}(\delta)$ is less than $\hat{\sigma}(\Delta)$ because, as indicated in **Table 1**, $\hat{\sigma}^2(\delta)$ involves fewer variance components than $\hat{\sigma}^2(\Delta)$. In short, relative interpretations about persons' scores are less error prone than absolute interpretations.

Coefficients

Two types of reliability-like coefficients are widely used in generalizability theory. One coefficient is called a generalizability coefficient and denoted $E\rho^2$. The other coefficient is an index of dependability and is denoted Φ .

Generalizability coefficient, $E\rho^2$. The generalizability coefficient is the ratio of the universe score variance to itself plus relative error variance:

$$E\rho^2 = \frac{\sigma^2(\tau)}{\sigma^2(\tau) + \sigma^2(\delta)} \quad [10]$$

It is the analog of a reliability coefficient in classical theory. For the Writing assessment with $n'_t = 6$ and $n'_r = 2$,

$$E\hat{\rho}^2 = \frac{0.691}{0.691 + 0.069} = 0.91$$

The right-hand panel of **Figure 1** provides a graph of $E\hat{\rho}^2$ for n'_t ranging from 1 to 12 and for n'_r ranging from 1 to 3. As observed in the discussion of SEMs, little is gained by having more than two raters or more than 10 prompts.

Index of dependability, Φ . An index of dependability is the ratio of universe score variance to itself plus absolute error variance:

$$\Phi = \frac{\sigma^2(\tau)}{\sigma^2(\tau) + \sigma^2(\Delta)} \quad [11]$$

Φ differs from $E\rho^2$ in that Φ involves $\sigma^2(\Delta)$, whereas $E\rho^2$ involves $\sigma^2(\delta)$. Since $\sigma^2(\Delta)$ is generally larger than $\sigma^2(\delta)$, it follows that Φ is generally smaller than $E\rho^2$. The index Φ is appropriate when scores are given absolute interpretations, as in domain-referenced or criterion-referenced situations. For the Writing assessment with $n'_t = 6$ and $n'_r = 2$,

$$\hat{\Phi} = \frac{0.691}{0.691 + 0.079} = 0.90$$

Restricted Universes of Generalization and D Studies

The previous section assumed that the D study employed a $p \times T \times R$ design and the universe of generalization was infinite, consisting of two random facets, *T* and *R*. Recall that

the G study also employed a fully crossed design ($p \times t \times r$) for an infinite universe of admissible observations. In short, up to this point, it has been assumed that both designs are fully crossed and the size or extent of both universes is essentially the same. This need not be the case, however. For example, the universe of generalization may be narrower than the universe of admissible observations.

Suppose the Writing assessment investigator is not interested in generalizing over prompts. Rather, if the investigator were to replicate the measurement procedure, a different set of two raters would be used each time with the same six prompts. (Strictly speaking, it might be argued that the G study estimated variance components should be recomputed using only the actual six prompts under consideration, but we overlook this matter here.) If so, we would say that the investigator's universe of generalization is restricted in that it contains a *fixed* facet, *T*. Consequently, the universe of generalization under these circumstances is narrower than the universe of generalization for the random model. In ANOVA terminology, we are discussing a mixed model.

Suppose the investigator decides to use the same D study design structure as before – namely, the $p \times T \times R$ design. Under these circumstances, the last column of **Table 1** indicates which of the random effects D study variance components need to be summed to obtain estimates of universe score variance, $\sigma^2(\tau)$, as well as $\sigma^2(\Delta)$ and $\sigma^2(\delta)$. With $n'_t = 6$ and $n'_r = 2$.

$$\hat{\sigma}^2(\tau) = \hat{\sigma}^2(p) + \hat{\sigma}^2(pT) = 0.691 + 0.159 = 0.850$$

$$\begin{aligned} \hat{\sigma}^2(\Delta) &= \hat{\sigma}^2(R) + \hat{\sigma}^2(pR) + \hat{\sigma}^2(TR) + \hat{\sigma}^2(pTR) \\ &= 0.005 + 0.024 + 0.001 + 0.018 = 0.048 \end{aligned}$$

and

$$\hat{\sigma}^2(\delta) = \hat{\sigma}^2(pR) + \hat{\sigma}^2(pTR) = 0.024 + 0.018 = 0.042$$

It is particularly important to note that, with prompts fixed, $\sigma^2(pT)$ contributes to universe score variance, not error variance. Consequently, for a restricted universe of generalization with *T* fixed, universe score variance is larger than it is for a universe of generalization in which both *T* and *R* are random.

Given these results, it follows from eqn [10] that

$$E\hat{\rho}^2 = \frac{0.850}{0.850 + 0.042} = 0.95$$

Recall that, for these D study sample sizes ($n'_t = 6$ and $n'_r = 2$), when prompts were considered random, $E\hat{\rho}^2 = 0.91$. The estimated generalizability coefficient is larger when prompts are considered fixed because a universe of generalization with a fixed facet is narrower than a universe of generalization with both facets random. That is, generalizations to narrow universes are less error prone than generalizations to broader universes. It is important to note, however, that this does not necessarily mean that

narrow universes are to be preferred, because restricting a universe also restricts the extent to which an investigator can generalize. For example, when prompts are considered fixed, an investigator cannot logically draw inferences about what would happen if different prompts were used. Kane (1982) exploits and extends these notions in his discussion of a sampling model for validity (see also Kane, 2006).

Multivariate Generalizability Theory

Here, a brief introduction to some of the features of multivariate generalizability theory, which Cronbach *et al.* (1972) considered their most novel contribution to generalizability theory, is provided. (See Brennan (2001a, chapters 9–12) for a detailed, integrated treatment of multivariate generalizability theory).

For the details of the Listening and Writing assessment (Brennan *et al.*, 1995), which we will abbreviate *LW*, the reader is referred to the beginning of the section entitled ‘Univariate generalizability theory’. When we focus on Listening *or* Writing scores, only, the analysis is univariate. When we focus on both sets of scores simultaneously, the analysis is multivariate.

In characterizing the multivariate *LW* assessment, it is important to note that: (1) all tasks contributed to *both* Listening and Writing scores and (2) the three raters who evaluated responses for listening skills were different from the three raters who evaluated responses for writing skills. Under these circumstances, the multivariate G study design is symbolized $p^{\bullet} \times t^{\bullet} \times r^{\circ}$ with $k = 2$ dependent variables (Listening scores and Writing scores). The closed

circle after p indicates that Listening and Writing scores are obtained for all persons. The closed circle after t indicates that all tasks contribute to both Listening and Writing scores. The open circle after r indicates that different sets of raters are associated with Listening and Writing scores. A closed or open circle is sometimes said to refer to a linked or independent facet, respectively.

At its simplest level the variance components, $\sigma^2(\alpha)$, in univariate generalizability theory are replaced by variance–covariance matrices, Σ_{α} , in multivariate generalizability theory. The diagonal cells of these matrices always contain the variance components from the k univariate analyses, and some of these matrices contain covariance components in their off-diagonal cells. The second column in **Table 2** contains matrices of the estimates of the variance and covariance components for the *LW* assessment. Matrices contain covariance components when α contains only linked facets, that is, those with closed circles. For example, Σ_t contains covariance components for tasks because the same tasks contribute to both dependent variables. By contrast, Σ_r is diagonal because different raters are associated with Listening and Writing.

It is evident that $\hat{\sigma}_L^2(p)$ and $\hat{\sigma}_W^2(p)$ are large relative to the other estimated variance components, which suggests that examinees differ considerably with respect to their levels of proficiency in Listening and Writing. Furthermore, since $\hat{\sigma}_W^2(p) = 0.691$ is much larger than $\hat{\sigma}_L^2(p) = 0.324$, examinees appear to be much more variable in Writing proficiency than Listening proficiency. The estimated variance components $\hat{\sigma}_L^2(pr)$ and $\hat{\sigma}_W^2(pr)$ are also notably large, which suggests that the rank ordering of examinees differs by task for both Listening and Writing. By contrast, $\hat{\sigma}_L^2(r)$, $\hat{\sigma}_W^2(r)$, $\hat{\sigma}_L^2(pr)$, and $\hat{\sigma}_W^2(pr)$

Table 2 Multivariate results for the *LW* assessment with two raters

G study $p^{\bullet} \times t^{\bullet} \times r^{\circ}$ design		D study $p^{\bullet} \times T^{\bullet} \times R^{\circ}$ design	
		$n_t = 6$	$n_t = 12$
$\hat{\Sigma}_p$	$\begin{bmatrix} 0.324 & 0.356 \\ 0.356 & 0.691 \end{bmatrix}$	$\hat{\Sigma}_p$	$\begin{bmatrix} 0.324 & 0.356 \\ 0.356 & 0.691 \end{bmatrix}$
$\hat{\Sigma}_t$	$\begin{bmatrix} 0.127 & 0.039 \\ 0.039 & 0.025 \end{bmatrix}$	$\hat{\Sigma}_T$	$\begin{bmatrix} 0.021 & 0.006 \\ 0.006 & 0.004 \end{bmatrix}$
$\hat{\Sigma}_r$	$\begin{bmatrix} 0.012 & \\ & 0.010 \end{bmatrix}$	$\hat{\Sigma}_R$	$\begin{bmatrix} 0.006 & \\ & 0.005 \end{bmatrix}$
$\hat{\Sigma}_{pt}$	$\begin{bmatrix} 0.393 & 0.030 \\ 0.030 & 0.159 \end{bmatrix}$	$\hat{\Sigma}_{pT}$	$\begin{bmatrix} 0.066 & 0.005 \\ 0.005 & 0.026 \end{bmatrix}$
$\hat{\Sigma}_{pr}$	$\begin{bmatrix} 0.014 & \\ & 0.047 \end{bmatrix}$	$\hat{\Sigma}_{pR}$	$\begin{bmatrix} 0.007 & \\ & 0.024 \end{bmatrix}$
$\hat{\Sigma}_{tr}$	$\begin{bmatrix} 0.022 & \\ & 0.008 \end{bmatrix}$	$\hat{\Sigma}_{TR}$	$\begin{bmatrix} 0.002 & \\ & 0.001 \end{bmatrix}$
$\hat{\Sigma}_{ptr}$	$\begin{bmatrix} 0.317 & \\ & 0.218 \end{bmatrix}$	$\hat{\Sigma}_{pTR}$	$\begin{bmatrix} 0.026 & \\ & 0.018 \end{bmatrix}$
		$\hat{\Sigma}_{\Delta}$	$\begin{bmatrix} 0.128 & 0.011 \\ 0.011 & 0.078 \end{bmatrix}$
			$\begin{bmatrix} 0.070 & 0.006 \\ 0.006 & 0.053 \end{bmatrix}$

are all quite small, suggesting that raters are not nearly as large a contributor to total variance as are tasks.

There are positive estimated covariance components for p , t , and pt . The estimated covariance component for persons is particularly large (0.356) relative to the estimated variance components (0.324 and 0.691) suggesting that universe scores for Listening (μ_{pL}) and Writing (μ_{pW}) are highly correlated. The estimate of this disattenuated correlation is

$$\hat{\rho}_{LW}(p) = \frac{\hat{\sigma}_{LW}(p)}{\sqrt{\hat{\sigma}_L^2(p)\hat{\sigma}_W^2(p)}} = \frac{0.356}{\sqrt{0.324 \times 0.691}} = 0.75$$

Also, by the same line of reasoning, universe scores for tasks on Listening and Writing are highly correlated [$\hat{\rho}_{LW}(t) = 0.69$] suggesting that the rank ordering of the tasks in terms of difficulty is quite similar for Listening and Writing. By contrast, the pt interaction effects are only slightly correlated [$\hat{\rho}_{LW}(pt) = 0.12$].

The right-hand side of **Table 2** provides D study variance-covariance matrices for the $p^\bullet \times T^\bullet \times R^\circ$ design with two raters and two sample sizes for tasks. Just below these matrices are the associated $\hat{\Sigma}_\Delta$ matrices, which are obtained by summing all of the D study matrices except $\hat{\Sigma}_p$. The fact that the $\hat{\Sigma}_\Delta$ matrices have covariance components is a direct indication of the correlated error induced by using the same tasks to obtain both Listening and Writing scores. For example, when $n'_t = 6$, the correlated Δ -type error is $0.011/\sqrt{0.128 \times 0.078} = 0.11$. Multivariate generalizability theory is one of the few psychometric models that permits (indeed encourages) an explicit consideration of correlated error without much additional effort.

Multivariate generalizability theory does not require that a composite of the k scores be considered, but often one or more composites is/are of interest. In general, the composite universe score is

$$\mu_{pC} = w_1\mu_1 + w_2\mu_2 + \cdots + w_k\mu_k$$

where the w_j are investigator-specified weights. A simple example is difference scores, for which $w_1 = 1$ and $w_2 = -1$.

For the LW assessment and the Listening-minus-Writing difference-score composite, estimated universe score variance is

$$\begin{aligned}\hat{\sigma}_C^2(p) &= \hat{\sigma}_L^2(p) + \hat{\sigma}_W^2(p) - 2\hat{\sigma}_{LW}(p) = \\ &0.324 + 0.691 - 2(0.356) = 0.304\end{aligned}$$

For $n'_t = 6$ and $n'_r = 2$, the difference-score estimated absolute error variance is

$$\begin{aligned}\hat{\sigma}_C^2(\Delta) &= \hat{\sigma}_L^2(\Delta) + \hat{\sigma}_W^2(\Delta) - 2\hat{\sigma}_{LW}(\Delta) = \\ &0.128 + 0.078 - 2(0.011) = 0.183\end{aligned}$$

Therefore, $\hat{\Phi} = 0.304/(0.304 + 0.183) = 0.62$. Note that positively correlated error decreases $\hat{\sigma}_C^2(\Delta)$ when the composite is a difference score, which increases $\hat{\Phi}$.

Other Issues

One of the distinct advantages of multivariate generalizability theory is that it obviates otherwise complex estimation problems for designs that are unbalanced with respect to fixed facets, only. By contrast, unbalanced designs create complexities for estimating random effects variance components, as discussed extensively by Brennan (2001a, chapters 7 and 8). The essential problem is that there are numerous estimation procedures that give different estimates, with no obvious criterion for choosing among them.

Estimated variance components and functions of them (e.g., error variances and coefficients) are subject to sampling variability, as discussed extensively by Brennan (2001a, chapter 6). If it can be assumed that effects are normally distributed, often relatively straightforward procedures exist to estimate standard errors. When such assumptions are unreasonable (as they often are in generalizability analyses), nonparametric jackknife or bootstrap procedures can be considered. Recent research on the jackknife is provided by Feng (2002). Recent research on the bootstrap is provided by Brennan (2007), Tong and Brennan (2007), and Wiley (2000).

In most applications of generalizability theory, examinees or persons are the objects of measurement. Occasionally, however, some other collection of conditions plays the role of objects of measurement (e.g., class, district, or school means). It is relatively straightforward to apply generalizability theory in such cases (see, e.g., Brennan, 1995; Brennan *et al.*, 2003; Kane and Brennan, 1977).

Some general purpose computer packages for statistics (particularly SAS Institute Inc., 1996, Varcomp) can be used to estimate random effects G study variance components; other results for generalizability analyses usually are not provided by such packages, however. A few computer programs have been specifically designed for generalizability analyses. For any univariate, complete, balanced design GENOVA (Crick and Brennan, 1983) provides both G and D study results. urGENOVA (Brennan, 2001c) provides estimated G study random effects variance components for unbalanced designs. mGENOVA (Brennan, 2001b) provides multivariate G and D study results for a selected set of designs. These three programs are coordinated with Brennan (2001a).

In a sense generalizability theory is a macro-measurement model in that it pays particular attention to test scores, whereas item response theory focuses much more on item scores. Brennan (2006) argues that one of the most important challenges to psychometrics for the twenty-first century is to integrate these two models, if possible.

Impact of Assessment on Classroom Practice

J L Herman, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Since its inception, assessment has been advanced as a tool for improving educational practice. Initially, assessment was thought to exert such influence through the information it provided to educators and policymakers and thus presumably to improve decisions. Over time, however, recognition has grown of assessment's sociocultural and broader influences on teaching and learning, and recently researchers have differentiated between the effects of assessments of learning, the historical focus of assessment policy, practice, and research, and those of assessments for learning, the use of assessment during the course of instruction to directly inform and improve the learning process. These two types of assessment, summative and formative respectively, operate from distinct theoretical bases and have unique theories of action, which are explored below. The article begins by providing perspective on the purpose and uses of assessment of learning and how these may impact classroom practice before considering the research base on assessment's actual effects on practice and the factors that influence such impact. Finally, the article addresses theory and research on how assessment for learning, so-called formative assessment, influences classroom teaching and learning practice, and draws implications for future research.

This article uses the terms test and assessment interchangeably as denoting measures of student learning, although the former tends to denote traditional, multiple-choice-dominated standardized tests and the latter a broader array of methods. Similarly, a number of terms have been used in the literature to capture the concept of the impact of assessment, including assessment effects, consequences, washback, and backwash. These terms also are to be considered interchangeable.

Historical Perspective: Assessments for Selection and Improvement Purposes

The imperial examinations of the Han Dynasty (220–206 BC) are credited as the first use of standardized testing and the idea that gathering standard information on individuals' capabilities could lead to better and more equitable advancement decisions, in this case decisions about coveted civil service appointments. One can imagine that faced with the examination, elite, would-be candidates would prepare for the test and engage tutors to do so, a first instance of the impact of assessment on educational

practices. Used for purposes of selection, the Han Dynasty assessments also are a first example of how an assessment result can influence the practices in which individuals are subsequently placed.

From this very early precedent, educational assessment's use in selection thrived in the last century and continues today worldwide. Following World War I in the United States, for example, many school districts used standardized, intelligence tests for placing students into homogeneous classrooms, reinforcing tracking schemes that provided lower-track students with less rigorous instruction than higher-track students. Similarly, Great Britain's tradition of using assessment to certify, select, and track students for subsequent education dates back to the nineteenth century. Although more essay-based than those in the United States, these set the stage for tests that motivate performance and with it the substantial influence of testing on educational practice.

Side by side with traditions of testing for selection and placement developed that of using assessment to improve educational effectiveness. The father of modern educational measurement, Edward Thorndike, advocated the value of testing for guiding teaching, and Ralph Tyler's 8-year study (in the 1930s) created assessments designed to support progressive education goals. With a new objectives-based framework as the foundation for development, Tyler articulated the ways in which assessment could support teaching and learning, for example, monitoring student learning to inform instructional planning; affording school- and program-level accountability and improvement; and in loosening the confining influence of traditional scholarship tests. That is, predating current interest in assessment consequences, Tyler recognized that traditional tests constrained instructional practice, and that new forms of assessment were needed to permit new, progressive approaches to education to take hold. Similarly, like Hope for performance assessment in the United States nearly 50 years later, Tyler's assessments were intended to educate the public about important goals of schooling and to help teachers' clarify their instructional goals and practices, serving also to sow the seeds for changes in practice.

Assessment Impact in the Context of Overlapping Purposes

These fundamental, formal functions or purposes of measurement – to sort and select students, to certify

accomplishment, and to provide data for purposes of improving the quality of education – have coexisted since the beginning of educational testing. Further, while measurement experts advise that tests be designed to serve a specific purpose, the reality is that current educational policy tends to intertwine multiple purposes, and thus large-scale assessments of learning can impact instructional practice through multiple pathways. Whether the context is the test-based accountability systems in the United States, or the operation of A- and O-level type examination systems in many countries across the world, testing serves not only to provide technical evidence that informs multiple categories of decisions and policy functions (e.g., accountability, admissions/selection, placement, diagnosis, progress monitoring, certification, accreditation, and evaluation), but attention to and use of the technical data also carries important sociopolitical meanings that can translate into important consequences for educational practice.

Consider, for example, high school exit examinations common in the United States that students need to pass for a high school diploma; Key Stage, the General Certificate of Secondary Education (GCSE), or A-level type examinations in the United Kingdom; and higher education admissions tests that operate in countries across the globe. The ostensible purpose of the assessment is to certify that students have the knowledge and skills that the state has determined as needed for subsequent success.

As doing well on the assessment is important to students' futures, the existence of the test is expected to motivate students to learn, to prepare for the test, and to acquire the knowledge and skills that are assessed, as well as to motivate parents to pay attention and support their children's education. Moreover, even in the absence of tangible rewards and sanctions, educators will be motivated to help their students to do well, both because they care about their students' futures and because they see public reports of their students' test performance as evidence of their own professional efficacy. Accordingly, schools are motivated to do what they can to assure that their students will succeed and to do so may modify the content of their classes, may develop or purchase special materials to prepare students for the test, identify and establish new programs to help students succeed, etc. Instructional materials providers may respond by adapting existing materials or creating new products to meet the needs created by the test. In the case of high school exit examinations, educators also may use test results of students who do not pass the test to place them in special classes, provide extra tutoring options, and if the test provides subscale data on different aspects of performance, they may use the results to diagnose individual students' learning needs.

Those same results aggregated at the class, school, or district levels may be used to analyze and respond to curriculum strengths and weaknesses, to suggest specific

topic areas on which new or supplementary materials may be needed and in which teachers may benefit from professional development, or to infer priorities for budget allocations. Actors at the district, regional, state, and/or federal levels may be similarly analyzing and responding to the same data at different levels of aggregation, identifying schools and districts that are doing particularly well or that are in most need of help, including deriving implications for system priorities, needed changes, and/or new programs. Thus, data from a single test may fuel analysis and decisions at multiple levels, which in turn have cascading effects on instructional practice.

As another example, take a state-mandated teacher competency assessment that teachers must pass to gain tenure. By mandating such an assessment, state policymakers communicate their commitment to educational quality, their recognition of the importance of students having access to good teachers, and their responsibility for assuring the quality of the teaching force. As the assessment is developed, it makes concrete and communicates valued knowledge and competencies for fresh teachers. Just as secondary schools may respond to the requirements of high school exit or college-readiness examinations, so also can teacher preparation institutions be expected to adapt their curriculum and instructional pedagogy to the expectations of the teacher assessment and to use their students' results to strengthen their program's success in enabling students to pass. To the extent that sizable proportions are not passing, an institution may change its admission procedures, create special test preparation courses or tutoring opportunities, and/or try to pressure pre-preparation institutions to better prepare potential candidates. To the extent that the assessment delves deeply into meaningful aspects of teachers' content and pedagogical knowledge and requires demonstration of quality practice, preparing for the test may well help new teachers become more effective, and responding to the assessment requirements may strengthen and deepen existing preparation programs. In any event, unless it is a trivial assessment, the assessment may function to homogenize or standardize preparation programs and the content and pedagogical knowledge that teachers gain from them. As they can influence the what and how teachers learn in teacher-preparation programs, and who is allowed to enter the profession, such teacher assessments may substantially influence subsequent instructional practice.

These examples are not meant to be exhaustive, but rather to illustrate the confounding of test purposes, the merging of accountability/summative and improvement/formative functions, and of the technical, sociopolitical, and symbolic roles that high-stakes or high-visibility assessments play in influencing practice. A single test can launch a whole network of interrelated motivations and cascading actions, only some of which directly involve the technical use of the test.

These same overlapping functions also may accrue in classroom assessments of learning, particularly those that are used for grading. They too function to motivate and focus students' effort, communicate what is important to learn and how to do it, and, for learning-oriented teachers and students, to stimulate reflection on what has been learned, how to fill the gap between that and intended learning goals, and how to improve the teaching and learning sequence (see also the section on formative assessment).

Research on the Effects on High-Visibility External Tests

What of the actual impact of high-visibility tests? Researchers around the globe have studied this question, drawing largely on interview and survey methods, sometimes supplemented with observations of practice.

Consistent Results on Potential Benefits

The rigor of design and methodology vary substantially from study to study, but results have been quite consistent regardless of locale, for example, studies of state accountability tests in more than a dozen states in the United States, of A- or GCSE or Key Stage examinations in England, and language and higher education admissions testing programs in countries such as Australia, Central and Eastern Europe, China, Hong Kong, Israel, Japan, New Zealand, and Sri Lanka:

- *Testing signals priorities for curriculum and instruction: high-visibility tests serve to focus the content of instruction.* School administrators and teachers pay attention to what is tested, analyze test results, and adapt curriculum and teaching accordingly.
- *Teachers tend to model the pedagogical approach reflected on high-visibility test.* When a high-visibility assessment is composed of multiple-choice tests, teachers tend to rely heavily on multiple-choice worksheets in their classroom instruction. However, when the assessments use open-ended items and/or extended writing and rubrics to judge the quality of student work, teachers prepare students for the test by incorporating these same types of activities in their classroom practice.
- Curriculum developers, particularly commercial interests, respond to important tests by modifying existing textbooks and other instructional materials and/or developing and marketing new ones to address test content and format. These products in turn may become primary resources that influence not only practice but also teachers' understanding of test expectations.
- *Test results can make visible and promote responsiveness to the needs of students who previously have been underserved.* In the United States, for example, where all students are held

to the same standards and schools must reach test-based accountability targets for all subgroups, research shows schools and teachers paying more attention to traditionally low-performing students, including second-language learners and students with disabilities. Test results are used to identify and provide special help for faltering students, for example, through the creation of new courses, purchase of new materials, and provision of extra school opportunities (e.g., before or after school tutoring and summer school).

Consistent Results on Problematic Effects

While the above points demonstrate some ways that assessment, depending on the nature of the test, can leverage productive changes in instructional practice, research shows unintended, negative consequences:

- *Schools and teachers may focus on the test rather than underlying standards or learning goals.* With sanctions and incentives riding on test performance, educators give primary attention to what is tested and how it is tested, rather than to the standards or learning goals the test is intended to measure. For example, teachers may shift how much classroom instruction time is accorded to particular topics or curriculum subjects depending on the content emphasis of the test.
- *What is not tested can become invisible.* As a corollary to focusing on the test rather than the standards, that which is not tested tends to get less attention or may be ignored altogether. Both the broader domain of the tested disciplines and important subjects that are not tested may get short shrift. In the United States, for example, many state tests tend to give relatively little attention to complex thinking and problem solving and tend to focus on lower levels of learning, which can lead to similar emphases in classroom practice.
- *Focusing on the test, rather than underlying learning, may encourage performance orientation and transmission-type teaching.* When passing the test, rather than learning, becomes the goal, schools may unwittingly promote a performance orientation in students, which can work against students' engagement and persistence in learning, metacognition, and self-regulation. Particularly for high-visibility tests that are predominantly multiple choice, teachers may concentrate on direct instruction to help students acquire specific content, rather than using pedagogy that helps students build conceptual understanding and problem-solving capability.
- *Instructional time is diverted to specific test-preparation activities.* Schools provide students with practice on the specific types of tasks and formats that are expected on the test, through commercial test-preparation packages, special classes, and homework. Such activities aim specifically to help students do well on the test,

rather than promoting students' learning, and depending on the school and the pressure to improve test scores, can divert weeks or more of instructional time.

- *Assessment-driven instruction can spur more and more testing.* In the United States, more and more districts are mandating interim assessments during the school year, largely mimicking the expected content and format of their annual state tests, to provide quarterly or so feedback on how students are doing, and to encourage teachers to keep their eye on student progress on the knowledge and skills that will be tested. Moreover, many districts have become more prescriptive about how and what teachers are supposed to teach and have created pacing guides detailing what is to be covered when.
- Rather than motivating teachers to improve teaching and learning, high-visibility testing can cause teachers to feel pressured and demoralized, particularly when they view testing targets as unrealistic.
- *Testing schedules can distort teaching and learning plans.* Teachers may even adjust the amount of time they devote to basic subjects (e.g., reading and math) depending on when each subject is assessed. For example, if math is tested after grade 4 and reading in grade 5, then math may receive relatively more attention in grade 4 and reading in grade 5. Similarly, the best teachers may be moved to the particular grades at which important assessments are given. The desire to boost test scores thus can trump goals for teaching and learning in curriculum and personnel decision making.

Factors that Influence Assessment Impact

While research shows various potential effects of assessment on instructional practice, it also makes clear that such effects are not automatic – neither do they tend to be uniformly positive or negative. A first issue in shaping potential impact is the nature of the test itself. In fact, worry in the 1990s that traditional, standardized multiple-choice testing in the United States was producing a narrow, drill-and-skill curriculum led advocates to advance large-scale performance assessments to be, in the words of Lauren Resnick, “tests worth teaching to.” By requiring students to engage in more authentic tasks that required complex thinking and problem solving and extended responses, performance assessment was intended to drive instruction in a similar constructivist direction, an early case of testing policy being explicitly used to leverage change. Similarly, more than 20 years ago, J. Charles Alderson identified the potentially powerful washback of language testing and argued that changes in testing could support desired changes in language curriculum and teaching. The 1993 Hong Kong Certificate of Education in English, as an example, was launched to encourage secondary teachers of English to adopt a more communicative and purposeful approach, rather than a structural approach, to

language development. The new assessment included more authentic and interactive tasks that required students to integrate listening, writing, reading, and/or speaking and to apply their skills in context; or more recently, Great Britain's key stage tests ostensibly are designed to encourage teachers to address a broad curriculum within each assessed subject, to enable students to respond to and create a variety of forms of writing and to engage students in applying mathematical and scientific knowledge and skills.

Yet, the path from potential or intended impact to actual changes in practice is neither simple nor clear-cut. The move from policy mandate to operational test involves a process of implementation, from public dialog and public discourse about the meaning of the policy, to how and by whom the test is specified and developed, and through a complex chain of visible and invisible decisions and actions that may redefine initial intentions. From operational test to impact on practice similarly involves a circuitous and unpredictable process, as the concept of impact necessarily involves some change in practice.

Succinctly summarizing the many factors that influence it, theorists have noted that change requires both the will and the capacity to change and have suggested that policymakers hoping to use assessment to leverage changes in practice must consider the resources and strategies needed to support such change. From a motivational perspective, for example, in response to any new testing mandate, stakeholders may choose to accept and use it, ignore it, or fight it. Only those in the first category have immediate potential for intended effects and if change is to occur, action must be taken to convert those in the other two categories.

Yet even with willingness, intended changes in practice will occur only when educators understand what is expected and have the prerequisite knowledge, skills, and understandings, as well as relevant resources, to make the change. As a new test rolls out, for instance, educators may differ in their understandings of what the test actually assesses and thus in its implications for their practice. Teachers will vary as well in their capability to engage in new, expected practices, depending on how complex intended changes are and how far from existing practice. Thus, what “teaching to the test,” a common response to high-visibility tests, actually means depends on the beliefs and capacities of the educators who are responding and the resources and support they have available to them. In response to the same test, some schools and/or teachers may make meaningful and productive changes in teaching and learning, while others may react more mechanically with test-preparation activities simply mimicking the test.

Research on the consequences of assessment worldwide, in fact, indicates that while teachers may easily modify the content of their teaching, pedagogy is more resistant to change. Teachers' initial pedagogical responses tend to be superficial, for example, simply incorporating samples of

the new assessments as an add-on to existing curriculum. Over time and only with sufficient support do new practices become more integrated with the ongoing instruction and new standards and quality criteria are more deeply understood and acted upon. Effects on practice, in short, are not the product of a test, but the result of a process that is influenced by stakeholders' attitudes and efficacy, the meanings they make of what is expected, the school context, power or other relationships in which the change is embedded, the stakes riding on test results, the nature of the intended change, and the resources and strategies used to help teachers incorporate new practices, to name just a few. Assessments may be mandated top down with the intention of accomplishing various impacts, and even bolstered by policy incentives and sanctions but the actual impact is neither easily controlled nor easily predicted.

The Effects of Assessment for Learning: Classroom Formative Assessment

In contrast to assessments of learning that are mandated top down, assessments for learning, so-called formative assessments, occur bottom up, within the actual context of classroom teaching and learning. Similar to standardized testing of learning, however, the roots of formative assessment also can be found in ancient history, that of Socrates in fifth-century BC Greece. Socrates educated his students through questioning and dialog, breaking down important ideas into a series of questions, whose answers, with probing, gradually helped students to acquire new insights. Questions and answers were not judged right or wrong, but were the means to building knowledge and understanding. Similarly in formative assessment, assessment is used to elicit students' understanding in order to form subsequent teaching and learning.

The last decade has seen increasing, worldwide interest in formative assessment, fueled in large part by Black and Wiliam's landmark meta-analysis showing the strong effects of formative assessment on student learning, particularly for low-ability students. Policymakers and educators increasingly have recognized that while external tests of learning may help to communicate priority goals, motivate improvement, and identify who has succeeded or not-summative functions, results are too little and too late to directly improve practice. Rather the most powerful use of assessment occurs hand in hand with classroom teaching and learning.

The use of data is key to the idea: to be considered formative, assessment evidence must be acted upon during the course of classroom instruction. Rather than focusing backward on what has been learned, formative assessment helps to chart the learning road forward, by identifying and providing information to fill any gaps between the learners' current status and goals for learning.

Moreover, more than solely a source of evidence that informs subsequent teaching and learning, formative assessment may enhance student learning directly. For example, in asking students to make public their thinking, formative probes can provide scaffolding that helps students to confront their misconceptions, refine and deepen their understandings, and move to more sophisticated levels of expertise. By making learning goals explicit and involving students in self-assessment, formative assessment can also promote students as agents in their own learning, increasing student motivation, autonomy, meta-cognition, as well as learning.

Formative assessment itself involves a change in instructional practice. Rather than imparting knowledge in a transmission-oriented process, in formative assessment teachers guide students toward significant learning goals and actively engage students as assessors of themselves and their peers. Formative assessment occurs when teachers make their learning goals and success criteria explicit for students, gather evidence of how student learning is progressing, partner with students in a process of reciprocal feedback, and engage the classroom as a community to improve students' learning. The social context of learning is fundamental to the process as is the need for classroom culture and norms that support active learning communities—for example, shared language and understanding of expected performance; relationships of trust and respect; and shared responsibility for and power in the learning process. Theorists observe that enacting a meaningful process of formative assessment influences what students perceive as valued knowledge, who can learn, and who controls and is valued in the learning process. However, as with the effects of assessments of learning on practice, those of formative assessment do not happen automatically but involve a complex process of change. Moreover, at this point, the anticipated effects of formative assessment on instructional practice are based on theoretical argument and are yet to be fully confirmed through empirical or other research.

Conclusion

Available theory and research suggest the ways in which assessments of learning and those for learning may exert influence on instructional practice. In both cases, such effects are not automatic but rather dependent on a complex process of change that is influenced by many, difficult-to-control, factors. Marshaling the power of assessment to improve practice requires better understanding of how such change occurs and the nature of the assessments and support processes that can best achieve positive effects while minimizing unintended negative ones. Continuing research needs to explore whether high stakes and formative assessments are effective in meeting their intended aims, how effective each is relative to other

strategies for influencing instructional practice, and whether and how assessment may undermine or support other teaching and learning goals, including effects on educational equity. Most studies thus far have examined short-term effects. Also needed are longer-term studies that examine implementation and effects over time.

Introduction

Different models of educational measurement engender different instructional practices in the classroom or within intelligent instructional systems, and thus have different effects on student learning. Historically, the main aim of measuring students' educational progress was to identify differences among students in order to rank order them by achievement. This type of measurement model makes heavy use of summative assessment, which is useful for accountability purposes but only marginally useful for guiding day-to-day instruction and supporting student learning. In contrast, student-centered measurement models rely mostly on formative assessment, which can be very useful in guiding instruction and supporting student learning, but provide an inadequate basis for accountability purposes. Now, instead of considering these as disjunctive measurement models, it may be possible to effectively combine them within new, enhanced intelligent systems that use both kinds of assessments – summative and formative – and which leverage computer technology, educational measurement, and cognitive science to address problems that face education today.

A unified approach to educational measurement may be justified based on the following assumptions: (1) individual differences among students have powerful effects on learning, (2) these effects can be quantified and predicted, and (3) technology can capitalize on these effects to the benefit of teachers and students (as well as others, such as administrators and parents). The goal is to figure out how to effectively and efficiently integrate appropriate assessment and instruction to improve student learning and education in general. This is substantially easier said than done, although significant advances have been made in both educational-measurement technologies and intelligent systems.

We begin this article by broadly defining educational measurement, specifically in terms of the critical role assessment plays in education. Summative and formative assessment both have their place in education and we examine how they may be more tightly and strategically coupled. Next, we define intelligent systems, focusing on the usage of assessment data by computers to make inferences about students' cognitive and other attributes. This provides the foundation for rendering decisions about what content to present next to the student. Measuring what students know and do not know (and to what degree)

is the first step in remediating students or advancing them to higher levels. This requires the development and use of valid and reliable assessment tools and results to make accurate diagnoses and guide learning. We conclude with an outline of an approach to incorporating evidence-based assessments into intelligent systems to improve learning.

Definitions

Educational Measurement

Educational measurement may be broadly defined as the application of a standard scale or measuring tool to determine the degree to which educationally valuable knowledge, skills, and abilities have been acquired. According to the website of the National Council on Measurement in Education, this includes theory, techniques, and instrumentation available for measurement of educationally relevant human, institutional, and social characteristics. We measure to obtain information, and such information may or may not be useful, depending on the accuracy of the instruments and the skillful manner with which they are used.

Assessment is a general term that includes testing. Progress toward educational goals is typically assessed through testing. Assessment is both an instrument and a process by which information is obtained relative to a known objective or goal. Since inferences are made about what a person knows on the basis of his/her responses to a limited number of assessment tasks or items, there is always some uncertainty in inferences made on the basis of assessments. The goal in educational measurement is to minimize uncertainty or error; thus, key aspects of assessment quality are validity and reliability. Reliability refers to the consistency of assessment results – the degree to which they rank order students in the same way. Validity refers to the extent to which the assessment accurately measures what it is supposed to measure, and the accuracy of the inferences made from task or test results.

Types of Assessment

We consider here two main types of assessment: summative and formative. Summative assessment reflects the traditional approach used to assess educational outcomes. This involves using assessment information for high

stakes, cumulative purposes, such as promotion, certification, and so on. It is usually administered after some major event, like the end of the school year or marking period or before a big event, like college. Benefits of this approach include the following: (1) it allows for comparing student performances across diverse populations on clearly defined educational objectives and standards; (2) it provides reliable data (e.g., scores) that can be used for accountability purposes at various levels (e.g., classroom, school, district, state, and national) and for various stakeholders (e.g., students, teachers, and administrators); and (3) it can inform educational policy (e.g., curriculum or funding decisions).

Formative assessment reflects a more progressive approach in education. This involves using assessments to support teaching and learning. Formative assessment is tied directly into the fabric of the classroom and uses results from students' activities as the basis on which to adjust instruction to promote learning in a timely manner. This type of assessment is administered much more frequently than summative assessment, and has shown great potential for harnessing the power of assessments to support learning in different content areas and for diverse audiences. In addition to providing teachers with evidence about how their students are learning so that they can revise instruction appropriately, formative assessment may directly involve students in the learning process, such as by providing feedback that will help students gain insight about how to improve, and by suggesting (or implementing) instructional adjustments based on assessment results.

We now turn our attention to intelligent computer-based systems which have been around for several decades, but have yet to be fully embraced by education. Their primary goal is to enhance student learning; so assessment should, in theory, play a key role in these systems.

Intelligent Systems

Intelligent systems (also known as intelligent tutoring systems) refer to educational software containing an artificial-intelligence component. The software tracks students' work, adjusting feedback and providing hints along the way. By collecting information on a particular student's performance as well as other cognitive and noncognitive variables, the software can make inferences about strengths and weaknesses, and can suggest additional work.

A summary of requirements for intelligent systems was presented by Hartley and Sleeman in the early 1970s. They argued that these systems must possess: (1) knowledge of the learner (student model), (2) knowledge of the domain (expert model), and (3) knowledge of teaching strategies (pedagogical model). It is interesting to note

that this simple list has not changed in more than three decades; however, advances have been made in each of the three areas. All of the computer-resident knowledge marks a radical shift from earlier knowledge-free, computer-assisted instructional programs. Furthermore, the ability to diagnose students' errors and adapt instruction based on the diagnosis represents a key difference between intelligent versus other computer-based systems, such as simulations. Intelligent systems are also aligned with the features and goals of formative assessment. The three main components of intelligent systems – student, expert, and pedagogical models – are now briefly described.

A student learns from an intelligent system primarily by solving problems – ones that are appropriately selected or tailor-made, and that serve as learning experiences for that student. The system may start by assessing what the student already knows. Information about the student is maintained within what is called the student model, which is updated during the course of learning. The system then must consider what the student needs to know. This information is embodied in the domain-expert model. Finally, the system must decide what unit of content (e.g., assessment task or instructional element) ought to be presented next, and how it should be presented. This is achieved by the pedagogical model (or tutor). From all of these considerations, the system selects or generates a problem, then either works out a solution to the problem (via the domain-expert model), or retrieves a prepared solution. The intelligent system compares its solution to the one the student has prepared and performs a diagnosis based on differences between the two as well as other information available in the student model. Feedback is offered by the system based on considerations such as how long it has been since feedback was last provided, whether the student already received some particular advice, and so on. After this, the program updates the student model, and the entire cycle is repeated, starting with selecting or generating a new problem.

Despite the great promises of intelligent systems, they are currently not widely used in classrooms, partly because of their cost, and also because of measurement limitations. We now focus on the latter in more detail, describing how assessments differ between traditional intelligent systems and newer, enhanced intelligent systems. This is intended to provide the foundation on which to consider a new view of educational measurement within intelligent systems.

Assessments' Role in Intelligent Systems

For the most part, traditional intelligent systems use a formative assessment model, where different student actions invoke different instructional decisions or paths. This comprises the basis for adaptive instruction. New

enhanced intelligent systems extend the assessment capabilities of traditional systems. Some of these enhancements include the use of: evidence-based assessment data, explicit links to state curriculum standards, formative and summative sources of assessment information, new measurement techniques from educational psychology and cognitive science, and an explicit and strong role for teachers. Both types of intelligent systems are now discussed in turn.

Traditional Intelligent Systems

As noted earlier, formative assessment is explicitly intended to support student learning, defining the role of the student as an active, creative, and reflective participant in the learning process. Learning environments that make use of formative assessment typically include individualized instruction, along with hands-on, authentic learning activities. Assessments are used primarily to inform teaching and improve student learning.

One major downside of this model is that formative assessment is often implemented in a nonstandardized and hence less-rigorous manner than summative assessment. This can hamper the validity and reliability of the assessment tools and data. As the validity and reliability of the assessment data affect the accuracy of the student diagnosis, and the diagnosis informs instructional support, if the first part of the chain is weak, the rest (i.e., diagnostic accuracy and effective instructional support) would consequently be compromised. In other words, the effectiveness of an intelligent system in achieving its goal hinges on the goodness of information in the student model (i.e., the inferences about what the student knows and can do).

Traditional intelligent systems that employ formative assessment utilize a rich source of student data from which to draw inferences. For example, evidence is captured from all past and current student–system interactions, and may differ in type and grain size. Thus, in addition to the nonstandardization of methods for implementing formative assessment in traditional intelligent systems, there are also problems with accurately modeling student knowledge within such multifaceted environments. This poses a number of psychometric challenges (e.g., modeling of multiple abilities, capabilities, and other learner characteristics) regardless of the measurement model employed.

We now take a closer look at new intelligent systems that are starting to integrate formative and summative sources of assessment information, and are employed within real classroom settings.

Enhanced Intelligent Systems

Most current intelligent systems reside primarily in the laboratory. This isolation from real classrooms explains why their designs have not been overly concerned with

summative types of assessment, and also explains to some extent why they have not been widely adopted. That is, learning systems deployed within laboratory-based environments do not have to comply with the same high standards (e.g., accountability requirements), as in real-classroom environments. However, as these systems move out of the laboratory and into the classroom, the need for accountability (e.g., standards and norm-referenced assessments) increases.

Summative assessments are explicitly designed for accountability purposes. They represent a source of valid and reliable evidence of student knowledge. Due to national and international accountability requirements and interests, summative assessments are widely used in schools. For example, in the US, summative assessments have received increased attention after the US Congress passed the No Child Left Behind (NCLB) initiative in 2001. And on the international front, the Programme for International Student Assessment (PISA) is being used to compare student achievement in countries all over the world. The measurement community has made important advances in the development of psychometric models (e.g., Rasch, item-response theory) that provide reliable and valid assessment information, typically presented as a single measure of ability at a particular point in time for any given student. These data, however, have limited use for formative purposes. And one often-cited downside of this emphasis on accountability is that teachers tend to view testing as time taken away from valuable instruction and learning.

Over a decade ago, Snow and Mandinach called for the development of principles for creating valid and useful instructional-assessment systems. We are, only now, beginning to see intelligent systems entering classrooms that integrate sound assessment and instruction. These systems are characterized by (1) a strong presence of teachers in all phases of the project, (2) a cognitive model that is used to drive instructional and assessment interactions, and (3) explicit connections to state standards and standardized state tests.

An example of a successfully deployed intelligent system can be seen in the web-based cognitive tutors designed and developed by Anderson, Koedinger, and colleagues at Carnegie Mellon University. A derivation of their cognitive-tutor approach is called *assistsments* – the merging together of robust assessment with instructional assistance into one system. *Assistsments* use real (i.e., released) items from the Massachusetts comprehensive assessment system (MCAS) state exams within the system for both assessment and instructional purposes.

Table 1 summarizes the main features that separate traditional from enhanced intelligent systems with regard to the role assessments play.

While assessments provide a good example of joining formative and summative models within an intelligent

system, this important blending is still uncommon despite calls for their union. A few other systems demonstrating similar capabilities include: Sistema de Evaluacion Inteligente mediante Tests (SIETTE) by Conejo and colleagues, adaptive content for evidence-based diagnosis (ACED) by Shute and colleagues, and English assessment-based learning environments (ABLE) by Zapata-Rivera and colleagues. The next section presents an evidence-based approach designed to create valid assessments for summative or formative purposes, and which may be implemented as part of an intelligent system.

Evidence-Centered Design and Intelligent Systems

An intelligent system that includes valid assessments, for formative and/or summative purposes, must elicit behavior from the student that bears evidence about key skills and knowledge. In addition, the system must provide principled interpretations of that evidence in terms that

suit the purpose of the assessment. **Figure 1** sketches the basic structures of an evidence-centered approach to assessment design, formulated by Mislevy and colleagues at Educational Testing Service (ETS).

Working out these variables and models and their interrelationships is a way to answer a series of questions posed by Messick in the early 1990s that get at the very heart of assessment design:

- What complex of knowledge, skills, or other attributes should be assessed? A given assessment – formative or summative – is meant to support inferences for some purpose, such as a licensing decision, provision of diagnostic feedback, guidance for further instruction, or some combination. Variables in the competency model describe the knowledge, skills, and abilities on which the inferences are to be based. The term student model is often used to denote a student-instantiated version of the competency model. That is, values in the student model express the assessor's current belief about a student's level on variables within the competency model.
- What behaviors or performances should reveal those constructs? An evidence model expresses how the student's interactions with, and responses to, a given problem constitute evidence about student-model variables. Observable variables summarize aspects of specific task performances, and may come from either formative or summative sources. Then depending on the type and origin of the source(s) of evidence, different parameters are used to update the student model.
- What tasks or situations should elicit those behaviors? Task-model variables describe features of tasks or situations that will be used to elicit performance. A task model provides a framework for characterizing and constructing situations with which a student will interact to provide evidence about targeted aspects of knowledge. The task models will vary in line with the purpose of the assessment and its administration.

Within intelligent systems employing such evidence-based assessment, the student model would accumulate and represent belief about the targeted aspects of skill. These beliefs are often expressed as probability distributions

Table 1 Assessments' role in traditional vs. enhanced intelligent systems

Issue	Traditional Systems	Enhanced systems
Design methods based on evidentiary argument	Mostly absent	Present
Assessment focus	Mostly formative assessment	Formative and summative assessment
Links to standards	Mostly absent	Present
Measurement models	Largely <i>ad hoc</i>	Variegated, informed by advances in educational measurement and cognitive science
Evaluations	Mostly laboratory based	Classroom based
Role of teacher	Very limited or absent	Strong

Figure 1 The three central models of an evidence-centered assessment design. Reproduced from Mislevy, R. J., Steinberg, L. S., and Almond, R. G. (2003). On the structure of educational assessment. *Measurement: Interdisciplinary Research and Perspective*, 1(1), 3–62.

for student-model variables. The way that this works in practice is that the evidence model extracts observables (e.g., scores) from student work (i.e., what the student says or does), and provides a way to aggregate scores that are then used to update the student model. In other words, the evidence model describes how evidence about a set of skills is connected to the competency-model variables using a psychometric model. Task models express situations that can evoke required evidence.

Based on the information in the student model, a viable approach to select and deliver content to the learner is needed – one that fits his or her needs at the time. This would provide context and coherence for delivering adaptive instruction, one of the main goals of intelligent systems. Following is an example of a model to support the select-and-deliver goal. It has been extended from the simpler two-process model that resides at the core of intelligent systems – diagnosis and prescription – and from a process model to support assessment, by Mislevy, Almond, and colleagues at ETS.

Four-Process Adaptive Cycle

The success of any intelligent system to promote learning requires accurate diagnosis of student characteristics (e.g., algebra knowledge, troubleshooting skill, and engagement). The collection of student information then can be used formatively for the prescription of optimal content, such as hints, explanations, hypertext links, practice problems, encouragement, metacognitive support, and so forth. Student information can also be used in a summative manner, such as providing reports on student achievement. The framework, described in this section, involves a four-process cycle connecting the student to appropriate educational materials and other resources (e.g., learning objects, peers, applications, and pedagogical agents) through the use of a student model, shown as the small human icon at the top of **Figure 2**.

The main components of this four-process cycle are (1) capture, (2) analyze, (3) select, and (4) present. The solid arrows in the figure show a normal, complete loop used in many intelligent systems, while the dashed arrows show variations of the cycle that have been used in other kinds of systems. For example, the dashed line that goes upward from the student (i.e., the large human icon in at the bottom of **Figure 2**) to the student model depicts an intelligent system where the student is allowed to interact directly with the student model. The nature of this interaction and the effects on the student model can vary, such as negotiating the value of a particular variable with the system or the teacher. The four processes are now briefly defined.

- **Capture.** The capture process entails gathering personal information about the student as he or she interacts with the environment. Relevant information, obtained

Figure 2 Four-process adaptive cycle. Reproduced from Shute, V. J. and Zapata-Rivera, D. (2008). Adaptive technologies. In Spector, J. M., Merrill, D., van Merriënboer, J., and Driscoll, M. (eds.) *Handbook of Research on Educational Communications and Technology*, 3rd edn, pp 277–294. New York: Lawrence Erlbaum Associates, Taylor & Francis Group.

through formative or summative assessment, can include cognitive as well as noncognitive aspects of the learner. This information is used to update the internal student model maintained by the system.

- **Analyze.** The analyze process requires the creation and maintenance of a student model by properly integrating evidence sources from student performance in the environment. This usually involves representing information in the student model through inference mechanisms in relation to students' proficiency states based on specific performance data.
- **Select.** Information (i.e., content in the broadest sense) is selected according to the model of the student maintained by the system and the goals of the system (e.g., next learning object or test item). This process is often required to determine how and when to intervene.
- **Present.** Based on results from the select process, specific content is presented to the learner. This entails appropriate use of different media, devices, and technologies to effectively and efficiently convey information to the learner.

Discussion

Educational measurement involves obtaining observations from students' responses in order to make inferences about their knowledge and skills. Reliable instruments are critical in this effort. The way in which information from assessments is captured, analyzed, and ultimately used, strongly influences the student model. First, the

granularity of the assessment information influences the kinds of assessment claims that the system can make at any point in time (e.g., general ability vs. component-skill level). Second, the type of evidence that is available from assessment tasks influences the reliability of the claims that the system can make about the student (e.g., data from calibrated test items are more reliable than data from, say, homework assignments). Third, the type of evidence available from assessment tasks influences the validity of the claims that the system can make about the student (e.g., the student is fully proficient at a particular skill vs. more evidence is needed to support the claim). Finally, the complexity of the assessment information – or the manner in which assessment information is interpreted – can range from very simple methods to quite sophisticated ones, such as using probability-based models. To effectively handle the diverse types of assessment information, from either formative or summative sources, an evidence-based assessment framework (e.g., evidence-centered design) is recommended.

Merging instruction with valid formative and summative assessment information in the form of intelligent systems opens up new possibilities and challenges that, if surmounted, could result in improved student learning and educational outcomes. New tools and methodologies are needed to get a more complete profile of the learner. These tools should focus on functions such as: (1) helping create student models that go beyond skills (e.g., conceptual understanding, social aspects of learning, emotional states, and other noncognitive attributes); (2) creating a framework to analyze incoming student work and update student model(s) properly (e.g., evidence-centered design (ECD), along with the four-process adaptive cycle); (3) informing the teacher, in easy-to-understand language, what to do next with the class and/or student and how to understand the data that are derived from the system; and (4) encouraging students to become more active and accountable for their own learning.

Early intelligent system design and development was typically accomplished without much input from psychometricians and/or assessment specialists. This may be partially explained by the chasm between traditional and emergent models of educational measurement. Current advances in intelligent systems, cognitive science, and educational measurement provide the opportunity for integrating assessment and instruction into powerful new intelligent systems. These new systems have the potential to improve student learning and also standardized test scores. Additional benefits of integrating formative and summative assessments with instruction include: (1) re-using rigorous assessment tasks and items from summative tests directly in the service of learning, and (2) increasing the chances of successful adoption of intelligent systems into mainstream education.

Item Response Theory

W J van der Linden, CTB/McGraw-Hill, Monterey, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Ability parameter – Parameter in a response model that represents the person's ability, skill, or proficiency measured by the test items.

Adaptive testing – Mode of testing with real-time ability estimation in which each item is selected to be optimal at the last estimate.

Cognitive-component models – Response models with parameters for the individual cognitive operations required to solve the test item.

Dichotomous response models – Response models for items with dichotomously scored responses, such as correct–incorrect, true–false, and agree–disagree items.

Hierarchical response models – Response models with random item and/or person parameters for which a distribution is specified.

Information function – Fisher's measure for the information in an item or test score as a function of the ability parameter.

Item parameter – Parameter in a response model that represents a property of the item, such as its difficulty and discriminating power.

Multidimensional response models – Response models with a multidimensional ability parameter.

Optimal test design – Use of techniques from mathematical programming to design tests that are optimal with respect to an objective function and meet the set of constraints representing its content specifications.

Polytomous response models – Response models for items with polytomously scored responses.

Response function – Probability of a specific response on an item as a function of the ability parameter.

Item response theory (IRT) has many roots, and it would be wrong to single out anyone as the most important. But the contributions by Louis Thurstone (1925) have been decisive in many respects. These contributions built on Binet's intelligence test developed to separate students in Paris schools that needed special education from regular underachievers (Binet and Simon, 1905) as well as earlier work in psychophysics by Fechner.

Although Binet's test has been hailed as the first to be a fully standardized test in the history of educational and

psychological measurement, his most significant contribution was his idea to scale the items before using them in the test. Of course, there is no natural intelligence scale, and neither were there any points of view to look at the matter in Binet's days. Binet's solution to the problem, however, was equally simple as ingenious: he chose chronological age as the scale on which he mapped his items and students. Using an empirical pretest, he defined the scale value of an item as the age group of which 75% of its members had solved it correctly. These scale values were then used to estimate the age group for which the student's achievements on the test were representative. The age of this group was the mental age of the student.

The chronological age scale used by Binet allows for direct measurement. Thurstone's innovation was to put Binet's items on an intelligence scale that cannot be measured directly. He did so because he recognized that intelligence is an example of what is now known as a latent variable; that is, an unmeasured hypothetical construct. The scale of this variable was defined by postulating a normal distribution for each age group and inferring the scale values of the items from the response data. Thurstone also showed how to check this distributional assumption. The assumption of a normal cumulative distribution function as a response function was not new but borrowed from the earlier work on psychophysics by Fechner, who used them to describe how psychological sensations vary with the strength of experimentally manipulated physical stimuli. But Thurstone's idea to separate intelligence from age and define it as a latent variable with a scale defined by such response functions was entirely new.

The idea of response functions on a latent variable was picked up again by authors like Ferguson, Lawley, and Mosier in the 1940s (and led to much confusion between the use of the normal ogive as a definition of a population distribution and a response function on a latent variable). But we had to wait until the seminal work by Lord (1952) and Rasch (1960) until the developments really began. From a more statistical point of view, later contributions by Birnbaum (1968) were important. He replaced the normal ogive by the logistic function, introduced additional item parameters to account for guessing on items (which is typical of most educational measurements), derived maximum-likelihood estimators for the model, and showed how to assemble tests from a bank of calibrated items to meet optimal statistical specifications for their application.

The next two decades showed much research on IRT models for test items with other response formats than simple dichotomous scores as well as on newer procedures for parameter estimating and model evaluation. Especially, the development of Bayesian procedures for parameter estimation and model validation was prominent. When computers became more powerful and cheaper in the 1980s, the routines for maintaining common scales and test assembly used in most large-scale educational testing programs became IRT based. The first programs to exploit IRT to score test takers in real time and deliver computerized adaptive tests were launched in the 1990s. Nowadays, IRT models and procedures are no longer the main instruments only in the educational testing industry but are becoming increasingly popular in psychological testing as well. In addition, they have hit areas such as medical diagnosis and marketing research.

Review of Response Models

Unidimensional Logistic Models for Dichotomous Items

Due to Thurstone's pioneering work, the assumption of a normal-ogive function as response function for test items remained popular for a long time. Lord's (1952) treatment of IRT for dichotomously scored items was also based on this assumption. Let U_i denote the response to item i , where $U_i = 1$ if the response on item i is correct and $U_i = 0$ if it is incorrect. The normal-ogive model describes the probability of a correct response as a function of the test taker's ability θ :

$$p_i(\theta) = \Pr\{U_i = 1|\theta\} = \int_{-\infty}^{a_i(\theta - b_i)} \frac{1}{\sqrt{2\pi}} \exp^{-z^2/2} dz. \quad [1]$$

where $\theta \in (-\infty, \infty)$ and $b_i \in (-\infty, \infty)$ and $a_i \in (0, \infty)$ are parameters for the difficulty and discriminating power of item i .

Observe that the model has its parameter structure in the upper limit of the integral. For this reason, it was rather intractable at the time, and hardly used in routine applications in testing. The model also seemed to ignore the possibility of guessing on test items. These two points were addressed in Birnbaum's (1968) model, which is now generally known as the three-parameter logistic (3PL):

$$p_i(\theta) = \Pr\{U_i = 1|\theta\} = c_i + (1 - c_i) \frac{\exp(a_i(\theta - b_i))}{1 + \exp(a_i(\theta - b_i))} \quad [2]$$

where additional parameter $c_i \in [0, 1]$ represents the height of a lower asymptote for the probability of a correct response. The asymptote is approached for $\theta \rightarrow -\infty$. This limit is assumed to represent random guessing without any knowledge.

The two models have no fixed unit and origin for the scale of θ . In practice, we therefore fix the scale following a practical convention. All later models in this article need comparable constraints to become identifiable. For an appropriate choice of scale unit, the models in eqns [1] and [2] predict success probabilities for identical sets of parameter values that are virtually indistinguishable from each other.

A graphical example of the logistic response function for a set of item parameter values is given in **Figure 1**. Difficulty parameter $b_i = 1$ controls the location of response function along the θ scale. A more difficult item has its location to the right of $\theta = 1$ and requires a higher ability to give the same probability of success. Discrimination parameter $a_i = 1.4$ controls the slope of the response function. A more discriminating item has a response function with a steeper slope than in **Figure 1**. Finally, a value of 0.23 for discrimination parameter c_i indicates the height of the lower asymptote for the response function. Typically, for multiple-choice items, the estimated values for this guessing parameter are close to the reciprocal of their number of response alternatives.

The two-parameter logistic (2PL) model is obtained if we put $c_i = 0$ in eqn [2]. The result is the logistic analog of eqn [1]. If we also assume equal values for the discrimination parameter (that is, $a_i = a$ for all i), the Rasch (1960) model is obtained. This model belongs to the exponential family of distributions in statistics and is statistically quite tractable.

Due to its parameter structure, the 3PL model is flexible and has been shown to fit large pools of items written for the same content domain in educational and psychological testing. In fact, it has become the standard of the testing industry for tests with dichotomous items

Figure 1 Example of a response function for the 3-parameter logistic model in eqn [2].

that measure a unidimensional ability. For more narrowly defined domains of educational items, or psychological tests of well-defined constructs, the Rasch model becomes an attractive alternative.

Models for Polytomous Items

Test items have a polytomous format when the responses are scored in more than two categories. Such models have a response function for each different category. **Figure 2** shows a typical set of response functions for an item with five different categories for one of the polytomous response models below.

Although the response categories of dichotomous items typically have a fixed order (e.g., correct–incorrect; true–false), this does not necessarily hold for polytomous items. Polytomous items have a nominal response format if their response categories can be classified but an *a priori* order between them does not exist. The nominal response model below is appropriate for items with this format. If an *a priori* ordering of the categories does exist, a graded-response model or partial-credit model should be chosen. The two models differ in the problem-solving process that is assumed to lead to the responses.

Models for a graded-response format are more generally known as cumulative models in ordinal categorical data analysis. The partial-credit models below are known as adjacent-category models. These two options do not exhaust all possibilities, a more comprehensive review of different polytomous response formats and IRT models is given in Mellenbergh (1994).

Nominal-response model

Response variable U_i is now assumed to have possible values $b = 1, \dots, m_i > 2$. Observe that different items in

Figure 2 Example of response functions for a polytomous response model with five categories.

the same test may have different numbers of possible responses. According to the nominal-response model (Bock, 1972), the response function for category b is

$$p_{ib}(\theta) = \Pr\{U_i = b|\theta\} \quad [3]$$

$$= \frac{\exp(a_{ib}(\theta - b_{ib}))}{\sum_{b=1}^{m_i} \exp(a_{ib}(\theta - b_{ib}))}. \quad [4]$$

Parameters a_{ib} and b_{ib} maintain their interpretation as a discrimination and difficulty parameter. **Figure 2** illustrates that b_{ib} represents the location of the response function for category b along the ability scale, where the location is defined as the value of θ at which the function shows its largest change in curvature. The value of the discrimination parameters a_{ib} is proportional to this change.

In spite of the nominal response format, the values for the parameters b_{ib} , $b = 1, \dots, m_i$, do imply an order for the response categories. However, the actual order is only known when these parameters are estimated; it is thus empirical, not *a priori*. This feature makes the model less suitable for educational measurement, where performances on test items can always be ordered from worse to better in advance. Another reason why the model in eqn [4] may be less appropriate for this application is that it does not allow explicitly for guessing. A version of the nominal response model that does allow for guessing is given in Thissen and Steinberg (1997).

Graded-response model

Suppose index b reflects an *a priori* ordering of the response categories. The graded-response model (Samejima, 1969) addresses the probabilities of the compound events $U_i \geq b$,

$$P_{ib}(\theta) = \begin{cases} 1 & \text{for } b = 1 \\ \Pr\{U_i \geq b|\theta\} & \text{for } b = 2, \dots, m_i \\ 0 & \text{for } b > m_i \end{cases} \quad [5]$$

as a function of ability parameter θ . The more interesting probabilities are those for $b = 2, \dots, m_i$. They increase monotonically with θ because the probability of responding in any of these categories or higher goes to one if $\theta \rightarrow \infty$.

A typical choice for $P_{ib}(\theta)$ for $b = 2, \dots, m$ in eqn [5] is from the logistic functions in eqn [2] for $c_i = 0$. If the parameters a_i are free, the result is known as the nonhomogeneous case of the model. If we set $a_i = 1$ for all i , a more stringent version of the graded-response model is obtained, which is known as its homogenous case.

The response functions for the individual categories $b = 2, \dots, m_i$ can be derived from eqn [5] as

$$p_{ib}(\theta) = P_{ib}(\theta) - P_{i(b+1)}(\theta). \quad [6]$$

The shape of these response functions may not differ much from those for the nominal-response model.

The most distinctive feature of these functions, however, is that they reflect an *a priori* order, which is specified by the test specialist when assigning the labels $b = 1, \dots, m_i$ to the categories. These labels determine the way in which the differences in eqn [6] are calculated.

Partial-credit models

These models derive their name from an increasing credit given to the responses $b = 1, \dots, m_i$. All models are based on a sequential response process in which the test taker is assumed to compare two adjacent categories at a time and decide to prefer one category over the other with a certain probability.

The first version of the partial-credit model (Masters, 1982) was based on the assumption that the probability of preferring response b relative to $b - 1$ can be represented by the Rasch model. Upon some probability calculus, this assumption can be shown to lead to the following response functions for $b = 1, \dots, m_i$:

$$p_{ib}(\theta) = \frac{\exp\left(\sum_{k=1}^b (\theta - b_{ik})\right)}{\sum_{b=1}^{m_i} \exp\left(\sum_{k=1}^b (\theta - b_{ik})\right)}. \quad [7]$$

A generalized version of the model exists in which the probabilities of adjacent responses are based on the 2PL model with free discrimination parameters a_i (Muraki, 1992). The model therefore has parameter structures $(\theta - b_{ib})$ extended to $a_i(\theta - b_{ib})$.

Further, if we adopt a common number of categories m for all items, the generalized partial-credit model can be specialized to a model for a set of rating scales of the Likert type. Likert scales are well known in attitude measurement, where they are used to ask subjects to evaluate a set of attitude statements using scales with common categories such as strongly agree, agree, neutral, disagree, and strongly disagree. The steps necessary to obtain the rating scale model steps are: (1) decomposing the parameters b_{ib} additively as $b_i + d_k$, with b_i a location parameter for the entire item and d_k a threshold parameter for k th category on the Likert scale, and (2) constraining the discrimination parameters to special known constants. This rating scale model was introduced by Andersen (1977) and Andrich (1978).

Multidimensional Models

Test items may measure more than one ability, for example, a verbal ability in addition to the ability in another domain of achievement that is tested more explicitly. If this happens, the previous models have to be extended by more ability parameter. For the 3PL model in eqn [2], the extension with a second ability parameter may lead to response functions

$$p_i(\theta_1, \theta_2) = c_i + (1 - c_i) \frac{e^{a_{i1}\theta_1 + a_{i2}\theta_2 - b_i}}{1 + e^{a_{i1}\theta_1 + a_{i2}\theta_2 - b_i}}. \quad [8]$$

This model defines the probability of a correct response as a function of (θ_1, θ_2) . It has two discrimination parameters, a_{i1} and a_{i2} , which control the slope of the response surface along θ_1 and θ_2 , respectively. But it has only one (generalized) difficulty parameter b_i ; a similar model with two parameters $b_{i1} - b_{i2}$ would be nonidentifiable version of it. If $\theta_1, \theta_2 \rightarrow -\infty$, the probability of a correct response goes to c_i . The role of these parameters becomes clear if we view the graphical example of the response surface in Figure 3 as a two-dimensional generalization of the response function in Figure 1.

Cognitive-Component Models

IRT models in this class specify the probability of success on a test item as a function of the components of the cognitive task involved in solving the item. Two main types of models have been used. Both types agree in that they decompose the difficulty parameter as a set of more basic parameters for the relevant components. They differ, however, in how to impose a structure on these basic parameters.

Let $U_{ik} = 0, 1$ denote whether or not component $k = 1, \dots, K$ of the task involved in solving item i has been executed successfully. Suppose a correct response to item i requires a successful execution of each of these components. The probability of a correct response for this conjunctive structure is then given by the product of the probabilities for each of the components,

Figure 3 Example of a two-dimensional response surface for the logistic model in eqn [8].

$$\prod_{k=1}^K \Pr\{U_{ik}\}. \quad [9]$$

Models of this type were introduced by Embretson (1997). Her choice of success probabilities for the component tasks was the Rasch model with free ability parameters, θ_k , and difficulty parameters, β_{ik} , for $k = 1, \dots, K$. She also introduced a guessing parameter for the case a test taker misses a component and has to guess to the answer on the item.

A different approach is offered in the linear logistic model introduced by Fischer (1983). In this model, the structure is not imposed on the probabilities of successful completion of the component tasks, such as for the conjunctive structure in eqn [9], but directly on their difficulty parameters. Assuming the same set of component tasks $k = 1, \dots, K$ to hold for item i , the item-difficulty parameter is taken to be the following linear function of the component parameters:

$$b_i = \sum_{k=1}^K w_{ik}\beta_{ik} + c$$

where w_{ik} is the weight set by a content specialist to represent the impact of component difficulty β_{ik} on the difficulty of item i .

The idea of modeling underlying processes rather than the responses themselves has been a fruitful area of research. Its spirit is well captured by the name explanatory item response modeling given to the area by De Boeck and Wilson (2005).

Hierarchical Models

Hierarchical or multilevel modeling of responses is appropriate when the test takers can be assumed to be sampled from a population and the interest is in some of the features of its ability distribution. This application arises, for example, in large-scale educational assessments, where the development in the educational achievements of certain populations should be compared or followed over time. Alternatively, the interest may exist in test items that can be considered as randomly sampled, for example, from families of items generated from a set of parent items, as in the use of techniques of item cloning (Glas and van der Linden, 2003). In this case, to allow for the random sampling of items from different families, the distributions of their parameters in these families have to be modeled. Of course, it is possible to have applications in which the distributions of both the person and item parameters have to be specified.

As a first-level model, typically one of the earlier models is chosen, for example, the 3PL model for a correct response in eqn [2]. A second-level model for the ability distribution is the normal

$$\theta \sim N(\mu, \sigma^2) \quad [10]$$

with mean μ and variance σ^2 .

If the items are sampled from families $f = 1, \dots, F$, the second-level models for their distributions can be taken to be the multivariate normals

$$(a_{if}, b_{if}, c_{if}) \sim MVN(\mu_f, \Sigma_f) \quad [11]$$

where μ_f and Σ_f are the mean and covariance matrix for the item parameters of family f .

These models become more powerful if we are able to explain the second-level distributions of the abilities or item parameters by background variables or covariates, for example, group memberships of the test takers or structural features of the item families. This can be done by introducing linear regression structure for the means in eqn [10] or eqn [11]. Following the spirit of hierarchical linear modeling, the regression parameters can also be defined to be random at a higher level of modeling (Fox and Glas, 2001). In large-scale educational assessments, the introduction of such regression structures helps us to pinpoint differences in achievement between specific populations.

Other Models

The previous response models belong to the most important categories in the literature as well as the practice of educational measurement. But they do certainly not exhaustive the possibilities. To date, some 30–40 different response models have been proposed that are statistically tractable. The collection includes models for nonmonotone items. An item is called monotone if the function for its correct response is monotonically increasing with the ability measured by the items. This feature is typical of achievement test items but cannot be expected to hold for items in attitude scales or preference measurement, where respondents may endorse the same alternative for opposite reasons. The current review, moreover, does not include nonparametric approaches to IRT modeling or models for response times on test items. Nonparametric approaches avoid the assumption of a parametric family of response functions but try to use order assumptions with respect to probabilities of success, persons, and/or items only, which may vary in their degree of stringency. In addition, polytomous versions of nonparametric models exist (for a review, see Sijtsma and Molenaar, 2002). Response-time models have become important because of the increasing popularity of computerized delivery of educational tests with its automatic recording of the response times on the individual items. In order to use these times as an additional source of information on the persons or items, a response model with a typical IRT parameterization is necessary (van der Linden, 2006, 2009).

For more extensive introductions to larger collections of response models, the reader should consult Fischer and Molenaar (1995) and van der Linden and Hambleton (1997).

Applications in Educational Measurement

Item Calibration and Measurement

The use of IRT models in educational measurement typically consists of the stages of item calibration and measurement. During item calibration, response data are collected for a representative sample of test takers whereupon the item parameters are estimated from the data and the validity of the model is evaluated. The process of model evaluation may involve the checking of the model against the data for features such as the match between the dimensionality of the data and the ability parameters in the model, the assumption of local independence required to estimate the parameters, possible systematic differences in item parameters between relevant subpopulations (differential item functioning), and the general shape of the response functions. Additionally, it should be checked if the test takers tend to behave according to the response model. All checks take the form of statistical hypothesis testing, where the alternative hypothesis is the specific model violation against which the model is tested. For a more comprehensive treatment of these tests, see Glas and Meijer (2003) and Glas and Suarez Falcon (2003).

If the model fits and the item parameters are estimated with enough precision, the model can be used as measurement model. The test is then administered as part of operational testing and the person parameter is estimated for each test taker equating the item parameters to their estimates. The estimate is reported as the test taker's ability score. (Following a Bayesian approach, it would be more appropriate not to treat the item parameters as completely known but to account for their estimation error when estimating the person parameter. But this practice is rather unusual in educational measurement.)

Person parameters are typically estimated using the method of maximum likelihood (ML) or a Bayesian method. For the dichotomous model in eqn [2], these estimates are obtained as follows. Let (u_1, \dots, u_n) be the vector with the responses for a person on the items $i = 1, \dots, n$ in the test that is used to measure the person's ability, θ . In ML estimation, the estimate of θ is calculated from the probability of the response vector under the model taken as a function of θ . More specifically, this function is known as the likelihood function of θ associated with the responses,

$$L(\theta|u_1, \dots, u_n) = \prod_{i=1}^n p_i(\theta)^{u_i} [1 - p_i(\theta)]^{1-u_i}, \quad [12]$$

and the ML estimate is the value of θ for which this likelihood function reaches its maximum.

In a Bayesian approach, θ is estimated by its posterior distribution; that is, its probability distribution given the responses. The distribution is obtained by assuming a prior distribution of θ and combining this with its likelihood as:

$$f(\theta|u_1, \dots, u_n) = cL(\theta|u_1, \dots, u_n)f(\theta), \quad [13]$$

where $f(\theta)$ is the density of the prior distribution of θ , $f(\theta | u_1, \dots, u_n)$ is the density of its posterior distribution, and c is a normalizing constant. If a point estimate is needed, the mean of the posterior distribution can be taken (expected *a posteriori* or EAP estimation).

The power of IRT for educational measurement lies in the presence of the item parameters in the expression in eqns [12] and [13] from which the ability estimate is calculated. Due to this, the estimation automatically accounts for the properties of the items that were selected in the test. For example, if the items would have been more difficult, the values of the item difficulty parameters would have been greater, and the ability estimate for the response vector would automatically have been increased to account for this. This feature has been called item-free measurement – an expression that, when taken naively, seems to capture this feature nicely but is somewhat misleading because the statistical features of the estimate (e.g., its accuracy) still depend on the chosen items.

Another way of touting the power of IRT is by pointing at the fact that it is able to produce valid item calibration or educational measurement from response data collected using research designs with missing data. The applications in the next sections capitalize on this feature. Of course, the validity of parameter estimates from incomplete designs is only guaranteed if the fact whether or not the responses are missing does not contain any direct information on their correctness. It would be wrong to leave out a portion of the responses, for instance, because they were incorrect.

Specific Applications with Missing Data

Most of the large-scale educational testing programs now use item banking. In item banking, new items are written, pretested, and calibrated continuously. If an item passes all quality checks, it is added to the item bank. At the same time, new tests are assembled from the items in the bank. This practice differs dramatically from traditional test construction, which goes through a complete cycle of item writing, pretesting, and test construction for one test at a time. Obvious advantages of item banking are more constant use of the resources, permanent access to a large stock of pretested, high-quality items for test assembly, and less vulnerability to premature leaking of a test form. Its main advantage is, however, stable score scales defined by larger pools of items. Such scales permit testing programs to

produce scores that are comparable over time even when earlier stocks of items in the bank have been retired and replenished.

Item banking is possible because when using IRT, it is no longer necessary for two persons to answer identical collections of test items to have comparable scores. Likewise, in order to compare the parameter estimates of different items, it is no longer necessary for them to be taken by the same sample of test takers. It is therefore possible to build up banks with much less restricted versions of data-collection designs than in traditional pre-testing of test items. Likewise, once the items have been calibrated, we can deliberately select a subset of items for a specific measurement goal.

The idea of optimal test assembly capitalizes on the latter opportunity. One of the first to point at it was Birnbaum (1968). His idea was to translate the measurement goal into a target function for the accuracy of the test along the ability scale. The test was then assembled to match the target as closely as possible. For example, the test could be required to have a uniform target over a certain ability range when it is used for diagnostic purposes with respect to students in it, or a peaked function at a cutoff score when the goal is accurate admission decisions.

For this approach to be practical, it is necessary to have a measure of the accuracy of the test as a function of the ability θ measured by the items. A useful measure is Fisher's information in the item responses in the test, which for the 3PL model in eqn [2] can be shown to be equal to

$$I_i(\theta) = \frac{a_i^2 [1 - p_i(\theta)] \left[\frac{p_i(\theta) - c_i}{1 - c_i} \right]^2}{p_i(\theta)} \quad [14]$$

for item i . Taken as a function of θ , the measure is generally referred to as the information function of item i . The use of this measure for optimal test assembly is motivated by two different facts: First, information functions are additive. That is, if the items $i = 1, \dots, n$ are selected for a test, test information function $I(\theta)$ can be shown to be equal to the sum of the item information functions,

$$I(\theta) = \sum_{i=1}^n I_i(\theta). \quad [15]$$

It is thus straightforward to evaluate the effects of adding or removing an item to a test. Second, the sampling variance of the ML estimator of θ for a given test is asymptotically equal to the inverse of the information function in eqn [15]. This feature gives the use of the information function its statistical foundation. **Figure 4** illustrates the additivity of the information functions for a test of six items.

Although optimal test assembly can be illustrated graphically rather easily for a short test, the actual assembly of a test in a real-world application is no simple affair.

Figure 4 Example of six item information functions and their test information function.

In many applications no single tests but sets of parallel tests are to be selected. More importantly, tests always have to be assembled to sets of constraints that control their content specifications. In fact, it is not unlikely for real-world tests to be assembled to several hundreds of such constraints. Fortunately, such problems can be modeled to be a linear integer programming problem, which can easily be solved using standard commercial software. For solutions to a large variation of optimal test assembly problems with various objective functions and types of constraint, see van der Linden (2005).

In computerized adaptive testing (CAT), the items in the test are not selected simultaneously for a group of test takers but sequentially from the item pool for an individual test taker. The responses on the items are recorded and used to update the person's ability estimate in real time. Each next item in the test is selected to be optimal at the last estimate. Due to this adaptation, the ability estimate converges much faster to the person's true ability than for a traditional fixed test, even when it has been assembled to be optimal for a group of test takers.

In order to implement adaptive testing, a criterion for item selection is required. An obvious criterion is to use the information function $I_i(\theta)$ in eqn [14] and select the next item to have a maximum value for it at the last ability estimate among the items in the pool. This popular criterion of item selection is known as the maximum-information criterion. Alternatively, Bayesian item-selection criteria can be used, for example, a criterion that minimizes the variance of the posterior distribution of the test taker's ability in eqn [13].

Other practical issues that have to be addressed when implementing adaptive testing are how to impose a fixed set of content constraints on the test for different test

takers in real-time item selection, how to prevent different time pressure between test takers that get different selections of items, and how to maintain the integrity of the item pool against test takers that cheat and try to memorize and share test items. IRT-based solutions to these problems are reviewed in van der Linden (2005) and van der Linden and Glas (2010).

National Assessments

T J Crooks, University of Otago, Dunedin, New Zealand

© 2010 Elsevier Ltd. All rights reserved.

National assessment involves gathering and presenting information on national patterns of educational outcomes. The focus in this article is on assessment within primary and secondary education. Most commonly, national assessments concentrate on student achievement outcomes, such as knowledge and skills, but some national assessment programs focus on affective outcomes such as motivation, attitudes and dispositions as well.

National assessment programs have their core focus on educational outcomes for the whole school population at selected year levels. However, most also present information about outcomes for subgroups within that population, such as boys and girls, students with different cultural or ethnic affiliations, students attending schools with different characteristics, and students from different regions. This more differentiated information can be useful in identifying policy needs associated with particular groups or the progress being made towards achieving equity of educational outcomes.

Functions

National assessment programs may have control, accountability and diagnostic functions. The balance among these for a particular program is determined largely by the design of the program and the prominence that it achieves.

National assessment programs can exercise control over participants in the education system through the emphasis given to particular educational outcomes. If particular subsets of curriculum objectives are selected as the focal areas for national assessment, and participants feel strong pressure to demonstrate good performance in those areas, the designers of the national assessment program can influence, quite strongly, the curriculum coverage and emphases of administrators, teachers, and students, and even the teaching and learning styles adopted. In federal systems, national assessments have the potential to alter the balance of control between national and state or regional education authorities.

Accountability involves taking or assigning responsibility within an enterprise for achieving particular outcomes. In education systems, national assessment provides information that can be used to decide if desired outcome targets are being met, and can therefore play a significant role in the accountability of agencies or individuals with responsibilities in those areas.

A third function of national assessment is diagnosis: identifying strengths and weaknesses in educational outcomes and possible reasons for the patterns identified. Good diagnoses suggest the next actions to be taken to achieve the most desired outcomes.

These three functions are not independent, or even necessarily competing. For instance, accountability mechanisms are usually central to the effectiveness of control strategies, and diagnostic information can be very useful to help individuals or agencies to meet accountability requirements.

Models for National Assessment

Participation in International or Regional Assessment Programs

One way that many countries gain national assessment information is by participating in major international or regional multicountry assessment programs. For instance, at least 40 countries participated in each of the most recent international assessments of the Progress in International Reading Literacy Study (PIRLS), the Trends in International Mathematics and Science Study (TIMSS), and the Programme for International Student Assessment (PISA).

PIRLS, TIMSS, and PISA are open to countries throughout the world, but there are also multinational assessment programs that are restricted to countries within a given region. For instance, many countries have participated in assessments organized by the Southern African Consortium for Monitoring Educational Quality (SACMEQ), while countries further north in Africa have made use of the francophone assessments of the *Programme d'analyse des systèmes de la CONFEMEN* (PASEC).

For national assessment purposes, participation in such programs has significant advantages. The consortia involved have access to strong technical expertise that is not available in many single nations, and the processes are highly developed and systematic. The results give comparative information between nations as well as substantial information for individual national reports.

There are, however, significant disadvantages also. Because of the different curricula of different countries, the assessment items included in an international assessment represent a compromise between the curricula and wishes of the different countries involved, so that it may not fit really well with the curriculum of a particular country. Moreover, the security and technical requirements

associated with these assessments often place restrictions on the number of items that can be revealed in national reports, and therefore on the specificity and usefulness of the reports to educators.

National Testing of Student Cohorts

A second way that countries gain national assessment information is by testing entire national cohorts of students. In this approach, the testing usually also serves other purposes, such as providing systematic information on the achievement of individual students and the collective achievement of students in different classes or schools.

This approach appears to be attractive if all students in a given grade or year cohort are going to be tested anyway. All that is required is to aggregate the results from individual students and schools nationally and analyze them in the ways required for national assessment. This can be completed quite economically.

There are two main dangers for national assessment with this approach. The first is that the large number of students to be assessed requires that the cost per student is kept quite low. This limits the range of educational outcomes that can be assessed. For instance, the testing might be administered by the students' usual class teachers and consist entirely of multiple-choice items that can be marked by scanner and computer. This would preclude assessment of many outcomes that involve open-ended responses or performances. The second danger is that the reporting of results for individual students and schools can make these assessments somewhat high-stakes ones, especially if there is public reporting of the comparative performance of different schools or school districts and rewards and sanctions for high or low performance. As a result of the pressure this places on teachers and administrators, the national assessment results are likely to be distorted by schools placing special emphasis on preparing the students for the tests, or perhaps even manipulating to some degree who takes the tests.

Assessment of National Samples of Students

A third way that countries gain national assessment information is by organizing assessments with national samples of students specifically for the purpose of national assessment. Because these assessments usually involve no more than a few percent of the schools and students nationally, they are typically not used to provide information about educational outcomes of individual schools, classes, or students and are therefore are low-stakes assessments for the schools, teachers, and students.

These survey-type assessments have significant advantages. As the number of students assessed is small compared to the national population of students, fairly complex and

expensive assessment approaches can be used without making the overall costs too high. This allows assessment of curriculum areas and aspects thereof that would normally be excluded from national testing programs for reasons of complexity and expense. The low stakes associated with the assessments reduce the risk of schools declining to participate or trying to exclude students who are expected to perform poorly. These factors increase the extent to which the sample of students assessed is representative of the national school population at the year or grade level for the assessments.

However, the low stakes of these assessments can also be a disadvantage. As there is no possibility of sanctions for individual students if they perform poorly, or school recognition or reward if they do well, they may not give the assessment tasks their full attention or effort, in which case the national assessment results may under-represent student capabilities. This problem can be greater with item types that require greater student effort (such as those that ask for extended constructed responses), in curriculum areas that are relatively unpopular, or if students are distracted by other interests or priorities (as has been observed for the National Assessment of Educational Progress (NAEP) in the final semester of high school in the United States, where students often seem to be more interested in social, cultural and sporting activities rather than serious academic work).

Assessment by School Inspection

Another option used by some countries for monitoring the processes and outcomes of education is inspection of schools by teams of experienced educators. By looking at school documentation, teaching and learning processes, examples of students work, and class achievement data, the inspectors judge educational standards in each school. These judgments can then be collated nationally, often from a representative sample of schools, to form the basis of a report on education standards countrywide.

As the evidence sought and obtained about educational outcomes is likely to be quite variable from class to class and school to school, inspection is not a very strong basis for drawing conclusions about national educational outcomes. It is more apt as a comment on the educational processes used in schools, considering that it is often the primary source of evidence nationally. The focus in this article is on national assessment of educational outcomes, so school inspection will not be discussed further.

Key Design Considerations

Choice of Outcomes to Assess

A key decision in the development of national assessment is the range of outcomes to be assessed. This involves the

identification of the curriculum areas that will be included, the aspects of those curriculum areas that will be assessed or not assessed, and how closely aligned the assessment of those aspects will be to the specific emphases of the curricula.

Only a few national assessment systems attempt to assess all curriculum areas, or almost all areas. They are far outnumbered by national assessment systems that focus their effort on areas that are perceived to be of prime importance and suitable for the more commonly used assessment approaches. This selective approach reduces the cost and complexity of the national assessment, but raises the risk that performance in areas that are not assessed may decline because educators place increasing emphasis on the areas that are assessed. Such shifts in curriculum coverage and emphasis are particularly likely if national assessment is based on whole cohort testing because of the high stakes to students, teachers, and administrators associated with the assessment outcomes.

The most common areas assessed in national assessment systems are literacy (reading and sometimes writing in the main national language or languages), mathematics, and science. Social sciences and additional languages are less commonly assessed, and the arts and physical education outcomes are included in few national assessment systems.

Within the areas that are assessed, knowledge, understanding, and skills that are more easily assessed by paper-and-pencil tests often take priority over those that are not. In reading, oral reading skills such as decoding and self-correction are less likely to be included than reading passages and answering comprehension questions. Similarly, in science, students are much more likely to be assessed on knowledge and its application than on practical and research skills.

Another issue to be addressed is whether the assessments will be tightly linked to school curriculum objectives, or sampled from a broader domain that reflects the diversity of possible learning outcomes in a curriculum area and the range of ways in which the learning is achieved, inside and outside of schools. For instance, in the early design of NAEP in the United States, a decision was taken that:

Although subjects were defined by the structure of school curricula, NAEP would assess knowledge and skills that could be gained from any source, not just from school learning. What citizens know can be measured; to discover how they acquired their knowledge would be far more resistant to discovery (Jones, 1996: 15).

If a nation does not have a nationally defined curriculum, it is almost inevitable that the assessments will be more generally focused because they cannot be tightly linked to one curriculum document. The same is, of course, true of the international assessments that must find common ground across the varied curricula of 40 or more nations.

Age Levels

National assessment is usually located in certain grade levels (or, less commonly, age levels). It is rare for a nation to assess at more than three levels. The most common level is at the end of primary education, usually around the age of 13. The lowest level is usually decided by a requirement that most participants should be able to read and write reasonably competently, and typically falls in the middle years of primary schooling. The highest level is usually located at or just below the point at which substantial proportions of the population leave school.

Inclusion Criteria and Participation

National assessment results are difficult to interpret if the population to which they apply is not clearly specified. It is important that who is to be included in or excluded from the assessments is fully described and the inclusion criteria are consistently followed. For instance, it is necessary to be clear whether both public and private schools, students whose main or first language is not the language of assessment, and students with particular levels or types of disability are to be included in the assessment. Special accommodations allowed for identified categories of students need to be described.

Another factor that can undermine clear interpretation of the results is non-participation by selected schools or students. The greater the level of non-participation, the more doubt arises about how representative the results are for the national population that is the intended focus of the assessment. Good national assessment programs therefore take considerable care to define inclusion criteria clearly and maximize participation.

Data Analysis and Reporting

There are three main options for presenting the overall results of national assessments: statistics on the performance of students on individual assessment tasks (items), aggregated statistics for clusters of tasks that all relate to a particular aspect or strand of the curriculum area assessed, and aggregated statistics for the entire curriculum area assessed.

The results for individual tasks may be presented as percentages of students who succeeded or scored at different levels on the task as a whole, or on components of the task. Alternatively, if item response modeling is used, results for tasks and their components may be presented using item characteristic curves.

Aggregated results across tasks can be created by simple addition of scores on the individual tasks, or by converting scores on each task to a standardized score (such as a z-score) and adding these scores together (perhaps with weights that reflect the perceived relative importance of

the knowledge and skills assessed by the different tasks). The third option is to create scale scores using item response modeling, allowing the modeling process to assign weights to the different tasks based on the statistical criteria of the modeling process.

All forms of aggregation involve explicit or implicit theories about the relative importance of what is assessed by the different tasks, and how they relate to each other. For instance, most item response theory (IRT) modeling assumes that the relative importance of tasks should be determined statistically by the relationships between performance on each task and the unidimensional scale that best fits the patterns of results for all of the tasks involved in the aggregation. Tasks that are outliers, having small correlations with most of the other tasks, are assigned low effective weights, and are at risk of being deleted from the assessment. This can narrow the range of outcomes assessed. This contrasts strongly with what happens when the scores on all tasks are standardized and the standardized scores added together. This implies that the knowledge and skills assessed by all tasks are to be treated as equally important in creating the aggregated score. In this case, low correlations among the tasks can result in difficulty in ascribing meaning to the aggregated score, and may suggest that the scale should be subdivided into more specific subscales that are more unidimensional.

Most of the international and national assessment programs that use samples of students (rather than whole cohorts) assign different clusters of assessment items to different students, using a matrix sampling approach. This reduces the testing load on students yet allows many assessment tasks to be used, potentially increasing the validity and comprehensiveness of the assessment. As a consequence, however, the students-by-tasks matrix has many empty cells. For the purpose of estimating what the performance statistics would have looked like if all students had attempted all tasks, statisticians have developed procedures that estimate those statistics. Mazzeo *et al.* (2006) have written a good account of the nature and purpose of these marginal estimation procedures.

Comparisons across Time

While national assessment programs aim to give an accurate picture of national patterns of student outcomes when the assessment occurred, they usually also want to show how those patterns have changed between successive assessments of the same curriculum area or, more ambitiously, across multiple assessments. The latter goal can be approached in two ways.

The first is to retain substantial proportions of tasks from one assessment to the next and not release details of these tasks until they will no longer be used. This allows comparisons across time to be based directly on

performance on these common tasks. Alternatively, the common tasks can be used to statistically link the entire assessments on consecutive occasions so that statistical comparisons across the two or more occasions can be based on the complete sets of tasks. The latter approach is usually taken if item response modeling is used. The trustworthiness of these procedures increases as the proportion of tasks retained increases, but retaining a high proportion of items limits the extent to which the results of the earlier assessment can be reported meaningfully. Also, care has to be taken not to base comparisons across time on tasks that have changed in appropriateness because of curriculum or societal changes.

The second way of providing comparisons across time uses no common tasks in consecutive assessments. New tasks are pre-tested alongside the old tasks so that performances on the two occasions can be statistically linked and then compared. This approach is most common where national assessment is based on whole cohort testing and the tests from each occasion must be publicly released. Finding a suitable sample of students for the pre-testing can be problematic, especially if the assessments carry high stakes.

Maintaining performance-trend information across multiple assessments is especially challenging. If large numbers of tasks continue to be used throughout all of the assessments, their relevance or appropriateness may decline over the series of assessments. On the other hand, if tasks are not used for more than two consecutive assessments, the long-term trend has been based on statistical linking that involves increasingly dubious assumptions as the number of assessments linked increases.

Examples of National Assessment Programs

In this final section of the article, three national systems are briefly described, to illustrate the range of approaches currently being used in national assessment.

England

From the mid-1970s to the 1980s, England had sample-based procedures for national assessment, using substantial proportions of complex performance assessments, overseen by the Assessment Performance Unit of the Department of Education and Science. These were abandoned in 1987 when the government implemented a national curriculum in England for the first time. Since then, national assessment has been based on whole cohort assessment (Daugherty, 1995; James, 2000). Originally, assessment was to occur at ages 7, 11, 14, and 16, at the end of stages described as key stages 1, 2, 3, and 4. The assessment results were to be used for several purposes:

- to provide students, their teachers, and their parents with information about their achievement;
- to provide teachers, schools, parents and the public with aggregated information about the comparative achievement of the students attending different classes, schools, and local education authorities (LEAs); and
- to provide education authorities, the government, and the nation with aggregated information about the achievement of students nationally.

The original intention was to include nationally designed standard assessment tasks (SATs) that were administered to whole classes simultaneously (under standard testing conditions) or to individual students or small groups by classroom teachers during class instruction. Teachers were also to report on whether or not students had reached the numerous attainment targets set out in the curriculum documents. Before long, however, because of concerns about teacher workload and consistency of administration, and also political preference for external testing, classroom based SATs and tests were retained only for key stage 1, and replaced by national tests for key stages 2 and 3. The teacher assessment against attainment targets was modified to focus on profiles of student performance rather than the individual targets.

In 2008, the national tests for key stage 3 were eliminated, with assessment and reporting for that stage subsequently to be based solely on moderated teacher assessments. The nature of the key stage 2 assessments was also to be reviewed.

The nationally reported results for the end of key stages 1, 2, and 3 currently focus on English, mathematics, and science. At the end of key stage 1, they are based on moderated teacher assessments taking account of the results of nationally designed SATs and tests. At the end of key stage 2 there are moderated teacher assessment results, but national test results as well in the three areas. At the end of key stage 3, there are moderated teacher assessments in the three areas. The assessments in a wide range of subjects for the General Certificate of Secondary Education (GCSE) serve as the assessments for Key Stage 4.

These assessment results are reported to students and parents. They are also aggregated for each class, school, and LEA, with the school and LEA achievement statistics made available to the general public for key stages 2, 3, and 4. These features make key stage 2, 3, and 4 assessments very-high-stakes assessments for teachers and schools.

In this system, the national results are obtained by aggregating the assessment results for all students assessed throughout England. The advantages and disadvantages of this whole cohort testing approach were discussed earlier in this article.

New Zealand

Prior to 1995, New Zealand had no systematic process for monitoring achievement of students in the first 10 years of

schooling. National examinations gave some relevant information in years 11 to 13. In 1995, the National Education Monitoring Project (NEMP) commenced. It assesses national representative samples of students in years 4 and 8 (the middle and end of primary education). Matrix sampling distributes three sets of tasks among 1440 students at each year level.

NEMP operates on a 4-year cycle, covering about one quarter of the national curriculum areas for primary and intermediate schools each year. The areas covered are literacy (reading, writing, listening, speaking, and viewing), mathematics, science, technology, social studies, art, music, health, physical education, information skills, and the use of graphs, tables, and maps.

Assessment tasks are designed to interest students and stimulate them to do their best. Laptop computers are used to present video and audio material, and in some cases to record student responses. Many tasks involve use of equipment and hands-on resources. Task components vary widely in difficulty, so that all students can enjoy some success and some challenge.

Each student has four assessment sessions, lasting about an hour each, supervised by specially trained teachers. These four sessions are:

- *One-to-one interview.* A student works individually with a teacher, attempting 15–20 tasks, with the whole session recorded on videotape.
- *Team.* Four students work collaboratively on several tasks, recorded on videotape.
- *Stations.* Four students move around a series of stations where tasks have been set up.
- *Independent.* Four students work individually on tasks such as paper-and-pencil tests, surveys, making works of art, or demonstrating physical skills (videotaped).

Experienced teachers mark tasks that require high levels of professional judgment, while other tasks are marked by senior teacher education students. Task administration and marking offer substantial, highly valued professional experience to about 260 teachers and 40 teacher education students each year.

About 45% of the tasks are kept constant from one cycle to the next. This allows trends across a 4-year interval to be observed and reported. The remaining tasks are released, making them available for teacher use and allowing detailed reporting of students' responses. The results are reported alongside the task details, showing the percentages of year 4 and/or year 8 students succeeding with, or performing at different levels on, each task component. Total scores for each task are graphed for boys, girls and three different ethnic groups. Effect sizes and statistical significance tests are used to compare the performance of various population subgroups. Trends across 4 years are displayed task by task and are also averaged across tasks. Multiple copies of the reports are

sent to all schools, accompanied by an initial response for all teachers from a national forum of educators, highlighting areas of good news, concerns, and suggestions.

United States of America

The NAEP began in 1969, with design and goals quite similar to New Zealand's NEMP (Jones, 1996, 2001). The initial intention was to assess national samples at ages 9, 13, 17, and young adult (late 20s). Ten areas were to be assessed, and results were to be reported task by task.

Over its first 10 years, cost and other considerations led to the exclusion of assessment of young adults, and of children at the other ages not attending school. Reporting shifted from individual tasks to clusters of related tasks. In the early 1980s, the Educational Testing Service proposed a new design and became the main contractor. More complex sampling arrangements were introduced, item response modeling was used to present results as scale scores for entire subjects (and in some cases major aspects of subjects), and most assessments occurred at grades 4, 8, and 12 (age sampling and audio-assisted task administration were retained for special long-term trend assessments). Overall control and oversight was given to a newly established National Assessment Governing Board, which established national standards with target achievement levels for advanced, proficient, and basic levels of competence (Jones, 1996).

Another major change to NAEP was the addition of state level reporting of results, and more recently reporting of results for some large school districts. These changes have required substantial expansion of the total sample size, in order to have adequate samples in each area reported, and have somewhat increased the stakes associated with NAEP. The larger samples have constrained the use of performance assessment approaches, because of their higher cost per student. For this reason, and because of their political importance, assessments of literacy, mathematics, and science have become much more frequent than assessments of other curriculum areas. Almost 30 years of changes in NAEP have made it

more effective for national policy and political use, but less useful for the educational goals of the original design.

Mazzeo *et al.* (2006) give a quite detailed account of the current NAEP design and the technical procedures used in data analysis and reporting, which are too complex to report here.

Norm-Referenced Measurement

H D Hoover, University of Iowa, Iowa City, IA, USA

A norm-referenced interpretation of test scores involves comparing the scores obtained by individuals or groups of individuals. For such comparisons to be meaningful, the tests must be administered under uniform, that is standardized, conditions. The first-known standardized tests were Chinese civil service exams introduced in 2357 BC. These exams, administered every 3 years and covering topics such as civil law, music, and Confucian classics, were designed to ensure greater fairness in selection decisions. They employed a number of sophisticated refinements such as multiple scorers to improve score reliability and the use of copyists to minimize the effect of handwriting skill on an examinee's score. Testing in European universities from the thirteenth through the seventeenth centuries consisted primarily of oral examinations, with little attention paid to standardization. However, in 1599, members of the Jesuit order, who had extensively used written tests for both placement and student evaluation, published a set of rules intended to standardize the administration of examinations.

When Horace Mann carried out the first American school survey in the grammar and writing schools of Boston in 1845, he argued that these exams should be written rather than oral, that the same questions should be asked of all students, and that the exams should be administered under uniform conditions. He also stressed that an examination is a limited sampling of a student's knowledge and that there is chance error associated with success or failure.

Another important step in the development of modern norm-referenced achievement tests was the series of surveys of educational attainment in spelling, arithmetic, and language undertaken in 1894 by Joseph Rice, a retired physician. The same exams were administered to large samples of school children. Mean scores to be expected at different grades were determined. Rice saw his exams as important in evaluating the effectiveness of different teaching strategies.

The first individual intelligence tests, put forth by Alfred Binet in 1905, greatly influenced the future of standardized tests. Binet's age-equivalent scale was the forerunner of modern developmental scales and made possible explicit normative comparisons among individuals. The relationship between mental age and chronological age was the basis for the ratio intelligent quotient (IQ) scale, which was eventually replaced by deviation IQs. These scales became the model for many of the single-group status scales discussed later. Group intelligence tests soon followed, notably the

Army Alpha, in 1917. Standardized batteries of tests for measuring the academic progress of school children, such as the Stanford Achievement Test, California Achievement Test, and Iowa Tests of Basic Skills, followed in the 1920s and 1930s. Achievement test batteries such as these are often considered synonymous with norm-referenced testing.

The discussion that follows will center on the scaling, norming, and interpretation of scores from standardized achievement test batteries. Many types of tests, such as college entrance examinations, educational placement tests, aptitude tests, certification and licensure exams, and classroom examinations, use normative information to enhance test-score interpretation. However, standardized achievement test batteries for elementary- and secondary-school students can be used to illustrate nearly all the issues surrounding the use of normative information in interpreting test scores.

Normative Scales

An examinee's raw score, or the number of test questions answered correctly, by itself seldom has much meaning. Knowing the number of items on the test, the difficulty of those items, and the conditions under which the test was administered begins to offer a context for the interpretation of the raw score. But a raw score becomes much more meaningful when it is seen in a relative sense, that is, when it is referenced to a distribution of scores obtained from a single group or several groups of examinees who took the same test under very similar conditions.

In general, there are two kinds of reference-group, or normative, comparisons (Lindquist and Hieronymus, 1964). The first describes an examinee's score in relation to the distribution of scores of the examinees in a single reference group. Score scales determined in this way are status scales. The most familiar type of status scale is probably the percentile rank. By way of example, imagine the raw score of a fifth-grader on a test being referenced to the scores of a national sample of fifth-graders who took the same test. If the student's score was higher than 72% of the scores achieved by members of the reference group, the student's score would have a percentile rank of 72. Status scales can also be used to determine an examinee's relative strengths and weaknesses in achievement across different content areas.

The second kind of normative comparison makes use of a series of reference groups. The average score for each

group is computed. A student's raw score is then compared to these group averages, and the group whose average score is most nearly like the student's raw score is identified. Score scales based on the average test scores of a series of reference groups are referred to as developmental scales and are useful in measuring growth. Two commonly used developmental scales are age equivalents and grade equivalents. If a fourth-grade student receives a grade-equivalent score of 6.0, for example, it means that the student's performance on the test is most like that of a typical sixth-grade student at the beginning of the school year.

Status Scales

Status scales have a long history of use in the social sciences. Thorndike (1904) in his seminal text *Mental and Social Measurements* stated that "Measurement by relative position in a series gives as true, and may give as exact, a means of measurement as that by units of amount." He went on to note that "Measures by amount of some unit have been the subject of great development in the hands of physical science, while measures of relative position have been comparatively neglected, though for the mental sciences they have been of utmost importance." However, he also pointed out that "Measures by position have one grave defect. Ordinary arithmetic does not apply to them. . . . We can not equate different positions in the series with each other as we can different amounts of the same thing."

The belief that ordinary arithmetic cannot be used with relative-position scales such as percentile ranks led to the development of a large number of alternatives. In general, these alternatives are simple nonlinear transformations of percentile ranks, most often those that normalize the scores. That is, these transformations convert the original scores into a normal distribution of scores. Raw scores on intelligence tests, for example, are usually transformed into a set of normally distributed scores with a mean of 100 and a standard deviation of 15. These transformed scores are commonly referred to as deviation IQs. To interpret an examinee's IQ score of 115, one needs to know that in a normal distribution, a score that is one standard deviation above the mean exceeds 84% of the scores. That is, the examinee has a percentile rank of 84. In addition to deviation IQs, there are a number of other widely used normalized status scales, such as stanines and normal curve equivalents.

The widespread use of normalized scores has helped fuel a common misconception about norm-referenced tests – that test developers assume that most mental traits of individuals are normally distributed. In fact, the term norm is sometimes assumed to mean normally distributed, when it actually refers to the scores of the reference group that make possible the interpretation of test scores by means of normative comparisons. The rationale and

history behind normalizing scores were described in detail by Angoff (1984).

Developmental Scales

Developmental scales are most commonly used in tests or test batteries such as the Stanford Achievement Test and The Iowa Tests of Basic Skills that are intended for measuring ability or educational achievement across a series of age or grade groups. The derivation of developmental scales is quite complex and is thoroughly discussed in Kolen (2006).

Developmental scales are the basis for constructing growth models, which show how students at all achievement levels increase in knowledge as they progress through the educational system. A growth model is constructed in the following way. First, within each content area assessed, a common scale is obtained linking the different grade levels of the test. Then, within-grade percentile ranks are attached to the scale. This results in a series of distributions of scores representing the overlap in achievement from grade to grade. The development of such a scale was first explicated (and the name growth model attached to it and the associated within-grade distributions of percentile ranks) by Hieronymus and Lindquist (1974). For a detailed explanation of such models, see Petersen *et al.*, (1989). Carefully constructed growth models are especially useful in longitudinal comparisons of achievement.

In summarizing the necessity of normative information in interpreting test scores, Lindquist (1953) stated at the 1952 ETS Invitational Conference on Testing Problems, "Any meaning that a scaled score has, in addition to that contained in the raw score, it has because of the normative data incorporated in the score, and that meaning applies strictly only to the particular reference population involved in the scaling process. In other words, no scaled score has any fundamental meaning attributed to the scale itself. Whatever meaning it has . . . , it has because of the normative data incorporated in the score."

Types of Norms

Normative data are crucial for most test-score interpretation. Norms provide the basis for comparing the achievement of an examinee with that of a relevant group of examinees or of a series of such groups. They can be used to assess the relative strength of an examinee's performance among a number of different content areas or to assess how that performance compares to that of series of age or grade groups in a single content area. It should be clear that the usefulness of every type of norm is dependent on the appropriateness and significance of the reference population. Interpretations based on poorly defined, vague, or unusually restricted populations have

little merit. It is also important that the norms sample be drawn from these populations in such a manner as to be truly representative. Different reference populations are used to establish different types of norms.

National Norms

Norms that are based on a nationally representative sample of those individuals for whom the test was designed (e.g., examinees of a certain age or at a certain grade level) are referred to as national norms. For instance, the scores of a nationally representative sample of third-grade students might be used as the reference group to which the scores of other third-grade examinees are compared. National normative data are also sometimes gathered from specific subgroups of examinees, such as gender-based groups, ethnic groups, public-school or private-school students, students in large-city schools, or students who attend schools in specific regions of the country. In order for subgroup norms to provide an accurate basis for comparison of examinees scores, they must be based on a large, carefully stratified reference group.

Local Norms

Norms based on the scores of a reference group of examinees in a particular educational or geographical unit, such as those in a local school district, are referred to as local norms. Local norms can sometimes be more useful than national norms. For instance, for choosing students for courses in which enrolment must be limited (e.g., an algebra class offered only to relatively high-achieving middle-school math students), local norms may be a more relevant basis for selection decisions.

User Norms

Norms based solely on the scores of examinees who have taken a test at a given time are referred to as user norms. In a number of testing programs, these are the only norms available.

The norms for the two primary college-entrance examinations in the United States, the ACT assessment and the SAT, are based on the scores of the examinees who choose to take these tests during a given time period. These norms are neither nationally representative nor comparable between the two test batteries. One reason for this lack of comparability is that the SAT is more widely used on the east and west coasts and the ACT is administered more often in the middle of the country. The racial and ethnic makeup and the educational experiences of these self-selected populations also change over time. This lack of representativeness can be especially problematic when results from these tests are used to evaluate longitudinal changes in student performance.

In some cases, user norms can be quite useful, for instance, when the examinees who take a test can be viewed as the population of interest for a given decision. This is frequently the case for licensure and certification exams, where all the examinees attempting to be certified at a particular time period are tested and included in the norms.

Norms by Age and Grade

For K-12 achievement or aptitude batteries, percentile ranks within age or grade are usually reported, as well as age- or grade-equivalent scores or scores on some other developmental scale. Status scales and developmental scales present very different indications of growth from year to year. A student who remains at the tenth percentile over the years usually falls further and further behind on a developmental scale such as grade equivalents, while the above-average student moves further and further ahead.

Group-Level Norms

When the average performance of groups is compared, group-level norms are sometimes calculated. For example, group-level norms are used when US states are ranked based on their average national assessment of educational progress (NAEP) scores. Another widely used example of a group-level norm is the school average, which can be helpful in evaluating relative strengths and weaknesses across content areas within a school building.

Item- and Skill-Level Norms

For school achievement batteries, norms based on performance on specific items or sets of items measuring a specific skill are sometimes provided. These norms may be used in a limited way in assessing strengths and weaknesses of individual students and can be extremely helpful in evaluating either classroom or building performance in specific content areas.

Types of Score Interpretation

Standardized educational achievement batteries are designed to provide primarily norm-referenced interpretations of the scores that students obtain on them. For this reason, they are commonly called norm-referenced tests. However, it is possible to make criterion-referenced interpretations of the scores obtained on such tests.

A criterion-referenced interpretation of a test score involves comparing examinees' scores with a subjective standard of performance rather than with the performance of a norm group. For example, deciding whether examinees have mastered a skill or demonstrated certain

levels of proficiency constitute criterion-referenced interpretations of their performance. In order to make criterion-referenced interpretations of scores from standardized, norm-referenced achievement tests, someone, usually a teacher or a group of content experts, must make subjective decisions on the cut scores that will be defined as separating mastery from nonmastery or various levels of proficiency from nonproficiency.

The school reform movements of recent years have placed new emphases on the scores of groups of students, including subgroups identified by such characteristics as race, ethnicity, and language proficiency. What percent of fourth-grade students are reading well enough? Has there been sufficient improvement in grade 8 math performance among Hispanic students? These are questions that require criterion-referenced interpretation of scores, and they require the establishment of standards of goodness in reading and math before they can be answered. The establishment of such performance standards is a complex endeavor and is beyond the scope of this discussion. (For a detailed description of methods of standard-setting, see Cizek and Bunch, 2006.)

Labels such as advanced, proficient, and less than proficient are commonly used to describe achievement based on performance standards. Although the terminology has expanded since the term criterion referenced first began to be used, the nature of the score interpretation really has not changed. That is, performance standards are criterion levels, just like those that have always been used in making criterion-referenced score interpretations. Some test users have been surprised to learn that commonly used terms describing performance standards do not carry an established, generally accepted meaning across states, test batteries, test publishers, or even users of the same test battery.

This lack of comparability can be illustrated using data from the national standardization programs of three widely used K-12 achievement batteries and from the criterion-referenced achievement levels in reading and mathematics established by the publishers of these batteries. **Table 1** lists the labels that the three test batteries, as well as the NAEP, use for various achievement levels. Since virtually identical labels are used, it would seem reasonable to assume that the achievement levels would be comparable across the batteries and NAEP. **Table 2** reports

the percent of students labeled proficient or advanced in reading and math by the standardized test batteries and by NAEP. The achievement levels were developed by each publisher independently and apparently with a great deal of care and effort involving a large number of qualified standard setters and significant expenditures of time and money. The numbers reported were taken directly from published materials and represent the percent of students in each battery's representative national standardization sample scoring at the proficient or advanced level. These results indicate that the lack of comparability of the standards across grades and between different test areas should be of considerable concern in interpreting results reported by school districts and states on the percent of their proficient students.

On Test X and NAEP, for example, note the difference at grade 12 between the percent of students proficient in reading and the percent proficient in mathematics. For Test Y, the difference between the percent of proficient students at the lower grades and those at the upper grades is significant, especially in mathematics. Note also the differences in percent proficient at grades 2 and 3 for Test Z in both reading and mathematics. For each of these comparisons, reports made to the public regarding percents of proficient students would likely be difficult to explain.

These data do not say that there are problems with the national norms of these test batteries but rather suggest that there may be a lack of comparability of the criterion-referenced achievement levels. It is the norms that make the differences in standards apparent. Compared to these differences, the sampling error in grade-to-grade differences in percentile ranks that are associated with group averages in national standardization samples is minuscule. Similarly, the lack of comparability of state standards makes it very difficult to compare, among states, the proportion of students who have achieved proficiency (Olson, 2002) or even to compare, within a state, the proportion of proficient students across grades or within grades across test areas. If standards-based reporting systems are to be used to compare longitudinal growth in achievement among school districts or states, it is likely that any model for growth used for such purposes will need to be developed using normative information. Such a growth model would seem to require an underlying framework based on the normative developmental scales discussed earlier.

Many educators object to the use of norm-referenced tests because they think it is inappropriate to compare children developmentally or because comparing children with an average does not seem meaningful. Statements such as "I don't care how a student compares to others; I want to be told what the student knows and is able to do" or "Norm-referenced tests create winners and losers" are common. However, comparisons are embedded in most statements we make about the developmental level and

Table 1 Labels used by three achievement batteries and NAEP

<i>Test X</i>	<i>Test Y</i>	<i>Test Z</i>	<i>NAEP</i>
Advanced	Advanced	Advanced	Advanced
Proficient	Proficient	Proficient	Proficient
Basic	Basic	Nearing proficiency	Basic
		Progressing	
Below basic	Below basic	Step 1	Below basic

Table 2 Percent of students in the nation labeled proficient or advanced by three test batteries and NAEP

physical characteristics of any child. To say, for example, that a young child lacks self-control suggests that there is a notion of how much self-control children of this age usually exhibit. When we recognize that a student's language skills have developed early or that those of another are slow to develop, there is a norm (or standard of expectation) behind the judgment expressed. Infants are measured for height and weight, and the pediatrician reports the percentile ranks to the eager parents. Telling the parents of a 3-month-old son that their child is 64 cm (25.2 in) tall and weighs 6 kg (13.2 pounds) means little. However, telling them that he is taller than 75% and heavier than 50% of infant boys of his age clearly imparts important information.

Height and weight are different things observed on different metrics, and their comparison requires normative information. Comparing reading achievement and math achievement is no different. When the same reference group is used to establish score scales in more than one test-content area, these norms make it possible to identify relative strengths and weaknesses. This is the characteristic of norms that makes their use critical in evaluating the achievements of students and schools.

By way of example, consider trying to determine what a student knows and is able to do from both a standards-based (criterion-referenced) and a norm-referenced perspective. **Table 3** shows NAEP's grade-4 criterion-referenced achievement levels in reading. What kind of diagnostic information is available to a parent or teacher who receives a report on a student who has scored at the basic level, a level considered failing by current US educational policy? What intervention strategies are suggested?

By contrast, consider the norm-referenced report of a reading profile for a first-grade student shown in **Figure 1**.

Table 3 The NAEP reading achievement levels, grade 4

Basic	Fourth-grade students performing at the basic level should demonstrate an understanding of the overall meaning of what they read. When reading text appropriate for fourth-graders, they should be able to make relatively obvious connections between the text and their own experiences and extend the ideas in the text by making simple inferences
Proficient	Fourth-grade students performing at the proficient level should be able to demonstrate an overall understanding of the text, providing inferential as well as literal information. When reading text appropriate to fourth grade, they should be able to extend the ideas in the text by making inferences, drawing conclusions, and making connections to their own experiences. The connection between the text and what the student infers should be clear
Advanced	Fourth-grade students performing at the advanced level should be able to generalize about topics in the reading selection and demonstrate an awareness of how authors compose and use literary devices. When reading text appropriate to fourth grade, they should be able to judge text critically and, in general, give thorough answers that indicate careful thought

From National Center for Education Statistics (2008b). The NAEP reading achievement levels. <http://nces.ed.gov/nationsreportcard/naepdata> (accessed May 2009).

This report summarizes information from five of the eleven subtests on a level of the Iowa Tests of Basic Skills (Hoover *et al.*, 2003) typically taken by first-graders. At the top of the report, percentile ranks surrounded by error bands show the student's relative strengths and weaknesses in vocabulary, word analysis, spelling, listening, and

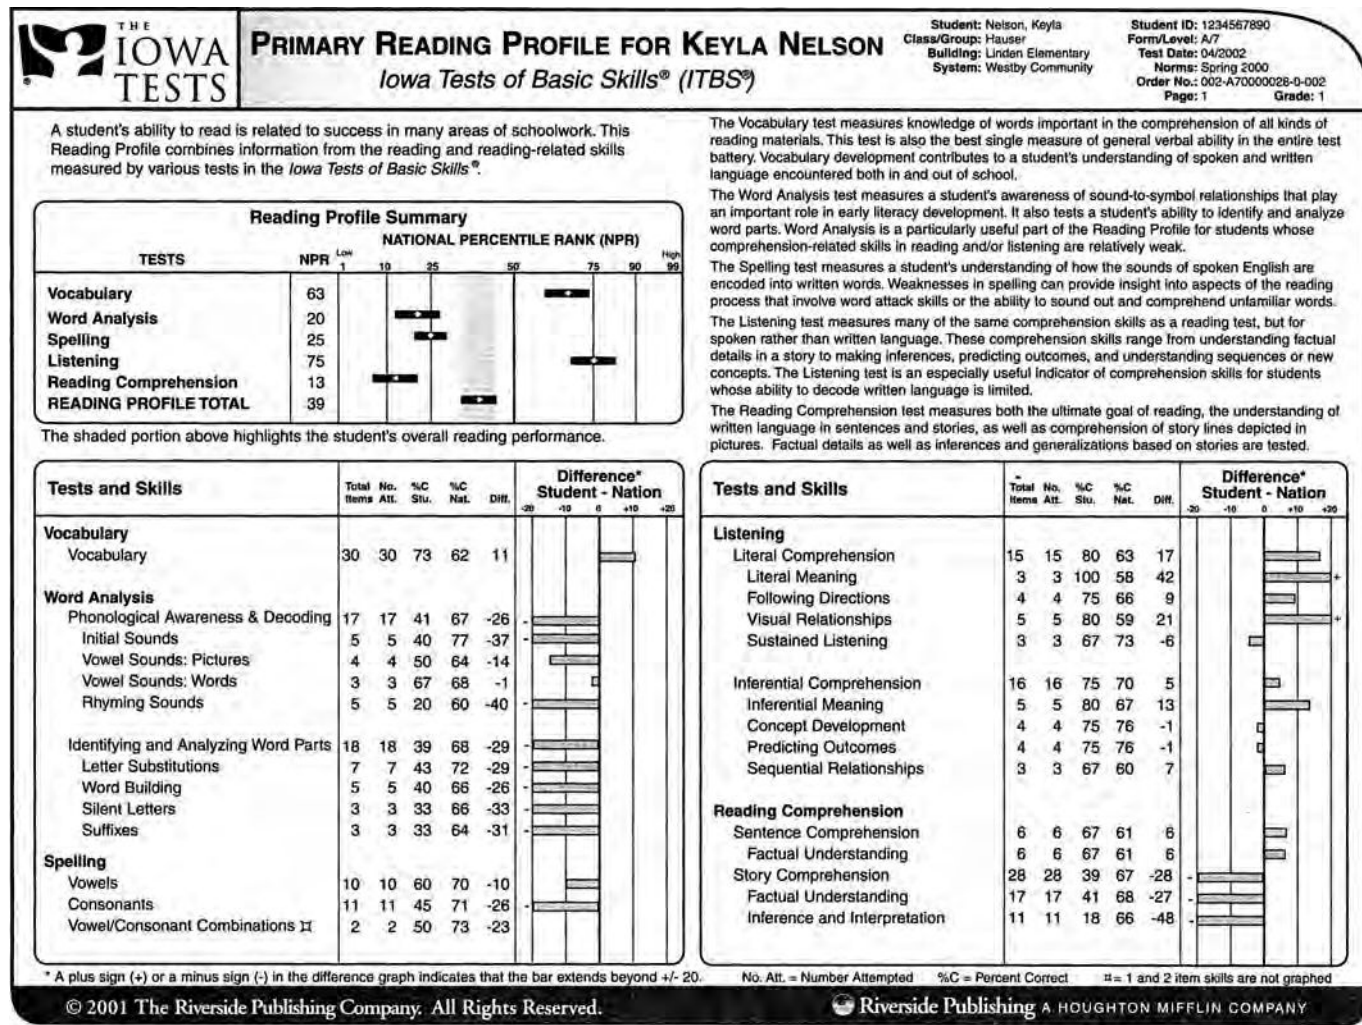

Figure 1 Student reading profile. With kind permission from Riverside Publishing.

reading comprehension. The text to the right of the profile explains to teachers and parents how each of the tests in the profile is helpful in understanding a student's reading comprehension skills. The poor reader with this profile, who shows a strong vocabulary and good listening comprehension skills, will need different instruction from that required by another poor reader who has strengths in word analysis and spelling. Comparisons like these are possible only when using norms. The bottom of the report gives a more detailed analysis of the student's performance on subskills within each test area. While criterion levels can be established for subskill scores, just as for total test scores, the low reliability of these levels is even more problematic than those for total test scores illustrated by the data in **Table 2**.

Summary

The number of questions an examinee answers on a test can seldom be meaningfully interpreted in an absolute sense. However, by referring a test score to the distribution of scores of some well-defined group of examinees, a relative judgment of the student's performance is easily obtained. The characterization of tests as either norm-referenced or criterion-referenced is unfortunate. It is score interpretations that are either norm- or criterion-referenced. Although many state and federal testing programs are viewed as criterion-referenced, it is inevitable that the test score information of most interest to the public and to policymakers is normative. For example, when results from an administration of NAEP are released, interest usually centers around the rank ordering of the states and whether there has been an increase or decrease in the proportion of students labeled proficient (a normative judgment) on the criterion-referenced achievement levels. Good score interpretation usually includes both norm-referenced and criterion-referenced components. In all cases, knowledgeable and well-reasoned interpretation of test scores should be the goal.

Glossary

Curriculum-based measurement – The assessment of a students' overall competence in the curriculum.

Mastery measurement – The assessment of students' mastery through a hierarchy of skills that constitute the year's curriculum.

Progress monitoring – The assessment of students' rate of improvement in the annual curriculum for the purposes of determining whether a student's academic development over an academic year is proceeding well and, if not, to design an individualized program that promotes better academic growth.

Responsiveness to intervention – A multi-tier prevention system used to prevent academic failure and to identify students with learning disabilities.

Screening – Assessment on a relatively brief, inexpensive measure to identify students who may be at risk for academic failure.

Slope of improvement – A student's weekly rate of increase on curriculum-based measurement, used to quantify learning.

As a form of classroom assessment, teachers use progress monitoring for two purposes. First, they determine whether a student's academic development over an academic year is proceeding well. Second, when a student is not progressing adequately, teachers use progress monitoring to design an individualized program that promotes better academic growth. Most forms of classroom-based progress monitoring represent mastery measurement, a form of progress monitoring that has been predominant for many years. Beginning in the 1970s, a research program to develop a more technically adequate form of progress monitoring was initiated at the University of Minnesota. This more technically adequate form of progress monitoring has come to be known as curriculum-based measurement. In this article, we provide an overview of mastery measurement and explain some of its limitations. We then explain how mastery measurement and curriculum-based measurement differ. We focus the remainder of this article on curriculum-based measurement. We provide an overview for how teachers use curriculum-based measurement to make instructional decisions and then explain how curriculum-based

measurement is an important component in the responsiveness to intervention education reform movement. We next describe the most common forms of curriculum-based measurement in mathematics and in reading. We conclude by discussing future directions.

Mastery Measurement

For many years, mastery measurement was the dominant approach to progress monitoring. Using mastery measurement, teachers specify a hierarchy of skills that constitute the year's curriculum. For each skill in the sequence, teachers devise a test to assess student mastery. When a student achieves mastery, the teacher shifts instruction as well as assessment to the next skill in the hierarchy. In this way, learning is conceptualized as a series of short-term accomplishments, which are thought to accumulate into broader competence. Mastery measurement was popularized years ago with the Wisconsin Instructional Design System and Precision Teaching. Even today, most core curricula incorporate mastery measurement as their approach to progress monitoring.

In the 1970s, Stanley Deno at the University of Minnesota conceptualized and oversaw a systematic program of research on the technical features, logistical challenges, and instructional effectiveness of progress monitoring. In the initial phases of that research program, the focus was on mastery measurement. Several technical difficulties associated with mastery measurement, however, quickly emerged. For example, to assess mastery of a skill, each item on a mastery measurement test addresses the same skill, which limits the generalizability of the conclusions that can be drawn on the basis of the testing. For example, let us assume that a first-grade teacher's initial skill in her skills hierarchy is consonant–vowel–consonant words (e.g., bat, log, and sun), and her mastery test presents students with a list of 50 consonant–vowel–consonant words. Many low achievers can read consonant–vowel–consonant words if they know that all the words on the test are in this same phonics pattern but cannot read consonant–vowel–consonant words in naturally occurring text, as is the case in the real world and on high-stakes tests. In the same way, some low achievers can solve addition with regrouping problems if they know they must add and regroup for every problem on the test. However, when a test mixes math problems of different types, as is the case in the real world and on high-stakes

tests, these same students no longer perform well on addition with regrouping. In this way, mastery measurement can be misleading. This also raises questions about the assumption that mastery of a series of short-term accomplishments accumulates into broad competence. It also means that students who have mastered many objectives during the school year may not be able to use their knowledge in flexible ways or score well on the end-of-year state test. Mastery measurement also suffers from other technical problems. For example, for most criterion-referenced measures that are embedded within mastery measurement systems, reliability and validity are undocumented, and mastery measurement provides an inadequate basis for determining maintenance of previously mastered skills or generalization to untaught skills.

Curriculum-Based Measurement: An Alternative Framework for Progress Monitoring

How Curriculum-Based Measurement Differs from Mastery Measurement

In the 1970s, Deno (1985) began to address this and other problems associated with mastery measurement. He conceptualized the approach to progress monitoring that has come to be known as curriculum-based measurement. With curriculum-based measurement, an alternate form of a test is administered each week. Each alternate form represents the many skills and strategies the teacher expects students to be competent with at the end of the year. In contrast to mastery measurement, therefore, curriculum-based measurement requires students to demonstrate and integrate the various skills required for competent year-end performance on every weekly test. As the student learns the components of the annual curriculum, his/her curriculum-based measurement score gradually increases. Importantly, because each weekly test is comparable in difficulty and construction, it is possible to compute an average weekly increase in score, called slope. Teachers use slope to quantify a student's responsiveness to the instructional program and to determine when a student's instructional program needs to be adjusted. Therefore, curriculum-based measurement differs from mastery measurement in these ways (Fuchs and Deno, 1991). First, each weekly test is equivalent weekly tests and spans the curriculum reflected in the school year. Second, curriculum-based measurement is standardized so that the reliability and validity of the testing procedures can be assessed, and adequate reliability and validity have been demonstrated for a variety of curriculum-based measures.

The following example shows how curriculum-based measurement is used. Mrs. Jones, a third-grade teacher,

sets a reading goal for year-end performance as competent third-grade performance. Using established methods, she identifies enough passages of equivalent, third-grade difficulty to provide weekly assessments across the school year. Each week, she asks each student in her class to read aloud from one passage for 1 min and she scores this performance as the number of words read correctly. Each week's simple, brief assessment produces an indicator of overall reading expertise. Reading text aloud requires, for example, skill at automatically translating letters into coherent sound representations, unitizing those sound components into recognizable wholes and automatically accessing lexical representations, processing meaningful connections within and between sentences, relating text meaning to prior information, and making inferences to supply missing information. As competent readers translate text into spoken language, they coordinate these skills in a manner that appears effortless (Fuchs *et al.*, 2001). This approach to curriculum-based measurement is known as the overall indicator approach.

A second approach to curriculum-based measurement is to systematically sample the various skills that constitute the year's curriculum. With curricular sampling, the weekly curriculum-based measurement test presents students with items that represent the variety of skills the teacher will address over the academic year. With either approach, each progress-monitoring test collected across the school year is of equivalent difficulty; and with either approach, each week's assessment reflects the performance that can be used to characterize overall competence in the annual curriculum for an academic domain.

Curriculum-based measurement can also be used to track its development through the primary grades. That is, scores can be graphed and compared to each other. Moreover, as mentioned, a slope (i.e., average increase per week) can be calculated on the series of scores to quantify the rate of improvement. This method for characterizing growth has been shown to be more sensitive to individual differences than those offered by other classroom assessments. Moreover, curriculum-based measurement is sensitive to academic development made under a variety of instructional procedures. In a related way, research shows that teachers' instructional plans developed in response to curriculum-based measurement incorporate a wide range of instructional methods. For example, in reading, instructional plans developed in response to curriculum-based measurement incorporate decoding instruction, repeated readings, vocabulary instruction, story grammar exercises, and semantic-mapping activities. Therefore, curriculum-based measurement is not linked to a particular instructional approach. Most importantly, studies show that curriculum-based measurement progress monitoring enhances teachers' capacity to plan programs for students with serious learning problems and effect superior achievement for those students.
