Drawing explicitly upon these ideas, science instruction has been planned and implemented as the enculturation of students into practices such as field ecology (e.g., Roth and Bowen, 1995), environmental activism

(e.g., Roth and Désautels, 2002), and basic scientific research (e.g., Ryder *et al.*, 1999). Although the practices described in these studies can be argued to be authentic in the sense that they refer to situations in which science is actually used, it is more difficult to argue that they are closely related to the everyday experience of most science learners. Furthermore, the authors' analyses of teaching focus more upon students' learning about various practices that involve science (the use of instrumentation and specific technical procedures, the construction of arguments, the social relationships of various communities) than upon the development of conceptual understanding by students.

Participative Approaches: Summary and Implications

The following insights about learning are common to the participative approaches outlined earlier:

- Learning is seen as a process of developing participation in the practices of a particular community.
- The learner takes on the role of apprentice, while the teacher is seen as an expert participant.
- That which is to be learned involves some aspect of practice or discourse.

Perhaps the biggest question to be raised in relation to the participative approaches concerns the issue of subject matter and the very aims of science education. For example, what does it mean to suggest that learning science should involve participation in the practices of a scientific community? What does it mean to suggest that students should engage in the authentic practices of science? To what extent is it possible to reconfigure the science classroom as a seat of authentic scientific practices? Is it reasonable to expect that the teacher can act as an expert practitioner within this scientific community of the classroom? What would be the aims of such an approach to science education? What would be learned?

Learning to Read

Essential Underpinnings of Reading

All beginning readers depend on language underpinnings that begin developing in the preschool years. During formal reading instruction, children continue to develop oral-language capabilities needed to approach and understand written language. As preschool children's oral language develops, their expressive oral language increases and their listening comprehension becomes more sophisticated. As this occurs, their ability to remember and use information increases and they learn how to listen differently when hearing expository text, storybooks, poems, and nonsense rhymes. They become aware of the sounds of the language and the phonemes and morphemes that comprise words. They learn the purpose of written language and the forms it takes. At a basic level, they learn how print works (concepts of print). A final but major part of an early literacy foundation is children's developing motivation to read. These essential skills and knowledge continue to develop during instruction in learning to read and as students continue to build reading competence (see **Figure 1**). Below, we elaborate on these underlying skills and knowledge.

Language and Listening Comprehension

Oral language begins in infancy and continues throughout life. It is the largest developmental domain relevant to reading. Oral-language skills form the foundation for the transition from understandings of spoken language to written language. During the preschool years, children develop their receptive language, which enables them to understand, remember, and use what they hear, as well as their expressive language, which gives them the ability to communicate their own needs and thoughts.

At the word level, young children develop speech discrimination in the languages they hear on a consistent basis. They hear words and also the separation between words, developing a sense of what a word is. They compare and contrast words, understanding that some begin with the same sounds and some end with the same sounds, developing phonological awareness. Through manipulation of this word-sound system, they begin to understand that words (speech) are made up of a sequence of sounds (phonemes) and are combined in different ways for different words. Given this opportunity and familiarity with many words, children eventually develop a mental model that enables them to break the code (i.e., understand

sound-letter correspondences). Children's model for learning and understanding new words is also rooted in morphological development. During the preschool years, children learn many aspects of morphology, for example, how to form past tense and possessives. A morpheme is the smallest unit of language that carries meaning, for example, the word play has one morpheme, that is, play, and the past tense of play, played, has two morphemes play and ed. Children develop phonological awareness and later morphological awareness, metalinguistic understandings. Words are connected and syntax developed.

Central to language development is semantic development and vocabulary. Young children learn sentential semantics, how phrases and sentences are ordered to obtain meaning. Lexical semantics and vocabulary flourish around 2–3 years of age when children acquire the naming insight, realizing that words are names for things. Developing vocabulary includes not only learning new words but the interrelationships between words. Young children play with word meaning as exemplified in the childhood joke, "Why did the girl throw the butter out the window? To see a butterfly." As children build upon these skills and gain experience with storytelling, they develop a sense of narrative and hone their listening-comprehensions skills.

Forms and Uses of Written Language

During the preschool period, children begin to learn that written language comes in different forms and is used for different purposes. They learn that words are arranged on paper in different ways (e.g., the food words on a menu vs. those on a grocery list vs. those in a cookbook). They simultaneously learn that the food words in these three different forms have different functions. They learn that a storybook (i.e., fiction) is different from a book in which they are learning new information (i.e., expository text). They learn the features of a narrative, how in a narrative a sequence of events relates to the central theme of a story. They learn that a written story has specific features such as quotes in parentheses along with an indication of who is saying the information in quotes (e.g., "Let's take the bicycles," said Mary).

Knowledge of the Written Symbol System and of Print Concepts

Before they can read, children as young as 3 years know we can read certain letter strings, like BOOK, but not

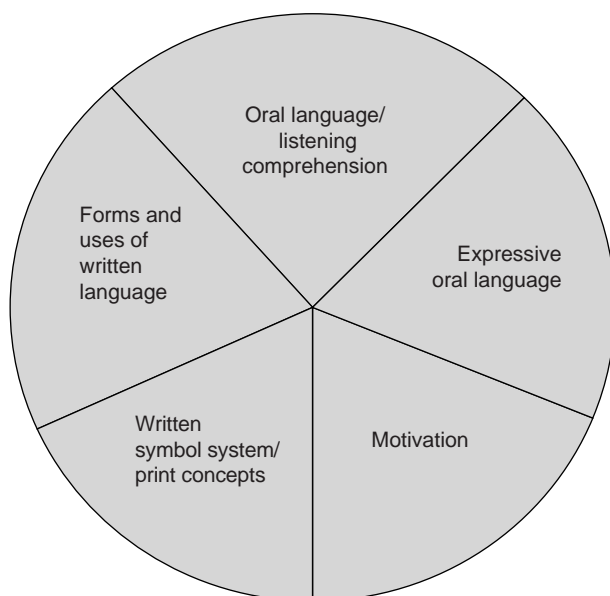

Figure 1 Essential underpinnings of reading.

TTTT. Young children also reliably classify BOOK as a word and 8965 as a number. They learn that it is the print in books that is read, and that it works in a certain way (e.g., in English it goes from top to bottom, left to right on the page). They learn knowledge of punctuation and letter knowledge. They develop the understanding that print can have meaning independent of immediate context.

Motivation: Becoming Enthusiastic About Reading and Writing

Literacy as a source of enjoyment takes place in the preschool years as children are read to in interactions that are positive and warm. These experiences are enhanced when the interactions address children's interests, take into account their prior knowledge, honor cultural continuity, and provide multilingual support.

Instruction That Develops Essential Underpinnings of Reading

Oral language, forms and uses of written language, knowledge of the written symbol system, concepts of print, and becoming enthusiastic about reading and writing are acquired before formal instruction in learning to read. These essential skills and knowledge continue to develop during instruction in learning to read and as students continue to build reading competence.

How do children learn the knowledge and skills during the preschool period? The social context is particularly important as young children communicate and participate in social and cultural activities, including experiences such

as storytelling, singing, and reading story books. Young children explore both the reading and writing systems when they, for example, pretend to read and write or act out stories that have been read to them. Peer play is essential. Sociodramatic play is especially important for supporting children's language. It is a time in which children use symbols for objects and participate in shared schemes with other children as they develop their play narratives. Adults enter interactions with children and teach and nudge by sharing their language, knowledge, and skills. The variety and richness of adult words (including rare words) used in those conversations influences children's use of vocabulary. Positive, warm exchanges have the most positive outcomes on children's language and literacy. Children develop their knowledge of the world and urge adults to provide new learning. These shared interactions between adults and children are sustained over time, developing depth of understanding of language and literacy.

Beginning of Formal Reading Instruction

Formal reading instruction builds upon these understandings of language and literacy that emerge as children interact with others and encounter language and literacy models in their world. When learning to read, children build upon what they know about language and text to simultaneously identify printed words and construct meaning. They draw upon their prior experiences, cultural knowledge, and developing vocabularies to make sense of the text. As they develop their abilities to decode and comprehend text, they become fluent readers who read with accuracy, prosody, and speed.

Identifying Printed Words

Identifying printed words requires knowledge of the relationship between letters and sounds and a developing repertoire of words that are recognized at sight. The development of letter-sound correspondences builds upon children's phonological sensitivity and their increasing awareness of phonemes. According to Ehri, children progress through five phases of alphabetic development. In the prealphabetic phase, children have no awareness that there is a relationship between letters and sounds. As children move to the partial-alphabetic phase, they gain an awareness of the relationship between letters and sounds, but focus their attention on the most prominent parts of words (e.g., initial letters). In the fully alphabetic phase, children know the sounds associated with the letters and blend the sounds together to pronounce the word. By the consolidated alphabetic phase, children recognize the whole word instantly and may use multiletter chunks to arrive at

the word. When reaching the automatic alphabetic phase, children recognize most words by sight and are able to apply a variety of strategies to decode unfamiliar words.

Movement through these phases requires increasing knowledge about letters and their associated sounds. Children gain this knowledge in a variety of ways. A focus on phonemic awareness combined with the development of letter–sound correspondences has been found to be beneficial in initial instruction. In this approach, children are taught to segment, blend, delete, and substitute phonemes as well as match and isolate sounds and match words. As phonemic awareness is developed, the sounds associated with particular letters are introduced, reinforced, and applied. Application of children’s knowledge of letter–sound correspondences can be seen in their written as well as oral representations of letter sounds. As children write to communicate their stories and ideas, writing the letters of the sounds heard reinforces the relationship between sounds and letters and provides insight into the development of letter–sound correspondences.

As children develop an awareness of letter–sound correspondences, a synthetic phonics approach that systematically teaches letters and their corresponding sounds can be helpful for some. This approach focuses on teaching the sounds associated with letters and then teaching children how to blend the sounds together to decode the word. However, many children use sequential decoding rather than synthetic phonics as they figure out unfamiliar words. Sequential decoding involves looking at all letters in an unknown word and then decoding the word by associating sounds with some but not all of the letters of the word. Children who decode in this way use what they know about letters and sounds as well as picture and context cues to predict the word. For example, children reading the sentence, “Stan pet the dog,” might use their knowledge of the sounds associated with the consonants in pet and dog along with the picture of a boy petting a dog and the context of the story to help decode both unfamiliar words. Caution has to be taken to ensure that students do not develop an overreliance on pictures for decoding as the overriding goal in decoding instruction is learning the letter–sound correspondences.

For many children who have some understanding of letter–sound correspondences, an analogy approach to learning to decode words is effective. This method of instruction focuses children’s attention on using patterns children know to decode unfamiliar words. This approach requires that children delete the initial consonants of a syllable, the onset, to segment the rime, the vowel and consonants that follow the vowel. For example in ‘dog,’ the ‘d’ is the onset and ‘og’ is the rime, and in ‘Stan,’ ‘St’ is the onset and ‘an’ is the rime. Once children recognize a familiar rime, they can decode unfamiliar words by substituting the onset in the known word with the onset in the familiar word. Therefore, children who can read dog, can

use the familiar pattern ‘og’ to read an unknown word fog by substituting the ‘d’ for an ‘f.’ This use of analogy is often more efficient and effective than sounding out each letter in a word and blending them together because the vowel sounds in these patterns are fairly constant. For example, the ‘a’ in ‘an’ remains stable whether used in Stan, can, or answer. Whereas, learning sounds for ‘a’ is variable depending on the letters that follow it (e.g., cat, cay, car, and care).

The reliance on patterns to decode words continues as children encounter multisyllabic words. However, the use of onset and rime is not nearly as prevalent as the use of morphemes in decoding longer words. Recognizing morphemes helps children decode words using familiar patterns, such as ‘jump’ and ‘ing’ to arrive at ‘jumping.’ As morphemes are the smallest unit of meaning, the use of morphemic patterns is important because they not only help children decode unknown words, but these patterns also help them construct meaning. For example, children who can decode bed, know what a bed is, and understand that adding an ‘s’ to form beds makes the word plural recognize that two or more beds are being referenced. Likewise, children who are familiar with bed and room comprehend what a bedroom is through their ability to decode and understand both morphemes.

As children’s decoding skills develop, so does their ability to recognize words automatically. Developing a sight-word vocabulary involves recognizing familiar words by linking printed words with words stored in memory to remember their meanings and how to pronounce them. As children are exposed to words, connections are made between the graphemes in the spelling of the words and their associated phonemes. The word spellings are a visual representation of the words stored in memory and serve to activate the pronunciation and meaning of these words as children encounter them in print. By developing a repertoire of sight words, children are able to expend less energy on the decoding of text and can focus on constructing meaning as they read.

The goal of decoding instruction is to foster automatic word recognition and enhance reading comprehension to produce fluent readers. Effective instruction builds upon the essential underpinnings developed before formal reading instruction, recognizes the influence of motivation on children’s willingness to interact with printed text, and develops decoding and comprehension skills and strategies simultaneously (see **Figure 2**). Children’s knowledge of the written symbol system and print concepts supports their ability to navigate the text (e.g., directionality; meaning of punctuation; knowledge of letters, words, and sentences) and helps them understand that identifying printed words is a process of not only being able to pronounce the written word, but also of being able to associate meaning. This requires children to use what they know about oral language, including their knowledge of phonemes,

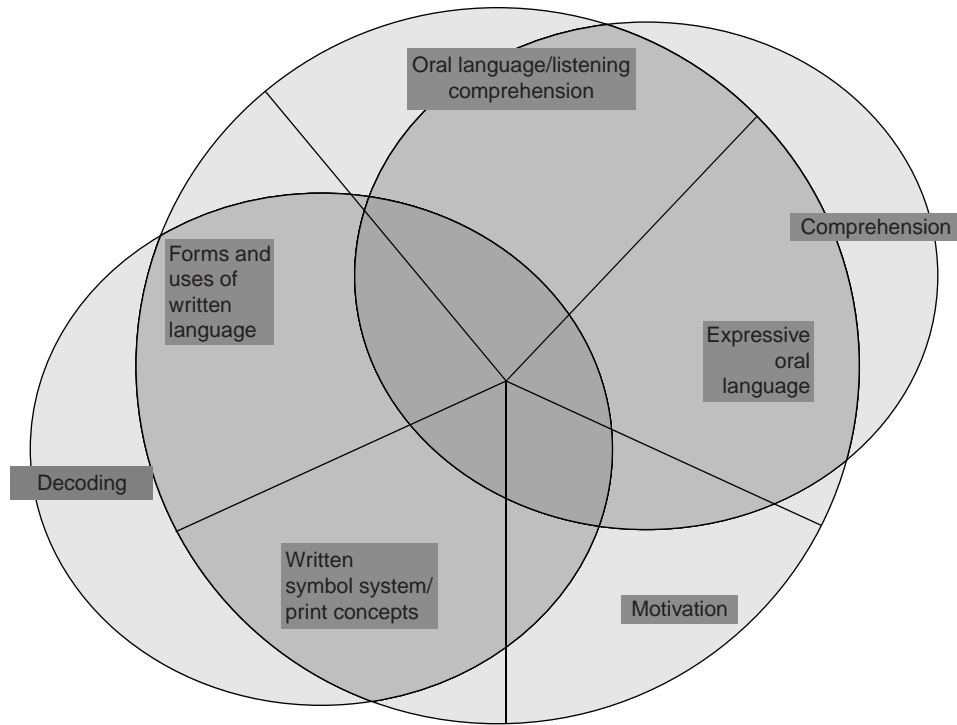

Figure 2 Formal reading instruction.

morphemes, syntax, and semantics, to read the word. For example, when encountering ‘read’ in print, children use sound–symbol correspondence, grammar, and the context to know how to pronounce and interpret the word. ‘Read’ used, pronounced, and understood in the past tense (e.g., she read the book yesterday) differs from ‘read’ used, pronounced, and understood in the future tense (e.g., she will read the book tomorrow). In essence, children use their knowledge of oral and written language to identify printed words to comprehend text while at the same time they rely on their comprehension of text to assist in their identification of the printed words.

Reading Comprehension

Reading comprehension occurs when readers construct meaning as they interact with the written word in an exchange of ideas between themselves and the message in the text. To comprehend text, readers rely upon their ability to decode text fluently, draw upon their extensive vocabularies, and employ comprehension skills and strategies to assist their understanding of the printed materials. This requires them to draw upon their prior knowledge and experiences to make connections between their existing knowledge and the information presented in the text. This interactive process between readers and text enables readers to understand, remember, and use information read and

is influenced by readers’ purpose for reading, motivation, and social context.

When learning to read, developing fluent word recognition is important for enhancing comprehension of text. Both decoding and comprehension demand memory which has a limited capacity. Effort devoted to decoding words detracts from the ability to expend resources on understanding text. Therefore, developing automatized decoding is vital to increasing comprehension. However, a focus on word recognition should not be at the expense of an emphasis on developing vocabulary and comprehension skills and strategies. All areas need to be developed simultaneously as children learn to read.

Vocabulary and concept development is also essential to developing comprehension in children learning to read. Knowledge of words and their meanings contributes to clearer understandings of the text. When vocabulary is unknown, children rely on clues from the text, which may result in an incorrect understanding of what was read. To build a rich vocabulary that enhances comprehension, children learning to read need to be immersed in language-rich experiences, both in natural as well as instructional contexts. Exposure to a wide range of vocabulary is needed, including contextualized oral language and the decontextualized language in oral storytelling and written text. These encounters with vocabulary that begin before formal instruction (see **Figure 2**) and continue over time enable children to develop deeper understandings of words and the meanings they convey.

The ability to identify printed words and attach meaning to the words enables children to construct literal interpretations of the text. To comprehend at a deeper level, children learn to activate their prior knowledge or schema to make inferences about what they read. Children reading about a trip to the park will use information based on their own experiences to help them understand. They will rely on what they know about parks to infer information that is not explicitly stated. When the connections they make are relevant and accurate, comprehension is fostered. However, if the connections they make are not relevant or are inaccurate or past experiences with and prior knowledge about the topic are minimal or nonexistent, drawing upon existing schema can limit comprehension. Therefore, children also learn to rely on the connections they make within the text to make inferences. This is especially helpful when they have limited knowledge about or experience with the topic. For example, children reading about an activity that is not familiar might infer that the activity is fun if the text refers to the characters' laughter as they engage in the activity.

As children learn to read, they develop a repertoire of strategies that promote active engagement before, during, and after reading. Prior to reading a text, children learn to establish a goal for reading and activate their prior knowledge. Children use their prior knowledge and the existing text to make predictions as they read. Active reading involves making predictions, confirming or modifying the predictions, and making new predictions. As children make predictions and confirm or modify those predictions, they are engaged in constructing meaning. However, when children hold on to incorrect predictions, comprehension is hindered. For example, children reading a book about the South Pole might originally make the prediction that the South Pole has a warm climate because they associate south with warm. As they read about the ice and the cold temperature, children who have learned to use the information from the text to modify their predictions will realize that the South Pole is cold and will use this information while continuing to read. Whereas, children who maintain their original prediction will not understand information that is reliant on knowing that the South Pole has a cold climate.

While reading, children also learn to monitor their reading. They become aware of the text structure, the relevance of what they are reading, and their own understanding or lack of understanding of the text. They learn to moderate their pace, reread when necessary, and use different reading strategies to enhance their comprehension. Their increasing repertoire of strategies may include generating questions, visualizing the text, and paraphrasing what they read. They learn to identify important information and organize details around the main ideas. The development of their metacognitive awareness enables children to regulate their reading and become more effective readers.

Reading Fluency

As with the previous processes addressed in this piece on learning to read, fluency is dependent upon and coordinated with all the previous mentioned aspects of reading as well as decoding and comprehension (see **Figure 3**) and is emphasized in instruction at all reading levels using various levels of text difficulty. Prosody, using emphasis and variations in intonation, pausing, etc., is a feature of reading that is observed in fluent readers. To achieve prosody, readers employ their knowledge of syntactic information and processing as they use meaningful phrasing and punctuation in the text being read. As mentioned in the section on identifying printed words, morphology and phonology play important roles in achieving decoding automaticity. Prior knowledge, vocabulary, and strategic processing are central in comprehension, as depicted in **Figure 2**. These processes overlap with each other and with the essential underpinnings of language and literacy. Listening comprehension and motivation explain variance in fluency.

Specific instruction to achieve fluency includes a number of forms of repeated reading, both assisted by teachers and peers as well as technology, to be effective. Silent reading with no accounting for comprehension is an additional practice that has been used to increase the amount of absolute reading but results are mixed for use of this method. It seems that the bottom line for fluency is that absolute amount of reading is the most important factor. Caution must be taken though to make sure that absolute amount of reading is defined as reading to get meaning from the text. Word calling without understanding, even if done with accuracy and expression, does not count. Fluency instruction focusing on decoding speech and accuracy and prosody can have such an impact, that is, word calling. The reader might not be reading accurately and comprehending during this time.

Levels of Reading

When children are learning to read, the children's levels of reading and the difficulty of the text must be taken into account. Children's decoding and comprehension of text and their ability to read fluently are affected not only by their reading development, but also by the text they are reading. The difficulty or ease in reading a text is influenced by textual features, such as the size and placement of the text; the presence or lack of pictures; difficulty of the words; the complexity of the sentence structure; and the children's familiarity with the content of the text. Recognizing that texts will pose different levels of challenge for children as they learn to read, it is important to match texts with children in ways that foster reading development. To facilitate this process, texts are generally

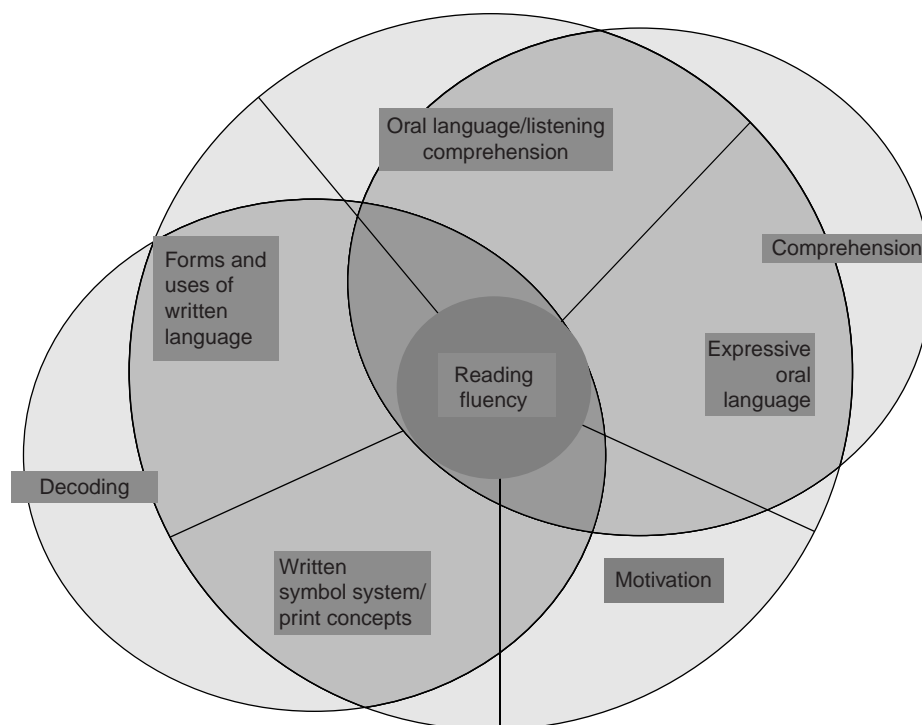

Figure 3 The fluent reader.

classified as being at children's independent, instructional, borderline instructional, or frustration level (see **Table 1**).

Texts at children's independent level are ones children can read fluently without assistance. Reading texts on their independent level provides children with an opportunity to practice and apply the reading strategies and skills they already possess and improves their decoding, comprehension, and fluency. Children's reading of instructional-level texts promotes reading development when support or scaffolding is provided by a more adept reader. The use of instructional-level texts during reading instruction enables teachers to instruct within the children's zone of proximal development and optimizes the potential effects of the instruction provided. This is also true when reading materials at the borderline instructional level are read during instruction. However, texts at this level require a high level of teacher support. This is often the level used when children are working with a reading specialist or tutor who can provide more intensive instruction and scaffolding. Texts at children's frustration level require such a high level of support that children typically do not benefit from instruction. With these levels in mind, teachers can enhance reading development by providing children with opportunities to read a variety of texts on their independent and instructional levels with appropriate levels of support and scaffolding.

Table 1 Children's levels of reading in relationship to text difficulty

<i>Level</i>	<i>Word recognition</i>	<i>Comprehension</i>
Independent	99–100%	90–100%
Instructional	95–98%	75–89%
Borderline instructional	90–94%	50–74%
Frustration	Below 90%	Below 50%

Summary

To learn to read, learners need opportunities to learn and integrate numerous underpinnings of reading, identify printed words, develop comprehension, and increase reading fluency. Underpinnings include oral expressive language, listening comprehension, forms and uses of written language, knowledge of the written symbol system, concepts of print, and becoming enthusiastic about reading and writing, motivation. These essential skills and knowledge continue to develop during formal instruction in learning to read and as students continue to build reading competence. To identify printed words, children continue to develop their understanding of the alphabetic system and apply a variety of strategies to decode unfamiliar words. To comprehend, children construct meaning as they interact with the text and draw upon their prior knowledge and experiences. Reading fluency occurs

when children's decoding and comprehension enables them to read with speed, accuracy, and prosody. A focus on any one aspect of learning to read should not be at the expense of an emphasis on other aspects. To the extent possible, different aspects should be integrated into instruction and the relationship among the processes should be the focus of instruction.

Introduction

From some decades now, research in mathematics education has been emerging as a field of study in its own right. In building theoretical frameworks specific to its domain, while still productively drawing on cognitive and instructional psychology, this field is also dedicated to the mission of examining and improving the institutions and practices of school mathematics education. Accordingly, there is increasing interest in other social science disciplines and recognition of the cultural embedding of mathematics (education). After a long struggle for its identity, today one can say that mathematics education has become a full-fledged, interdisciplinary field of research and analysis, aiming at a better understanding of the processes underlying the acquisition and development of mathematical knowledge, skills, beliefs, and attitudes applied to the design of valuable tools and powerful environments for teaching/learning mathematics.

This article presents a review of important recent themes and developments in research on the learning and teaching of mathematical knowledge and thinking. As a framework we use a model for the design of powerful environments for learning and teaching mathematics that is structured according to four interrelated components, namely, competence, learning, intervention, and assessment (CLIA-model) (De Corte *et al.*, 2004). Space allows only a few specific examples, and like the research in the field, these are concentrated around primary and secondary school students' learning of numbers and arithmetic. For comprehensive reviews we refer to the following handbooks and handbook chapters (this list is itself testimony to the vitality of the field): Bishop *et al.* (2003); Bishop *et al.* (1996); De Corte *et al.* (1996); Ginsburg *et al.* (1998); Grouws (1992); Gutierrez and Boero (2006); and Lester (2007).

Components of Mathematical Competence

In recent times, discourse about what competence in mathematics means has been enriched by introduction of the notion of "mathematical disposition." For instance, in *Curriculum and Evaluation Standards for School Mathematics* (National Council of Teachers of Mathematics, 1989), it is stated:

Learning mathematics extends beyond learning concepts, procedures, and their applications. It also includes developing a disposition toward mathematics and seeing mathematics as a powerful way for looking at situations. Disposition refers not simply to attitudes but to a tendency to think and to act in positive ways. Students' mathematical dispositions are manifested in the way they approach tasks – whether with confidence, willingness to explore alternatives, perseverance, and interest – and in their tendency to reflect on their own thinking. (Curriculum and Evaluation Standards for School Mathematics, 1989: 233).

This enhanced view is in agreement with the characterization of "mathematical proficiency" in the report of the National Research Council (2001a: 5), *Adding it up*, wherein proficiency is defined in terms of five interwoven strands, namely:

- conceptual understanding, "comprehension of mathematical concepts, operations, and relations"
- procedural fluency, "skill in carrying out procedures flexibly, accurately, efficiently, and appropriately"
- strategic competence, "the ability to formulate, represent, and solve mathematical problems"
- adaptive reasoning, "the capacity for logical thought, reflection, explanation, and justification"
- productive disposition, "a habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one's efficacy".

The above descriptions are also consistent with more general models of competence which stress the acquisition of (1) a well-organized and flexibly accessible domain-specific knowledge, (2) heuristic methods, (3) meta-knowledge, (4) self-regulatory skills, and (5) affective components involving beliefs about, attitudes toward, and emotions about the domain and about thinking, learning, and teaching in this domain (De Corte *et al.*, 1996).

Using still another construct that was introduced in the literature more than two decades ago by Hatano and Inagaki (1986), one can say that what students have to acquire in mathematics education is "adaptive expertise" as opposed to "routine expertise." Hatano (2003: xi) describes adaptive expertise as "the ability to apply meaningfully learned procedures flexibly and creatively"; in contrast, routine expertise involves "simply being able to

complete school mathematics exercises quickly and accurately without (much) understanding” (Hatano 2003: xi). Like the other characterizations of (mathematical) proficiency or competence mentioned earlier, Hatano’s concept emphasizes that gaining expertise is accompanied by changes in interest, values, and identity besides changes in the purely cognitive realm.

A major point of agreement is expressed thus in the report of the National Research Council (2001a: 133): “Learning is not an all-or-none phenomenon, and as it proceeds, each strand of mathematical proficiency should be developed in synchrony with the others. That development takes time.” Consequently, from the very beginning of mathematics education, attention needs to be paid to the parallel and integrated acquisition of the different components of competence.

The handbook publications cited earlier contain numerous illustrations of the importance and interdependency of the different strands of proficiency in domains such as single-digit computation, multidigit arithmetic, estimation, word problem solving, etc. A prime example is the prominent position accorded to the notion of ‘number sense’ from the earliest grades of school, as mentioned in recent reform documents worldwide. Number sense refers to “a person’s general understanding of number and operations. It refers to a person’s general understanding of number and operations along with the ability and inclination to use this understanding in flexible ways to make mathematical judgements and to develop useful strategies for handling numbers and operations. It reflects an inclination and an ability to use numbers and quantitative methods as a means of communicating, processing and interpreting information. It results in, and reciprocally derives from, an expectation that numbers are useful and that mathematics has a certain regularity” (McIntosh *et al.*, 1992: 3).

Mathematics Learning

Research over the past decades has resulted in the view that mathematics learning is the active and cumulative construction – situated in a given community of learners but also within a broader sociocultural context – of mathematical meaning, understanding, and skills (De Corte *et al.*, 1996; Verschaffel *et al.*, 2007).

The view that learning is an active and constructive process has become common ground among mathematics educators, and there is substantial empirical evidence supporting it (see e.g., National Research Council, 2001a). What is essential in the constructivist view on learning is the mindful and effortful involvement of learners in the processes of knowledge and skill acquisition in interaction with the environment (physical and social) and building on their prior knowledge. This involvement is well illustrated in the idiosyncratic but accurate calculation procedures

that are invented by children in and out of school contexts (Ginsburg *et al.*, 1998; Nunes, 1992). However, the constructive nature of learning is also evidenced in a negative way in the misconceptions (such as the idea that ‘multiplication always makes bigger and division always makes smaller’) and defective procedures (such as, in multidigit subtraction, subtracting in each column the smaller digit from the larger) that many learners acquire (De Corte *et al.*, 1996; Verschaffel *et al.*, 2007).

The cumulative feature of learning, which is closely linked to its constructive nature, refers to the pivotal role of prior knowledge, again in both positive and negative ways. Research on conceptual change has yielded ample evidence that, as in scientific reasoning, students develop an initial framework theory about number, organized on the basis of certain core principles or presuppositions, based on their (out-of-school) experience with natural numbers, and that these framework theories facilitate some kinds of learning but inhibit others. For example, an early understanding of natural number and its properties strongly supports children’s further learning in the domain of natural numbers, while at the same time it stands in the way of their understanding of properties and operations of numbers beyond the natural numbers, such as rational numbers, negative numbers, and real numbers (Verschaffel *et al.*, 2007).

The idea that learning and cognition are situated activities emerged strongly in the late 1980s in reaction to the then dominant cognitivist view of learning and thinking as highly individual and purely mentalistic processes occurring in the brain, thus resulting in encapsulated mental representations (Brown *et al.*, 1989). The cognitivist view is in line with Sfard’s (1998) acquisition metaphor of learning focused on individual enrichment through acquiring knowledge, skills, etc. By contrast, the situated perspective converges with the participation metaphor that Sfard identifies, stressing that learning is enacted essentially in interaction with social and cultural contexts and artifacts, and especially through participation in cultural activities and contexts (Schoenfeld, 2006; Sfard, 1998; Verschaffel *et al.*, 2007). Such a socioculturally situated conception of learning and cognition is nowadays widely shared in the mathematics education community and encapsulated in the perspective of ethnomathematics (D’Ambrosio, 2006). The outcomes of a large series of ethnomathematical studies of the informal calculation procedures, problem-solving strategies, and learning mechanisms of particular groups of children and adults involved in everyday cultural practices such as business, tailoring, weaving, carpentry, grocery-packing, cooking, etc. has largely contributed to the popularity of the situated approach (for summaries see De Corte *et al.*, 1996; Nunes, 1992; Schoenfeld, 2006).

Although the situated nature of learning has been documented especially well within out-of-school contexts, it is obvious that this situatedness applies to school

learning also. For instance, the numerous examples of students' "suspension of sense-making" when doing school word problems (leading to computationally based solutions to absurd problems like "There are 26 sheep and 10 goats on a ship. How old is the captain?") can be considered as another line of evidence for the importance of the situatedness of mathematical thinking and learning (Verschaffel *et al.*, 2000).

Of special importance from an educational perspective is that the situativity view implies the importance of, and thereby reinforces the case for, interaction and collaboration in learning. Mathematics educators have broadly embraced the view that learning is not a solo and internal activity; rather, learning efforts are distributed over the individual student, his/her partners in the learning environment, and the (technological) resources and tools available. For instance, Yackel and Cobb (1996) consider social interaction essential for mathematics learning, with individual knowledge construction occurring throughout processes of interaction, negotiation, and cooperation. Although the situated approach has served an important role in de-emphasizing individual internal processes and stressing the sociocultural and collaborative aspects that were previously neglected, it also led to some misguided claims about mathematics learning and inappropriate educational suggestions (e.g., that learning is always grounded in concrete situations, knowledge has become less important, knowledge does not transfer between tasks, stimulating abstraction is of little value, etc.) (Vosniadou and Vamvakoussi, 2006). Accordingly, several researchers have warned against totally abandoning the individual acquisition perspective on (mathematics) learning and have made a plea for a proper balance between the individual and social (Sfard, 1998; Vosniadou and Vamvakoussi, 2006). According to Schoenfeld (2006), how to put things together – how to see everything connected to an individual (both in the sense of knowledge, identity, etc., and in terms of that person's relationship to various communities), and the communities to which the individual belongs, as a coherent whole – is one of the great challenges for the future.

The preceding discussion shows that recent research provides substantial evidence supporting the view that productive mathematics learning is a constructive and situated process of knowledge-building and skill-acquisition, involving ample opportunities for interaction, negotiation, and collaboration. Consequently, it will not come as a surprise that this integrated new perspective on learning mathematics has stimulated researchers and practitioners to take these basic characteristics of learning as major guidelines for the design of new curricula, textbooks, learning environments, and assessment instruments that aim at fostering in students the acquisition of a mathematical disposition. It should be acknowledged that such an approach to mathematics teaching and assessment was pioneered earlier by several (groups of) mathematics

educators, in particular Freudenthal (1983), who, with his colleagues, developed and implemented realistic mathematics education in The Netherlands long before these new ideas came into vogue.

Instruction

How can powerful mathematics learning environments be designed for inducing in students the intended learning activities and processes, and by so doing, effectively fostering in them the progressive development of a mathematical disposition?

Mainly over the past 15 years, this challenge has been addressed through intervention studies, under the banner of such terms as constructional research (Becker and Selter, 1996), developmental research (Gravemeijer, 1994), and design experiments (Cobb *et al.*, 2003). Becker and Selter (1996) define constructional research "as research that is connected with suggestions on how teaching ought to be or could be, to put it slightly more moderately. . . [it is] concentrating on the development of theoretically founded and empirically tested practical suggestions for teaching" (p. 525). According to Cobb *et al.* (2003: 9) "design experiments entail both 'engineering' particular forms of learning and systematically studying those forms of learning within the context defined by the means of supporting them. This designed context is subject to test and revision, and the successive iterations that result play a role similar to that of systematic variation in experiments." Note that, besides contributing to the innovation and improvement of classroom practices, this type of research is intended to advance theory-building about learning from instruction (Cobb *et al.*, 2003; De Corte *et al.*, 2004).

It is possible to identify many common features or family resemblances of the environments that have been designed, implemented, and evaluated in such studies, including: (1) the active and constructive view on mathematics learning; (2) the recognition of the crucial role of students' prior knowledge for future learning; (3) the orientation towards the integrated mastery of procedural skill, conceptual understanding and problem solving; (4) a reluctance to impose a single representational model or solution strategy on all learners and the pursuit of adaptive expertise (Hatano, 2003); (5) the importance of social interaction and collaboration in doing and learning mathematics, and more generally, of conceiving learning mathematics as a community activity; (6) efforts to embed mathematics learning in authentic and meaningful contexts; (7) the focus on basic principles or, on big ideas that underlie numerous concepts and procedures across topics; (8) the belief that the above instructional design principles do not hold only for teaching mathematics to mathematically able and/or higher socioeconomic status (SES) children, but also to low achievers and/or low SES learners; and

(9) substantial attention to the teacher's pivotal role in the children's learning process. These common features collectively imply a radical departure from a traditional skills approach to mathematics instruction based on the view that mathematics learning is a highly individual activity consisting mainly in absorbing and memorizing a fixed body of decontextualized and fragmented knowledge and procedural skills transmitted by the teacher (Baroody, 2003; Verschaffel *et al.*, 2007). Importantly, these features can also be differentiated from a *laissez-faire* approach to mathematics education, which was observed in the initial period of the implementation of the reform in countries such as the United States and the Netherlands. They generally fit with what Baroody (2003) called the investigative approach, that is, a blend of a conceptual and a problem-solving approach, aiming at the mastery of basic skills, conceptual learning, and mathematical thinking and characterized by both meaningful and inquiry-based instruction and purposeful learning and practice.

Assessment

A final component of the CLIA-model, namely assessment, is concerned with the design, construction, and use of instruments for determining how powerful learning environments are in facilitating in students the acquisition of (the different aspects of) a mathematical disposition. Assessments of mathematics learning can either be internal or external. Internal assessments are organized by the teacher in the classroom, formally or more informally. By contrast, external, usually large-scale, assessments are organized at the district, state, national, or even international level using standardized tests or surveys (De Corte *et al.*, 1996; National Research Council, 2001b). As argued by the National Research Council (2001b), assessments serve different purposes including assisting learning and teaching, measuring achievement of individual pupils, and evaluating school programs.

Particularly, but by no means exclusively, in the United States, external assessment of what students have learnt and especially whether they attain a certain achievement or proficiency level – high-stakes testing – is a hotly debated topic, especially in relation to mathematics learning and teaching. (The intensity of emotion generated by this topic, as described in Schoenfeld (2006), is particularly striking.) The massive use of standardized tests in education has always been more customary in the United States as compared, for instance, to Europe. But the 2001 No Child Left Behind Act and the related quest for accountability have both increased this practice and intensified the debates about the effectiveness and desirability of high-stakes testing. Especially since the beginning of the 1990s, traditional tests have been increasingly criticized (see e.g., De Corte *et al.*, 1996; Schoenfeld, 2006). Analyses

of widely used standardized tests show that there is a mismatch between the new vision of mathematical competence as described earlier and the content and style of those tests. Partly due to the excessive use of multiple-choice item format, the tests focus on the assessment of memorized facts, rote knowledge, and lower-level procedural skills (routine expertise, to use Hatano's (2003) phrase). On the other hand, they do not sufficiently yield relevant and useful information on pupils' abilities in problem-solving, modeling complex situations, communicating mathematical ideas, other higher-order components of mathematical activity and a mathematical disposition, and, generally, adaptive expertise (Hatano, 2003). A related criticism points to the one-sided orientation of the tests toward the products of pupils' mathematics work and the neglect of the underlying processes (De Corte *et al.*, 1996). An important consequence of this state-of-the-art is that assessment often has a negative impact on the implemented curriculum, the classroom climate, and instructional practices. Apart from the previous intrinsic criticisms on traditional standardized achievement tests, a major issue of debate is the accountability over their use as high-stakes tests, that is, their mandatory administration for collecting data on the attainment of students as a basis for highly consequential decisions about students (e.g., graduation), teachers (e.g., financial rewards), and schools and school districts (e.g., accreditation). According to the No Child Left Behind Act, this accountability use should result in the progressive acquisition, by all students, of a proficiency level in reading and mathematics. However, there are serious doubts whether current testing programs really improve learning and instruction (Amrein and Berliner, 2002). Moreover, there are many reports of unintended but unfavorable consequences, such as increased dropout rates, negative impact on minority and special education children, cheating on examinations by teachers and students, teachers leaving the profession, etc. Nowadays, most researchers in (mathematics) education believe that for large-scale assessments to indeed serve to improve student learning, it will be necessary to move away from the rationale, the constraints, and the practices of current high-stakes testing programs (Amrein and Berliner, 2002; National Research Council, 2001b).

Notwithstanding the relevance and importance of large-scale, external assessments, they need to be supplemented by internal classroom testing, whereby teachers continuously monitor students' progress in understanding and mastering knowledge and skills as a basis for guiding and supporting further learning and, if needed, for providing timely remediation. Such formative assessments also provide students themselves with informative feedback as a basis for monitoring and regulating their own learning (see e.g., National Research Council, 2001b). Whereas external assessments are useful and important for the large-scale monitoring of trends in mathematics education,

classroom assessment affords ongoing day-to-day basis information to improve student learning, taking into account the strengths and weaknesses of the class as a group as well as those of the individual pupils. Convincing examples of the usefulness of identifying students' reasoning underlying their responses as a valuable source for the regulation of learning are given by Wiliam (2007).

The preceding discussion shows that using assessment to assist instruction requires that assessment and instruction should be integrated as envisioned by the National Research Council (2001b): "Assessment should be an integral part of teaching. It is the mechanism whereby teachers can learn how students think about mathematics as well as what students are able to accomplish" (p. 69). For gathering data about pupils' performance and progress, teachers can use a variety of techniques: informal questions, seatwork and homework tasks, clinical interviews, portfolios, and more formal instruments such as teacher-made classroom tests, learning potential tests, and progress maps.

General Conclusions

Using the CLIA framework as an organizing device, this article has presented a selective review of research on development, learning, instruction, and assessment relating to mathematics that offers promise for innovation in, and improvement of, mathematics classroom practices in line with the new international perspectives on the goals and nature of mathematics education as manifested in reform documents worldwide.

With respect to each of the four interconnected components our empirically based knowledge has substantially advanced over the past decades, enabling a progressively better understanding concerning the components that constitute a mathematical disposition, the nature of the learning and developmental processes that should be induced in students to facilitate the acquisition of competence, the characteristics of learning environments that are powerful in initiating and evoking those processes, and finally, the kind of assessment instruments that are appropriate to help monitor and support learning and teaching.

An important question to ask here is whether this expanding knowledge base is relevant and useful in view of bridging the long-standing gap between theory/research and practice, and thus can contribute to the actual improvement of mathematics education practices. The available studies wherein reform-based instructional programs have been implemented and evaluated warrant some optimism. Indeed, the increasing number of "success stories" (e.g., see Becker and Selter, 1996; Verschaffel *et al.*, 2007) are building up increasingly to a critical mass of results, showing that under certain conditions, carefully designed, research-based learning environments can yield learning

outcomes in students, including weaker children and children from SES minority groups, that are in accordance with the current view of the goal of mathematics education as the acquisition of a mathematical disposition, including measures of conceptual understanding and problem solving, while showing either no significant differences or an advantage to the new curricula on measures of computational skills. However, while Schoenfeld (2006: 494) also concludes that "the 'score sheet' is uniformly in favour of the standards-based curricula," at the same time he acknowledges that at present "the evidence base is embarrassingly weak" (p. 494).

Optimism based on the available research is bolstered by the observation that inquiry-based ideas are gradually taking root in the mathematics education community, not just as manifested in the reform documents worldwide, and (subsequently) in curricula and textbooks, but also in the writings and practices of knowledgeable educational professionals (although, again for the United States, Schoenfeld's (2006) short-term view of the situation is much more pessimistic).

However, this general optimism in the long term is tempered by two major challenging problems for future research and development. The first issue relates to upscaling the new perspective on learning and teaching mathematics, and the design principles for learning environments that derive from it. The second (related) problem concerns the sustainability of innovative learning environments. Solving both problems has a serious price ticket and is largely a matter for educational policy and innovation and in preservice and in-service teacher professional development (see also: Schoenfeld, 2006; Verschaffel *et al.*, 2007; issues that are addressed elsewhere in this encyclopedia). As with the debate over assessment, and the perennial search for a proper balance and integration of routine expertise and adaptive expertise, it is increasingly being recognized within the field that these are fundamentally political issues (Schoenfeld, 2006) and that the endeavor of research in mathematics education is itself situated in social and political contexts (Valero and Zevenbergen, 2004).

Learning in Music

Learning is a natural process for human beings. We are pre-programmed to learn. In our everyday lives, during our interactions with others and with the environment, we are constantly engaged in learning. This may be deliberate and intentional or incidental and without conscious awareness. Whether what we have learned is retained in the long term depends on the extent of our ongoing engagement with it and how important it is to us. Learning in music is no exception to these general principles.

Music is a universal trait of humankind. We all have the capacity to learn in music, although whether everyone inherits the same level of potential continues to be hotly debated. While we cannot completely rule out the possibility that there may be some innate functional and structural brain differences which may predispose some individuals to become musicians, there is ever-increasing evidence that musical training itself leads to changes in brain function and structure (Schlaug, 2003). This suggests that whatever genetic inheritance an individual may have is greatly enhanced by a musically enriched environment.

Musical ability tests were first developed in the late nineteenth century to select children to play an instrument in formal educational settings, the underlying assumption being that musical ability was innate or at least determined at an early age. Resources were limited and the best way to ensure that resources were well used was to select children on the basis of their musical potential. The tests focused on aural abilities, usually pitch and rhythm, although some later tests attempted to assess musicality. We now know that these tests assess what has already been learned and may therefore discriminate against those who have experienced an impoverished musical environment prior to testing. They also neglect to assess many of the skills that are required for developing musical expertise.

Musical Skills and Endstates

A range of diverse and complex skills are involved in actively making music and in training to be a professional within the modern music industries as a composer, performer, producer, technician, critic, manager, retailer, or publicist. **Table 1** sets out the wide range of skills that may be involved in actively engaging in creating and making music.

Music Learning in Infants and Young Children

The implicit musical knowledge that adults acquire over time is built on structures present in infancy. These provide the basis for perceptual learning and enculturation, the process by which the child develops internal representations of the music of its culture. This process is mediated by the learning environment and begins when the human auditory system is functional, 3–4 months before birth. In early infancy, parents and the family provide musical stimulation including the use of motherese, nonverbal communication that takes place between parents and infants. These pre-verbal quasi-musical interactions constitute the beginnings of musical competences. Infants are also especially sensitive to lullabies. These have smooth pitch contours, a strong tonal center, repetitive rhythms, and a distinct vocal style, and when adults sing them to infants they tend to sing at a higher pitch than normal, with a slower tempo, and exaggerated emotion, a style of singing that is found in childcare contexts across cultures. Newborns and infants listen more attentively to singing which is in this infant-directed style.

From birth, the infant has very well-developed systems for processing music. Infants are predisposed to attend to melodic contour, rhythmic patterning, and consonant sounds and are similar to adults in their sensitivity to the pitch and rhythmic grouping of sounds. However, the complex skills required for understanding and analyzing music within any particular culture take time to develop and depend on the type and extent of exposure to music. The scale patterns of particular cultures are not innately known and have to be learned (Trehub and Trainer, 1990). In Western cultures, 1-year-old infants respond differently to diatonic and nondiatonic patterns before by 3 or 4 years, display the ability to respond to the degree of tonality of the stimuli. This process is likely to be aided by the tonal construction of nursery songs that usually emphasize the pitch content of basic scales. Depending on their musical environment, by the age of 5 years, children can generally organize songs around stable tonal keys but do not have a stable tonal scale system that can be used to transpose melodies. This develops later (Lamont and Cross, 1994). Children in their early years also begin to recognize musical depictions of emotion and respond to them. The specific age at which this occurs is likely to depend on the extent of the child's exposure to music within and across genres

Table 1 Musical skills*Aural skills are required for developing:*

- Rhythmic accuracy and a sense of pulse
- Good intonation
- The facility to know how music will sound without having to play it
- Improvisational skills

Cognitive skills are required in the processes of:

- Reading music
- Transposition
- Understanding keys
- Understanding harmony
- Understanding the structure of music
- The memorization of music
- Composing
- Understanding different musical styles and their cultural and historic contexts
- Evaluating and appraising

Technical skills are required for developing:

- Instrument-specific skills
- Technical agility
- Articulation
- Expressive tone quality

Musicianship skills are concerned with:

- Being able to play expressively
- Being able to project sound
- Developing control
- Conveying meaning

Performance skills include:

- Being able to communicate with an audience
- Communicating with other performers
- Being able to coordinate a group
- Presenting to an audience

*Learning skills are related to: being able to learn, monitor, and evaluate progress independently**Life skills include:*

- Social skills (being able to work with other musicians, promoters, the public)
- Planning and organizational skills (planning practice schedules, programs, travel arrangements)
- Time management (being punctual, meeting deadlines)

and their general cognitive and emotional development. A small number of children develop absolute pitch, the ability to identify or produce isolated pitches in the absence of a reference pitch. We may all be predisposed to develop this, but require an appropriate musical environment that provides exposure to specific pitches and a means of labeling them when young.

From 9 months, infants begin to make spontaneous babbling or singing sounds and, after 18 months, they begin to spontaneously generate music that has systematic form, uses discrete pitch levels, repeats rhythmic and melodic contours, and is recognizable as song. However, they lack a stable pitch framework and before in any single song, a very limited set of phrase contours are used. By the age of 5 years, individual contours and intervals are produced accurately and children can produce recognizable songs with stable tonality. They also improvise and invent songs.

Children are exposed to music in the home through the radio, recordings, or the television. The nature of that music will influence their musical enculturation. Globalization has meant that worldwide, most children are exposed to Western popular music. From infancy, children acquire implicit knowledge about the music they hear, its structures, rhythms, and tonality. The greater the exposure to music, the more fully and speedily this knowledge is acquired. It is not necessary for children to focus on listening to music for this knowledge to develop. It is learned without conscious awareness.

Listening, Responding to, and Appraising Music

When we listen to music, we process an enormous amount of information rapidly and often without conscious awareness. The ease with which we do this depends on our prior musical experiences and the culturally determined tonal scheme to which we have become accustomed. This knowledge is not always available to conscious thought and is applied automatically whenever we listen to music.

Human beings respond to music in a variety of different ways. Responses can be physiological, motor, intellectual, esthetic, emotional, or in relation to mood or arousal. In education, the focus has been on the intellect and the esthetic. However, other responses may be more powerful. Individuals can have very strong emotional experiences to music (see Gabrielsson, 2001 for a review), although music can also play an important role in helping overcome powerful emotions.

Listening plays a central role in the appraisal and evaluation of active music making, guiding future planning and activity. The process of appraising involves listening and making comparisons (implicit or explicit) with already-acquired internal representations of music. These may be specific, that is, of the same piece of music; generalized, but still pertaining to particular types of music; or generalized, relating to particular features of performance, for example, intonation, tone quality. Without comparison, with some already-held conception, appraisal cannot occur. Even quite young children are able to articulate ideas about their listening processes and as they get older they more frequently predict, compare, evaluate, express preferences, reflect, recognize, and make judgments about music. Musically trained children demonstrate similar skills to adults suggesting that the ability to think critically while listening to music is related to experience with music rather than age.

Acquiring Skills for Active Music Making

Learning to play an instrument, developing vocally, improvising, or composing, all require the acquisition of a wide range of skills. Three main stages have been

identified in skill development. In the initial cognitive-verbal-motor-stage, learning is consciously controlled, the learner understands what is required, and carries it out while consciously providing self-instruction. Learning is supported when the learner has a clear mental representation of both the process and the goal of learning and feedback is available, either directly from the environment or from an observer, usually a teacher. In the associative stage, the learner begins to put together a sequence of responses that becomes more fluent over time. Errors are detected and eliminated and feedback from others or self-monitoring continues to be important. In the final autonomous stage, the skill become automated, is carried out without conscious effort, and continues to develop each time it is used, becoming more fluent and quicker. As automaticity develops, the component processes become unavailable for conscious inspection and the learner has difficulty in explaining his or her actions to others (Fitts and Posner, 1967). A similar set of processes occurs in relation to the acquisition of knowledge. Initially, learners are unable to discern the difference between accurate/inaccurate and relevant/tangential knowledge. At the second stage, a foundational body of relatively cohesive, structured domain knowledge has been acquired which can be applied adopting surface and deep approaches to learning. To move to the third stage, a synergy among elements of knowledge is required. To attain high levels of coherence and automaticity requires increasing levels of personal motivation.

The acquisition of knowledge and skills is inextricably intertwined. Knowledge-based mental representations of what the music should sound like are required to check for errors; monitor progress toward performance, improvisational, or compositional goals; to select possible strategies for continued working; and to evaluate the final outcome. Due to the complexity of learning in music, as one set of skills becomes increasingly automated, others will be at earlier stages. The quality of the processing during these various stages is important in determining learning outcomes and is supported by having appropriate representations of what is to be attained and receiving appropriate feedback directly (from the sounds produced) or from observers. Knowledge of high-quality representations can be acquired through listening, imitation, analysis, and participating in making music with others who are more expert.

As the individual's expertise increases and skills become automated, s/he can more easily take a holistic view of the task and perceive large meaningful patterns. S/he is likely to spend longer analyzing the problem and represent it at a deeper level, while the speed of processing and memory related to the area of expertise increases. Monitoring of progress and evaluation of outcomes improves because of the high level of expert knowledge. Those with high levels of expertise know why they make

errors, why they fail to comprehend, when they need to check their solutions, and what they need to do next. They are better than novices in judging the difficulty of a problem and selecting appropriate strategies to solve it.

For high levels of musical expertise to develop, the individual needs to be actively engaged with music over a long, sustained period of time, in the case of professional musicians, many years. This may be in formal or informal learning contexts and involves systematic practice or playful, creative activity. Transfer of learning takes place in relation to some musical activities, for instance, in sight-reading, technical instrumental skills, and knowledge of a particular genre; but transfer between genres, for instance, classical and jazz, and music based on different tonalities is limited, and different types of skills are required for performance, improvisation, and composition. To perform well, particularly in formal contexts, in addition to being well prepared musically and technically, requires an understanding of how to utilize stage fright to enhance performance rather than allow it to disrupt it, while improvisation and composition require creative skills.

Practice is essential for all musical learning but is more effective when it is not merely repetitious but is systematic with careful monitoring of progress toward goals and the adoption of alternative strategies when progress is not being made. Learners benefit from having knowledge of a wide range of learning and problem-solving strategies, being aware of their own strengths and weaknesses, and having high-quality models to emulate. Mental rehearsal, where the learner imagines playing or performing, has been demonstrated to be effective as it stimulates the same processes in the brain as physically undertaking the activity. This requires no physical resources and therefore it enables practice to be undertaken at any time.

Metacognitive strategies concerned with the planning, monitoring, and evaluation of learning are crucial to all aspects of engagement with music and can be considered at the level of a particular task or in relation to the more global concerns of the learner to maintain or improve the standard of their work. In both cases, the knowledge of personal strengths and weaknesses, the nature of the task to be completed, possible strategies, and the nature of the learning outcome are important. There are considerable differences between beginners, novices, and experts in their knowledge and deployment of different learning and self-regulating strategies, as well as individual differences among musicians and novices at the same level of competence.

Managing self-motivation, and the working and learning environment are all-important in facilitating successful learning. High-achieving students maintain a balance between formal or required practice tasks and informal, creative, or motivating activities such as playing a favorite piece or improvising. The most creative student

composers set personal goals, negotiate the relationship between global and specific parameters, experiment and constructively criticize their work, and while demonstrating an optimistic outlook and internal locus of control, are more critical of their work than their peers (Priest, 2006).

To be successful, learning and creative problem solving must be thoughtfully approached and the strategies adopted tailored to the needs of the particular task. Learning may be exploratory, deliberate, playful, mental, physical, and expressive or performance oriented depending on the task and the stage reached in bringing it to fruition. Those wishing to become more effective learners and creators should:

1. develop metacognitive skills (identify the nature of the task and what will be most effective in tackling it, identify strengths and weaknesses, and monitor and evaluate progress);
2. identify clear goals and work toward them;
3. listen extensively to all kinds of music, comparing and critically evaluating it and its performance;
4. search out and act upon feedback from others;
5. think about the task when not actively engaged with it – engage in mental rehearsal;
6. invest time in analytic work;
7. plan;
8. develop strategies for managing motivation;
9. ensure that the learning or creative environment is conducive;
10. take advantage of opportunities to play, improvise, compose, and perform with others (this develops a wide range of skills); and
11. acknowledge the relationship between time engaged with music and achievement and set out to invest the time necessary.

Time invested in engagement with music and the quality of that engagement impact on the level of musical expertise attained. Learning how to learn and create leads to the time spent being more productive, challenging, and enjoyable.

Learning or Creating in a Musical Community

Participating in group musical activities (communities of practice), formal and informal, has many benefits. As members of musical groups, learners go through a progressive sequence of intentional stages through which they progress as auditors, competent listeners, inceptors, beginners, and competent players. Interacting musically with others develops a wide range of musical skills. Group music making or composition provides opportunities for collective involvement and decision making; support for the less confident; opportunities for playing and practicing together; exchange of ideas; opportunities for the less skilled to learn from the more experienced;

increased opportunities for experimentation; more choice of instrumentation; and shared opportunities for the rejecting and selecting of ideas. Other benefits can include increased confidence, the development of negotiation skills, the ability to defer to other people, respect for the work of others, the ability to give constructive criticism, and the ability to work freely within a disciplined environment. Informal learning based on combinations of trial and error, repetition, watching and taking advice from other players, reading, listening, and emulating develops metacognitive musical skills and can encompass organizational and practical skills, linguistic training, and the formation of personal identity.

Motivation

To attain high levels of skill in any aspect of music requires that a considerable amount of time be invested in active engagement with it. This requires motivation.

There are complex relationships between motivation, achievement, and time spent engaged with learning. While intrinsic motivation may be generated by interesting tasks in the short term, that interest must be internalized and become part of the individual's identity for motivation to be sustained over long periods of time. Internal motives include the desire for achievement, curiosity, and self-actualization, the need for personal fulfillment met by the emotion-inducing quality of music, satisfaction of a positive social response in performance settings, exploration of aggressive drives through the exploitation of the motor skills entailed in musical performance, and the satisfaction of some voyeuristic and exhibitionistic desires.

The particular musical activity engaged in is important for sustaining motivation. Choice of musical instrument should reflect interests and enthusiasms but it may be limited by convenience, availability, parents' views, the influence of the school or instrumental music provider, or friends. Gender may be a factor in that girls generally prefer small, high-pitched instruments, whereas boys choose large, low-pitched ones. Parents also tend to have stereotypical views of which instruments are appropriate. Those children violating these stereotypes may be subject to harassment.

To motivate learners, the early stages of active engagement with music need to be playful and intrinsically rewarding. The influence of early teachers, who are viewed as warm and sympathetic, seems to be particularly important in this respect. Relatively uncritical encouragement in the early stages of engagement with music encourages the development of a positive musical identity. Once this is established, later teachers provide high-status role models with whom the young musician can identify and emulate (Sosniak, 1985).

Sustained parental support is an important factor in the attainment of high levels of musical expertise. Parental enrichment of the musical environment from birth seems to stimulate the onset of early singing that in turn contributes to later success. (Howe *et al.*, 1995). Having musical parents or a musical home environment influences participation and success in music. Families can play a role in the identification of talent and parents of high achievers tend to have very high expectations and are demanding in those expectations. The child seems to internalize these and achievement becomes a need in itself. The parents of high achievers also tend to be more involved in initial practice, attend lessons with their children, and receive and act upon feedback from the teacher. Practical help in taking pupils to concerts and providing financial support is critical. However, there are exceptions where children have achieved professional status with little practical support from the family. Some highly effective individuals in music have histories marked by severe frustration, deprivation, and traumatic experiences. Personal determination enabled them to overcome these difficulties. The most highly accomplished young musicians appear to be self-motivated almost to the point of obsession, unable to separate their developing self-perception from that of being a musician. (Kemp, 1996) This enables them to overcome obstacles and bullying or loss of popularity as a result of their involvement. This high level of commitment may depend on the experience of intense, esthetic, emotional reactions to music, initially occurring in early childhood.

The development of a high level of commitment to music is also influenced by societal factors. Music is not valued equally in all cultures. In some places and at some times, the environment is very conducive to musical activity and there are considerable rewards for being musical. Educational institutions also vary in the level of support they give to musical activities. In some schools, music is highly valued and supported by senior managers and class teachers. An enthusiastic class teacher can modify pupils' attitudes toward music and counteract negative social influences.

In adolescence, the peer group is very powerful and can bring negative pressure to bear in relation to engagement with some types of music. To withstand this pressure, musical identities need to be well developed.

Those who drop out from specialist music tuition perceive that they are less musically able and receive less family encouragement. They tend to pursue other leisure activities as they view continuing to play as demanding too great a time cost for the relatively small rewards it offered. There are complex relationships between prior knowledge, motivation, effort, and perceived efficacy. When a child begins to learn an instrument, prior musical knowledge affects ease of learning and the time needed to achieve mastery of a task. While

undertaking additional practice may compensate for lack of prior knowledge, this has a time cost and requires perseverance. If a task proves challenging, the effort required to complete it may be perceived as too great and the individual may give up. Difficulties may be attributed to a lack of musical ability leading to a loss of self-esteem, loss of motivation, less practice, and a downward spiral leading to the termination of lessons.

Endnote

We are all born with the capability to make and appreciate music. The extent to which the individual develops musical skills depends on opportunity, the selection of an appropriate musical activity which s/he finds engaging, personal motivation and commitment, the adoption of effective learning and problem-solving strategies, and a supportive learning environment where music is valued.

Reading Comprehension: Reading for Learning

C E Snow, Harvard Graduate School of Education, Cambridge, MA, USA

Defining Reading Comprehension

The challenge of understanding reading comprehension derives, in part, from the difficulty of defining its borders. Comprehension was defined by the Research and Development (RAND) Reading Study Group (RRSG, 2002) as “the process of simultaneously constructing and extracting meaning through interaction and engagement with print.” This definition was intended to signal the importance of a number of key features of comprehension: the accurate decoding of print, a process of meaning construction through which inferences and information not available from the print are incorporated into the meaning representation, and active, motivated engagement from the reader. This definition works well for prototypical cases: the 10-year-old laughing while reading a joke book, the 15-year-old engrossed in a science fiction novel, and the 25-year-old being guided by a manual to install and run a new piece of software. The processes that occur during these prototypical comprehension events have been the subject of considerable research (see RRSG, 2002 for more detailed information about those processes), which has made clear that the success of any reading comprehension event is determined by variation on three dimensions: the text, the reader, and the task, all defined within a sociocultural context. The RRSG characterized successful comprehension as what occurs when the demands of the text, the challenges of the task, and the skills and proclivities of the reader are all well aligned, as exemplified by the prototypical cases listed above. Any pair of these dimensions can be the site of a mismatch that causes comprehension to fail and, as is described below, each introduces some ambiguity about where real reading comprehension begins and ends.

Texts

Consider a candidate text that might be found in a first grade reader:

Alex and Ali ran to the swings and jumped on.

What constitutes comprehension for this text? At a minimum, a mental representation of two individuals moving quickly toward and using some playground equipment should be conjured up, but is the inference that Alex and Ali are probably children part of the comprehension process or does that go beyond basic comprehension? Is it required that the comprehender assign genders to Alex

and Ali, or that gender assignment be postponed, recognizing that Alex could be short for either Alexandra or Alexander, that Ali could be a boy's name or a nickname for Alison? If Ali is provisionally classified as a boy, is it part of comprehension processing to infer that he comes from a Muslim family, or is that an inference that goes well beyond basic comprehension? If the reader has, for example, just arrived from China and has never encountered these first names before, has that reader fulfilled expectations with the inference that these are animate creatures – perhaps as likely to be cats as children? Must the reader infer that Alex and Ali actually started swinging, or does that go beyond comprehension into the realm of prediction? Does an inference that Alex and Ali were enjoying themselves belong to the realm of comprehending this sentence or comprehending the world? In other words, what is a sufficiently elaborated representation of this simple sentence to qualify as comprehension?

The dilemmas posed by considering different levels of processing of this brief text are, of course, greatly expanded if we consider the comprehension of longer and more complex texts, from paragraphs to newspaper reports or scientific articles to entire novels, let alone trying to establish what constitutes comprehension when reading an array of texts – reports of a political speech in right-wing versus left-wing newspapers, or scientific articles reporting conflicting results, or the entire oeuvre of a novelist – in conjunction with one another. At some point between the simple sentence above and the several volumes of *Remembrance of Things Past*, the definition of comprehension shape-shifts from a simple representation of an event to deep understanding of a worldview, but fixing the boundary between those activities is not easy.

Readers

Considering students at different points in development also dictates emphasis on different aspects and levels of comprehension, whether one is motivated to design instruction, select assessments, or investigate the underlying comprehension processes. For example, researchers and practitioners focused on reading to learn for students in secondary grades must take into account the overwhelmingly important contribution to successful comprehension of students' access to relevant background knowledge. Thus, in science, social studies, and math classes, there is often considerable emphasis on ensuring that students know something about a topic (using

lectures, videos, diagrams, hands-on demonstrations, or other nonliterate means) prior and as a support to their reading a text about that topic. On the other hand, researchers and practitioners more interested in early reading instruction and/or in remediation for struggling readers tend to emphasize issues related to reading and understanding the words in the text because that is where beginning readers encounter comprehension challenges, and it is often (though not always) the reason struggling readers do not comprehend well. In between these extremes of teaching beginning and struggling readers and teaching reading for learning, there is instructional emphasis on what might be thought of as simple comprehension – comprehension by students who have mastered word reading, reading texts which only make limited demands on background knowledge, but which do require (1) building and continually revising/expanding a text representation while reading, (2) making some inferences about connections among sentences and about connections to real world situations, and (3) perhaps some comprehension monitoring and comprehension repair mechanisms.

These differences related to developmental stage are also reflected in comprehension assessments, which for younger readers typically include items testing literal comprehension or basic inferencing, while items for older readers may require inferences that go farther beyond the text or draw more deeply on background knowledge (Snow, 2003). In other words, the definition of successful comprehension must be made conditional on at least the age and stage of development of the reader as well as the level and complexity of the text being read.

Task

A further complicating factor in defining successful reading comprehension has to do with the task being undertaken. There are important cultural, educational, and individual differences in the conceptualization of comprehension. In some literary and religious traditions, for example, literal memory for text is valued above interpretation of the text, whereas in others, attention to the actual words of the original text is much less important than coming to a justifiable interpretation of it, making connections to it, and even perhaps critiquing it.

Stark differences in task can be observed within cultures across disciplinary boundaries as well. For example, a science textbook is meant to be read for information, and comprehension can be said to occur when the reader expands and/or revises his/her understanding of some phenomenon by reading the information in the book; all too often, of course, the science textbook reader simply remembers the new information long enough to pass a test on it, without actually revising his/her enduring understanding. Therefore, the question that then arises is

whether this is a failure of comprehension or a failure of science learning.

In contrast, though successful comprehension of a novel read in a language arts or literature class does require learning the basics of characters, setting, and plot, just acquiring that information is not considered successful learning unless some appreciation is also engendered of the mood, the characters' and author's perspectives, the theme, the author's goal in writing the book, and other such ineffable features. One might well, in the course of reading some literary works, incidentally pick up information about scientific or historical or interpersonal topics treated in the book, and that would signal comprehension in one sense, but a literary reading would demand much more from the reader. Therefore, in literature classes, the question arises whether the dutiful student who can write an accurate plot summary of a novel, but fails to recognize, for example, that the narrator has taken an ironic stance or that the plot is a modern reenactment of the *Odyssey*, has failed at reading comprehension or at literary analysis.

Integrating Information about Reader, Text, and Task

Predicting comprehension success requires calculating information about the reader's stage of development, the complexity of the text being read, and the task being engaged in (see RRSg (2002) for further elaboration of each of these three aspects of any comprehension experience; **Figure 1**, reproduced from the RAND report, is a visual representation of this model). Successful comprehension occurs when these three dimensions are well

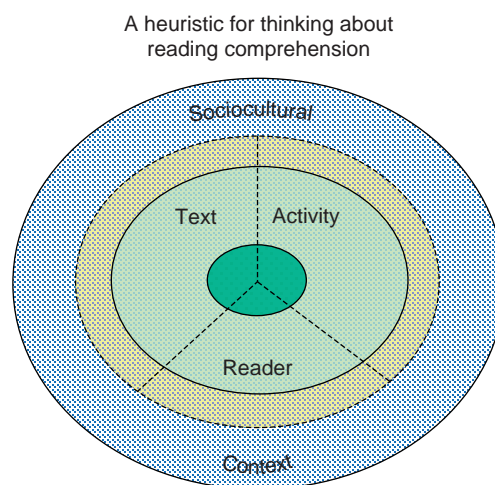

Figure 1 A heuristic for thinking about reading comprehensions devised by the Research and Development (RAND) Reading Study Group (2002) to depict the interaction of text, reader, and activity (or task) on reading comprehension.

aligned. For each of these dimensions of comprehension, though, there are simple cases and more marginal, gray areas where comprehension shades into learning or interpreting or functioning disciplinarily. The vast differences in what we would call successful comprehension across different levels of reader skill, text challenge, and task definition pose a challenge in summarizing what we know about reading comprehension, and in integrating or even providing a road map to the extensive research literature on comprehension development, assessment, instruction, and intervention.

A Taxonomy for Comprehension

For the purposes of this overview, we argue that identifying exactly where the boundary between reading comprehension and some other activity occurs is, to some extent, the individual's prerogative; even experts in the field achieve better agreement on identifying prototypical comprehension events than on placement of the boundaries. Furthermore, while the difficulty of deciding when a reading activity incorporates too many additional demands to be considered real comprehension may be obvious, there are also difficulties in deciding where comprehension begins at the bottom end, considering young readers and simple texts. What about the Jewish American or Muslim Turkish child who learns to read a sacred text, following the print faithfully while accurately pronouncing words that neither understands? It may seem obvious that this does not count as comprehension; however, what if that child has been told what the text is about, or has even been given a careful and complete translation of it? If the child is thinking of the translation while reading, is that comprehension? What if the child can understand a few of the words in the text, but has no understanding of the grammar of the written language? What if the child understands that verse, but none of the others in the book? When does reciting stop and real reading comprehension begin?

Reading comprehension might be thought of, then, as located on the radius of a set of concentric circles (see **Figure 2**). In the center circle are the basic reading processes that must be in place in order to access the text and form a mental representation of it: accurate word recognition, fluent access to word meaning, recognition of syntactic cues to sentence meaning, and short-term phonological memory. Variations of skill on these dimensions are clearly related to reading comprehension success – the reader who misidentifies words, who does not know the meaning of words in the text, who cannot parse the syntax of utterances, and who forgets the first sentence in a paragraph while reading the second will have difficulty comprehending (RRSG, 2002; Vellutino, 2003).

The second circle can be thought of as core comprehension processes – the ability to construct a mental representation of the ideas presented textually (Kintsch, 1998; Kintsch and Kintsch, 2005). Core comprehension requires text memory, making text-based inferences (e.g., tracing anaphors back to referents, keeping track of the order of events, and understanding implicit causal links), and making text-world links (e.g., bringing information about real dogs to bear in understanding what is strange and funny about a talking dog). Much early comprehension instruction focuses on helping learners activate relevant background knowledge before confronting text, on the theory that even children who have the required knowledge may not automatically access it while reading or integrate it with new information in the text. Another aspect of comprehension instruction for younger readers is a focus on self-monitoring, to ensure that the process of reading remains focused on building mental representations, and not just on reading the words.

The third circle comprises more elaborated comprehension processes, the processes involved in going beyond creating an unadorned text representation to a deeper understanding of the text. Many of the comprehension strategies that are recommended as part of comprehension instruction, for example, visualization, noting questions that arise while reading, and making text-to-text connections, are focused on these somewhat more elaborated comprehension processes. These processes also shade into ones that might be identified and taught as part of inquiry learning, such as figuring out how claims in one text relate to claims in another text, identifying the point of view a text presents, critiquing the argument in a text, and so on. In other words, rather than inquiry being a process applied to real-world phenomena, it is taken as a process to be applied to text itself. This is the theory underlying approaches to comprehension instruction such approaches to comprehension instruction as reciprocal teaching (Palincsar, 2003), questioning the author (Beck and McKeown, 2002), and reading apprenticeship (Shoenbach *et al.*, 1999).

An outer circle comprises highly elaborated comprehension processes that overlap with disciplinary studies or deep learning from text. Whereas ordinary readers might be expected to engage in moderately elaborated comprehension for purposes of understanding murder mysteries, psychological novels, columnists' political opinion pieces, or popular science articles, highly elaborated comprehension processes can only be expected of readers operating within domains where they have developed deep background knowledge and have had disciplinary training in how to read. These would encompass the processes involved, for example, in reading for purposes of literary criticism, historiography, constructing an intellectual history, or producing a parody.

The representation of these four kinds of reading in **Figure 2** as concentric circles with clear boundaries

Figure 2 Basic reading processes, basic comprehension processes, and elaborated and highly elaborated comprehension processes represented as concentric circles, with reading comprehension located somewhere on a radius depending on the reader, text, and task.

between them should be viewed cautiously. First, there is no strong basis for placing a particular reading comprehension event on either side of the boundaries between central, elaborated, and highly elaborated comprehension processes. Second, this depiction is not meant to license an approach to reading instruction that starts in the middle and moves slowly outward; meaning construction, new learning, and interpretation should be part of the earliest literacy instruction, though these activities may be engaged in while reading texts aloud to children who are still mastering the code. Furthermore, the degree to which more sophisticated and elaborated comprehension might be expected of a lay literate versus a disciplinary literate depends, to a large extent, on the decisions a society makes about educational goals. Nonetheless, it may be useful in categorizing research, analyzing comprehension assessments, and understanding the challenges facing teachers of reading and of content areas to at least stipulate that reading comprehension is quite different when it occurs during code-focused reading as compared to reading for new learning and intellectual development.

Theories of Reading Comprehension

A few theories of reading comprehension have been particularly useful in guiding research and informing instruction. The simple view of reading (Gough and Tunmer, 1986) conceptualizes comprehension as the product of two capacities: the capacity to decode and the capacity to understand spoken language. The simple view claims, then, that comprehension is limited not only by speed and accuracy of word reading, but also by oral comprehension ability, and that if either of these abilities

is zero, then comprehension does not occur. Children following a normal developmental trajectory are subject to comprehension limitations stemming from constraints on word reading during the early years of schooling, and stemming from the limits on oral language skills thereafter. Under this view, it is clear that building oral language skills (vocabulary, comprehension of complex syntax, and comprehension of extended discourse forms) constitutes a key contribution to reading comprehension.

The simple view underemphasizes, though, the role of background knowledge and of motivation. The theory formulated by Kintsch introduces background knowledge by articulating how the textbase (the product of core comprehension processes) interacts with the mental model (the meaning representation constructed from the textbase and world knowledge; Kintsch, 1998; Kintsch and Kintsch, 2005). Kintsch (1998) also notes the importance of attending to the genre and the rules of reader–writer communication within the genre. Key in understanding the textbase and its links to the mental model, the genre, and the larger communicative act are various signals at the sentence level (e.g., after, same, and but) and the larger discourse level (e.g., headers and lists) of how the bits of information in the text are meant to be related to and integrated with one another (see also Graesser *et al.*, 2003; RRSg, 2002).

The role of motivation is emphasized in the work of Guthrie (2003), who points out that background knowledge is likely to be richer in areas of personal interest, and that readers are more likely to persist in wrestling with text if (1) they are interested in the topic and (2) they experience self-efficacy as readers. Reader self-efficacy grows with comprehension skill, which in turn supports reading engagement, which in turn further builds comprehension skills and background knowledge.

Instruction in Reading Comprehension

Instruction in reading comprehension is much less emphasized than instruction in basic reading skills or instruction focused on content areas without attention to the challenges of reading in these areas. Given the importance of background knowledge and vocabulary to successful comprehension, young children should have access to oral language-focused instruction, in which comprehension is modeled and vocabulary and background knowledge are taught by reading aloud from both fiction and nonfiction books.

The most frequent form of comprehension-focused instruction involves teaching comprehension strategies (National Reading Panel, 2000). While strategies such as monitoring one's own comprehension, stopping to note questions that one has, and visualizing can be supportive, it is important that instruction in these strategies focus on when to use them and why they can be helpful in creating meaning representations. A focus on content teaching creates a context for introducing comprehension strategies as targeted learning tools, as happens in Guthrie's program called Concept-oriented Reading Instruction (2002) and in Reading Apprenticeship (Shoenbach *et al.*, 1999), rather than teaching them as all-purpose comprehension aides.

Intervention with Struggling Comprehenders

Providing intervention to help struggling comprehenders before they fall far behind is a key responsibility in light of the overwhelming evidence that poor comprehension is associated with reduced opportunities to learn vocabulary and general knowledge (Stanovich, 1986), difficulties in learning across academic areas (RRSG, 2002), and ultimately, frustration with schooling and a higher likelihood of failure to graduate from high school or to achieve access to higher education. A challenge in providing comprehension intervention is that poor comprehension can be a product of a breakdown in any of a wide variety of reader skills (word reading accuracy, fluency, vocabulary, background knowledge, text memory, deployment of appropriate strategies, and engagement in reading), and effective intervention requires identifying the challenge and responding to it. For adolescent learners struggling with comprehension because of difficulties with word reading or fluency, it is often difficult to access instructional materials that offer minimal textual challenge, but are engaging and of appropriate cognitive level.

Deshler *et al.* (2007) provide an extensive review of interventions for struggling comprehenders, indexed by target of the intervention as well as developmental level

and type of learner (e.g., vocabulary focus for intermediate second-language learners). Unfortunately, very few of the programs they review, many of which have solid theoretical foundations, have been extensively evaluated or analyzed to determine under which circumstances and for which subgroups of learners they are most useful.

Summary

Reading comprehension is a complex topic. Predicting success in comprehension requires knowing about the reader, about the text being read, about the task being undertaken, and about the sociocultural context in which the reading is occurring. Since reading comprehension shades into learning, constructing a worldview, and discipline-specific literacy practices, it is difficult to establish firm boundaries around comprehension; nonetheless, it is clear that more attention to comprehension is needed across the grades. In preschool and primary grades, opportunities for building vocabulary and background knowledge and practicing oral comprehension should be provided while children are learning to decode. In later grades, students need explicit instruction in how texts are constructed and how language cues signal meaning at sentential and discourse levels, as well as practice and support in wrestling with content-rich texts for well-defined and engaging purposes.

Second Language Learning

Theories of Second Language Acquisition

Contrastive Linguistics

The first major paradigm of language-acquisition theory was the behaviorist–structuralist school which was informed by the contrastive hypothesis. This was built on the observation that learners with common mother tongues developed similar difficulties with specific foreign languages. The general principle of the hypothesis was that difficulties in second- or foreign-language learning were caused by structural differences between the mother tongue of the learner and the language to be acquired. The hypothesis had two degrees (Wardhaugh, 1970). The strong version claimed to be able to predict the difficulties of learners on the basis of a contrastive analysis, that is, a systematic comparison of the structures of the two languages involved. The original contrastive hypothesis was closely related to structuralist linguistics and its emphasis on *langue* (Lado, 1957). The view on learning was that of behaviorist psychology. Language was considered a set of habits, and second-language learning was a task which primarily involved a change of habits. The mother tongue of the learner would, in its capacity as a set of habits, interfere with the learner's new language (Weinreich, 1953). Contrastive analysis of entire languages were planned and carried out. Depending on the structural salience of the features involved, contrastivists also found that they were able to determine different degrees of difficulty. James (1980) suggests that contrastive analysis can be used by curriculum planners and teachers in their preparation, but not necessarily as a wholesale explanation of difficulties. Based on studies of learners' actual difficulties, however, a criticism of the contrastive hypothesis developed. It was found that difficulties predicted by contrastive analysis sometimes never appeared, and in other cases, difficulties arose which contrastive analysis did not explain. Furthermore, so-called errors came to be seen as necessary steps in the acquisition of a language (Corder, 1967). Many error analyses were carried out in order to shed light on real-life difficulties of learners. In some cases, the characteristics of the target language (L2) appeared to be more important than the mother tongue (Hyltenstam, 1978). The focus soon shifted to the study of the L2 performance of the learner as a language in its own right, a so-called interlanguage (*interlingua* or approximative system, Richards, 1974). An interlanguage has a grammar which follows universal principles just like any other grammar; it is just more variable.

This understanding of language differed from traditional structuralist linguistics. Interlanguage studies further led to theorizing over the patterns of acquisition of second-language learners. This theorizing was likewise far removed from the behaviorist view of learning, it concentrated on cognitive aspects of language acquisition.

A Cognitive Approach to Second Language Acquisition

The cognitive approach to language acquisition has its starting point in the human brain's capacity for processing and organizing information. The central notion that (second) language learning is skill learning opens the field to psychological accounts of the processes leading to language acquisition. The first major contributions (e.g., McLaughlin, 1987) to the upcoming field were to a certain extent based on the L1 (first language)-acquisition studies of Slobin (1985). Slobin argued that the mind is programmed to process information which is perceptually salient, and to organize this information according to specific operating principles eventually leading to language learning. This explains cross-linguistic similarities in first-language acquisition. In later studies Slobin (1996) points to a close connection between language typology and language processing. A process similar to Slobin's earlier studies was believed to work for second-language learning (Andersen, 1990), and different models were proposed to account for the information processing necessary for the automatization of second-language learners' linguistic knowledge and fluent speech. Both McLaughlin's (1987) information-processing model and Anderson's (1985) adaptive control of thought are related to this line of research. Like L1-acquisition, second-language acquisition (SLA) is considered to follow a concise developmental order by which certain parts or features of the language are acquired before others (e.g., Givón, 1985). These thoughts are further elaborated in Pienemann's (1998) processability theory, which claims that language acquisition follows similar patterns even across language families. In cognitively oriented language-acquisition studies, the role of memory is taken into consideration in more detail. Such studies also drew on cognitive psychology in order to investigate the limits of perception, that is, how many different items the brain is capable of processing. Short-term memory is able to process only a limited amount of new information at a time, and by ways we can still only hypothesize about, information is

stored in the long-term memory after being processed repeatedly and thereby automatized. However, when information is stored in long-term memory, it is considered difficult to retrieve it for further processing, for instance, if the structure of the linguistic information is incomplete (i.e., incomplete morphology, syntax, or pronunciation). Krashen (1985) attempted to formulate a comprehensive theory for SLA, consisting of five major hypotheses. His comprehensive theory has been criticized for being difficult to test empirically. Nevertheless, the discussions it has raised have been fruitful for the further development of the field. One of the outcomes of Krashen's comprehensive theory was the extension of the input hypothesis proposed by Long (1985), in the field generally known as the interaction hypothesis. Through studies from the 1980s onward, Long pointed to the interesting differences in conversations carried out among native speakers compared to conversations involving both a native speaker and a learner. Conversations and communicative difficulties and how they were managed were studied through conversation analysis. They showed a significant use of conversational strategies (e.g., repetitions, repairs, requests for clarification, and comprehension checks) by both parties to ensure that the meaning and content of the conversation were not lost due to misunderstandings. During language acquisition, through negotiation of meaning, the learner focuses on content as well as form (Long and Robinson, 1998). The idea that language is learned through interaction, and thus tied to a social practice, is part of a wider pedagogical movement which shifts the focus from teaching to learning. The learner is considered an active part of a learning process. Schmidt and Frota (1986) point to the importance of consciousness and noticing as central phenomena in the language-acquisition process. Noticing specific aspects of language is closely linked to cognitive development as well. Through the 1980s, this interactionist approach was further developed. The notion of communicative strategies which accounted for the psycholinguistic aspects of interaction from comprehension to production was widely discussed, e.g., Kellerman and Bialystok (1997).

Motivation

Two major paradigms dominated the studies of motivation in language learning from the beginning of the 1970s. One was the view on motivation considered in terms of instrumentality and integrativeness (Gardner and Lambert, 1972). According to this view the motivational drive to learn a second language is the prospect of achieving specific goals (e.g., job or education) by learning the language (instrumental motivation), or the drive stems from a desire to adapt the culture and habits associated with the language (integrative motivation). The other paradigm distinguished between intrinsic versus extrinsic motivation (Deci and Ryan, 1985). This approach is more

sociopsychological. Motivation is considered the outcome of individual regulation of behavior. Extrinsic motivation is connected with the demands and expectations formulated by persons (e.g., parents or teachers) in the individual's surroundings under the promise of reward or the threat of punishment. As the individual becomes more and more socialized into a certain behavior, the motivation to fulfill specific expectations would come from within (intrinsic motivation). In both paradigms, the relation between the motivation types is complex, as one type may be dominant in some situations, but not in others.

Dörnyei and Ottó (1998) express the idea that motivation could be subject to change during the learning process. They introduce time as a factor in their model. The learner regularly adjusts her or his goals and strategies according to an ongoing evaluation. Noels *et al.* (2000) point to a strong correlation between instrumental motivation and external regulation (parallel to the extrinsic-intrinsic motivation paradigm). Travels, friendship, and knowledge are all involved, and important. Norton (2000) points to the complex relationship between identity, language learning, and setting, including socioeducational and socioeconomic factors as relevant to the development of the individual's motivation to learn a new language. Norton's introduction of the concept of social investment reflects the complex conditions that govern motivation.

Social Theory in SLA

With the sociolinguistic turn in SLA research, focus shifted from seeing language learning as the gradual development of a language system in individuals to a perspective on language learners as language users in real-life environments. Dominant cognitive theories were replaced by or supplemented with sociocultural theories focusing on actual language use. One characteristic aspect of learners' second-language use is the high level of variability in their interlanguage at any given time, that is, their use of different versions of the same language construction (e.g., marker of past tense in verbs). In the 1980s and early 1990s, results from a number of descriptive case studies on variability were analyzed in the SLA literature to discuss the theoretical concept of acquisition. Among others, Tarone (1988) and Ellis (1994) discussed how accurate the use of a linguistic form must be in order to say that the learner has acquired the basic rule. Another consequence of the rise of sociocultural theories in SLA research was a focus on the model of communication evoked in different approaches. Whereas the majority of cognitive studies as well as early sociolinguistic studies were based on a transmission model of communication, sociocultural studies assumed an interactionist perspective. Firth and Wagner (1997) argue that a dialogic view on language is a fundamental concept in modern SLA research, thus criticizing the traditional view on language as monologic in

nature. A third and partly related aspect of sociocultural theories is the focus on the social environment of language learning and on the interplay between language learners and their community. Based on Hymes (1972), an ethnographic approach to language learning implies seeing learning as socially and collaboratively constructed in interaction in different contexts or speech events. Different speech events provide learners with different opportunities for interaction, affordances (van Lier, 2000), as they draw on different communicative patterns and are governed by social hierarchies and power relations. In instructed second-language learning, there is typically an orientation toward target norms in the social context and in the dialog between student and teacher. However, recent studies show that other less-institutionalized kinds of interaction also develop as participants negotiate their social identity through individual style or group patterns (e.g., through new rituals, Rampton, 1999).

This has brought about discussions of the role of normativity in second-language learning, similar to the debate on socialization in child-language studies (e.g., Ochs, 1996). Insofar as language learning consists of picking up conversational routines or adjusting to specific norms of language use, both learner and child may be seen as apprentices moving from the periphery toward the center of a community through interaction with experts (Lave and Wenger, 1991). Although normativity is an important characteristic of instructed second-language learning, views on language learning as a uniform process of approaching predefined target norms have come under attack from poststructuralists who see learning as “a non-linear and relational human activity, co-constructed between humans and their environment, contingent upon their position in space and history, and a site of struggle for the control of social power and cultural memory” (Kramsch, 2002: 5). According to this sociocultural or ecological position, the sociolinguistics of second-language learning is not restricted to background variables which explain the speed and rate of success in the process of language learning. It is placed at the core of theories on the dynamics of language learning. Language is seen as part of the complex and dynamic processes of social membership, culture, and identity. Language learning is not only a matter of individual capability, but also of opportunities for interaction at the microsocial level and of power relations and linguistic norms at the macrosocial level. The role of social interaction is to provide supporting structures or scaffolding for individual competencies and thus to mediate language learning through communicative patterns and other semiotic tools (van Lier, 2000; Lantolff, 2000). At the macrosocial level, language proficiency is developed in social settings shaped by social structures and orders of discourse. Language development interacts with identity issues, such as the manifestation of agency in a negotiation of competing

subject positions in conflicting discourse communities (Canagarajah, 2004). Due to the increasing complexity of modern multilingual and multicultural societies, both learners and native speakers belong to several speech communities with a range of membership roles. Consequently, the idea of the native speaker is criticized for being a political rather than a theoretical concept. Kramsch (1998) replaces it with the concept of intercultural speaker and Dabelsteen and Jørgensen (2004) with the concept of the languager.

Interlanguage

Selinker (1972) introduced the term interlanguage to refer to the language produced by a learner, seen as a unique linguistic system different from the learner's L1 and from the target language, but using elements from both. The term describes learner language as systematic, and yet as dynamic and transitional. The gradually growing complexity of learner language is seen as a continuum of interlocking systems.

Since the 1980s, the term interlanguage has come to be used with different meanings: On the one hand, it refers to the mental grammar which the learner constructs while developing a second or foreign language. The learner's competence at any given time is hypothesized to be the guiding principle behind instances of language use. On the other hand, the term refers to the learner's actual language use in a social situation. The understanding is that learner language is a systematic variety of language (Færch *et al.*, 1984). According to both uses, deviations in learner language use are not seen as imperfect learning, but rather as signs of learning through hypothesis testing or as linguistic expressions of social identity.

Acquisition and Variation

SLA leads to variation in the L2 production of learners. Interlanguage is a highly variable phenomenon which changes with a range of factors, including oscillating precision, in reaching the target-language norms. In addition to this, SLA leads to variation which is sociolinguistically related in the way L1 variation is. Around 2000 minority groups of young second-language speakers of majority languages in the European cities developed styles which were marked as minority-related, but nevertheless also used by young majority members (Kotsinas, 2000). It remains to be seen whether these phenomena develop into ethnolects of the majority languages, or perhaps socially stigmatized urban varieties.

Variation in the production of learners may also involve loans and code switching. Contrary to conventional wisdom in traditional textbooks on language learning and language teaching, switching may be productive for the understanding between learners, or between learners and

native speakers (Arnfast and Jørgensen, 2003). The learner may achieve on several levels by code switching away from the L2 in an otherwise L2 conversation. Switching can be a strategy to maintain fluency, and therefore obtain at the level of social relations. It may also represent a learning strategy to expand the learner's knowledge of L2 – or the culture in which the L2 is being learned. In learner groups, perhaps, particularly school classes, the L2 may come to represent specific values (or stereotypes) which can be exploited in the everyday interaction among the learners (Rampton, 1999) in code switches into the L2 during otherwise L1 interaction. An intricate and complex pattern of code choice by young Londoners is described by Rampton (1995) as crossing which involves both English, Punjabi, Creole English, and other varieties. Crossing is characterized by the fact that the speakers do not necessarily know very much of the languages from which they borrow in their interactions. Similarly, Turkish-Danish students switch between a range of different languages, several of which have been taught to them, in what has been termed languaging (Dabelsteen and Jørgensen, 2004). Languaging is the use of linguistic items and features – regardless of where they belong – by human beings in order to achieve communicative goals.

Code switching and crossing are (as yet) controversial phenomena which are often discouraged by language instructors. There could be a future development in language-acquisition research which attempts to demonstrate to what extent learners can achieve by employing all the linguistic skills they have.

Age and SLA

The relationship between child SLA and adult SLA is a crucial problem in acquisition theory and empirical studies. Behaviorism formulated the critical-age hypothesis which states that language learning changes profoundly with the lateralization of the brain in adolescence, and the individual's ability to acquire new language deteriorates, and the acquisition of the mother tongue must be well under way before the age of 13, or the acquisition will never be complete (Lenneberg, 1967). This has also been applied to acquisition of a second language. The theory has been criticized, for one, because experiments have shown that adults acquire some aspects of language faster than children. On the other hand, the end result apparently is more native-like, the earlier a continuous acquisition has begun. A crucial review article is by Long (1990). Long concludes that the concept of a critical period is not irrelevant. However, it is not one specific period, but a continuum of maturation which affect different aspects of language at different times. He relates the maturational constraints to a physiological process, myelination, an

ongoing process which renders the nervous system less flexible, and which runs parallel with the automatization of linguistic features. The effect of age on language learning is a richly discussed issue (e.g., Singleton and Lengyel, 1995). Evidence for the critical-age hypothesis is found in studies which conclude that adults fail to acquire second-language features which are different from their L1 (e.g., Schachter, 1996). Evidence against the hypothesis is presented and reviewed by Bialystok (1997). Abrahamsson and Hyltenstam (2004) find evidence that neither young learners nor adult learners achieve complete native-like command of a second language, and like Long, they cite physiological reasons. Burgo (2006) reaches a similar conclusion. A different perspective of age-related differences has its focus on the identity work performed by learners when investing personal resources in acquiring a second language. The reactions of particularly adult learners range from rejection of, and isolation from, the second language and the cultures associated with it to completely embracing the language and cultures (Norton, 2000). Identities ascribed to learners, especially minority learners, by society at large may also affect the outcome of the learning process (McKay and Wong, 1996). Expectations as well as identities affect young learners and adult learners differently, and may affect motivations differently.

Second-Language Learning and Foreign-Language Learning

The distinction between foreign- and second-language learning is traditionally considered to be a matter of learning environment and the possibility to encounter, outside a formal learning setting, the language being learnt. The distinction between the two becomes clearer, when the who, how, what, and why are compared.

Foreign-language learning is generally directed to students, usually children or adolescents in primary and secondary school, who are taught the primary *lingua franca* of their country as a part of their general education. At a later stage within the educational system, foreign-language learning is either a goal in itself (e.g., Scandinavian philology in Asia) or a means to qualify other educational goals (e.g., studying German in order to read philosophers in the original language or to specialize in business school). In most countries, the number and selection of foreign languages offered in the educational system is determined by historical, political, cultural, and sociolinguistic factors. Outside the educational system, foreign-language learning is most often associated with adult education on a leisure-time basis, and rarely with special instruction for instrumental reasons. The second-language learner, on the other hand, is typically considered to be an immigrant (or in some

cases the children of immigrants), learning the language that plays an institutional and social role in the community (Ellis, 1994). Learning a second language may take place in formal settings (e.g., language courses) in the target country, or in the informal settings of the workplace, contact with authorities or social institutions, or other specific communities of practice. In this way, second-language learning takes place in a much more complex setting and under much more complex conditions than foreign-language learning. Since the 1990s, the distinction between formal and informal second-language learning tends to be regarded as a question of sociolinguistic setting. In this view, it is important to consider the interaction between the two settings, with an overlap between the two.

With the ongoing globalization of communication, it is no longer possible to regard foreign-language learning as an activity isolated from the community where the language in question is spoken as the primary means of communication. School classes communicate with other classes in twin towns, students seek out communities of interest on the Internet, and possibilities of traveling are expanding, just to mention a few. This promotes intrinsic motivation to improve specific linguistic and communicative skills in order to participate in social activity – real or virtual.

Second-Language Learning for School

In schools, language is not only taught, but also used in specific ways to transmit and reproduce relevant knowledge in relevant ways. This develops the specialized academic registers of school. At the same time, language is used to socialize children into (what counts as) competent citizens. Thus, language is both a means and an end to school activities. Language is also an instrument which links children's everyday experiences and cultural and family background with relevant school categories and learning practices, through recontextualization of their knowledge (Bernstein, 1990). Schools make use of a communicative code which draws on the social and thematic priorities that are given in the local context, and which overlaps only little with the functions of everyday language. For younger children, schools tend to link their language use with bodily activities, visual and sensory support, etc. to provide a physical basis for new concepts. For older children, the development of new conceptual categories is predominantly based on linguistic cues and explanations. Other kinds of problem solving, for example, math activities, also become gradually more dependent on the child's mastery of the relevant semiotic systems. The role of language is crucial in understanding why schooling in general is intellectually and socially difficult for children who do not master the communicative code of the school, and why the so-called fourth-year

slump (e.g., Thomas and Collier, 2001) marks the onset of a growing gap between high- and low-performing students. As a consequence, language plays an important role in counteracting children's problems with school.

For minority students, who attend school in their second language, the situation is often particularly difficult. It takes several years to achieve high proficiency in a new language across several domains (Cummins, 2001), and especially to develop the academic language suited for educational purposes. The learning situation of the minority children is often hampered by lack of response to their special linguistic needs. Many school systems are misled by a monolingual, common-sense view on language learning, which claims that it is a limited process shared by all learners regardless of their age, social, or linguistic background. According to this view, learning will eventually lead to the same outcome, whether it takes place before or after school starts. As a consequence, there is a political pressure toward preschool language learning in several industrialized countries. The logic behind this is the idea that an earlier introduction of the majority language leads to better results. This idea has been termed the fallacy of early start by Skutnabb-Kangas (2000). The idea draws on a simplistic, quantitative view on language learning. It is in line with another common fallacy – that so-called natural acquisition of language automatically develops into school language. According to this, children pick up everyday language through interaction in the playground and gradually transform this into the academic language of schools. Crawford (2000) among others has cautioned against the so-called sink-or-swim-method in which minority children are left to cope on their own with the intellectually and linguistically demanding learning of curriculum without instructional support. In this situation, efficient language learning may be hampered by gate keeping and silencing (Santa Ana, 2004). This may lead to social marginalization and – at a very practical level – to reduced opportunity of using the target language in situations that could have promoted learning.

The quantitative perspective is challenged by a view on language proficiency as a complex and dynamic combination of skills, knowledge, and reflexivity, relevant for both majority and minority children. In order to change the situation of educational underachievement in general, the role and norms of language must be made explicit in the classroom. Discourses must be established which may form the bridge between students' everyday language and prior knowledge on the one hand and their development of the academic school registers on the other (Gibbons, 2006). For minority children, this must include strategies to incorporate the actual multilingualism of the students' environment as part of their learning potential (Thomas and Collier, 2001).

Introduction

The history of teaching-of-writing approaches at advanced levels over the last 50 years or so can be characterized into two broad phases: the pre-computer phase, and the phase informed by reciprocal co-evolution with information and communication technologies.

The 1950s and 1960s saw an approach to writing which set high store by literary quality within a limited range of genres derived from nineteenth-century rhetorical categories. There was little emphasis on the processes of writing; more on the finished product and on a distanced, academic command of language types. Exercises deriving from the Renaissance and Elizabethan grammar school practice of *progymnasmata* (rhetorical models and imitation) were designed to build up competence. This period marked the high point in the teaching of formal grammar in the hope of improving writing quality and accuracy. It is against this background that much of the development in approaches to the teaching of writing at advanced levels can be gauged.

This article divides the main phases in the teaching and learning of writing at advanced levels into the decades from the 1960s to the 1980s; and from the 1980s to the present. Between these two phases, it looks at a number of different transitions that are critical to writing pedagogy.

1960s to 1980s

From the 1960s to the early 1980s there was more emphasis on expressiveness and the emergence of a personal voice in writing than in the previous decades. The foregrounding of the imaginative and creative (in a literary sense) continued, with a move away from tried and tested school genres toward experimentation. There was a celebration of self within societal contexts, best characterized by *Growth through English* (Dixon, 1967), the book emerging from the Dartmouth seminar of the International Federation for the Teaching of English in 1966. Two other key works in the late 1960s were Moffett's (1968/1987) *Teaching the Universe of Discourse*, and *Language, the Learner and the School* by Barnes *et al.* (1969/1989). The former charted the range of discourses that a student could expect to cover in formal education, with a clear indication that narrative modes and genres must come first, followed by expository and argumentative types of writing. This work,

therefore, sat very much in the rhetorical tradition, but marked a step forward from the conventional theorizing and practice of the 1950s, where theory was ignored or taken for granted and practice fell into well-trodden ways. As Moffett states (1987, vii), in reflecting on the first edition of his book "I wanted to recast into the psychological terms of human growth those familiar but opaque academic elements such as rhetoric, logic, grammar, and literary technique. . ." Perhaps the most salient aspects of Moffett's hypothesis is that language development takes a course from drama through narrative and exposition to argumentation. Although such a series – with the famous sentence that "whereas adults differentiate their thought into specialized kinds of discourse such as narrative, generalization and theory, children must for a long time make narrative do for all" (my italics) (1987: 49) – seems to suggest a Piagetian fixed sequence, Moffett suggests that the strands of discourse run through young people's development concurrently. The basis in dialog and drama still feels contemporary in the light of Vygotsky's theory of cognitive development and, for example, Alexander's (2006) notions of dialogic teaching.

Language, the Learner and the School was more seminal than Moffett's work, in that it took a fresh empirical look at practice in classrooms and found it wanting in a number of respects. First, speech in the classroom was seen to be teacher dominated, with little space for pupils or students to try out ideas or expound at length. Second, although there was a higher proportion of open questions in English as a secondary school subject than in other subjects, there were fewer questions that required reasoning than in mathematics or science lessons. Third, questions asked by teachers tended to seek factual rather than reasoned answers, thus downplaying the dialogic, negotiated potential of the curriculum for learning and knowledge building. The investigations recorded in the book suggest that a closer relationship between active pupils' talk and their writing would enhance performance in both modes of communication; nevertheless, there was not only a gap between teacher and pupil discourses, but also one between pupil talk and pupil writing. However, Barnes (1989: 72) notes that "though this paper focuses on spoken language, much of what I have said applies equally to written language." In many ways, the connection between talk and writing was made, bringing an expressive, thinking-through-writing, dialogic (and potentially dialectical) character to learning to write at advanced level. Such a connection is also made

in Britton (1967) and in the work of Dixon (op. cit.). The complex interdependency of speech and writing is also reflected, for example, in the work on Ong (1982/1988).

The period also marked the rise of narrative as a primary act of mind (Hardy, 1977) or even human paradigm (Fisher, 1989). Rosen (1985) continued his interest in narrative speech and writing with publications in the 1980s celebrating the power and ubiquity of narrative, not just for expressive writing in autobiography and storytelling, but also in transactional, nonfictional kinds of writing. The interest in the oddly negative nonfiction category was captured in Pavel's (1986) *Fictional Worlds*, which brilliantly charted the position of fiction in relation to other forms of writing, reading, and cultural engagement. In many ways, this period marked the beginning of the breakaway from the personal growth model of English which emphasized creative and imaginative fictional and poetic expression to a broader conception of the subject which celebrated a wider range of genres and text types, not without their own kinds of creativity, expression, and imagination (as had already been presaged by Moffett, 1968/1987).

An interest in genres and their place in the teaching of advanced writing increased in the second half of the 1980s, following the publication of Miller's (1984) article, 'Genre as social action'. The notion of genres and their importance to writing curricula and pedagogies derived from film studies and from sociological theory. Essentially, Miller's conception of genre was influential because it saw genres as constituted in social action rather than in text types. The spectrum of possibilities between the social, contextual view of genre and its more narrow textual (formal properties of texts) version has defined the debate and practices in the field, not least because it is at advanced stages in learning to write that the social and textual differentiation between kinds of writing manifests itself. On the one hand, the social, contextual view is represented in writing by Kress (1982/1994), Freedman and Medway (1994); the more linguistically focused view finds expression in the Sydney School of Australian Halliday-derived genre theory and practice, as evidenced in the work of Martin (1991), Christie (1987) and others. Excellent surveys of the field and of the contribution of genre theory to the development of writing abilities are found in Reid (1987) and Cope and Kalantzis (1993). The influence of such theory on curriculum design is felt in many countries.

A greater understanding of writing processes in expert writers that can be modeled in novice writers emerged in the 1980s to early 2000s, deriving from the work of psycholinguistic and discourse modeling by Graves (1983) and Scardamalia and Bereiter (1987). The understanding and mapping of process was reified into a formal system for teaching writing (Calkins, 1986), and creating an abreaction

(e.g. Harwayne, 2001) among those who believed it to be fossilized. The emphasis of this movement to celebrate and teach process was on drafting, editing, and peer conferencing (aided by use of word processing), aiming all the time to capture the voice in writing. Sometimes this movement was linked to or ran alongside a widening of the range of written (and spoken) forms – a development that in itself was reacting against the preponderance of a single, unified narrative/expressive mode and by taking such a wider perspective was aiming to prepare young writers for the world. Such widening of the range of discourse manifested itself in the later versions of the National Curriculum (UK) and in the Australian (specifically, the Sydney School, e.g., Christie, 2002) celebration (and calibration) of a range of genres in writing.

Transitions

There are at least three types of transition in writing at advanced levels that need to be mentioned:

1. one is concerned with the transition from literary or inward-looking textual composition to real-world discourses;
2. another is between imaginative, informational, and an often-neglected argumentative mode of writing; and
3. a third concerns the transition from primary/elementary schooling to secondary/high school, and again from school to college.

The first transition that gets too little attention is that between the classroom and the real world. Although Britton *et al.* (1975) made the distinction between poetic and transactional writing – the latter doing the work of the world and thus giving status to it – much of the writing that was practiced under that heading was informational and/or factual rather than making a difference in the world. In other words, it was inert rather than transactional. Indeed, writing curricula is often divided into creative and imaginative types of writing on the one hand, and informational and instructional writing on the other, suggesting not only that these are the two main types of writing, but also that they are somehow opposed. There are two exceptions to such reductive categorization: writing that made a difference in the world, and argumentative writing; both of which, from time to time, are temporarily given higher profile in writing curricula.

Writing that makes a difference in the world was the subject of an under-published report by Brown *et al.* (1990) which looked to develop English for the UK's Technical and Vocational Education Initiative (TVEI). The key change made to writing practices in this project was that the contexts and audiences for the writing reached beyond the classroom. For example, in one subproject, pupils were

commissioned by the school librarian to survey and make recommendations to her on the journals and magazines to which the library subscribed. A 65-page report, compiled and written over 6 weeks by a group of pupils, was delivered and made a significant difference not only to the library subscriptions, but also to the number of pupils reading in the library. The composition of the report was complex and highly motivating; the accuracy was enhanced by the need for public presentation.

Work on the place of argumentative writing in the curriculum was undertaken by Andrews (1995) and Mitchell (2000), suggesting that at secondary school and at further and higher education levels, the emphasis on the formal essay was not only in need of better teaching, but could be reinvigorated and diversified by exploration of the dialogic and dialectic nature of argumentation as well. To see the basis of learning to write at advanced levels as being in dialog suggests also the close and complex connection between writing and speech. Ong's exploration of orality and of oral cultures on the one hand, and Bakhtin's notion of a dialogic imagination (Bakhtin, 1982) on the other (composed in the 1930s, but published in the West in the 1970s and early 1980s) bring a new dynamic to the learning of and teaching of writing at advanced levels. Essentially, Ong's study of the shift from oral to chirographic (writing) cultures is both historical and synchronic. He sees writing cultures returning to a second orality in which dialogic forms are preferred, and short interchanges in writing (akin to speech) become prevalent. Bakhtin's notion that all writing is created in response to some existing discourse is helpful in that it makes writing appear to be more of a cultural exchange, and more like speaking, than is usually assumed.

The transitions from primary/elementary schooling to secondary/high schools, and/or through the middle school phase constitute a particular concern for the learning and teaching of writing.

Tabor (2004) sets out the particular problems in the teaching of writing in the transition from age 11 to 12 in the English system. In a doctoral study based on the progression of four pupils, he suggests that despite efforts made to ease transition by schools and by curriculum design and implementation (e.g., the National Literacy Strategy in England, followed by the Primary and Secondary National Strategies – with their particular focus on literacy development for 11–14-year-olds), there remains a dip in performance in writing at the start of secondary schooling. Such a dip would not be of concern if the progress of pupils was recovered, but some students do not make a recovery. The problem is part of a larger issue of progression in writing at advanced levels. Tabor (2004: 18–21) provides a very useful table on conceptualizing progression in writing, drawing on many of the key works mentioned in the present account and adding others. What is particularly interesting is that few, if any, of the theories or models of writing account for progression.

1990s to the Present

The period from the mid-1990s to the present has seen a tension between the functions of writing in wider society and those in schooling and assessment. The place of writing within multimodal communication, and especially recognition of its relation with the visual (still and moving images) in popular and indeed all culture(s) has begun to be explored, inspired by writers such as Lanham (1993) or Mitchell (1986). Lanham suggested that the “turn to the visual” in the 1990s, supposedly inspired by the visual/verbal interface of computer screens, was not new but was a phenomenon that had been a preoccupation for cultural analysts since at least the medieval period (through illuminated manuscripts and textual commentaries on iconic images). Mitchell took the idea further, exploring the spectrum of means of representation from image through icon to (written) text, linking the range of media to narrative. Although both writers operate at a high level of theory, their work has been instrumental in helping us to understand the relationship between word and image, and thus the particular characteristic and functions of writing, in late twentieth-/early twenty-first-century practice both within and without the classroom.

Writing processes moved from an understanding and practice of drafting and editing to design issues (Kress, 1995). A move away from the notion of a single personal voice to a multiplicity of voices was registered; and, indeed, through the improved quality of sound on computers (not quite up to general speech recognition and instant translation-into-writing quality). The advent of the mobile learner (see Sharples *et al.*, 2007), accessing written, visual, and audio material anytime, at anyplace, brought about an extension of academic and social space, especially for 11–16-year-olds. Writing began to be conceived as text-box filling, but not always briefly; there was much scope for extended writing, both of an in-depth and functional nature. The need for keyboarding skills became apparent as writing increasingly took place through word processing. One of the key papers of this period was by the New London Group (1996/2000): ‘A pedagogy of multiliteracies: Designing social futures’. This paper put the teaching and learning of writing within a multimodal conception of literacy; and furthermore, within changing social and economic patterns in personal, working lives and with regard to citizenship. It thus would see writing as embedded within school cultures (what Sheeran and Barnes (1991) call school writing), but as critically needing to reflect wider social practices and patterns or representation in order to stay relevant and engaging for advanced writers. The pedagogic problem of engineering such a productive relationship is seen to be a question of design: designs of meaning and the available designs of the grammars of various semiotic systems, providing the basis for the act of designing and redesigning.

In school practice, learning to write is often a matter of taking material from one genre (used in the social process sense) and redesigning it for another. The pedagogy of multiliteracies approach extends this conception in two ways: into the visual and other semiotic codes in hybrid combinations with the verbal spoken and written codes (often foregrounded or highlighted by information and communication technologies); and by looking for more interaction between the practices of school life and social/political practices beyond the classroom.

The major challenge posed by the place of writing in a universe of discourse, and the pedagogies associated with it, is shaping a writing curriculum for 11–19-year-olds that would:

1. Recognize the place of writing within multimodality.
2. Reengage and motivate disaffected or unengaged young people by:
 - a. bringing the genres of schooling closer to the genres of the wider social world, and
 - b. giving writing a range of real purposes.
3. At the same time, use the power of writing to explore depth in thought, reflection, and feeling.
4. Recognize the place of creativity and imagination in nonliterary forms of writing, as well as in literary forms;
5. Recognize and exploit the fact that writing and reading are reciprocal – investigate the similarities and differences, strengths and weaknesses of speaking and writing in different contexts and for different functions – and thus reestablish the link between speaking and writing.

The last point needs further exploration. Speaking and writing are primarily skills of language production, whereas listening and reading are primarily skills of reception.

Speaking and writing can be demanding in that they require expression, articulation, framing, and shaping. To explicate these terms briefly: expression requires motivation to speak or write and the intellectual and motor facility to do so; articulation requires clarity of intention and thought, or at least a move toward such clarity; framing requires selections from the repertoire of socially embedded and generated speech genres and text types (sometimes these genres are hybrid or newly created); and shaping requires the manipulation of language within the those frames of reference, often at the point of utterance. Expression and articulation are part and parcel of the current curriculum but both need to be reemphasized; framing derives from sociological and discourse theory (see, e.g., Tannen, 1993) as a way of making sense of the demands of meaning-making at text level; shaping derives from Britton's notion of shaping at the point of utterance (Britton, 1980), that is, giving credit to the fact that much oral and written communication is not preplanned, but is shaped at it happens.

Expression is important because it engages the self or personae and releases what may be felt and/or thought. It affords channels of communication and creates contact with others.

Articulation aims to make such communication clear. In speech terms, articulation is associated perhaps most readily with surface features such as clear enunciation of utterances; more importantly, the notion of articulation (joining) is about logical or a-logical connections between ideas, thoughts, feelings, and language, in speech and/or writing. Andrews *et al.* (2006b), in a systematic review of research on the teaching of argumentative writing at KS2 and 3, draw attention to the need for cognitive as well as linguistic work in improving writing in this mode. The findings of this report are mirrored in a recent report by the US-based Alliance for Excellent Education – see Graham and Perin (2006) – which, based on a meta-analysis of research studies, concludes there are 11 strategies for improving writing in middle and high schools, including writing strategies, summarizing, collaborative writing, specific product goals (audiences), word processing, sentence combining (cf. grammar review by Andrews *et al.*, 2006a), prewriting (planning), inquiry activities (research), and a process writing approach.

With framing and shaping, the emphasis needs to move from a focus on the end products – the frames (pedagogic scaffolds, genres, text types, and forms) and shapes that language uses and that need to be learned – to the act of framing and shaping that is at the heart of composition (literally, putting things together). Such a move will entail thinking more deeply about the early stages of composition: how ideas are formed; how they are framed; how inspirational ideas are supported by a climate for learning and development; how choices are made, early on, about the medium or media in which it is best to convey the message; how drafting and editing can be improved by critical dialog and reflection at the deeper levels of composition (structure, voice, position, and tone); how momentum and interest can be sustained; how speaking, reading, and listening can contribute to the composing process in writing; how issues of design, balance, and elegance (when is a piece finished?) can be taught and learned; and how a community of learners (speakers/writers/makers) can support such committed and high-quality composing.

One possible reason for the fact that writing performance lags behind reading for the most part is that when listening or reading, the material is given. The intellectual load on the audience or reader might be said to be lighter than when composing in speech or writing, although that load will vary with content and substance in each case. It is generally accepted that writing is the most difficult, if not the most complex, of the four language skills, requiring solitary, creative, thoughtful, accurate, and focused compositional energy; as well as a higher degree of reflective thinking and (usually) personal engagement.

Much has been done, for example, to introduce pupils to nonfiction text types, and to improve their control of stylistic features associated with them. Where practice is weaker is in generating the motivation and purpose to write; without such direction, pupils know how to write but not why they write, how to start or how to engage an audience, and how to generate and marshal ideas. Producing writing of such quality, along with other text types, is one of the keys to overall improvement in English.

It worth reciting how speaking and writing can support each other at advanced levels. First, speaking can be an important rehearsal for writing. Ideas can be discussed in pairs, small groups, in whole-class discussion, and in larger forums, then distilled, translated, and developed in writing. Such writing can be dialogic as well as monologic. Dialogic writing includes planning for Socratic dialog (question-and-answer format), colloquia, play scripts, and other dual- and multi-voiced text types. Monologic writing includes the more conventional forms such as essay, story, letter, and report, where translation from the multiple voices of speech to the single authorial voice of the writer can be more difficult.

Second, writing can be a rehearsal for speech. Individual and/or joint composition in writing can prefigure delivery in speech, as in the making of a speech, the production of an oral narrative, the composition of a persuasive case, or the scripting of a (radio) play or advertisement. Speech as a product in these cases is more than mere performance: it is part of a dialog that invites response in spoken, written, and other formats. It is in such transformation between different means of communication and different genres within those means that the day-to-day practice of English in classrooms takes place.

The problem of insufficient space for sustained speaking and writing in school curricula is compounded by assessment practices.

What is clear is that speaking and writing are central to learning in formal education because they afford the learner the ability to reflect, think, compose, and rearrange as well as respond spontaneously (particularly in the case of speech). Furthermore, as Meek (1983) proves, such emphasis on the productive language skills can be the key to improvements and even breakthroughs for weaker learners not only in speaking and writing themselves, but also in reading and listening as a result of increased motivation, commitment, and investment in making meaning in language; and increased awareness and exploitation of the reciprocity between writing/reading, and speaking/listening.

A further phase of development in writing practices, yet to arrive, will probably see advances in speech-recognition technology that might or might not obviate the need for keyboards or writing implements. The emphasis on composing written text (expression, articulation, framing, and shaping) will shift toward oral composition, while not

abandoning writing. There will be a renewed dynamic relationship between speaking and writing, with each finding their roles in a new economy of communication.

Conclusion

Writing pedagogy is in need of reform to keep up with developments in the digital age and with multimodal perspectives. In particular, there has been little research on writing development at advanced levels. There is no doubt that writing will continue to be an important mode and medium of communication in the twenty-first century. What is a matter of concern is that teachers of writing are not necessarily equipped themselves as writers at advanced levels in a wide range of genres; they thus find the teaching of writing more difficult than that of reading. This article has indicated the range of skills and capabilities required to be a competent and inspiring teacher of writing.

Glossary

Hidden curriculum – The knowledge and understandings that students learn in school that are not part of the official syllabus curriculum, and not intentional. For example, if textbooks consistently show men in positions of authority and women in subordinate roles (or if principals are always men and infant teachers always women) this is seen as shaping girls' and boys' expectations of their pathways in and beyond school.

Social construction/social constructionist – A description of how identities are shaped and formed by social factors, such as language, roles, traditions, expectations, and the like. It is contrasted with views that see identity as solely the result of fixed biological or natural impulses and orientations.

Voice, women's voice – In educational research, voice refers to the expression of someone's identity, as communicated in many ways, not only in speech. Women's voice conveys a sense of women's distinct qualities, orientations, and differences, such as preferring humanistic rather than abstract orientations to problems.

One of the most prominent developments in educational thinking in the last three to four decades has been the rise of gender as a central issue for learning and curriculum, and for education more broadly. This reflects a world where equality between women and men is a formal expectation for education systems and where there is a good deal of monitoring and research on patterns of educational participation and achievement by gender. The attention to gender in research and policy on learning also reflects some significant changes that began in the second-half of the twentieth century, with researchers moving away from simply accepting sex differences as an explanation for different patterns to focusing in much more detail on the

ways teaching practices and school arrangements interact with the characteristics and experiences girls and boys bring to learning. In this work, learning (and teaching) is understood as shaping gender as well as the converse.

A large array of different kinds of research and policy-making has been carried out on gender and learning. It can now be found in most disciplines (or foundations) that study education, in many areas of school curriculum subject-specific study, and in many different kinds of research: longitudinal, qualitative, quasi-experimental, and action-research projects as well as in large-scale data monitoring. Research on gender and school learning also encompasses a broad range of topics, including attitudes to subject areas and subject choice; the effect of the portrayal of males and females in text books; the influence of teacher and classroom language; effects of male and female teachers and role models and of different teaching methods and class arrangements; the impact of peer culture; cognitive style; assessment methods and their effects; and patterns of achievement in cohort or end-of-school examinations as well as in curriculum areas. The last four decades have seen some significant shifts of interest across the field of gender and learning: moving from debunking deficit assumptions of sex differences in the 1970s, through a broad concern with girl-friendly and inclusive approaches in the 1980s, to a new kind of concern with boys' learning in the 1990s.

The article begins with a snapshot of shifts in thinking about gender and learning and a brief comment on terms and concepts. This provides background to a mapping of key themes and dilemmas addressed in research on gender and learning, particularly following the influence of feminist and equal-opportunity reforms in many education systems from the 1970s onward.

Gender Compared to Sex Differences

The term gender itself is used in a variety of ways, and has been the subject of much debate. In general, the term gender

signals an attention to the socially formed nature of male and female identities, relationships, and orientations rather than seeing these as simply inherent or biological differences. This contrasts with earlier uses of the term sex to denote differences between males and females, which often assumed such differences to be a fixed, empirical, and innate phenomenon. From the late 1970s, gender began to replace sex as the preferred descriptor of male/female identity differences, and this is seen in a shift from a focus on sex differences in learning to a focus on gender and learning.

In the sex-differences mode, researchers tended to assume that the category of sex was stable, and research was concerned to investigate its effects. In the gender-research approach, research was looking to investigate how patterns of differentiation were produced, and, in the case of learning, how practices could be changed to produce more equal outcomes. With this latter approach, learning is viewed as an outcome of the social experiences in and out of schools to which young people are exposed. Gender was differentiated from biological sex, and was used to describe differences in what students liked and did not like, what skills and knowledge they found easy and what they found difficult. If girls did not progress as well in science, for example, the explanation might be found in their preschool play with dolls rather than mechanical objects; similarly, boys' weaker literacy skills were attributed to less-early-years involvement in group and language-based play. Or it might be the result of in-school social influences, such as particular types of teaching and assessment practices that are discussed below.

Initially, in many public and policy contexts, gender was regarded as a term denoting a rather radical perspective, a code for feminist approach. Sex remained the preferred, more familiar term. However, this view of the terms has shifted markedly in the last three decades in the English-speaking world. Many official sources now label their formal policy and data categories as gender rather than sex. Simultaneously, as research on gender has continued to develop, much of it no longer takes such a strong social-constructionist position about the desires and orientations girls and boys develop in the preschool years and beyond. A range of different research traditions, from brain researchers to cultural studies practitioners, now understand human differences and developments as arising out of interactions between biological and social. On the one hand, biology and drives are seen as producing some predispositions in individuals and, on the other, social, educational, and familial environments are seen as driving how and whether these dispositions are developed (including biologically) or turned into behaviors, preferences, and outcomes. Individuals are not seen as a *tabula rasa* upon which social messages are neatly inscribed. Nevertheless, the social environment is seen as a key formative shaper of individual identities and learning outcomes because of the way it interacts with and develops inherent biological character-

istics. The implication for school learning remains one that emphasizes social arrangements, in and out of school. To see gender as an important element in how learning takes place and in what learning occurs, requires attention to experiences and values developed and conveyed in families and the broader society, as well as attention to what is said and conveyed in a classroom.

In summary, since the late 1970s, there has been an explosion of research on the social construction of gender and an accompanying recognition of the importance of gender in relation to learning. This, in turn, has contributed to changes in conceptions of learning that have expanded beyond models or measures of individual cognition to include a strong focus on the sociocultural processes and contexts shaping learning. This research on learning also shows the influence of ideas coming from the new sociology of education, particularly notions such as the hidden curriculum, which drew attention to the powerful knowledge and know-how that was not part of the official syllabus and classroom program but which was a vital part of students' overall learning.

An additional point to emphasize here is that research on gender and learning is not only concerned with how gender influences learning, but also with how school learning influences gender. This is both in terms of individuals' developing sense of who they are, and what potential they have (or lack), and in terms of broader patterns of outcomes for men and women in the world. A further point is that although the definition of terms offered here explains some broad differences in how sex-differences research and gender-and-learning research have been oriented, the use of these terms is not invariable or mutually exclusive. A lot of sex-differences research still continues, and large-scale national and international testing, such as the Organization for Economic Cooperation and Development (OECD)'s Programme of International Student Assessment (PISA), continues to routinely monitor differences by sex or gender, as well as by the intersection of such differences with other social variables, such as level of parental education, country of birth, and numerous proxies for socioeconomic status.

Shifts in Focus of Work on Gender and Learning

Gender and learning became an issue for education as much because of social developments and new expectations regarding the roles of women and girls outside education research fields, as from developments within these fields. For example, the tendency for girls not to continue with mathematics and science and to do less well in some subjects had been known for some time, but to some extent was taken simply as natural. It was when different expectations about women's social outcomes

were raised from the 1970s onward that researchers began to give serious attention to whether such outcomes were, in part at least, the result of how schools and teaching were organized, and that these arrangements and practices could be changed.

Initially, in its translation into school policies and practices, gender was predominantly addressed as an issue that affected girls (Yates, 1998), and in reality much discussion and policy was directed to girls rather than to gender or gender relations. The new problem was understood to be why are girls not doing as well as boys? The challenge was to expose and critique what had been taken for granted as the normal state of affairs, and to show that differences in learning expectations, opportunities, and outcomes that systematically disadvantaged one gender group were unacceptable.

Research on gender and learning initially took two main forms: exposing flaws in previous research that had seemed to prove the innate inferiority of girls compared with boys, and identifying practices in schools where girls might be given different opportunities and messages than boys (AAUW, 1992). Before the 1970s, for example, it was common for the higher achievement and retention of boys in mathematics compared with girls to be attributed to innate differences, in particular to differences in spatial cognition, with boys on average judged to be naturally more adept at this than girls. A wave of influential feminist-based research in the following decade systematically reexamined this earlier work, exposing flaws in its design and arguments and encouraging greater participation of girls in traditionally male learning domains (e.g., Kelly, 1981; Fennema and Leder, 1990; Friedman, 1995). Research on the different ways schools conveyed implicitly different messages to girls about their potential included work on language and images in textbooks and work on teachers' different kinds of interactions with male and female students, as well as peer interactions.

One example of such research investigated how children responded to teacher feedback and found this shaped the learning and sense of competence of both girls and boys. Wood (1998) reported that while boys often received negative feedback from mathematics teachers, this was usually directed at their lack of attentiveness rather than their mathematical ability. When boys received positive feedback, it was likely to be in terms of their intellectual competence. In contrast, while girls tended not to receive a lot of negative feedback, any such responses were likely to be directed to their lack of ability. Thus "for boys criticism is common . . . and it does not reflect upon their competence. . . . Because negative feedback is rare for girls, when a girl does receive it, it forms a notable event and is likely to convey the idea, to herself and her peers, that she is not very good at the subject" (Wood, 1998: 287).

Another influential body of work examined the hidden or implicit but powerful expectations teachers held about

what kind of students were the right kind of learners. Valerie Walkerdine's studies of early childhood and primary-school classrooms showed some of the complex and subtle ways in which teachers' beliefs about what good learning looked like were gendered, with boys typically regarded as potentially more disruptive in the classroom but also more risk taking and independent as learners, and girls as more cooperative and diligent but less likely to be exceptional or brilliant students (Walkerdine, 1989). Walkerdine argued that conceptions of learning and cognitive development were themselves deeply gendered and that the ideal rational learner was implicitly masculine.

In other work, a wave of interest in women's ways of knowing or women's voice sought to identify specific qualities in women and girls' learning and to devise pedagogies and forms of curriculum that would promote the realization of these qualities. The work of Carol Gilligan was particularly influential. Gilligan's (1982) revisionist account of Kohlberg's framework of moral reasoning argued that hierarchies of intellectual development had been founded on male styles of reasoning, particularly valuing abstraction and judgment. She laid out ways in which connectedness, or reasoning that included attention to human effects, can be seen not simply as a lower stage of the first hierarchy, but as a different hierarchy altogether with similar stages of complexity. The well-known American study, *Women's Ways of Knowing* (Belenky *et al.*, 1986), influenced by Gilligan's work, argued that women had been silenced by traditional educational processes and that they were more likely to find their own voice and develop as learners when the learning is connected. This occurs when learning is connected to first-hand experience, values question posing, learning in context, and relative, context-specific truth. Such an orientation is contrasted to traditional masculine ways of learning that value objectivity, abstraction, and general principles. Considerable debate and further research followed from these attempts to identify female and male learning style, particularly in terms of whether these paid sufficient attention to differences within the category of girls, especially in relation to race and social-class differences.

By the mid-1990s, a new focus of gender research and policymaking began to emerge – the issue of boys and their learning preferences and needs (Weaver-Hightower, 2003). In part, this was motivated by concern about boys who were dropping out of school, and in part by a perception that there had been a lot of reform attention given to girls but little to boys. Some of this work took a similar form to the earlier gender-based research on girls, focusing on the disadvantaging effects of teaching methods. In the case of boys, targets included the growing need for higher levels of language skills in all subjects, and assessment practices – essay-based compared with short-answer testing – and how these interacted with patterns of achievement for boys (Epstein *et al.*, 1998). Other research tended more toward

a sex-differences approach, in emphasizing the strength of different innate drives, and questioning how well schools dealt with these. Within the boy turn in research on gender, there are some sharp disagreements about directions for boys and recommended school practices. But all the research broadly falls within a focus on gender as defined earlier in this article, because it all pays some attention to the interaction between social arrangements inside and outside schools, and the ways these produce orientations and outcomes in relation to schooling for a particular group.

The research on boys and learning is often crudely divided into pro- and anti-feminist work. Pro-feminist work rejects the idea that boys rather than girls are disadvantaged by school practices, and sees the need for attention to both. It sees its approach as building on the earlier work on girls and gender, and often focuses on the way gender (learned ways of being masculine) disadvantages boys' learning and needs to be changed. Anti-feminist approaches tend to argue that boys have replaced girls as the new disadvantaged group, and to see boys' gendered preferences as a given with which schools should work, rather than as socially constructed or sometimes detrimental. Weaver-Hightower (2003) provides a good overview of the different lines of work in this area.

Gender-Equity Reforms and Reviews

During the 1990s, after about two decades of deliberate gender-equity reform, many national governments and international agencies commissioned major studies of gender and school participation and performance (e.g., Arnot *et al.*, 1999). While there were national differences, one overwhelming finding from much of this overview research was that girls' participation and retention had increased, and that in many subject areas the average girl was performing at a higher level than the average boy. At the same time, this research drew attention to the question of who actually was the average girl or boy, and what factors other than gender were influencing school learning and educational outcomes. For example, although there were some average differences in outcomes between girls as a group and boys as a group, these were usually smaller differences than differences within the category of girls or within the category of boys, particularly in relation to socioeconomic status or social class. As noted above, the OECD's PISA continues to produce its own comparative data on these issues, showing some of the relative effects of different variables on school achievement.

The various national reviews of the effects of large-scale policy attention to gender in schooling have shown that changes in school teaching and assessment practices do produce different patterns of outcomes in relation to gender. That is, they have confirmed the understanding that changes in education practices – school teaching, learning, and assessment – are able to influence patterns

of outcomes by gender. This, in turn, raises some questions that are at issue in contemporary debates about boys. Should the mandate of schooling be to produce identical patterns of outcomes for girls and boys (e.g., regardless of how hard they work)? Should teachers and teaching approaches proceed on the assumption of gender-based differences in learning preferences and styles? Should there be common or differentiated expectations of learning? How far should forms of assessment be modified to produce gender-neutral outcomes?

For example, it is generally agreed that on average boys and girls develop at different rates in the early and primary years (for discussion of this issue see MacNaughton, 2003), but the degree to which school-starting age and national age-based or year-based testing should take account of that continues to be in some dispute in different policy settings. Similarly, a range of studies have found that boys are overrepresented in both remedial and gifted streams, where these exist, and in named learning difficulties categories, such as attention-deficit disorder, but there is debate on the extent to which social practices and assumptions in relation to gender produce such results and need to be changed.

Single Sex and Coeducation and Learning

The heightened interest in learning and achievement patterns by gender, and the recognition that school and classroom arrangements are important, has produced a continuing interest in the impact of single sex compared with coeducational arrangements. A very large number of studies have been conducted on this topic and it continues to prompt considerable scholarly, policy, and community attention (Salomone, 2003). The topic itself is an interesting case of the multifaceted way in which gender and learning come together, since whether or not a school or a classroom is girls-only or boys-only is only one of a number of important elements of the gender and learning environment, which includes the school culture overall, curriculum choices and supports, the expectations of teachers, and the expectations of students themselves and their parents. It is not surprising, then, that empirical data comparing the results of single sex and coeducation have often not been consistent between different studies or over time. However, they do show small overall indications that, controlling for other aspects of school-intake difference, single-sex groupings may have a slightly beneficial effect on girls' achievement and self-esteem and on their likelihood of choosing masculine subjects; and, further, that coeducational groupings may have a slightly positive effect on boys' achievement.

However, overall patterns here are of less significance than how particular arrangements may affect specific groups of girls or boys, or particular purposes. Some single-sex

arrangements have been put in place almost as a form of action research. These include a range of experimentation with single-sex classes to encourage greater participation in certain subject areas, such as single-sex classes for girls in for mathematics in the middle years; as well as attempts to establish small alternative single-sex schools for students who are at risk, especially boys.

Gender in Interaction with Other Factors

Much research has taken place on gendered preferences and achievement in different school subjects. Such research often attends to the ways in which particular subjects themselves have gendered identities (e.g., mathematics as male, English as female) that produce different patterns of take-up and achievement. But gender is not a single or simple phenomenon, and patterns of take-up are strongly influenced by socioeconomic and ethnic backgrounds of students as well as by expectations and practices of different kinds of schools. How gender intersects with social-class background leads to well-documented differences in patterns of achievement. Based on achievement data, it would appear that the higher their socioeconomic status, the fewer disadvantages girls experience in mathematics and science and the fewer disadvantages boys experience in English. Gender relativities in learning outcomes are thus weakest – but not absent – among those with the greatest material and cultural advantages (Teese and Polesel, 2003).

Current and Emerging Issues

The kinds of monitoring and comparisons involving gender are now well established in most national systems (at least those covered by the OECD) and are likely to continue. If obvious disparities are evident, these generate a new wave of research attention to that subject area, or to parts of the education system. In recent years, for example, new technologies and particularly the more widespread use of computers have been a significant issue for learning in schools and for work opportunities beyond schools. This has produced a strong focus on gendered take-up and preferences within this work, often mirroring the kinds of work that took place earlier in relation to mathematics and science, including attention to role models, the way the subject is portrayed culturally, and in schools, peer attitudes, and assessment practices.

Within broader policy directions, the increasing emphasis on international benchmarking, school effectiveness, and more intense testing commonly includes gender as a basic category for comparison, yet often works to downplay the range of the social and identity factors that students bring into classrooms. Its emphasis tends to be on effective techniques for teaching or

managing school systems, rather than social interactions within schooling and the classroom.

In terms of a global perspective, a lot of work on gender has focused on issues of access to schooling or to levels and programs within schooling systems. This research has received new impetus with the UN Millennium Development Goals, which included a target of eliminating gender disparity in primary and secondary education, preferably by 2005, and to all levels of education no later than 2015. The goals and targets here give continued attention to the ongoing strong interaction between schooling and social expectations and practices around gender. Two areas that are subject to renewed attention as part of this work are also areas of heightened concern in developed countries: bullying and sexual harassment as a hidden component of school learning; and the legitimacy or illegitimacy of promoting gender-differentiated expectations via the curriculum, including religious framing of education.

A focus on gender and learning has produced some ongoing attention to differences in what students bring to schooling as part of the learning environment, and some changing expectations of the responsibilities of schooling to acknowledge, support, or attempt to modify these. It has also produced a continuing attention to patterns of subject choice, retention, and success and failure in schooling as something that are not simply a given or produced by what students bring to the task, but in part at least an effect of what schools and teachers do, an effect of how learning environments operate for different kinds of students. The framing of research on gender and learning also reflects political differences in the questions and assumptions researchers bring to education and its relation to broader social forms, as well as changing social expectations about standards and outcomes for education for both women and men in the twenty-first century.

Parent–Child Relationships in Early Learning

Glossary

Autonomy – The developmental achievement of the capacity to take care of one's own basic needs (e.g., feeding and dressing oneself, or toileting oneself); functioning in an age-appropriate way in one's usual settings (e.g., sitting at the dinner table or playing with peers at preschool); and exhibiting emotional self-regulation (e.g., controlling anger and distress or using cultural-display rules in expressing one's needs and feelings). Autonomy is always interpreted within a context defined by age, culture, and gender rules and involves interdependence as well as independence.

Curriculum of the home – The interactions and environment for child learning provided by parents and other family members. Parents provide for their young child's general learning both at home and outside the home in many direct and indirect ways, as apparent in their daily routines, strategies for teaching, disciplining, and scheduling children's lives. Some of this behavior and provision by parents is conscious and intentional, but much of it takes place without conscious planning and intent and is part of the implicit culture.

Nurturance – The behavior intended to promote the health, learning, or development of another person, through offering attention, approval, instrumental help, food, material goods, permission to proceed, or other kinds of emotional or physical resources.

Parent engagement – The nurturing behavior by children's primary caregivers (usually mothers or fathers, but sometimes guardians) intended to promote their survival and pass on skills important to their present and future success in their society. Parental engagement can be expressed in many styles and may focus on physical, emotional, and/or cognitive aspects of children's learning, development, and well-being.

Parental behavior during a child's first 5 years of life is critical for the development of important social and cognitive outcomes in children. The child's first relationships, it is now clear, are critical for the establishment of competences – cognitive, social–emotional, and self-regulatory skills – that set the stage for lifelong adaptation and functioning. The interactions and experiences that

children have in the home and family setting provide a framework for how the child will interpret his or her world and give meaning to culturally framed events. Even the degree to which children are prepared to benefit from later schooling is predicated in part on what transpires before they enter the school door. This article reviews some of the key findings about the importance of parent–child relationships in early learning. The term, parent, will refer to the primary parenting figure in a child's life; it may refer to the child's guardian or even to a small number of attachment figures who closely share parenting duties.

Parental behavior consists of an almost infinite variety of specific actions that unfold over time as the child develops, but in our work we have found it useful to summarize three key dimensions of parental behavior that we call parent engagement (Sheridan *et al.*, in press). These three dimensions appear to facilitate child learning and develop in conceptually distinct and practically important ways that are described. The dimensions of parent engagement include: (1) warmth and sensitivity, (2) support for a child's emerging autonomy, and (3) active participation in learning. All three dimensions influence the developmental pathways, including neural capacities, leading to social–emotional, cognitive, and communicative competence (Shonkoff and Phillips, 2000).

Parental Warmth and Sensitivity

The first dimension of parental engagement clusters around warm and sensitive responsiveness to the child's needs and cues. It includes all those behaviors variously described in the child development literature as loving nurturance, warmth and sensitivity, responsive contingency to children's cues, and emotional availability toward the child. Beginning in the neonatal period, parental responsiveness can be seen in adults imitating and highlighting infant behavior, pausing to give the infant an opportunity to respond, respecting the infant's needs for an occasional break from communication, responding enthusiastically and appropriately to the infant's interests, following the infant's attentional focus, and letting the infant initiate interactions. As children grow older, parental warmth and empathy have been identified as global qualities that lead children to interact more smoothly with their parents and to form a strong identification

with parental values that extends outside the home to cooperation with other adults and peers as well.

Children's very survival and development depend on parental warmth and sensitivity because children are inherently relationship-seeking beings. From the beginning of life, children seek to engage and interact with the people around them. When comfortable and fed, they direct their attention and interest outward toward others who seem friendly, exciting, or loving. They reach out to get responses from these people and to send them signals of distress or pleasure as they try to help manage the pace, flow, and intensity of interaction. They actively strive to participate in the life around them. Without intimate, nurturing responses from others, children become too upset and exhausted to accept food and comfort. They cannot make sense of sensory stimulation and understand the world, connect to it, or care about it. Warm and sensitive parents create the framework for this vital interaction in the process of meeting their infant's basic needs.

Ample evidence exists that this first dimension of loving care is positively related to the all-critical development of the child's first attachments and close, secure relationships with a few significant others. Warm and sensitive caregiving that includes encouragement and support, lays the foundation for secure behavior and exploration such as through extended play episodes and pretend play (Ainsworth *et al.*, 1972). Much of the evidence emanates from research conducted within the attachment paradigm. Securely attached children tend to engage in more spontaneous reading activities and perform better on emergent literacy measures than insecurely attached children. In preschool, observers describe securely attached children as more curious, self-directed, sensitive to others' needs, and eager to learn than children who were insecurely attached as infants. Children with less-secure relationships with their caregivers tend to have lower levels of behavioral and emotional control, less adaptive levels of autonomy, and to experience difficulties approaching learning tasks (e.g., Sroufe, 1983).

Parental interactions that include displays of affection, physical proximity, contingent positive reinforcement, and sensitivity have repeatedly related to children's cognitive growth over time. Specifically, research has identified that positive, early relationships between children and caregivers contribute to neural connections that facilitate children's long-term developmental success (National Scientific Council on the Developing Child, 2004). Children in more highly connected parent-child relationships tend to display more positive socioemotional outcomes, such as stronger prosocial orientations, more numerous and higher-quality friendships, and higher levels of peer acceptance in kindergarten (Clark and Ladd, 2000). Through connected interaction with parents, children appear to develop an empathic socioemotional orientation that serves as a foundation for interpreting social situations and responding more prosocially to age-mates and teachers.

Clearly, young children benefit in the short and long term from nurturant caregiving that is emotionally warm, available, and responsive. Yet, there are many styles in which this caregiving can be delivered. Nurturance can be demonstrated in many ways all of which seem to promote infant health and well-being. No single cultural group or set of parents uses all of the available techniques, but instead each selects out some of them to make the customary approach. Parents and communities often use styles that emphasize either a physical, social, or cognitive style of expressing warmth and sensitivity. For example, certain kinds of parents may emphasize a physical style of nurturance, for example, focusing on the child's desires for food, holding, and responsive touch (by day or night) (Edwards and Whiting, 2004; Whiting, 1994; Whiting and Whiting, 1975). Through provision of food, holding, and other primary care oriented to the child's survival, these parents communicate to their children that they love them and are devoted to them. Through gentle touch, physical games, or use of massage, they communicate their nurturing feelings and tell their child that they wish her to feel ease and comfort throughout her body. In contrast, other kinds of parents may take greatest pleasure in a social style of nurturing by singing to the child, grooming their child's hair, dressing the child up, taking her on visits, and teaching her social words and gestures. Indeed, in many cultures, adults take great delight in the social forms of nurturance and communicate their affection through beautifying their child and teaching the child the rudiments of good manners. Finally, a third kind of parents may emphasize a cognitive style of expressing warmth and sensitivity by responding to the child's developing interests and preferences, offering them objects to look at and manipulate, and following their eyes to see what they are looking at, in order to label those things and expand on the child's exclamations and words. These parents often are verbal in their interaction with even the youngest children, and they treat their babies as conversational partners and intelligent beings who wonder about how things work and what causes things to happen. Of course, all three styles can be combined.

In today's postindustrial societies, it is the third style, focused on cognitively stimulating interactions, which seems to lead to the optimal outcomes for children's school readiness and academic success. Warm interactions of the mother provide the foundation for compliance and internalized controls in young children; and limit setting and discipline may be less effective in the absence of positive, warm relationships. The expressions of positive affect and emotional availability are also associated with improved short-term cognitive performance and long-term effects of positive academic performance. The emotional, social, and behavioral competence of young children predicts their academic performance in first grade over and above their

cognitive skills and family backgrounds, whereas the absence of a secure attachment with a caregiver or multiple caregivers leaves a child at a distinctive disadvantage. Qualities of parental engagement have been linked to a number of adaptive characteristics in preschool children, such as good work habits, frustration tolerance, fewer behavior problems, and better social skills.

Parental Support for Autonomy

The second dimension of parental behavior clusters around parental guidance and support for autonomy. It includes all those behaviors variously described in the child development literature as discipline, positive guidance, and support for the development of independence, self-reliance, and self-regulation. Children cannot remain infantile forever and must learn to do things for themselves so they can get along without constant supervision. They must individuate from their attachment figures and develop a certain initiative in relation to their surroundings. This dimension of parent behavior begins at the child's birth but becomes particularly salient (and conscious to parents) during the toddler years when children begin to be resistant and to want to do things independently. Parents promote autonomy by helping children to care for their own needs in the areas of eating, dressing, and personal hygiene. They support their capacity to function maturely in the home, neighborhood, or school classroom by teaching them to regulate the expression of their needs and emotions, respond cooperatively and compliantly to adult authority and direction, resist temptations to misbehave and violate rules, and find ways to tolerate frustration and stay on task.

Parental support for children's autonomy has been associated with the development of many positive cognitive and social outcomes for young children. Parents teach and model skills that help children to recognize and express feelings in culturally appropriate ways so that they are not rejected by others for crying, screaming, or expressing anger in ways that are too violent and uncontrolled. By supporting their child's independence and inviting children to participate in decision making, parents foster self-regulatory skills and intrinsic motivation in children that serves them well in any situation, but especially in school and work-related settings. By providing developmentally sensitive support for problem solving, they promote children's ability to learn from others and work cooperatively on home or school tasks. Parent-child interactions that are attentive but nondirective provide children some guidance, but they also allow children the freedom to be expressive, initiating, and self-directed. Interactions that are monitored and responses that are matched to children's developmental abilities and interests can foster continued interest in a current activity,

comfortable exploration of its potential dimensions, and mastery motivation.

Research indicates that by promoting autonomy, parents promote desired outcomes such as effective communication with peers, self-regulation, adaptive levels of social assertiveness, and self-directedness in social and play interactions at preschool, and increased levels of cognitive competence in young children. By supporting their child's independence and inviting children to participate in decision making, parents foster self-regulatory skills and intrinsic motivation to accomplish tasks set by adults, peers, or themselves. Children of parents who support autonomy have shown higher scores on standardized tests of literacy and numeracy skills, as well as more appropriate social assertiveness and self-directedness. In contrast, parents who undermine autonomy through greater frequency of controlling, hostile behaviors have children with more disruptive behavior problems in early childhood. Children of parents who provide inconsistent guidelines, are harsh or coercive, disengaged, and/or are unable to appropriately monitor child behavior are likely to display more aggression and antisocial behavior. In studies of child-mother interaction, differences in parenting discipline account for a substantial portion of the variance in behavior problems in childhood.

As with warmth and sensitivity, there are many styles by which parents can promote their children's autonomy. Some families encourage motoric or physical autonomy by allowing their child lots of opportunity for active movement. They might allow their child to explore independently in a carefully childproofed home or yard, or take the child outside for regular vigorous exercise. Still others might encourage physical autonomy by being exceptionally patient as the child struggles to climb stairs, use a fork, put on shoes, wash their hands, pour cereal and milk, or put things away. Another dimension of autonomy is social. Some parents may emphasize social autonomy because it helps the child to function in a social group without constant parental intervention. Parents orient their babies toward social autonomy, for instance, when they help them learn to remain patient and pleasant during a long family meal or to control their jealousy of a smaller baby visiting their house. Socially oriented families might also encourage their child to enter a playgroup of same-aged peers, to freely share their toys, or to accept another adult's care to the extent of being able to join the fun of the family outing to the park or swimming pool. Still other families put a premium on cognitive styles of autonomy, and they demonstrate this by encouraging early mastery of language skills, so that the child can use words to express his needs ('up,' 'milk,' 'do car'). They may put special energy into helping the children solve their own problems and make independent use of a nice playroom with its rich store of books, creative art materials, and constructive toys.

Cultural values about autonomy influence the manner in which parents and other family members evaluate and set limits with their children. For instance, there are many ways that parents can express praise and approval for what a child is doing. Some parents and cultural groups tend to use applause and hurrahs to encourage small children to show off and do little performances. In other cultures, parents do not want their children to seek attention or be boastful and proud; so instead of giving overt praise, they comment to another adult how well the child is doing, give the child another responsibility that indicates his success with the first one, or wordlessly display the child's lovely picture to share it in the family. The child notices what the parent is doing and feels a quiet pride that does not make him the center of attention.

Parents' values about appropriate autonomy also influence what they see as too indulgent and as spoiling a child. All cultures have some areas in which they expect early attainment of autonomy and mature behavior, and other areas in which they are relatively lax and indulgent. When people are looking at families from other cultures, they tend to notice those areas of childrearing where the other culture is either much stricter or more indulgent than their own. However, they are unaware of what aspects of their own culture others tend to find either overly indulgent, or overly strict.

Parental Participation in Learning

The third dimension of parental behavior clusters around promoting and participating in children's learning. It includes all those behaviors variously described in the child development literature as teaching, scaffolding, facilitating, and promoting language and learning. This dimension of parent behavior begins at the child's birth but becomes particularly salient (and conscious to the parent) during the toddler or preschool years. Parents provide for their young child's general learning both at home and outside the home in many direct and indirect ways, and this is sometimes called the curriculum of the home. For example, they promote their children's learning by interacting with them in an attentive and interested way and by providing them ample opportunities to gain new information and encouraging or permitting them to solve their own problems. Parents have many opportunities throughout the day to engage in responsive language and learning interactions with their children and allow the child to learn through complex and constructive play, asking questions, shared book-reading, or involvement in household tasks, and open-ended exploration.

Ample evidence exists for the importance of parents' participation and engagement in their children's early learning. Well before starting school, children interact with materials that are important for the emergence of

literacy. By interacting with all the forms of environmental print, children gain valuable information about print, signs, and books; sounds, letters, words, and sentences; and when they practice the de-contextualized language associated with songs, rhymes, and stories they are enjoyably prepared for later, more formal literacy instruction in school. Parents play a critical role in influencing early-language learning by commenting, mimicking, and expanding on their children's play schemes and speech. The richness of the literacy environment strongly predicts children's language and academic outcomes. Specific interactions during shared storybook-reading, such as labeling pictures, pointing out words and letters, and relating the story to a child's own life are important for learning early literacy rules/conventions and children's later school success (Wood, 1980). Parents also influence children's learning by modeling and supporting simple verbal and written productions such as the alphabet song, nursery rhymes, or how to write their name on a greeting card. Young children who experience reading and writing as pleasurable events are generally more successful later in school. Mothers who use comments and open-ended questions during conversations and shared reading activities, rather than predominantly verbal directives and closed questions, usually have children who develop more advanced vocabulary and language skills (Hart and Risley, 1995). Parents who frequently engage in responsive language and literacy interactions with their children, and who provide a home environment rich in opportunities for learning through shared book-reading, constructive play, and exploration, have children who display higher language and cognitive skills in the preschool and primary years.

Additionally, parents directly and indirectly provide natural learning environments for young children by determining their everyday activities (i.e., mealtimes, interactions with siblings, or outdoor or indoor play) in the settings and community locations frequented by young children of a similar age, culture, and geographic region. Children interact with parents in routine daily activities (e.g., dialing the phone, reading the mail, writing a grocery list), and thereby learn and practice a variety of skills that will serve them well once they start school. The degree to which parents engage their children in these activities (e.g., by providing the opportunity to watch, imitate, practice, or ask questions) influences the amount of information children take from these interactions, and has been found to be associated with optimal developmental changes. Informal activities, such as eating a meal or getting dressed or playing in the park or backyard, are also important natural learning opportunities for children if parents use them to engage with children in positive ways and use language and problem-solving strategies to highlight the experiences and express high, realistic expectations for achievement, and become involved with their child's explorations. Parents' ability to provide such

a curriculum at home has been related to early-childhood language outcomes and literary success and positive academic outcomes.

Finally, parents play an important role in arranging for young children's out-of-home learning opportunities, by how they select a quality childcare or preschool experience for their children and how they engage fully with the children and staff. Assuring language- and literacy-learning opportunities at childcare or preschool or kindergarten involves parents' participation and collaboration with teachers and education professionals. Parents' regular participation in school activities, such as parent-teacher conferences, as well as involvement in class activities, observation visits, and take-home activities (songs, books, etc.) have been linked to young children's later academic success. However, successful home-school collaboration is the responsibility of both parents and education professionals, and effective communication between parents and schools is critical to the successful bridging of home and school learning opportunities for children (Christenson and Sheridan, 2001). A strong connection between schools and families assists children in developing the skills needed to be successful socially and emotionally, as well as academically, and has been shown to be a significant factor in children's overall achievement. When parents are involved in their children's schooling, children show improvements in many adaptive outcomes, including pro-social behavior, self-esteem, perseverance and mastery motivation, and participation in learning activities.

As with warmth and sensitivity, and promoting autonomy, there are many styles by which parents can participate in their children's learning. Parents in different cultural communities have distinctive beliefs about what they believe children should learn, and in a general way, these parental beliefs match the demands of the cultural context. For instance, a physical style of participating is promoted in cultural environments that contain strong physical dangers for young children (drowning, falling, getting burned, getting run over, or getting lost). By using a physical style, parents promote the acquisition of gross and fine motor physical skills that help children learn to move safely and efficiently through the world and to begin to handle and manipulate necessary tools and implements, whether they be spoons, knives, digging tools, or pens and pencils.

The social realm of language and learning is also important to most families, as has been described. Parents promote their child's incorporation of social skills and knowledge by letting them participate in household work and including them in the joyful celebrations and rituals that are most meaningful to the family. They can achieve similar effects by incorporating their youngest children in events that give the whole family pleasure, such as sports events. For infants and toddlers, sitting with the family on the sidelines through long games can be either barren and boring (when they are primarily

pacified with food and drink) or instead rich in learning and literacy experience, when family members take time to draw them out in extended conversation, teach them meaningful routines (e.g., the rudiments of the game), and show them all the numbers, letters, and words on the score boards, food containers, programs, and uniforms.

Today, however, the pre-academic or cognitive side of parental participation in learning has become at least as important as the social and physical sides because of its connection to readiness for school success. Indeed, explicitly symbolic learning that promotes emergent learning in the domains of literacy, math, science, and creative arts, reaches all the way down into the infant and toddler years. Parents set the stage for their babies' later school readiness treating them as conversational partners (echoing and expanding their vocalizations and utterances, e.g., when they say, "You want more milk in your bottle?" after their child says, "Bot-tle"). Likewise, they expand their children's future command of language by modeling and encouraging the pleasure of using words, whether in naming, describing, explaining, rhyming, joking, telling a story, singing, counting, comparing, or computing. Parents also support an early love of language and learning by introducing their children to the cultural arts (by providing drawing and listening materials, or taking the child to a puppet show, library, public garden, swimming pool, or park). Finally, they cultivate a pleasure in reading and future literacy by reading stories to them from infancy and providing a rich supply of books, literacy tools, and imaginative play materials in their home. The pre-academic methods of fostering school readiness are very desirable as part of the curriculum of the home, but they are not everything. Any and all of the parenting styles of promoting language and learning – physical, social, and cognitive – have their own merit and are positive supports to young children's present and future socioemotional and intellectual growth and development.

Acknowledgment

The work was supported by a grant awarded to Dr. Susan Sheridan and Dr. Carolyn Pope Edwards by the Department of Health and Human Services (DHHS) – National Institute of Child Health and Human Development (NICHD), Administration for Children and Families (ACF) and Office of the Assistant Secretary for Planning and Evaluation (ASPE); and the Department of Education (ED) – Office of Special Education and Rehabilitative Services (Grant #1R01H00436135). The opinions expressed herein are those of the investigators and do not reflect the funding agencies. Special appreciation is extended to the families and teachers who participated including the Head Start agency administration for their willingness to cooperate and learn with us throughout the project.

Peer Interaction and Learning

Introduction

In the broadest sense, situated peer learning can unfold in any human interaction between peers, children, or adults, when different viewpoints emerge against a backdrop of social equality and active participation. In the adult world, it may involve interaction between a lay person and a professional (learning new software on the computer), friends or acquaintances (exchange of recipes), and be either planned or unplanned (college students tutoring in math vs. casual conversation between friends). In a parallel fashion, peer learning in the world of children can take many forms, some institutionalized, as in group work in classrooms and labs, and others in natural settings, as in interaction between siblings in the family or between friends in preschool or school. From the educational perspective adopted here, the discussion of research on peer learning encompasses both the sites of children's natural habitus, as in ethnographic studies of socialization, and those of the more formal settings of schools, as in educational-psychology studies of peer collaboration. Included in this spectrum are children and young people of all ages, from kindergarteners to young adults.

Research on peer learning encompasses a wide variety of interests, including language, social skills, many subject matters at school, and more. Peer learning has been studied both experimentally and through participant observation of naturally occurring interaction; it has been of interest to scholars coming from at least four research traditions: (1) studies in cognitive psychology, focused on cognitive development, that have generated an abundance of experimental studies of the relative benefits of peer learning compared to child-adult learning (for a review see Garton, 2004; O'Donnell and King, 1999); (2) the educational psychology tradition, within which child collaborative learning has been widely adopted for its effectiveness in promoting subject-matter achievement, in math and science (e.g., Schwarz *et al.*, 2000); (3) the cross-cultural psychology approach to socialization, based on which researchers have studied the role of siblings in patterns of child-rearing in different communities around the world (Rogoff, 2003); and (4) the linguistic ethnography tradition, with its focus on the ways in which peer talk functions in children's acquisition of discourse skills and the co-construction of peer culture (e.g., Goodwin, 1990).

The methods used in these studies follow two major methodological groups or some combination thereof. The first group, mainly representing the cognitive approach in

the psychological and educational traditions, is often carried out in classroom settings during the academic year, and is based on classic pretest-posttest experimental design, with clear hypotheses and measurable outcomes (Calhoon and Fuchs, 2003). The second group, representing the sociocultural and language socialization approach, consists of studies in which the basic data consist of transcripts of natural talk among children; data analysis tools draw from both discourse-analytical and quantitative traditions, and the focus of analysis is on process rather than outcome (see Kyratzis, 2004 for review).

Studies of peer learning also vary in terms of the context of the situation focused on, age of participants, and domain studied. Structured contexts, such as classrooms, have been studied much more extensively (for review see Fuchs and Fuchs, 2005) than nonstructured ones, such as peer interaction among siblings in the family or talk among young peers in preschool (for a review see Blum-Kulka and Snow, 2004). Age of participants studied varies from young preschoolers to school-age children (for review see Ginsburg-Block *et al.*, 2006), high school (Schwarz *et al.*, 2000) and college students. Interests shift with age: in studies of young children, the focus is often on language-linked domains, such as second-language literacy and discursive skills (Blum-Kulka and Snow, 2004; Cekaita and Aronsson, 2004), whereas with school age the interest shifts to the learning of subject matter, such as math and science (King *et al.*, 1998), history, and social skills (Ginsburg-Block *et al.*, 2006). The overall conclusion from all the studies is that peer learning is a highly effective mode of learning.

Theoretical Underpinnings

The effectiveness of peer learning can be grounded in at least four theoretical perspectives on learning. From a Piagetian perspective, the learning process at large is triggered by states of cognitive conflict between what is understood and what is encountered in active interaction with and manipulation of the environment. Peer interaction promotes such cognitive conflict by exposing discrepancies between different participants' level of knowledge, resulting in a state of disequilibrium. Through dialog and discussion among individuals of equal status – as in peer interaction between children unhindered by the status and cognitive superiority of adults – a higher level of understanding evolves, cognitive change occurs,

and equilibrium is restored. This is regarded as an internal process, which then manifests itself in behavior (an inside-out theory Garton, 2004). Studies grounded in a Piagetian constructivist framework have largely supported this view by showing experimentally that working with a peer leads to greater cognitive benefit than working alone (Garton, 2004).

From a Vygotskian perspective, social activity at large is important as the primary site in which concepts are formed, before they become mental functions for the individual. Cognitive development depends on active social interaction, including reasoning and explanation, with a more-competent partner. The interaction unfolds presumably within the novice's zone of proximal development, namely with one of the participants entering the interaction with an initial gap in knowledge that can be closed in interaction with the more expert partner. The expert is considered as having responsibility for providing the appropriate support or guidance (scaffolding) to fit the novice's zone of proximal development. In his view, a child may learn more when interacting with a peer at a similar age than when interacting with an adult, due to the fact that they are both operating within one another's proximal zones of development, and can change roles as novice and expert, providing each other with appropriate scaffolding on different occasions. As a result of the process, a shared, intersubjective understanding is co-constructed from the participants' differing viewpoint which in turn is internalized by all participants (an outside-in theory Garton, 2004). The Vygotskian framework has been evoked to explain gains in peer learning in both experimental (e.g., Fawcett and Garton, 2005) and natural settings (e.g., Nicolopoulou and Richner, 2004). In line with the zone of proximal development (ZPD) idea, it has been shown that small differences in cognitive level between children were more effective than large differences (Kuhn, 1972).

More recent theories of situated learning (Lave and Wenger, 1991) take the Vygotskian argument further, claiming that all learning is quintessentially social. In this view, learning is a process of participation in communities of practice, participation that is at first legitimately peripheral but increases gradually in engagement and complexity. Legitimate peripheral participation (LPP) theory alters the locus of learning. It is not the individual mind that acquires mastery, since learning is a process that presumably takes place not in an individual mind, but in a participation framework. The shift in focus toward the socially constituted nature of learning resonates in cognitive theory that views thinking as a socially distributed process, with knowledge emerging from the language-mediated collaborative activity of several participants (Resnick *et al.*, 1991).

A fourth tradition, coming from social psychology, locates the locus of learning in the motivational factors explaining the interaction between the individuals in the

group (Slavin, 1996). Here, the interest in peer learning is restricted to certain forms of cooperative learning in school, and not to peer learning at large. The central process this theory emphasizes is the structure of the reward or goals under which the student operates (Slavin, 1996). The reward is given to the group as a whole, making the individual interest and the group interest as one. This kind of reward structure motivates the group members, not only to maximize their abilities, but also to help others in the group to do so. The most effective structure is attained when the group is rewarded based on the individual learning of its members. This procedure is intended to make group members more accountable, and to that end avoid social loafing. A related conceptualization emphasizes the importance of social cohesion, claiming that the reason the group's interest has been served by its members is not motivational, but rather emotional, building on the members' wish to help each other (Sharan, 1994). Though there is no one-to-one correspondence between theory and research tradition, in general terms, the cognitive approach tends to be associated with Piaget, while the sociocultural approach is affiliated with Vygotskian and situated-learning theories.

Peer Learning in the Cognitive Tradition: Empirical Evidence

In educational psychology, peer learning has been referred to by various terms, such as collaborative learning, cooperative learning, peer-assisted learning, and peer tutoring. It is beyond the scope of this article to enlist the conceptual differences between all these terms, and we shall focus instead on two often-cited definitions. Collaborative learning, in its radical version, "involves learners working together in small groups to develop their own answer through interaction and reaching consensus, not necessarily a known answer" (Ehrlich, 2002). Monitoring the groups or correcting "wrong" impressions is not the role of the trainer since there is no authority on what the answer should be.

Cooperative learning, on the other hand, is geared toward solving problems with right solutions. It has been defined as "classroom techniques in which students work on learning activities in small groups and receive rewards or recognition based on their group performance" (Slavin, 1980: 315). Three distinct types have been identified – information learning, formal learning, and study teams – varying in terms of the length of the task required to be done together, a parameter that affects the degree of involvement and relationship within the learning group (see Nastasi and Clements, 1991 for review).

The majority of the empirical studies conducted in education and psychology used a strict pre-post experimental

model, mostly in the field (though some were held in laboratories), with a very similar structure:

1. Children who are a representative sample of the population (that can be different from one study to the other in age, learning abilities, and so on) were randomly assigned to the control or experimental group; sometimes, this process is dependent on the child's scores in school.
2. A measure of the specific educational field, usually by standardized tests.
3. Applying the intervention that varied from one study to the other in a given length of time, the level of structuring in the assignment the dyads/groups receive, differences in children's academic level, and so on. The condition in the control group is also varied: in some studies, the children in the control group carry on with the original educational program of the school; in others, there is a different intervention, such as studying in small groups with close supervision/guidance of the teacher, which has been compared to peer learning.
4. Testing the children again in the same standardized test.
5. Testing to see a significant statistical improvement following the intervention, in comparison to the control group.

This approach, which uses a very specific outcome and a very specific definition for the effect of peer learning, has advantages as well as disadvantages. On the one hand, it is easy to establish the child's gains from peer learning and to identify improvement and the necessary conditions for it. On the other hand, we may be missing data that will help explain the ways in which peer learning works. Research in this tradition has become increasingly sensitive to the role of verbal communication during peer learning, either by including a +/-talk condition in the experimental design (Fawcett and Garton, 2005), or more frequently, by assessing the quality of discourse during peer interaction (see Nastasi and Clements, 1991 for review).

The effectiveness of peer learning has been demonstrated in many curriculum areas as well as in social and communication skills. In the child's early years, the main focus in the literature revolves around reading and writing abilities. Studies conducted as early as in kindergarten found that peer-assisted learning strategies (PALSs) have a beneficial effect on reading vocabulary and comprehension, decoding skills, and writing (Fuchs and Fuchs, 2005). These findings were significant over and above the impact of the child's socioeconomic background and his initial level (high vs. low).

The effects of peer learning on mathematical skills were assessed for both elementary and high school students. Overall, peer learning was found to have a

positive effect on the child's mathematical abilities. Studies conducted in elementary school showed that peer learning helped students generate conceptual mathematical explanations and helped high-achieving students' performances on complex mathematical tasks (Fuchs and Fuchs, 2005) and improved students' grades in both curriculum-specific tests and standardized tests (Slavin, 1980).

Studies on elementary schools have also shown that interventions that focus on academics can also improve social skills. PALS encourages making new friends among children who are less popular (Fuchs and Fuchs, 2005), promoting the social acceptance of children with handicaps (see Nastasi and Clements, 1991 for review) or intellectual disabilities (Yarrow and Topping, 2001), and improving social and self-concept. Those, in turn, are correlated with high academic scores (Ginsburg-Block *et al.*, 2006).

The number of studies conducted on high school students is significantly lower than the studies done in elementary school. Obviously, there is not much work on reading and writing. The main focus in high school is mathematical skills and social skills. Peer learning increases mathematical reasoning and understanding. The positive effect of peer learning for mathematics has been attributed to the peers' inquiry and raising of questions (King *et al.*, 1998), discursive practices which require the student to explain and defend his opinion (Schwarz *et al.*, 2000).

Peer learning also improves the adolescent attitude toward school, the dropout rate, and their self-concept (Raswal *et al.*, 1995). More recent studies are trying to assess the interaction between the learning method and the student's basic needs and personality (Hänze and Berger, 2007).

Peer learning has also been convincingly shown to be beneficial for special education students. In this case, studied extensively, peer learning proved to be beneficial from kindergarten to high school. It improved the reading abilities of the child, mathematical abilities (Calhoon and Fuchs, 2003), and social skills (Yarrow and Topping, 2001). These findings are valid for children with emotional and behavior disorders as well (Ryan *et al.*, 2004).

Peer Learning in Sociocultural Tradition: Empirical Evidence

One of the basic tenets of sociocultural theory is that children are active agents in their own socialization, learning language and culture through participation in linguistically marked meaningful events. The perspective on learning in this approach is conceptualized as becoming competent participants in communities of practice, as entering new worlds of discourse, rather than as just acquiring new skills and concepts. From this viewpoint, peer interaction is the essential condition for peer learning. Peer (and sibling) interaction is viewed as crucial for the

development of cognitive and linguistic skills, including pragmatic skills. As in all ethnographic and cultural approaches to development, the focus of the observation is on the process of the interaction in its potential contributions in the wider sociocultural context, rather than on measurable gains. Arguably, the outcomes of children's interactions need to be viewed in terms of their contributions to children's co-construction of their social identities and peer culture, as well as in terms of their cognitive and linguistic gains. Two major contextual features of peer interaction can be considered conducive to learning in this site: (1) its collaborative, multiparty, symmetrical participation structure and (2) its shared worlds of childhood culture. Peer interaction unfolds unhindered by the inherent asymmetry of adult-child interactions and hence presumably can promote a free and reciprocal exchange of ideas; the specifics of peer-group participant structure allows for reciprocity in expert-novice configurations with shared trajectories of ZPDs, inviting momentary teaching-learning opportunities in different domains, ranging from the use of computers to language learning (Blum-Kulka and Snow, 2004; Rogoff, 2003).

Evidence in this approach for the essential role peer interaction plays in socialization comes from three domains of study: (1) cross-cultural, ethnographic studies of socialization across cultures; (2) second-language learning studies; and (3) linguistic ethnography studies.

For many centuries and even in recent times and in diverse cultures, children have been acting as the major agents of socialization. In these societies, the care of toddlers is entrusted to their older siblings, as is the case for Polynesian children, Mayan children in Mexico, or African-American children in Louisiana, offering them ample opportunities to learn varied aspects of social behavior – from how to help with household chores to how to manage conflicts and compromises. Simultaneously, older siblings are young children's primary source of linguistic input, and have also been shown to engage in direct language teaching, as in the case of African-American children in Louisiana who taught their younger siblings to recite the alphabet, play word games, and name colors and numbers; the African-American girls in Piedmont who engaged younger children in word play, counting and naming body parts; and the American-Israeli bilingual teenagers who engaged their younger siblings in bilingual word play (Blum-Kulka and Snow, 2004; Heath, 1983; Rogoff, 2003).

Peer interaction is essential for second-language learning. For immigrant children, in many countries whose home language is different from school language, school experience is the major resource for learning the target language. Depending on the type and quality of educational support given, interaction with native peers may prove crucial in the process. Once immigrant children have acquired the rudiments of communication in the second language, their native peers willingly engage them in

talk and play, enhancing indirect language learning, and also act as explicit language teachers, correcting pronunciation and teaching vocabulary (e.g., Tabors *et al.*, 2000). From a theoretical viewpoint, the case of immigrant children can be considered a prime example for learning through legitimate peripheral participation; from an initial silent position at the periphery of their peers' participation structure, they move with time (and confidence in second language) to the center of this structure, aided in the process by their native peers. Second-language learners in immersion classrooms with limited second-language proficiency recurrently employ language play in conversations with peers, a speech genre which generates extended repair sequences serving as informal language lessons (Cekaita and Aronsson, 2004). Studies that show scaffolded help provided by peers include Japanese and American immersion preschool and kindergarten classes, British bilingual classrooms, and English as second language (ESL) classrooms (Kasper and Rose, 2002).

Linguistic ethnography studies of children's peer talk reveal that deep involvement in shared worlds of childhood culture creates interest and motivation, facilitating peer interaction and presenting rich opportunities for the mutual learning of a wide range of cognitive, social, and discursive skills, such as: the intersubjective skills of following collaboratively constructed complicated plots of pretend play (Sawyer, 1997); negotiating power asymmetries and gender identities in same-sex and cross-sex groups (Goodwin, 1990); practicing and refining their narrative skills, and developing child peer culture through narration (Maybin, 2006; Nicolopoulou and Richner, 2004); fostering conversational skills (Hamo and Blum-Kulka, 2007); and developing cultural styles of negotiation (Corsaro and Rizzo, 1990).

Summary

Peer learning emerges from this article both as an educational framework for a variety of educational practices (tutoring, collaborative learning, cooperative learning, etc.), as well as an interactional framework fostering learning in many forms of life. Theoretical interest in the field has a long and well-established history, going back to the two pillars of developmental psychology, Piaget and Vygotsky. The educational domains where peer learning has been shown to be effective include school subjects like mathematics, history, and literature, as well as social skills and self-confidence. Yet, research shows that the degree of success achievable with peer learning can depend on a host of contextual features, including age, gender composition, level of group heterogeneity, degree of task structuring, quality of interaction, and type of reward (Ginsburg-Block *et al.*, 2006; Jacob, 1999; Slavin, 1980). The gains and affordances of PL in natural settings are manifest in sibling care in traditional societies, second-language acquisition by

young children, and child-to-child talk in various contexts. Traditionally, in the cognitive tradition, gains are evident mainly by measurable outcomes; in the sociocultural tradition, gains are evident by close scrutiny of the interactional processes. Yet, research on peer learning has also seen a growing cross-over from sociocultural to cognitive approaches in fields traditionally associated with the latter, like mathematics education; embracing discursive approaches to research on math education entails replacing the language of personal acquisition by talk about learning as becoming participants in a collective activity, accompanied by detailed descriptions of the learning process backed by transcripts of student interactions (Kieran *et al.*, 2003). Arguably, the common denominator in all cases considered is communication: peer learning, whether planned or unplanned, institutionalized or natural, unfolds mostly through talk. It follows that the quality of talk is an essential component of its potential success. Indeed, several educational studies have shown that engagement in verbal pre-planning, active debate, explicit negotiation, listening to each other's explanations and arguments, and reflection on their logical consistency while working on tasks with peers is positively associated with individual cognitive gains on posttests (e.g., Barbieri and Light, 1992). The role of verbal active exchange of ideas as a key (if not the key) element of effective peer learning has been recognized by at least some researchers in the cognitive tradition, and has led to a rising emphasis on transcripts as a major source of data, and to some application of discourse-analytical methods to pinpoint the discursive strategies fostering learning (e.g., Fawcett and Garton, 2005; Jacob, 1999; Asterhan and Schwarz, 2009). Attention to language and discursive practices as primary to the inquiry of issues of socialization and development has been essential to most research in the sociocultural tradition; for some, like in the study of argumentation, the nature of the argumentative dialog is taken to be the very essence of the learning process (Pontecorvo and Girardet, 1993); for others, peer talk is conceived of as providing affordances for learning in a broad spectrum of domains and skills, leading to cultural, social, linguistic, and cognitive gains.

Glossary

Capital – In sociology, the word “capital” is a general term for four specific forms of capital: cultural, economic, human, and social capital. *Cultural capital* refers to the knowledge and experience that individuals gain chiefly through participating in cultural events. *Economic capital* essentially refers to wealth. *Human capital* refers to the knowledge and skills that individuals gain through education and experience. *Social capital* refers to the tangible benefits and resources that individuals build up because of their inclusion in social networks.

Field dependence/independence – This concept is also known as psychological differentiation and perceptual style. Individuals who are more *field-dependent* are less able to view objects separate from the overall environment. They are likely to be influenced by the prevailing context. Individuals who are more *field-independent* are good at identifying objects that have surroundings that might obscure their view. They tend to see things as discrete from their backgrounds.

Intellectual styles – This term is the general one for concepts such as cognitive styles, learning styles, teaching styles, and thinking styles. All these styles address people’s preferred ways of processing information.

Learning approaches – Ways of learning a task that are contingent upon the student’s intentions. Three common learning approaches are: *surface*, which involves meeting the minimum requirements by reproducing what is taught; *deep*, which involves a true understanding of what is learned; and *achieving*, which involves using a strategy that would maximize one’s academic grades.

Self-construal – A specific dimension of self-definition. Broadly speaking, there are two types of self-construal: interdependent and independent. Individuals with an *interdependent self-construal* have a tendency to view themselves in terms of their close relationships with others. Individuals with an *independent self-construal* are likely to perceive themselves as being autonomous and separated from others.

Thinking styles – This refers to people’s preferred ways of using the abilities that they have.

For nearly a century, researchers have sought alternative ways to account for learning gaps among various cultural groups. As a result of increasing globalization, understanding learning in a cross-cultural perspective has become more important than ever before. There is no such thing as a context-and/or meaning-free environment (LeVine *et al.*, 1988). We learn and make sense of our learning experiences within cultural contexts. Indeed, a substantial amount of literature concerning cross-cultural learning is converging on one conclusion – culture has a great impact on student learning. However, the major findings in this research have created several paradoxes. What could have happened? What are some of the major explanations regarding differential learning across cultures? What can scholars do to move the field forward?

This article aims at addressing the above questions in three parts. First, we describe important works concerning the learning process, focusing on intellectual styles. Second, we introduce the major works on learning outcome, centering on academic achievement. Finally, we draw some conclusions and suggest future research directions.

Intellectual Styles as Learning Processes

What are Intellectual Styles?

Intellectual styles, an encompassing term for such constructs as cognitive styles, learning styles, and thinking styles, refer to people's preferred ways of processing information and dealing with tasks (Zhang and Sternberg, 2006). The field of intellectual styles has a long history, dating back to Allport's (1937) study of personality types. One of the major reasons that theorists and researchers have maintained their interest in styles is that styles play an important role in the process of learning. They also account for individual differences in learning outcomes. Research suggests that intellectual styles are malleable to some degree, depending on many factors. One is culture. Sternberg (1997) proposed that culture is the foremost variable that helps shape people's styles and argued that some cultures are likely to be more rewarding of particular styles than of others.

Intellectual Styles and Culture

The impact of culture on intellectual styles is indisputable. However, very little concerted effort has been made to systematically investigate cross-cultural differences (or similarities) in intellectual styles. Most existing research examining intellectual styles in relation to culture has focused on testing the relationships between intellectual styles and academic achievement in different cultures, rather than on making direct comparisons of intellectual styles among students from different cultural settings. Direct comparisons may promote stereotypical views about certain cultural groups.

The studies documented in the literature have identified a certain degree of universality of intellectual styles across cultures as well as style differences based on culture (e.g., Berry, 1966). They have also presented challenges to some of the stereotypical views about particular cultural groups. These challenges pertain to claims that: (1) Black and Hispanic (including Mexicans, Puerto Ricans, Cubans, and people of other Hispanic origin) students have a higher preference for the surface approach to learning (see Watkins and Mboya, 1997); (2) Asian students are rote learners; (3) Black and Hispanic students are more field dependent than are Anglo-American students; (4) students from group-oriented societies tend to be more field dependent than students from individualistically oriented societies (see Bagley and Mallick, 1998); and (5) students from group-oriented cultures are more norm-conforming in their thinking styles (see Sternberg, 1997). The challenges to the first two claims (1 and 2) are the result of research based on Biggs' (1978) construct of learning approaches. The challenges to the next two claims (3 and 4) are

derived from research grounded in Witkin's (1962) concept of field-dependence/independence. The challenge to the final claim (5) is manifested through research based on Sternberg's (1997) theory of thinking styles.

Learning approaches

One group of cross-cultural studies of students' intellectual styles has been based on Biggs' (1978) three approaches to learning: surface, which involves meeting the minimum requirements by reproducing what is taught; deep, which involves a real understanding of what is learned; and achieving, which involves using a strategy that will maximize one's grades.

However, with regard to the first two claims above (1 and 2), recent studies have found no evidence to support them. Comparative studies on the learning approaches of Black (and Hispanic) and White students in several cultures (e.g., Watkins and Mboya, 1997) have failed to reveal any significant differences in learning approaches. Similarly, the results from research comparing the learning approaches of Asian students with those of Caucasian students are at odds with the stereotypical view that Asian students are rote learners. Traditionally, Asian students' higher academic achievement has been attributed to the value they place on hard work mainly characterized by rote learning, among other factors. However, such a view has not been supported. On the contrary, there is evidence indicating that White American students show a greater tendency to rely on the surface approach to learning than do their Asian peers.

Field dependence/independence

Field dependence/independence (FDI), alternatively known as psychological differentiation and perceptual style (Witkin, 1962), refers to the extent to which people are dependent on versus independent of the organization of the surrounding perceptual field. Field-independent individuals are thought to be better at cognitive restructuring because of their propensity for being free from external referents. Field-dependent individuals are considered to be more socially oriented as a result of their higher levels of sensitivity to external referents. Based on the definition of field dependence and of field independence, one would expect that students from individualistically oriented societies in which people enjoy social looseness (Pelto, 1968) would be more field independent and that students from group-oriented cultures would be more field dependent. Indeed, this hypothesis has been supported by numerous empirical studies.

At the same time, there is also evidence at variance with this hypothesis. For example, Buriel's (1978) comparative study found no difference in the level of field dependence/independence between Anglo-American and Mexican-American school children. In a review of the literature,

Bagley and Mallick (1998) concluded that, compared with their Western counterparts (in this case, students from Canada, the UK, and the US), students from group-oriented cultures (in this case, Chinese and Japanese cultures) were more field independent.

Thinking styles

A relatively recent theory of intellectual styles, Sternberg's (1997) theory of mental self-government, states that there are 13 different ways in which people can use their abilities (i.e., thinking styles). Zhang and Sternberg (2005) classified these styles into three types. Type I thinking styles tend to be more creativity generating and denote higher levels of cognitive complexity (e.g., the global style – the tendency to focus on the holistic picture; the liberal style – the propensity for adopting a new approach to tasks). Type II thinking styles denote a norm-favoring tendency and tend to require lower levels of cognitive complexity (e.g., the local style – the preference for focusing on details; the executive style – the inclination to implement tasks with given guidelines). Type III styles may manifest the characteristics of styles from either Type I or Type II groups, depending on the stylistic demands of a specific task (e.g., internal style – preferring to work on one's own; external style – preferring to work in groups).

One might predict that the internal style and Type I styles would be more encouraged in individualistically oriented cultures and that the external and Type II styles would be more beneficial in group – or collectively oriented cultures. However, this appears to be true in some cases, but not in others. For example, Type I styles have been found to be related to higher academic achievement among American students (e.g., Grigorenko and Sternberg, 1997), whereas Type II styles have been strongly associated with better achievement in collectively oriented cultures such as Hong Kong and the Philippines. However, contrary to the prediction, better academic achievement has been found to be related to Type I styles among university students in Korea, a highly collectively oriented society, whereas better achievement has been associated with Type II styles in Spain, a more individualistic society. Finally, higher academic achievement has been found to be related to the internal style in all cultures investigated so far, be they individualistically oriented or group oriented.

Academic Achievement as Learning Outcome

The two major bodies of literature on academic achievement as learning outcomes concern Asian and African students.

Research Centered on Asian Students

In the earliest and most comprehensive study of cross-cultural learning among 625 000 students from six ethnic groups (Coleman, 1966), Asian Americans emerged as the only ethnic minority group that performed as well as or outperformed Caucasian students on many indicators of intellectual value, aspiration, and achievement. The superior achievement of Asian students in the international arena has been maintained to this day (Trends in International Mathematics and Science Study, 2008).

This finding is puzzling for several reasons. Traditional educational and psychological theories assume that better academic performance should be associated with higher levels of self-efficacy and with a stronger sense of individuality; yet, the Asian students who outperform their Western peers do so despite their expressed lower levels of self-efficacy (e.g., Eaton and Dembo, 1997). Likewise, although psychologists generally maintain that higher academic achievement tends to be positively correlated with attributions to ability, not effort, Asian students tend to attribute their academic success to effort. Anthropologists and sociologists believe that school performance has a great deal to do with wealth and socioeconomic status. However, Southeast Asian refugee students thrive academically despite their low socioeconomic status. Such paradoxes require alternative explanations of Asian students' high academic performance.

Consider three explanations of the paradoxes. The first is from the perspective of cultural values; the second uses Markus and Kitayama's (1991) concept of self-construal; and the third is based on Sue and Okazaki's (1990) notion of relative functionalism.

Cultural values

Asian students' superior achievement is believed to be largely the outcome of the strong influence of Confucian philosophy, which emphasizes authoritarian moralism, collectivism, effort, endurance, filial piety, modesty, passion for learning, and self-improvement. Many scholars have argued that, as a result of such traditional values, students of Asian origin tend to be more respectful of their elders. Asian parents have been/are known for having higher expectations of and making greater sacrifices for their children's learning. In return, Asian students feel a strong obligation to repay their parents' devotion and sacrifice with good academic performance, which is normally perceived to be one of the best forms of filial piety. Empirical evidence also suggests that Asian people often show greater passion for learning than Westerners, who usually put more emphasis on fun, self-esteem, and social development (e.g., Chao, 1996).

Cultural values have also been used to address the paradox that Asian students outperform their Western peers despite attributing their superior performance to

effort rather than to ability (as would be expected by attribution theories), and while reporting lower levels of self-efficacy. Eaton and Dembo (1997) have suggested that modesty is deeply rooted in Confucianism. When Asian students do well academically, instead of boasting how naturally talented they are, they express their need to work harder and do better.

Modest people may tend to be more aware of their inadequacies and, as a result, feel the need for self-improvement through being engaged in their work more diligently. On a similar note, other researchers have proposed that Asian students may score lower on tests of self-efficacy because their Western counterparts overestimate their own abilities by evaluating themselves based on their underachieving peers or on their parents' lower expectations. Western students' higher levels of self-efficacy could also be attributed to the Western view that students need to feel good about themselves and about their achievements. For example, in both the United Kingdom and the United States, it is commonly accepted that having positive self-regard is critical for students to strive to achieve in all aspects of life.

Markus and Kitayama's concept of self-construal

Recently, several authors have borrowed Markus and Kitayama's (1991) concept of self-construal to resolve the paradox of high Asian achievement. According to Markus and Kitayama, the way in which achievement motivation drives goal-directed behavior is culture specific. Westerners tend to perceive goals as an expression of individual wishes. They consider themselves as independent selves, in contrast to Asians, who tend to view goals as an expression of their family or other communal objectives. Asians are more likely to consider themselves as interdependent selves. Moreover, Westerners tend to perceive individual action as the means of achieving personal goals, whereas Asians are likely to perceive the individual as being reflective of past and future generations. Such a strong sense of responsibility, not only for one's own success, but also for glorifying one's own family and community, has been found to be an important factor in Asian students' motivation to work harder and to find ways to fit their interests with the expectations of others.

Sue and Okazaki's relative functionalism

Sue and Okazaki (1990) have argued that in explaining the differential achievement between students of immigrant cultures and students in the host cultures, one should take into account the economic and social status of the immigrant groups in the host cultures, as well as the immigrant groups' traditional cultural values. The authors put forward their theory of relative functionalism to accommodate both cultural and social factors. They believe that immigrants make great efforts to take advantage of the opportunities (such as for education) not available in

their motherlands, with the ultimate goal of upward social mobility via education. The authors have further argued that education can be the principal vehicle for upward social mobility when other means are impossible, which is often true for the Southeast Asian refugees in Western cultures. Consequently, superior academic achievement is a principal route to achieving higher social status.

Research Centered on Black and/or Hispanic Students

Most research on the academic achievement of minority students has used the cross-race comparative paradigm. Typically, Blacks and/or Hispanics are compared with their Caucasian counterparts and with their Asian peers studying in industrial countries. Such studies have usually obtained largely the same finding – Black and/or Hispanic students' academic performance lagged behind that of their Caucasian and Asian peers. Black and Hispanic students underperform on many indicators of academic achievement (DeBlassie and DeBlassie, 1996). In early research (especially between the 1960s and the early 1970s), scholars turned their attention to the notion of compensatory education, viewing minority students' academic failure as the result of some kind of culturally or racially related deficit, most noticeably, poor home preparation for school experience (Deutsch, 1964). The essence of this viewpoint is best illustrated by Crow *et al.* (1966), who listed 60 alleged psycho-educational deficits of the culturally disadvantaged child.

Yet, this culturally/racially related deficit model cannot explain the academic success of some of the minority students and has given rise to several competing explanatory models. Below, we first discuss an explanatory model that is oriented toward racial/cultural differences – that of social class, wealth, and capital. We then discuss two alternative models that take within-culture differences into account, specifically, (1) types of minorities and (2) school structure.

Social class, wealth, and capital

Social class and wealth affect school achievement (e.g., Adler, 1968; Davis, 1948). Sociologists have integrated the concepts of social class and wealth with Bourdieu's theory of capital in explaining the achievement gap between Blacks/Hispanics and Whites. According to Bourdieu, there are four forms of capital: cultural, economic, human, and social. Although varying in their degrees of liquidity (or, the levels of ease by which they can be converted), the four forms of capital are convertible. Economic capital (i.e., wealth) is the most convertible and the most important for school achievement. Wealth, as economic capital, can enable parents to provide children with many important educational resources, such as books, computers, and access to school that is of higher quality.

Wealth can also be transformed into cultural capital – broadly defined as “instruments for the appropriation of symbolic wealth socially designated as worthy of being sought and possessed” (Bourdieu, 1977: 488). Cultural capital can be represented by activities such as attendance at art performances or exhibitions, symphony concerts, and other types of live shows. Activities such as these that require great financial expenses can enhance school achievement (e.g., Hattie *et al.*, 1997).

Wealth can also affect human capital, which in turn, affects children’s school achievement. Wealthy parents may be more cognizant of the role of self-confidence in school achievement than are less wealthy parents. Such awareness may help wealthy parents to pay more attention to adopting strategies that boost their children’s self-confidence.

Finally, wealth can also be transformed to social capital, which in turn affects academic achievement. Social capital is defined as the concrete benefits and resources that people build up by virtue of their inclusion in a social structure/network. Students from wealthy families have the opportunities to interact with people of greater social capital, who serve as role models for success. Seeing these role models can be very conducive to the positive development of learning motivation, and thus to the enhancement of academic achievement.

As Blacks/Hispanics are substantially less wealthy, on average, than are Whites, wealth, as manifested in different forms of capital, can be used to explain at least a portion of the racial-achievement gap. However, using social class, wealth, and capital to account for the racial-achievement gap can also be perceived as using a race-related-deficit approach, for it stresses the disadvantages associated with lack of wealth and capital commonly experienced by Blacks and Hispanics. Furthermore, it cannot explain the success of some Black and Hispanic students.

Ogbu’s two types of minorities

Ogbu (1978) differentiated between two types of minorities in accordance with their initial terms of incorporation and treatment by the majority in the host culture: voluntary minorities and involuntary minorities. Voluntary minorities are those who choose to go to the host country because of perceived opportunities for economic advancement and political freedom. Involuntary minorities refer to those who were either originally brought to the host country in the form of human labor or were subdued through colonization.

A major difference between the two minority groups is what Ogbu called cultural frame of reference. Voluntary minorities tend to hold a positive frame of reference, interpreting various obstacles they are confronted with in their host countries as temporary problems that can be solved

through hard work and education. In contrast, involuntary minorities tend to hold an oppositional cultural frame of reference, distrusting dominants and their institutions and perceiving them as the gatekeepers obstructing them from channels to success and social mobility.

Ogbu suggested that children from voluntary minority groups tend to achieve better than those from the involuntary groups because the parents of the voluntary minority children tend to adopt schooling strategies that are conducive to the social adjustment and academic success of their children. By contrast, the oppositional cultural frame of reference held by the involuntary minorities has promoted an anti-educational orientation that is counterproductive to academic success.

Ogbu’s model accounts for some of the differences in achievement across minority groups. However, the model has been criticized on the grounds that it does not explain why some students fail whereas other students succeed even though they are from the same minority group, be it voluntary or involuntary.

Institutional practice

Explaining the achievement gap between Blacks/Hispanics and Whites from the perspective of institutional practice is a relatively recent endeavor in response to Ogbu’s (1978) argument that involuntary minorities tend to take an oppositional stance toward school and that Black/Hispanic high achievers tended to act White. According to this alternative view, many institutional practices may affect the academic engagement and achievement of Black/Hispanic minority students (e.g., Flores-Gonzalez, 2005). We highlight three such factors.

The first is known as the subtractive schooling process, in which minority culture is devalued by school teachers and administrators. Under such a school system, teachers and administrators select and reward students who possess mainstream cultural attributes and deprive minority students of important cultural and social resources, “leaving them progressively vulnerable to academic failure” (Valenzuela, 1999: 3).

The second school institutional practice that is thought to be responsible for Black/Hispanic students’ low academic achievement is what is known as cultural tracking (see Flores-Gonzalez, 2005; Valenzuela, 1999). Cultural tracking is an institutional practice that puts students into particular programs based on their dominant-culture proficiency within schools. The result of such a practice is that students are divided into two main groups – those students who are believed to be equipped with dominant culture skills and those who are not. As minority culture is often devalued, the majority of minority students are sorted into the lower tracks. On the other hand, because White students have the advantage of possessing dominant culture skills, they (along with a very small number of minority students who demonstrate dominant-culture

proficiency) are placed into more advanced programs. Not only does such an institutional practice shape opportunities for academic success, it also places students into different peer groups on the basis of their socially defined racial backgrounds (e.g., Lucas, 1999).

A final institutional practice believed to underlie the low achievement of Black/Hispanic students is what has been identified as Eurocentric curricula and pedagogy. Although the call for culturally responsive curricula and pedagogy was made more than two decades ago (e.g., Boykin, 1983), the curricula used in industrial countries (in particular, the United States where the minority groups being considered reside) are designed to address issues in the predominant White culture. The pedagogy used often does not take into account minority students' ways of learning. Such an institutional practice tends to discourage minority students from being active in their learning because they see little connection between their educational experiences in predominantly White schools and their own cultural values.

Conclusions and Future Directions

Convergent empirical evidence on students' learning processes and outcomes enables us to draw several conclusions. First, culture does have a significant impact on student learning. However, the influence of culture on student learning is rarely direct. Rather, the relationship between culture and student learning is often mediated by other factors of a sociological or psychological nature. Existing studies on both learning processes and learning outcomes cast doubt on some of the stereotypical views about particular cultural groups. To achieve a better understanding of learning in a cross-cultural perspective, further research is needed regarding both learning process (as represented by intellectual styles) and learning outcome (as represented by academic achievement).

On Intellectual Styles

Research on intellectual styles may help resolve some of the issues arising in this article. First, cross-cultural research on intellectual styles should be conducted among a wider range of populations. Second, we need to know more how culture interacts with intellectual styles. Third, we need better instruments to assess styles – ones that can be used in a variety of cultures.

On Academic Achievement

We also need to have a better understanding of academic achievement. First, cross-cultural research on academic achievement should involve more countries.

At present, many countries in the world have been left out in existing cross-national studies. Furthermore, the bulk of the immigrant literature is about comparing the academic achievement of students from the so-called underdeveloped countries with that of students from Western industrial countries. Practically nothing is known about the differential (or similar) achievement among students across underdeveloped nations. Second, more attention should be given to the learning gaps between students from different regions or different ethnic groups within countries. Third, we need to examine more closely the impact of the interplay of culture, social class, family and school environment, psychological factors, and other student-developmental dimensions (e.g., cognitive development and psychosocial development) on student learning. Fourth, research comparing students' academic achievement should go beyond using results from tests of basic skills. Other intellectual skills such as higher-order cognitive skills, critical thinking, and creative problem solving should be examined. Finally, cross-cultural research on academic achievement should go beyond studying school achievement. Progress is being made, but there is a long way to go. Given the costs to nations of slow progress, there is little time to lose.

Learning Outside of School

T Nunes, University of Oxford, Oxford, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Learning is the acquisition of knowledge. Learning may be about new ideas, symbols, ways of performing (more automatically, more flexibly), or the use of something known in a new way (learning transfer). Learning happens everywhere but it is easy not to notice this because we are used to linking teaching and learning, so we tend to look for learning where there is teaching. This leads to a focus on learning in schools, colleges, and universities. In this article, the focus is on learning outside school, where much learning takes place without teaching.

This analysis is organized by a series of contrasts, which aim at making visible what is often invisible, because what we learn outside school is seen as common sense, everyday knowledge, social knowledge, professional knowledge – that is, knowledge that is taken for granted, which is part of the general culture or part of the culture of a group. “Like fish in water, we fail to ‘see’ culture because it is the medium within which we exist” (Cole, 1996). By contrasting learning in and out of school, a picture of the products and the processes of learning outside school are sketched. However, before we work our way through these contrasts, it must be said that looking at learning outside school is not a criticism of school learning. Schools have specific aims and functions, and one of these is to make learning an explicitly pursued venture, where the knowledge obtained can be examined critically and communicated; thus its refinement and transmission are, if not assured, made more likely, so that future generations may inherit it and build on it. Informal knowledge and learning are, by comparison, more difficult to share and their future is uncertain.

Formal and Informal Learning and Knowledge

Eraut (2000) proposed a definition of formal learning on the basis of these characteristics: (1) a prescribed learning framework; (2) an organized learning event or package; (3) the presence of a designated teacher or trainer; (4) the award of a qualification or credit; and (5) the external specification of outcomes. Not all of these are necessary to define formal learning; any one may suffice, but they tend to go together. Outside school, learning happens without explicit learning outcomes, a curriculum, or a designated teacher. The contrast between formal and informal

learning also applies to knowledge: formal knowledge receives recognition and informal knowledge, though often necessary for learning formal knowledge, does not. In fact, informal knowledge is taken for granted, considered obvious, and only identified as an achievement through research.

An example from mathematics learning can help clarify the difference between informal and formal knowledge. Outside school, children are used to sharing different sorts of things: chocolate bars, sweets, turns in games, etc. They learn that these are not shared in the same way. For example, turns in games are not a matter of equal shares: one child’s turn ends when a mistake is made, so you skip rope until you step on it, you play the video-game until the game is over. Turns in games are earned and regulated by the rules of the game. It is rather different when children share a chocolate bar or sweets: the assumption is that the shares will be equal, even if perfect equivalence of the shares is not attained. Children also learn through sharing that, the more people sharing, the smaller each one’s share will be. This informal knowledge of fractional quantities requires an insight into the inverse relation between the divisor (i.e., the number by which something is divided) and the quotient (i.e., the result of the division). Few 5-year-olds realize this, but the majority of 7-year-olds knows it. This important insight into mathematical relations can be used to give meaning to the learning of fractions in school. However, this idea is neither taught nor receives recognition in school – it is taken for granted and not perceived as knowledge of fractions. Children are only credited with knowledge of fractions if the symbols used to represent fractions are involved in the questions that they are asked. The formal equivalent of this insight would be to know, for example, which fraction is bigger, $1/3$ or $1/5$. If the children can answer this, they are credited with some knowledge of fractions.

What is the difference between these two forms of knowledge, if they involve the same insight into the inverse relation between the divisor and the quotient? The comparison between $1/3$ and $1/5$ is a comparison of two written symbols; mastery of written symbols and their manipulations are recognized school-learning outcomes. The oral forms one-third and one-fifth are readings of these written forms, and as such they also obtain recognition in school. In contrast, when one talks about one chocolate shared among three children, and one chocolate shared among five children, this is a description of a situation, and its understanding is not given the same

status as comparing two symbols that have a general meaning. Schools include in their curriculum the teaching of fractions through formal representations that can be used to designate quantities; they typically do not aim at teaching children about sharing chocolates or sweets – children should learn this at home or in preschool.

This example illustrates how some forms of knowledge are seen as aims for formal teaching and learning, whereas others are not. Two aspects of formal knowledge in this case merit further consideration – the emphasis on written versus oral forms of knowledge and the emphasis on general versus specific and situated knowledge. Each of these contrasts is discussed in turn in the context of mathematics knowledge.

Written and Oral Practices

The three R's – reading, writing, and 'rithmetic – are standard aims of Western schooling. The emphasis on written practices and their transmission is a mark of schooling; people are divided into literate and non-literate for comparative descriptions of the level of education across countries. There is no similar distinction in mathematics but the emphasis on mastering the use of written symbols is so strong in school that knowledge necessary to learn these symbols can be taken for granted and not recognized as a form of knowledge.

Analyses of written and oral arithmetic practices emerged as the interest in contrasting European and African thinking grew in anthropology and psychology. Gay and Cole (1967), Zaslavsky (1973), Reed and Lave (1981), and Lancy (1983) described mathematical thinking learned without schooling, in the market, playing games, or in the course of learning a trade. Perhaps the most systematic description of mathematics learned outside school was carried out in Brazil. The Brazilian school curriculum includes teaching children to write and read numbers and to calculate using algorithms applied to written symbols. The focus on the use of written symbols and their manipulation renders children's knowledge of mathematics developed outside school invisible. Therefore, many children fail arithmetic assessments in school when they are perfectly able to perform the same calculations outside school.

A powerful demonstration of the difference between mathematics learned in and out of school comes from a study where five young vendors working in the informal economy, selling produce at street markets and corners, were asked to solve the same set of problems as part of their commercial activities and, later, in school-like situations (Nunes *et al.*, 1993). The children were very successful when they solved problems in the course of their work in the market: 98% of their answers were correct. In contrast, when they were presented with the same numbers in the

form of computation exercises, only 37% of their answers were correct. The main difference between what the children did in these two situations was that they solved the problems in the market using oral numbers – they spoke to the customers as they solved the problems – whereas they tried to solve the operations by writing them down and using the computation routines that they had been taught in school. **Figure 1(a)** shows a young vendor in his work setting, a beach in Brazil. **Table 1** presents a contrast between how one of these young people solved the same

Figure 1 (a) A young vendor selling ice-cream on the beach. (b) A young man selling hats.

Table 1 A child's answers to 35×4

M, a boy aged 12 years, who had 5 years of schooling, was presented with the question 35×4 when selling coconuts and later asked to solve the same sum.

In the informal setting:

Customer: I'm going to take four coconuts (each coconut costs 35 Cruzeiros, the Brazilian currency at the time). How much is that?

M: Three will be 105, plus 30, that's 135 . . . one coconut is 35 . . . that is . . . 140 (. . . indicates pauses where the intonation suggests that the sentence is still being continued).

Solving the computation exercise 35×4 :

C writes down 35×4 in the traditional arrangement, with 35 on one line and $\times 4$ under it, and calculates out loud: Four times five is 20, carry the two (writes 0 as a partial answer). Two plus three is five, times four is 20 (writes 20 to the left of the zero). 200.

From Nunes, T., Schliemann, A. D., and Carraher, D. W. (1993). *Street Mathematics and School Mathematics*. New York: Cambridge University Press, p 24.

arithmetic problem presented as part of a sale and later, as a computation exercise.

Brazilian young people and adults who had different occupations – fishermen, carpenters, farmers, and foremen in construction sites – and either no, or at most primary, schooling can solve many different types of problem without recourse to written symbols. Their learning outside school enables them to solve problems with any of the four basic arithmetic operations and different contents: finding out the unit price from the price for a lot, how much wood is required for building a piece of furniture, how much shrimp a fisherman has to fish if a customer wants a certain amount of shelled shrimp, how many liters of wine are needed to fill a certain number of bottles, or the size of a wall from its representation on a scale drawing. Calculating with negative numbers, simple proportions, averages, area, and volume are within the domains of what can be learned outside school. What is learned depends on the trade but the type of reasoning is not trade specific. For example, fishermen know roughly how much shelled shrimp they can get from a certain amount of untreated shrimp. They are also able to apply this proportional reasoning to agricultural products: if they are told how much cassava flour you can get from a certain amount of cassava, they can use this information to say how much cassava flour you can get from other amounts of cassava. Learning arithmetic on the job, outside school, does not only lead to job-specific knowledge, but also leads to a more general understanding of how to operate with quantities.

General versus Specific Learning

Schools are transitional places. Students are not being prepared to be students, but to go on to do something

else. Neither they nor their teachers know what they will do after they leave school. The solution to this difficult task of preparing students for doing something not yet specified is to try to teach them general knowledge, which could be used in many different occupations and settings. The expectation is that they will be able to apply this general knowledge to specific situations in which it is required. However, the application of general knowledge to specific settings is not a trivial matter. Spatial learning illustrates well the issues of general and specific knowledge. General spatial knowledge is about how to organize space: left and right, north and south, east and west can be combined with measures of space and knowledge of shapes to support spatial learning. This knowledge can be used when we arrive in a new town, but it is not the same as knowing the town. We get to know the town by looking at maps, going around, recognizing landmarks, and ordering them so that we know what is farther north than what. This type of spatial learning involves the acquisition of specific knowledge, and also more general learning: when we use a map to get to know a town, we also learn about using maps in a more general way.

General spatial knowledge can be learned in school; getting to know a town requires learning outside school. When we focus on getting to know a town, we use general spatial knowledge embedded in the knowledge of the town. We may not say “going north” but say “going towards the Bronx”; this latter way of speaking often reduces the number of steps in our thinking about spatial relations. There is often a tension between the use of general knowledge, which is focused on general representations, and the use of specific knowledge, where these representations are interpreted through the meanings that they have in the situation where we learn. This contrast is explored in the next section.

Focus on Representations versus Focus on Meaning

Concept learning involves putting meanings together with their representations, which are often conventional. Learning vocabulary, for example, which starts many years before school, is about learning words – a verbal representation – and their meanings. Although representations and meanings are closely related, learning outside school influences the way we speak: we speak about the meanings rather than about the general aspects of knowledge.

A very simple example, which we encountered in our study of mathematics learned outside school, is that of a 9-year-old boy, R, solving a problem in a simulated shop situation. He used written arithmetic to solve the problem, as he would have used in school, but it was his understanding of the meaning in the situation that showed him that something had gone wrong with his calculations.

Table 2 presents an extract of his interaction with the interviewer.

A school-like argument, which a teacher could present to R, would be: if you take something away from 200, the answer cannot be 200 or greater than 200. This argument, formulated in a general way, contrasts with R's argument, which has the same sense but is presented embedded in the meaning that 200 has in this situation. He argues that he should not hand back to the customer the 200 note that the customer just gave him.

The focus on meaning when learning happens on the job was also observed by Noss *et al.* (1999), who asked nurses to read blood pressure charts and say what average blood pressure meant. Students usually learn in school a concept of average as a measure of central tendency, used to describe a population. Nurses look at blood pressure charts to see whether changes in the blood pressure of a patient are significant enough to call for medication. This gives them a different concept of average, as they add to the mathematical concept the meaning normal for the patient, which is not part of the mathematical concept. When they look at a blood pressure chart, they do not calculate the mean but consider the variation of the measurements, estimate the average to be around the most frequent value at the center of these variations, and then make a judgment about the need for medication. The meaning of average is placed in the context of their activities. When asked about the variations that are observed in the chart for a child, they think about what the child could have been doing at the time. In a statistics class, these could be treated as random variations or

measurement error. A quote from an interview illustrates this focus on the meaning of average interpreted in situational terms.

She was... it was settled here, the early hours of the morning... I don't know, what with the activities of the day probably getting on top of her here, so she's probably a bit more agitated there, so you could allow for the increase [in blood pressure], or whatever. But probably in the morning she's more settled... Yeah, I'd like to think that she was asleep then, so she had a settled blood pressure (Noss *et al.*, 1999: 37).

Noss *et al.* (2007) further illustrate this attribution of meaning in another situation where graph reading was learned on the job. Jim, a shift leader in a large factory that makes plastic sheets, had learned, through 31 years of experience on the job, to read the complex graphs that recorded variations in tension and temperature of the materials over time and at different places in the production process. When a problem occurred in the production process, he would take the graphs and examine what was happening just before the problem occurred. Using this information, he was able to identify the location of the problem, and maintenance engineers would then be called in to check the item he had identified as the likely cause. This was not seen by the chemical engineer, who was responsible for the overall production, as a simple accomplishment: Jim had to be able to identify readings in a graph as normal, thus attributing to them a meaning that was learned in the situation. She described briefly what he had done in one instance when he thought that one straight line on the graph (which contained many different lines, including some straight ones) looked too good to be true.

By examining the "revs [revolutions] per minute" historical data and seeing that it wasn't fluctuating as Jim expected but was a constant value, he determined something was wrong with it. He alerted the maintenance engineers who found the motor on the controller had been fitted to run backward after some work done on it the previous day and so the signal it was sending for revs per minute was false. Jim doesn't know anything about motor control – he just knew that the historical data looked "wrong" (Noss *et al.*, 2007: 377).

Thus the process of learning on the job, outside school, involves going beyond the information given in the representations, by attributing to them specific meanings taken from the situation, which the representations would not convey by themselves. R's argument that it is not sensible to return to a customer the note that he just received in payment for a merchandise, the nurses reading into the blood chart that the child's blood pressure was settled while she was asleep and went up when the activities started in the ward, and Jim's identification of a specific

Table 2 Using meaning to assess the results of a computation

Interviewer (I): Now I'm buying this, and it costs 35 Cruzeiros. I'm going to pay with a 200 note. How much will you give me back?
R: (writes 200–35 in the traditional alignment, and says): Five, to get to zero, nothing. Three, to get to zero, nothing. Two, take away nothing, two.
I: Is it right?
R: No. So you buy something from me, and it costs 35, you pay with a 200-cruzeiro note and I give it back to you?
I: Do it again, then.
R: (writes down 200–35 in the same way) Five, take away nothing, five. Three, take away zero, three. Two, take away nothing, two. Wrong again.
I: Why is it wrong again?
R: Now you buy something and it costs 35. You give me 200 and I give you 200, and 35 on top?
I: Do you know what the result is?
R: If it were to cost 30, then I'd give you one seventy.
I: But it is 35. Are you giving me a discount?
R: 165.

From Nunes, T., Schliemann, A. D., and Carraher, D. W. (1993). *Street Mathematics and School Mathematics*. New York: Cambridge University Press, p 46.

straight line on the graph as too good to be true, all exemplify this process of going beyond the information given in the symbols by imbuing them with situation-specific meaning.

Thought versus Action

Sylvia Scribner, one of the most distinguished researchers of learning outside school, argued that models of the mind based on the metaphor of the mind as a computer fail to capture those significant aspects of learning that are based on action. In a series of works about thinking in action (Tobach *et al.*, 1997), she reasoned that learning, memory, and thinking in everyday life are not separate from what we do but part of what we do. Therefore, what we do is also part of our learning, memory, and thinking. In order to develop this argument, she drew on Luria's (1973) concept of functional systems as the basis for higher mental functions. Luria's example of how memory works helps us understand the basic notion that there is no opposition between thinking and action, or mental and manual work. When we want to remember something, we might repeat what we want to remember many times to ourselves, and be able to recall it later. However, our memory function would be greatly restricted if this were all we could do. Fortunately, we can also write down what we need to remember, and be so organized about where we write what down that we know where to look for the information when we need it. Therefore, Luria argued, memory is not an activity restricted to the brain: it can be accomplished through functional systems that maintain the task of remembering constant but accomplish it through a variety of means, including the incorporation of external objects into our memory system.

Learning outside school leads people to incorporate into their thinking systems the tools and the characteristics of the objects that are used in the environment. Scribner (in Tobach *et al.*, 1997: 338–366) analyzed how product assemblers in a dairy factory in the US incorporated the characteristics of packing into their thinking as they pre-packaged items for an order. Products were packed as different units: a case equals 4 gallons, 8 half-gallons, 16 quarts, 32 pints, or 48 half-pints. When a product assembler is putting together an order, he might have a load-out form that shows 1 – 6, that is, 1 case minus 6 units. If this order called for something that is packaged in quarts and the assembler filled it literally, he would start from a full case (which has 16 quarts) and remove six from it. However, this is not necessarily how assemblers work. If there is a half-empty case close by, the assembler is much more likely to add 2 units to it, translating the order into half-case plus 2, a solution that saves effort and time. Scribner compared product assemblers' performance with that of students,

who would be able to use the same reasoning but had not learned about assembling on the job and had limited experience of assembling products through their participation in Scribner's study. Product assemblers were about 3 times more likely to use effort-saving strategies than students, when these did not coincide with the literal solution. Learning on the job granted product assemblers greater flexibility in treating the units in cases as units of thinking: in the same way that we think easily using the decades of our number system, they had learned to use the units of packing as thinking units. Just looking at a half-full case of quarts allowed them to know that there were 8 units there, and move smoothly to the action of adding 2 units.

Scribner concluded from her different studies of thinking in action that higher-order solutions such as those illustrated above had a major effort-saving impact on the manual execution of the work: in one estimate, she concluded that literal solutions with one item assembled at a time would involve walking roughly 4 miles to complete the jobs; this contrasted with the actual solutions, which involved a little more than 2 miles. Assemblers had not learned this effort-saving from lingering over the order forms or engaging in discussions with each other. Thus, Scribner concluded, they must have learned by representing quantities and space in a way that synthesized the different forms of organizing and regulating their own actions; they learned by thinking in action.

The incorporation of cultural and cognitive tools into the learner's thinking system is not a defining characteristic of out-of-school learning. Wertsch (1998) provides a convincing example of this incorporation in his discussion of how we solve multi-digit multiplications. If we are asked to say what is 343 times 862 without using a calculator, we would write down these numbers in vertical alignment and carry out the algorithm that we learned in school. This algorithm is a cultural and cognitive tool, which we incorporate into our thinking, and without which we would not be able to solve the problem. It differs across countries slightly – for example, in some countries, when we multiply 343 by the 6 in 862, we write the product one row to the left. We are, in fact, multiplying 343 by 60, not by 6, and this is simplified by acting as if the multiplication is by 6, thereby making the multiplication routine more similar across the units, tens, and hundreds. Learners can carry out the procedure without full awareness of why a place is skipped in the process – they are, in this case, relying on a tool and downloading part of the difficulties of the process onto the paper-and-pencil record (to use Hatano's, 1997, expression).

Learning in and out of school is a process that allows people to participate in socially organized activities, so incorporating the tools that are used in these activities into our thinking is a common feature of learning in and out of school.

Table 3 Some of the idealized characteristics of informal and formal education

<i>Informal education</i>	<i>Formal education</i>
1. Embedded in daily-life activities	1. Set apart from the context of everyday life
2. Learner is responsible for obtaining knowledge and skill	2. Teacher is responsible for imparting knowledge and skill
3. Personal; relatives are appropriate as teachers	3. Impersonal; teachers should not be relatives
4. Little or no explicit pedagogy or curriculum	4. Explicit pedagogy and curriculum
5. Learning by observation and imitation	5. Learning by verbal interchange, questioning
6. Motivated by social contribution of novices and their participation (in real activities)	6. Less-strong social motivation

Some of the idealized characteristics of informal and formal education (adapted from Greenfield & Lave, 1982, p. 183) from the book *CULTURAL PERSPECTIVES ON CHILD DEVELOPMENT* ed. by D. A. Wagner and H. W. Stevenson. Copyright 1982 by W. H. Freeman. Reprinted by permission of Henry Holt and Company, LLC.

The Places and Processes of Learning

There are similarities between learning in and out of school. However, it is important not to forget the differences, which are related to how roles are defined for the teacher and the learner in and out of school, what is expected of each, and what is the focus of their attention as education takes place. Greenfield and Lave (1982) summarized, some years ago, the processes by which schooling and informal education seek to promote learning; the characteristics relevant to this analysis are presented in **Table 3**.

Their analysis can be complemented by a more detailed description of the implicit pedagogy that emerges from analyses of learning outside school. Rogoff (2003) analyzed how novice girl scouts become experts in selling cookies and how mothers guide their children's learning in a variety of settings outside school. She termed *guided participation* the implicit pedagogy used by adults outside school, a term that indicates that novices do not take full responsibility from the outset in learning situations, but still have some responsibility for the activities they engage in. Girl scouts are able to participate in selling cookies, even as novices, through the use of forms that they fill in, which work as tools that organize the activity, and through their interactions with peers, as they work together.

Rogoff distinguished different forms of guided participation when mothers have the role of tutors. In middle-class US families, adults organize child-centered learning events, and structure the children's learning by directing their attention, promoting their motivation, and maintaining

their engagement. European and US middle-class mothers involve their children in events that are similar to school lessons in the family. Tizard and Hughes (2002) observed European mothers playing games that are aimed to prepare children for what they will learn in school (e.g., Mother: "I spy, with my little eye, something beginning with S"; child has to identify something in the room whose name begins with the letter S) and lesson-like activities in the home, where the mother writes something and the child copies it. Heath (1983) also observed, in the US, how mothers read stories to their children at bedtime and prepare them for adopting the concept of a story and for comprehension questions that are similar to those asked of children in school. In contrast, mothers from traditional societies, where tradition is a value, expect children to learn through watching and manage their own attention, motivation, and involvement. Rogoff cites examples from Japanese, Polynesian, and Mayan communities, where children are expected to learn through intent participation, being able to observe and listen in ongoing processes that were not set up for their learning. Guided participation then takes the form of encouragement of observation and responsive assistance, for example, rather than through school-like lessons enacted outside school.

Conclusion

In summary, learning outside school is learning in action, by doing something with an aim that is different from learning itself, by participation in an activity where the learner has some responsibility. Thinking in the course of these activities incorporates the representational tools and objects that are part of these activities, and does not single out, as more valuable, written over oral representations, or general over situated arguments and explanations. When using representational tools, such as number systems and graphs, people go beyond the information given in the representational tools, adding meanings from their learning in the situations where the tools are embedded. Outside school, learning is often guided, monitored, but not tested or given official recognition. There is no explicit curriculum, no designated teacher, no explicit learning outcome, and no accreditation – all of which make the learning that happens outside school invisible to some extent. The sample of studies presented here should help make out-of-school learning more visible, less taken for granted.

Reasoning and Explanatory Talk: Learning in Everyday Settings

D E Beals, The University of Tulsa, Tulsa, OK, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Explanatory talk with, and by, children offers a unique opportunity to examine both cognitive and linguist development and outcomes. Children may learn the relationship between objects, concepts, and/or events delineated in an explanation. Conversely, they must understand the relationship in order to explain it to someone else.

Historically, there have been two basic approaches to children's explanation. The first is based in the philosophy of science – linking scientific explanation with children's reasoning. The second is based in sociolinguistic and sociocultural theories – focusing on the interaction between children and more knowledgeable others that allows the child to participate in the language of reasoning. Although the two approaches have two somewhat distinct research and theoretical literatures, each perspective benefits the other by linking what a child learns and knows to what linguistic, social, and cultural contexts the child is exposed to and participates in. The first approach focuses on what is going on inside the child's mind (cognition), while the second focuses on what is going on in the world outside the child's mind (interaction). While these two approaches examine children's talk from different perspectives, there is much crossover. It is almost a cliché to say that a child's speech is a window to its mind. The window glass, however, is not transparent, but translucent – allowing researchers to infer what a child thinks from the forms and shadows of the internal workings of the mind visible from the outside. This article focuses more specifically on the sociolinguist approach; however, the cognitive approach provides a strong foundation – theoretically and historically – for the framework of the interactionist approach.

Definition of Explanation

The philosophical literature on why we seek and give explanations and what kinds of things need explanation is a long one. In the last century, much work has been limited to a logical-positivist concentration on explanation as mathematical proof – allowing for deductive-nomological thought (Hempel, 1965). According to Hempel and others, an explanation of a scientific phenomenon is a deduction from natural laws the nature of consequences or effects; major views of explanations in the last century have concentrated on the ability to predict future events based on

these deductions from laws of nature. There is a strong flavor of the language of logic and rationality in these definitions, focusing entirely on scientific explanation.

Keil (2006), however – in review of the literature – took issue with the narrow range of Hempel's explanation. He outlines several purposes for explanation, including: (1) predicting events in the future based on laws and consequences (Hempel's definition); (2) diagnosing system failures and repair of the system based on these; (3) placing of blame *post facto* since a specific prediction in advance is unlikely (Keil's example was with regard to the car crash that killed Princess Diana); and (4) justifying a specific action as result from reasonable or beneficent intentions. While the first two generally follow more traditional definitions and scientific explanation of reasoning, the last two are less about logic and more about human intention, which is not always rational. Keil refers to these as everyday explanations. He sees the social nature of these everyday explanations, claiming that “explanations view people less as autodidacts and more social interacting agents” (p. 230). The work of several developmentalists have examined children's ability to comprehend and produce scientific explanations and even argue for the similarities between the children as developing explainers, scientists, and psychologists.

Explanation as Discourse Genre

Bruner (1985) posited the existence of two major modes of thinking: narrative – which deals with intentions and actions and their consequences – and paradigmatic – which uses formal logical and scientific description and explanation. The narrative mode attempts to emphasize the particular and locate it in time and space, the paradigmatic mode attempts to “transcend the particular by higher and higher reaching of abstraction” (p. 13). These two modes are played out in different forms of discourse genres such as stories and plans for narrative thought and arguments and explanations for paradigmatic thought.

Bruner assumed that narrative is the earliest mode and discourse genre accessible to young children, with the paradigmatic thought and discourse emerging later. In fact, he argued that narrative thought is natural, untrained, and even primal. The ubiquity of story-telling and storybook-reading discourse in interaction with children is a reflection of such an assumption (Pappas, 1993). If the assumption is correct, it is important to examine the

emergence of paradigmatic discourse genres, such as explanation and argumentation.

Considerable attention has been paid to the development and display of narratives by numerous researchers, for example, Nelson and her colleagues (Nelson, 1986) – who examined a variety of narratives and charted the linguistic resources children use in narratives; and by Slobin and collaborators (Berman and Slobin, 1994) – who examined narrative production across cultures. In comparison, relatively little research has focused on the development of explanatory discourse, with the exception of the naturalistic, descriptive work of Barbieri (1991), Landolfi (1989), and Beals (1993). Additional developmental work on explanation has focused entirely on explanations at the sentence level.

Narratives and explanations share a number of features that might lead one to expect more or less parallel development. Both are structured forms of extended discourse around a specific topic that require formulation of a general goal and control over inter-utterance cohesion markers. Both require the participants to talk about topics outside of the immediate present. Both forms occur with relative frequency in everyday conversations and are characterized by collaborative multiparty participation structures. Exposure to both discourse forms relates to early indicators of school success, such as vocabulary, skill in rendering formal definitions, and comprehension. Further, research has shown that even young children such as kindergartners demonstrate no more difficulty remembering and retelling information in explanatory forms than in narrative forms found in children's books (Pappas, 1993).

There does not always appear to be a clear distinction between narrative and explanation in the literature; some scholars have argued that explanation is not a separate genre but a primary function of narrative. Kemper's (1984) work on narrative structure claimed that causal (and intentional) relationships are generally found in stories people tell. According to Kemper, stories lay out events in terms of intentions and evaluations of the storyteller through the use of temporal and causal connections. Ochs *et al.* (1992) studied the use of narrative as a form of problem solving at mealtimes in which family members co-narrate stories, and in the process, use and polish the social, cognitive, and linguistic skills that underlie scientific and other scholarly discourse. Ochs and co-workers claimed that the collaboration around narrative supports theory building among speakers, not unlike the work of scientists. Even more extreme views exist; some consider all forms of discourse to be some kind of narrative.

There are a number of crucial interrelated features to extended discourse. First, extended discourse requires paying attention to the needs of the audience. Bakhtin refers to the addressivity of utterances: speakers are always responding to utterances previously spoken and

in anticipation of the potential responses of their listeners. Discourse is then constructed by speakers from what they assume the point of view of the listener to be. Another audience requires that speakers take into consideration how much knowledge they have in common with their listeners in order to gauge how much detail and explicitness to provide in the course of discussing a topic. Listeners in conversation are able to provide feedback to the speaker by asking clarifying questions or by facial expressions, and the speaker monitors how effectively his talk or text is in meeting the audience's needs both in terms of the amount of information needed and in terms of preparing a response to the content of the interlocutor's utterance(s). This allows the speaker or writer to recognize when he is not connecting well with the listener or reader, and to revise his discourse in order to get his point across.

Another aspect of extended discourse is its structure. Discourse comes in a variety of genres, each with its own purposes, demands, and affordances. In written discourse, there is frequently a common structure that aids readers in comprehending the text by allowing them to predict and recognize relationships within and across sentences. Much work has been done identifying structures of various types of children's narrative genres and others have studied explanatory genres. While written discourse is more likely to demonstrate the usual structure of a genre, conversational discourse is less predictable in form and sequence, but generally the kinds of information found in the written forms are found in the conversational genres as well.

Children's Explanations

Talk between adults and children can take many forms, but one type that has been shown to have both cognitive and linguistic benefits is a type of talk that Sigel (1981) calls parental distancing behavior and Snow calls extended discourse (Snow and Kurland, 1996). In this sort of talk, the parent talks in ways that allows the child to distance herself from the immediate present, to represent mentally some other place and/or time. This sort of talk places not only cognitive demands on the child in order to comprehend and produce it, but it also makes linguistic demands on the speaker to be more explicit about people, places, objects, events, and the relations among them. As the topic is not necessarily present in the immediate social and physical context, the speakers must make assumptions about what the listeners know and what they are thinking about at the moment of conversation. Much research has demonstrated the relationships between children's exposure to such talk and their cognitive and linguistic skills.

Underlying a child's ability to explain something is its understanding of the logical relations involved.

These abilities, at least in the case of causal relations, have been shown to emerge early in language development. While the work of Piaget (1926, 1930) suggested that children do not have true understanding of causality and causal connectives (such as *because* and *so*) until age 7 or 8, other researchers have demonstrated that some understanding of cause and its linguistic expression emerge prior to age 3. Observational studies of children's spontaneous production of causal explanations in conversation with familiar adults provide some evidence that children as young as 2.5 years begin to use their first expressions of causal relations and use causal connectives correctly.

In his studies of children's conceptions of causality, Piaget (1928) suggested three types of causal relations: (1) physical or empirical (between two events); (2) psychological (between two psychological activities, mental states, and/or intentions; and (3) logical (between two ideas or judgments, or between a judgment and its proof or logical antecedent). Piaget's hypothesis was that – because of their egocentric thought – preoperational (ages 2–7) would fail to distinguish between these three types and would tend to overgeneralize the psychological relations (e.g., “The door slammed because it was angry”). In his analysis, children come to understand psychological relations first, followed by physical relations, then logical relations. His research confirmed this hypothesis. Later research on very young children (prior to age 3) confirmed that the most frequent explanations express psychological causality.

Following Piaget, Donaldson (1986) referred to these categories of explanations as the content of explanations. Each content category is based on the type of rules or laws that are invoked in the explanation. The following sentences illustrate these content categories (p. 3):

The window broke because a ball hit it. (Physical)
 Mary hit John because he pulled her hair. (Psychological)
 Half nine is not four because four and four make eight.
 (Logical)

Donaldson distinguished these content categories from modes of explanations. Modes correspond to the types of questions that explanations answer. The four modes of explanation are (1) empirical (answering the question “what caused it?”); (2) intentional (“for what purpose?”); (3) deductive (“how do you know it?”); and (4) procedural (“how do you do it?”). Donaldson emphasizes that content categories and modes of explanation are not totally independent. A specific content type constrains the mode for linguistic expression of that content type to some extent. Psychological content may be asserted in an empirical, intentional, or deductive mode of explanation, indicating a broad range of possibilities for expression. However, logical content is expressed exclusively by a deductive explanation mode, although physical and

psychological relations may be presupposed within the explanation.

Donaldson performed a series of studies on children's abilities to produce explanations of the three types of content. Utilizing tasks that focused on each of the three content categories, she elicited causal statements from children at different ages. She found that children as young as age 3 produced well-formed and appropriate explanations of psychological, physical, and logical phenomena. This contradicts Piaget's (1928) findings that children are unable to produce appropriate explanations until the age of 7 or 8, and once they can, they tend to psychologize, or give psychological explanations of physical phenomena. She attributes these contradictory findings to the fact that children in her studies were asked to explain events and emotions familiar to them, while Piaget asked children to explain for esoteric phenomena. Donaldson's results coincide with the earlier work that indicates, in spontaneous speech, that preschool children produce causal explanations for all kinds of things. Donaldson also performed a series of studies aimed at eliciting each mode of explanation (except procedural, which she chose to exclude from her research). The results of each study indicate that children, by age 5, have considerable skill in producing empirical, psychological, and deductive explanations.

Explanation as Social Interaction

Explanation – like other types of talk – is a social activity. Much of the research on children's production of explanations has focused on explanations of causality, exploring children's use of sentential connectives such as ‘*because*’ and ‘*so*’. The decision to focus on a causal definition of explanation was, most likely, a methodological one; this definition is easily operationalized by a search for the use (or implication) of causal terms and connectives in children's talk. There is another line of research that draws sociolinguistic and sociocultural theories – using discourse-analysis methodology to examine children's participation in everyday explanatory talk. This line generally differs from the more cognitively focused research by defining explanatory talk as a conversational exchange in which one speaker recognizes that another person needs some information, and as a result, offers the information. This information is often causal or intentional links are a major category, there remain other kinds of explanations that express a variety of logical relations, such as definitions and procedures. The focus on connectives, such as ‘*because*’ and ‘*so*’, implies that the sentence is the unit of analysis. However, social interactionists emphasize the fact that explanations occur in the give and take between interlocutors – in longer segments of discourse, often over several speaker turns. These studies examine the talk of the child and those around her in the conversation. Children hear explanations, give

explanations, and jointly construct explanations with parents, siblings, and friends.

Minimally, an explanation occurs when one person makes some connection (between events, actions, ideas, or judgments) clear to another. An explanation, however, is rarely a simple utterance. It is often prefaced by a request for information, interrupted by requests for clarification or expansion, elaborated by additional information from other persons, and closed by an acknowledgement of understanding. A more sociolinguistic approach to the study of the development of explanatory talk emphasizes examination of the immediate physical and social context of the conversations for evidence of the occurrence of an explanation. Such an approach has been utilized by Barbieri (1991) and Landolfi (1989).

Barbieri, arguing that explanations are defined not by content only, but also by context, studied explanations that arise in naturalistic settings. Analysis of children's conversations in play with other children revealed another category of mode of explanation. While Donaldson's modes of explanation posed 'why' and 'how' questions, Barbieri *et al.* found, in addition, that children produced 'what' explanations. These explanations answer such questions as "what is the type and/or the characteristics of an object?" and "what does a human action or verbal expression mean?" She found that six out of nine of her 3-year-old subjects produced such explanations spontaneously in conversation.

While Barbieri's dependence on context to reveal the presence of an explanation is intuitively appealing, operationalizing such a definition is not a simple matter. She suggested two sets of conditions necessary for the existence of an explanation in conversation. These include: (1) the preparatory conditions: joint attention to what is to be explained, and the belief on the speaker's part that such an explanation is called for; and (2) the essential conditions: the explanation is comprehensible to the hearer, and there must be something to be explained and some new information about it. These two conditions highlight the interactional nature of explanation, and provide a broader move toward an operational definition for explanations in children's conversations.

Based on her work on discourse in adult second-language classrooms, Landolfi (1989) distinguished between the synchronic and diachronic aspects of explanation. The synchronic aspect refers to "explanatory activities as they occur within social interactions (i.e., inter-subjective development)" (p. 137), while the diachronic aspect refers to "the history of synchronic explanation as internalized by each individual (i.e., intra-subjective development)" (p. 137). Only synchronic explanations are observable, while diachronic explanations are inferred.

Landolfi posited that synchronic explanations are jointly constructed by interlocutors, and that they unfold in a cycle (see Figure 1), which begins with a trigger

(a direct or indirect question or an observable fact or event) that creates a state of dissonance in a person's universe of knowledge. This causes the person to seek other sources of knowledge (e.g., another person, a book, the Internet) that re-establishes a state of assonance. The new knowledge that brings about assonance rearranges the prior universe of knowledge, producing a new universe of knowledge. The cycle then begins again, resulting in a diachronic spiral (Figure 2) – a repeating cycle bringing interlocutors into deeper and shared understanding of the universe of knowledge. In this way, an explanation is co-constructed by the person seeking new knowledge and the source of new knowledge. Although Landolfi's model grows out of research with adults in a structured learning environment, it provides a reasonable framework for identifying explanations and observing their joint construction with children in formal and informal conversational settings.

This social interactionist approach to the study of children's participation in explanatory talk has yielded

Figure 1 Synchronic cycle. T, trigger; UK, universe of knowledge.

Figure 2 Diachronic cycle. T, trigger; UK, universe of knowledge.

much fruit. Following the work of Donaldson, Barbieri, and Landolfi, several researchers have analyzed everyday conversational settings, such as mealtimes and play time, in order to examine how children used explanations in spontaneous talk with adults and with other children. Drawing on data from a large longitudinal study, Beals (1993) examined spontaneously emerging explanatory talk in 160 transcripts of mealtime conversations of children in the study at age 3, 4, and 5. On average, 13–14 explanations took place in a mealtime (average length of recordings was about 20 min), accounting for about 15% of the all talk in the conversation. Beals found that approximately two-thirds of all explanations were about the intentions of a person in doing or saying something. Causal explanations were present but relatively infrequent.

This line of research has been further expanded to cultural comparative work. In a study comparing the use of explanatory talk during mealtimes in American and Norwegian families, Aukrust and Snow (1998) adapted Beals' categories of explanation. The findings indicated that American families tended to engage in more explanatory talk than did Norwegian families. Americans talked more of intentions and causes, while Norwegian families focused on social norms and violations of them. Aukrust and Snow interpreted these findings as reflecting the relatively individualistic norms of Americans and collectivistic norms of Norwegians.

Summary

The two approaches to the study of children's exposure to and engagement in explanatory have generated rich theoretical and research bodies, many of which merge into outlines of a portrait of children as explainers and seekers of explanations. The cognitive approach points to children's early understanding of causality and intentionality, based on their naive biological, physical, and psychological theories. Children as young as age 30 months are able to comprehend and participate in talk concerning explainable phenomena – much sooner than thought by Piaget – and they are able to do this with increasing frequency and facility throughout their preschool years. The developing mind of the child – able to comprehend and predict basis scientific and psychological phenomena – engages with the social world around it and expresses it in co-constructed discourse in a wide range of explanatory topics and forms.

Glossary

Apprenticeship – Training in an art, trade, or craft under a legal agreement defining the relationship between master and learner and the duration and conditions of their relationship. There are different connotations of the Anglo-Saxon apprenticeship and the German–Scandinavian *mesterlære* (master learning). In the Anglo-Saxon apprenticeship, the learning of the apprentice is stressed. Prevalence of the master's role for learning is implied in the Scandinavian–German term for apprenticeship – *mesterlære*.

Apprenticeship in the guilds – The formal European apprenticeship of the guilds involves a written contract between master and apprentice, stating obligations for both parts, with the term of apprenticeship often ending after a 4-year period with a journeyman's test and an official accreditation as a journeyman of the trade.

Community of practice – A term especially introduced in Lave and Wenger's *Situated Learning. Legitimate Peripheral Participation* (1991) meaning an activity system about which participants share understandings concerning what they are doing and what that means in their lives and for their communities.

Scaffolding – The concept of scaffolding is a metaphor from building constructions used to illustrate the interaction between tutor and child/pupil. The notion of scaffolding is influenced by Vygotsky's concept of zone of proximal development which is understood as the distance between the

actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers.

Scholastic approach to education – An approach to education characterized by a narrow concern for book learning and formal rules excluding knowledge or experience of practical matters.

Learning through apprenticeship was, for centuries, the central way of introducing youth to the skills, knowledge, and values of a craft and a profession. In this and the last century, apprenticeship has been replaced by schooling in many areas. Whereas learning in schools has been extensively researched, apprenticeship learning has enjoyed less attention from educational researchers. In the last few decades, a new interest in apprenticeship learning has emerged: in anthropological studies of learning as social practice, in philosophical analyses of skill learning and tacit knowledge, and in educational experiments with cognitive apprenticeship in the school curriculum.

In this article, some key issues are outlined from the renewed focus on apprenticeship. First, some definitions, main aspects, and varieties of apprenticeship are outlined. Second, different theoretical approaches to apprenticeship are emphasized – anthropological, philosophical, and psychological. Two dynamic perspectives on the dynamics of the learning process are presented: a person-centered versus a decentered approach. Different conceptions of the

nature of apprenticeship learning are described such as learning in a community of practice, learning through participation in practice, bodily learning and imitation, and learning through assessment of practice. Finally, some reasons for the current interest in apprenticeship are discussed.

Delineation of Apprenticeship

Today, the term apprenticeship is used in several different ways. This calls for some distinctions concerning definition, main aspects, and varieties of apprenticeship to be mentioned.

Definition

Apprenticeship is defined in *Encyclopedia Britannica* (2007) as: “training in an art, trade, or craft under a legal agreement that defines the duration and conditions of the relationship between master and apprentice”. Apprenticeship originates from the French phrase *a prendre* which means to learn or to grasp mentally (Webster, 1968). There are different connotations of the Anglo-Saxon apprenticeship and the German–Scandinavian *mesterlere* (master learning). In the Anglo-Saxon apprenticeship, the learning of the apprentice is stressed. The prominence of the master’s role for learning is implied in the Scandinavian–German term for apprenticeship – *mesterlere*.

Varieties of Apprenticeship

Apprenticeship occurs in many forms and fields. The formal European apprenticeship of the guilds involves a written contract between master and apprentice, stating obligations for both parties and terms of apprenticeship, which often end after a 4-year period with a journeyman’s test and an official accreditation as a journeyman of the trade. Within vocational education in parts of Northern Europe, the classical apprenticeship model has gradually been replaced by a dual system whereby the apprentices move between intermittent periods of practice at a workplace and attending lessons at technical schools (Christensen, 1995; Bailey, 1993; Hamilton, 1990). Other apprenticeships may be more informal, whereby the apprentices, so to speak, grow up with a trade. In Lave and Wenger’s (1991) development of a theory of situated learning, they draw upon five cases of apprenticeship: Yucatec midwives, Liberian tailors, naval quartermasters, meat cutters, and sober alcoholics. Of these, the apprenticeships of the meat cutters were formally defined in writing, the tailors in oral agreements, whereas the midwives grew up with the family trade.

While apprenticeship is commonly associated with the crafts, it takes place within a wide spectrum of fields. Within the field of classical music, apprenticeship learning is often used to describe the way the students learn at the

Academy of Music (Nielsen, 1999). Artists have long learned through apprenticeships with a master as, for example, in the studio of Rembrandt. Consequently, today, art historians have difficulties determining whether a painting is by the master or an apprentice of his. It is equally striking today how artists’ biographies emphasize the masters they have studied with; for example, see *Stocktakings of an Apprenticeship* by Boulez (1991). The role apprenticeship plays in learning advanced intellectual pursuits is documented by the Nobel laureates in the sciences (Kvale, 1997).

Apprenticeship is found in most cultures (Coy, 1989), as witnessed in the Asian spiritual traditions as well as in martial arts. The master–disciple relationship is essential for the transmission of truth in major wisdom traditions, such as Buddhism. While enlightenment and freedom cannot be obtained without relying on a master, it is the truth of the teaching which is all important; Buddha thus warned, “Rely on the message of the teacher, not on his personality” (Rinpoche, 1992).

Theoretical Approaches

Apprenticeship has been explored within different disciplines and theoretical positions. Three approaches – an anthropological, a philosophical, and a psychological–educational – are outlined shortly.

Anthropological Approaches to Apprenticeship

Inspired by fieldwork in third world countries, anthropologists have reconceptualized learning from the perspective of social practice. One background for this move was the increasing tendency in the Western industrial world to perceive learning as a mechanical consequence of teaching, as an individualistic endeavor to pass the next examination, or to fulfill the need of self-realization. By studying apprenticeship, anthropologists understood learning as a basic social phenomenon, initiating both change and continuity in a social practice (Coy, 1989; Lave and Wenger, 1991; Singleton, 1998). Learning was an aspect of cooperation between different participants in making a production work. This cooperation was embedded in everyday practice, and not isolated in educational institutions. From one perspective of anthropology, the real master in apprenticeship is the ongoing social and bodily activities, in particular organized practices, which in turn create a particular social habitus (Bourdieu, 1992).

Philosophical Approaches to Apprenticeship

One of the consequences of the efforts to create artificial intelligence has been an expansion of our understanding of

human competences and practical rationality. In the efforts to simulate different kinds of practical competences in a computer, the limitations of desituated and disembodied simulations of practice became apparent. Philosophers have turned to apprenticeship as a way to learn tacit and bodily competences (Polanyi, 1958). Not all competences could be formulated into explicit rules and transmitted verbally; some could only be transmitted through practical action. Only by observing the experienced master and by using the skills in a practical situation could the novice acquire these kinds of practical competences (Dreyfus and Dreyfus, 1986, 1999; Wackerhausen, 1996).

Psychological and Educational Approaches to Apprenticeship

A psychological approach to apprenticeship has been inspired by Bandura's theory of social learning, emphasizing identification and imitation as central means for learning (Jespersen, 1997). Cognitive apprenticeship is a term designated to a synthesis of school and apprenticeship and is based on insights gained from studies of apprenticeship in school curriculums. Through modeling and scaffolding, the teacher offers the students an understanding of the strategies behind solving a problem (Collins *et al.*, 1991). Gardner (1993) discusses in *Multiple Intelligences* apprenticeship and a scholastic approach to art education, and also depicts the use of apprentice-like situations in the classroom. Apprenticeship has also been used to designate the psychological and social development of the child. The interaction between parents and children metaphorically resembles the interaction between master and apprentices, and when the child learns cognitive structures from participation and observation of the parents' everyday activities (Rogoff, 1990).

The Dynamics of Apprenticeship Learning

Within the various theories of apprenticeship learning, different perspectives on the dynamics of the learning process are found. Two approaches – a person-centered and a decentered approach – are outlined.

A Person-Centered Approach to Apprenticeship Learning

With the absence of formal teaching in apprenticeship, the question remains of what advances the learning process – the master or the structures of the community in practice? In a person-centered approach to apprenticeship learning, the point of focus is centered on the relationship between master and apprentice (Dreyfus and Dreyfus, 1999; Polanyi, 1958). The master is the

practitioner, who, in practice, reflects and makes the thinking of the profession visible to the apprentice (Schön, 1987). The master may serve as a role model (Collins *et al.*, 1991), making the tasks to be learned visible, and also by serving as a source of identification. Ziehe and Stubenrauch (1983) have, in a discussion of learning at a school for clowns, pointed to a transition over time in the master–apprentice relation, moving from a personal to a structural identification. It is no longer the personality of the master, but his relation to the topic of the work and learning which is decisive. Learning is not merely an imitation of the master, but also based on the relation of the master to the topic of learning.

A Decentered Understanding of Apprenticeship Learning

In a decentered understanding of apprenticeship, the decisive factor is the participation of the learner in a community of practice. Lave and Wenger (1991) emphasize, in contrast to a strongly asymmetrical master apprenticeship relation, learning through legitimate peripheral participation in communities of practice. This leads to a focus on the intricate structuring of a community's learning resources: "To take a decentred view of master–apprentice relations leads to an understanding that mastery resides not in the master but in the organization of the community of practice of which the master is a part. . ." (p. 94). What motivates the apprentice is to become a fully legitimate member of the community of practice at the workplace.

From a decentered perspective on apprenticeship, suggestions for what is important for the learning process include: open structures of the community of practice, which facilitate observation and sharing of ways of solving problems; a gradual move to more central and important tasks in practice; access to observe older apprentices or journeymen's way of handling the production process; and the way the learning process is organized in relation to the production process and access to narratives of the trade (Lave and Wenger, 1991).

Central Features of Learning in Apprenticeship

The kinds of learning found in studies of apprenticeship introduce a shift in attention from the attributes of individual participants to the aspects of the environment, which make learning possible. This contextualization of the learning process implies a movement from individuals who learn in isolation to communities of practice where learning occurs.

The following is an elaboration of the specific features of learning processes that take place in apprenticeship such as learning in a community of practice, learning

through participation in practice, bodily learning and imitation, and learning through assessment of practice (see Nielsen and Kvale (2006) for an elaboration). Some rudimentary comments on how apprenticeship learning differs from learning in a school community are also offered.

Learning in a Community of Practice

Apprenticeship learning is often related to learning at a workplace. To learn in practice is of crucial importance if the workshop, shop, company, enterprise, or department wants to survive. Learning in apprenticeship entails becoming part of the culture of the workplace. The apprentice has to learn the rhythm and the jargon at the workplace, and show he or she is capable of participating in the various interhuman relations in order to gain access to the more professional tasks.

For the community of practice, it is essential that the workplace as a whole functions; the learning processes of the apprentices are secondary. In a school community, in contrast, it is essential that the individual student learns the knowledge of the subject, as it is outlined in the school curriculum. In a workplace, many different people from whom he/she can learn ideally support an apprentice's learning process. The apprentice is situated in a multi-generational environment and encounters a variety of different learning resources in the job situation (Akre and Ludvigsen, 1997). An important part of apprenticeship learning is for the apprentice to find the person who masters the specific part of the learning process which the apprentice is to learn (Hansen, 2003). In a school, the students are divided into classes, in which everyone is at the same level, and thus, some of the learning potential that exists in a manifold multigenerational environment is discarded. In other words, the school and the workplace as communities of practice are organized differently. Learning has often been comprehended as a hierarchical one-way process in keeping with an educational assumption that learning is a consequence of teaching. In descriptions of workplace activities, learning is situated in a multidimensional network of social and material resources (Nielsen and Kvale, 2006).

Learning through Participation in Practice

The notion of learning through participation in practice is used in a broad sense as a process in which the student changes his/her participation from just taking part to becoming a responsible participant in a community of practice (Elmholdt, 2003). If we look at the learning that takes place in practical situations, it may rarely be the result of direct teaching. Learning in apprenticeship is incorporated in daily activities, whereby one hardly notices that it takes place. At this point learning is indirect; it is a side effect when completing existing assignments. An

important element is that when learning happens through participation of practice, the individual apprentice is thrown into practical assignments (Aakrog, 2003). The apprentices are first thrown into different assignments, after which they develop an understanding for the context and the meaning of the assignments. In traditional schools, students are seldom thrown into different practical assignments right away. They are usually taught the principles and theoretical background first, whereby they gain an understanding of what they need to do in order to complete a given assignment.

Another aspect of learning through participation of practice is that the apprentices themselves have to be active and search for learning occasions in order to utilize existing learning resources in the workplace (Becker, 1972). Nielsen and Kvale (2006) present a number of examples of how apprentices make journeymen or masters aware of the fact that they need more demanding work assignments.

One way to conceptualize learning through participation in practice is to focus on responsibility (Hansen, 2003; Nielsen and Kvale, 2003). The concept of responsibility is brought to light in order to emphasize the relational and social dimensions of the learning process. By relating learning to responsibility, the learning process is seen as mutual interaction and an active dialog between individual and environment. In other words, responsibility is seen as being crucial to what one does in relation to others. To have learned something means to be capable of doing something responsibly. A substantial part of learning in apprenticeship is related to the fact that the apprentice is held responsible for a part of the production, which also means that he/she has to consider himself or herself as part of a larger unit. This is expressed in how the apprentice is not only responsible for own learning, but also faces responsibility in relation to others within the company. To participate responsibly also refers to a competence dimension, in which the individual as part of the learning process gradually improves in order to live up to and complete his/her assignments. The learning task is completed when the student or apprentice is properly capable of fulfilling the demands of the craft, which are required in order to fulfill an assignment, and the apprentice is capable of assuming the assigned responsibility.

In the apprentices' descriptions of their work, an assessment that leads to increased responsibility plays an important role. The different ways in which the apprentices participate in the work processes can be illustrated as a ladder of increasing responsibility (Wilbrandt, 2002). The apprentices move from the lower steps up in a continuous and mostly tacit assessment process. **Figure 1** illustrates the apprentices' increased responsibility on this ladder of tasks.

Figure 1 contains a description of workplace evaluation as a ladder of tasks with increasing responsibility,

Tasks	Steps
Work independently on assignments outside the workshop and managing the work of other apprentices.	7
Work alone (without journeymen) on complex tasks; the result of the work is unknown.	6
Work alone (without journeymen) on easy routine tasks; the apprentice knows the procedure and expected result.	5
Perform day-to-day tasks of the trade, as instructed by journeymen.	4
Observe journeymen work on complex work tasks, which display the skills of the craft.	3
Perform simple minor tasks; the apprentices take care of activities, which require no particular skills belonging to the trade.	2
Perform simple apprenticeship task (e.g., sweeping the floor, cleaning, and stocktaking), which are not specific to the trade	1

Figure 1 The apprentices' ladder of increasing responsibility.

starting from simple routine tasks (step 1), such as sweeping the floor, to more demanding tasks under the supervision of a journeyman, to performing the tasks alone, and finally, with full responsibility for the tasks and directing the work of the new apprentices and performing tasks outside (step 7). This implicit curriculum embedded in social practice has been termed the learning curriculum (see Lave and Wenger, 1991). The assigned tasks and the applied tools indicate which level of responsibility the apprentice has obtained in the workplace community (Wilbrandt, 2002).

Bodily Learning and Imitation

Learning processes in a workplace can be rather invisible. The execution of an assignment may appear as a daily routine, without being seen as learning. Imitation of other participants in a community of practice, and also identification with more experienced agents of the subject, takes place unintentionally (Jespersen, 1997). Learning through bodily action and by use of tools is incorporated in daily contact with the surroundings, and learning may take place without a deliberate plan for learning. It may not be until new apprentices enter the workplace that the person in question experiences that he/she has learned something.

In apprenticeship, the body is the learning subject. The body is rather absent in educational theory because learning is primarily understood as an intellectual activity. In schools, the body has simply been deported to practical subjects such as woodwork, sports, home economics, and art, which are traditionally low-status subjects within

the educational area. The pedagogical practice in many schools is often based on the deskbound and listening student, whereas in the workplace, the active, moving body is learning; the apprentice moves from area to area for different assignments in his or her learning process. The physical routines in a workplace are resources, and among the participants, it is unnecessary everyday to negotiate everything over and over again. In many cases, practitioners rely on bodily feelings and intuition instead of on calculated analyses of a given problem (Nielsen, 2006).

Imitations and routine work play a central role when addressing issues of learning in workplaces. Generally, today, educational researchers accentuate innovative learning, and ignore how innovation is rooted in familiar routines and traditions. Performing odd jobs and routine assignments may be viewed as a way of gaining access to a workplace culture, in which the apprentices learn to accept a shared responsibility for the workplace and become accepted members of the work community. In addition, performing routine assignments provides the new apprentices with an opportunity to obtain a general understanding of the various work processes (Museaus, 2003). Needless to say, performing only routine assignments throughout the whole period of workplace training is of little value to the apprentices.

In most workplaces, tools and equipment are dominant parts of the organization of the place. Screwdrivers, computers, hammers, briefcases, adjustable spanners, etc. hang on the wall, lie on a table, or lie on the floor. On an immediate level of experience, these tools address us in the daily performance of working assignments. The organization of the workplace itself has meaning for the

learning process. The order in which the tools are placed at the workplace, for example, in a garage, enables the mechanic, with a single look, to find the appropriate tool with the right dimensions needed in order to complete the task at hand. The tools and their positions in the room mean that they are a part of the work process, with which the apprentice does not have to be deliberately concerned.

Learning through Assessment of Practice

The survival of a workplace depends on the quality of its products. Therefore, ideally speaking, anyone who participates in the process of production is liable for the quality of the product. The apprentice's work is frequently checked to assess whether it fulfills the expected professional standards (Kvale, 2007). If the quality is unsatisfactory or mistakes have been made, it may have consequences for the entire community of practice. In other words, in a community of practice, the shared responsibility for the production also involves a responsibility for others' learning. Praise, recognition, or positive feedback make the apprentices grow through their own self-knowledge, whereas criticism, triviality, or negative feedback are experienced as hurtful. In both cases, emotional involvement plays an important role in the learning process.

The assessment aims of the individual apprentice's work pertain to its value for the work community. This means that actions are assessed in terms of their usefulness, providing the assessment with a crucial role in the process of learning. The apprentice is responsible for making a product; therefore, through the product, his or her process of learning is assessed. Is the table straight? Are the tiles even? Does the bread rise? These types of evaluations are made instantly as an integrated part of the work process in which it is decided whether a carpenter's, a tile maker's, or gardener's skills are sufficiently consolidated, when considering what he/she has produced. Professional assessments are part of the social structure in a workplace as the apprentice often spends substantial parts of his/her training with a journeyman. He or she functions both as a model to the apprentice and as the one who constantly keeps an eye on the quality of the apprentice's production. In a safe workplace, the apprentices themselves can freely test their skills without criticism. In the course of their training period, the apprentices gradually become capable of assessing their own and other workers' professional skills, whereby the professional, independent assessment becomes dominant in their working lives. Our actions have consequences for others in a community of practice. They acknowledge or invalidate the value of our acts. Older colleagues may assess the product with a brief comment, possibly just with a nod or a shake of the head. A significant type of assessment may take place with hardly any verbal comments on the

task performed, by assigning the apprentice to tasks that demand greater responsibility. The recognition for a well-done job is directly met by letting the apprentice participate in more complex and significant parts of the work process (see **Figure 1**)

Conclusion

A few conclusions on the present status of apprenticeship may be ventured. Today, there is a growing interest in apprenticeship learning. While the traditional forms of apprenticeship in the crafts have decreased, and more or less integrated with schooling, apprenticeship learning still exists in a variety of areas, in particular in the manual professions. Parallel to the modern advance of schooling, apprenticeship has existed in a variety of areas as an important type of learning. With the current anthropological and philosophical focus on apprenticeship, skill acquisition, and tacit knowledge, the many varieties of apprenticeship learning are coming to attention. Here, empirical investigations may clarify some of the contested claims of the merits and drawbacks of apprenticeship learning. A key issue remains the relevance of the traditional apprenticeship learning to the qualifications required by current forms of production.

Theoretically, the focus upon an institutionalized alternative type of learning as apprenticeship may serve to put school learning into perspective and question some of the assumptions taken for granted. Thus, leaving the presupposition of much educational research that learning depends upon teaching may open for investigating other potential sources of learning in the learner's environment. For educational practice, the question becomes how to design institutions that may advance apprenticeship types of learning today.

Glossary

1-of-n coding – A method of activation coding such that only one of a group of units is active.

Algorithm – Explicit instructions for solving a problem.

Base 10 – Having any of ten values, for example, 0–9.

Binary – Having either of two values, for example, 0 or 1.

Composite number – An integer greater than 1 having more than two divisors; thus, it is not a prime number.

Connection weight – A link between units in a neural network, represented as a real number. It is roughly analogous to a brain synapse.

Connectionism – A style of computing inspired by how brains are thought to function, using networks of simple interconnected units.

Constructivism – The idea that knowledge is constructed by the learner, often by building on top of existing knowledge.

Context – Incidental cues that accompany a learning experience.

Course coding – A method of activation coding such that one unit is very active and its neighboring units are a bit active.

Disequilibrium – In Piaget's theory, it refers to a mismatch between mental representation and environmental outcome, indicating a misunderstanding.

Divisor – An integer that divides equally (i.e., with no remainder) into another integer.

Dyslexia – Impaired reading.

Error – A measure of how far off a network is from learning its training patterns, computed as the sum of squared differences between actual outputs and target outputs, summed over all training patterns.

Error function – A hypothetical function relating network error to the size of a connection weight, usually conceptualized as a parabola with arms opening upward.

Excitation – Increasing the activity of a unit.

Generalize – To perform correctly on problems that have not been trained. It is used to distinguish understanding from mere memorization.

Gradient descent – A learning method that changes network weights in proportion to the slope of the error function in order to reduce network error.

Hidden unit – A unit that mediates between input and output units, thus hiding from the environment and enabling the learning of nonlinear relations.

Hz – The abbreviation for hertz: unit of frequency in cycles per second.

Inhibition – Dampening the activity of a unit.

Input – A vector of activations supplied to a network's input units. The pattern of these activations describes a problem to the network.

Integer – A whole number.

Integer part – The part of a real number preceding the decimal.

KBCC – Knowledge-based cascade correlation, a learning algorithm that builds a network topology by recruiting previously learned networks and single hidden units as needed.

Learning rate – A proportion that multiplies the error slope and, thus, controls the size of weight changes and the speed of learning. A programmer sets this proportion at the start of a simulation so that a network's weights change enough to support quick learning, but not so much that error oscillates across an error minimum.

Modeling – Building and running a computer program to simulate scientific phenomena.

Multiplicand – A number to be multiplied by another.

Net input – The net amount of input entering a unit, computed as the sum of products of sending-unit activations and respective connection weights.

Nonlinear – A kind of function that cannot be represented as a simple linear combination of its inputs, for example, distinguishing the points inside a circle from those outside the circle. The degree of nonlinearity typically makes learning more difficult.

Output – A vector of activations computed by the output units of a network. The pattern of these activations describes the network's response to a particular input pattern.

Prime number – An integer greater than 1 having only two divisors, 1 and itself.

Real number – A decimal number, not having an imaginary part.

Simulate – To reproduce natural phenomena, usually by presenting a computer program with the similar inputs to those found in nature. The program (or model) usually abstracts and simplifies so as not to be overwhelmed by natural complexity.

Slope – The rate at which one variable changes as a function of changes in another variable.

Source network – In KBCC, it refers to a previously learned network that may be recruited to aid the current learning task.

Target network – In KBCC, it refers to a network learning the current problem.

Target vector – The activation values supplied by a teacher or by the environment, indicating correct output values for a particular input pattern.

Threshold – The region in which a unit is highly sensitive to changes in net input.

Topology – The way a network is laid out in terms of its organization and connectivity.

Unit – The basic processing element of an artificial neural network. A unit has a fluctuating level of activity, represented as a real number, corresponding to the average firing rate of a neuron.

Vector – An ordered list of numbers.

Introduction

Connectionism is a style of computing that partly mimics the properties and functions of brains. Incorporating ideas from computer science, artificial intelligence, mathematics, physics, neuroscience, and psychology, connectionists build working computational models of learning and other psychological processes. A few connectionist projects have modeled educational phenomena such as reading and arithmetic, and these applications are highlighted here. After reviewing the basics of modeling and connectionism and focusing on some models of particular relevance to education, the broader implications of connectionism for education are discussed.

Importance of Modeling

The value of building computer models of psychological processes may not be immediately apparent. A general justification is that modeling was consistently useful in a variety of scientific disciplines. A good scientific model typically:

- implements a theory in a precise, concrete, easy-to-manipulate way;
- covers (or generates) a variety of interesting phenomena;
- helps to explain the phenomena that it covers;
- links various observations together, making them easier to understand;
- predicts new phenomena that can be tested; and
- can be improved when evidence reveals new facts or contradicts model predictions.

Since the renaissance of connectionism in the mid-1980s, all of these advantages have been realized to some degree. Indeed, of all the available techniques for psychological modeling, none has produced as many valuable insights into learning as connectionism has.

Modern Connectionism

The central idea of connectionism is that mental processes can be modeled by interconnected networks of simple units. These artificial neural networks can largely be understood in terms of activity and connectivity. As noted in the first row of **Table 1**, neural networks are composed of two elements: units and connection weights. Units are analogous to brain neurons, while weights are analogous to synapses, the connection points between neurons. Unit activity corresponds to the average firing rate in neurons, that is, how often they send an electrical impulse from their cell body down their axon to other neurons. Connection weights correspond to the ability of neurons to excite or inhibit the activity of other neurons. Both units and weights can be implemented in neural networks as vectors of real numbers. In psychological terms, unit activity corresponds to active memory, a focus on particular ideas, while weights encode long-term memory for how ideas are related. Unit activity changes over seconds, whereas changes to connection weights can occur rather quickly or over a period of years, enabling networks to learn.

An artificial neural network is thus a set of units and weights organized in a particular topology. Most neural networks are programmer designed and static, meaning that their topology remains constant, but others build their own network topology automatically during learning.

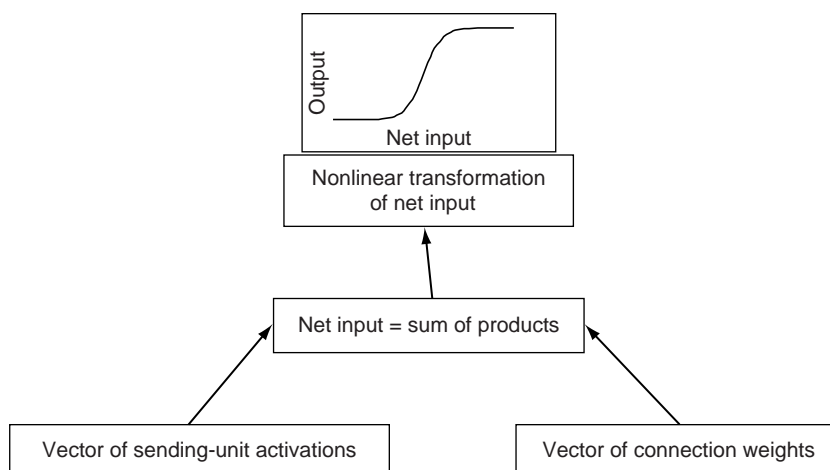

As shown in **Figure 1**, each unit in a network runs a simple program in which it computes a weighted sum of inputs coming from other units and then outputs a number, which is a nonlinear function of the weighted sum of inputs. This output is then sent to other units running this same simple program. Units are active at various levels and communicate their level of activity to other units in a way that modulates the activity of those other units.

As **Figure 1** shows, a receiving unit's level of activity changes in two steps. In the first step, a vector of sending-unit activations is multiplied by a vector of connection weights. Some of these products might be positive (with an excitatory influence on the receiving unit), while others are negative (having an inhibitory effect). The sum of these products constitutes the net input to the receiving unit.

In a second step, this net input is then passed through a nonlinear activation function like that shown in the top of **Figure 1**. Like real neurons, this function has a floor

Table 1 Activity and connectivity in artificial neural networks

<i>Feature</i>	<i>Elements</i>	<i>Brain analogy</i>	<i>Behavior</i>	<i>Implementation</i>	<i>Memory type</i>	<i>Time scale of change</i>
Activity	Units	Neurons	Firing rate	Real numbers	Active	Seconds
Connectivity	Connection weights	Synapses	Excitation, inhibition	Real numbers	Long term	Seconds to years

**Figure 1** Update of unit activation in a neural network.

(corresponding to no activity), a ceiling (corresponding to the maximum firing rate of about 300 Hz in real neurons), and a continuous but sharp transition between them (a threshold). As net input increases below the threshold, there is little change in activity of the receiving unit. However, as net input further increases across the threshold, there is a sharp increase in the activity of the receiving unit. Well beyond the threshold, if net input continues to increase, activity of the receiving unit would again fail to change much because it would be nearing its maximal level. Nonlinear activation functions enable the learning of complex, nonlinear target functions, which are common in the real world. They also prevent networks from overheating through continual increases in activity.

The primary way that neural networks learn is by adjusting their connection weights to reduce error. In supervised learning, connection weights are typically trained by being presented with examples – pairs of input values and target output values. Since there are often multiple inputs and multiple outputs, the example values (represented by real numbers) are presented in the form of vector pairs. In each pair, one vector holds input values and the other holds target output values. By processing such examples, a network gradually learns to produce the correct output vector in response to a particular input vector. The vector pairs used in such training are called the training set; those used in testing

generalization to untrained examples are known as the test set. Error at the output units is computed as the sum of squared differences between actual outputs and target outputs.

Imagine that the error contributed by a single connection weight is some unknown parabolic function of the value of that connection weight as shown in **Figure 2**. This makes sense on the assumption that there is some optimal value for each connection weight such that either increasing or decreasing the value of the weight from this optimum would increase error. If the precise shape of this error function was known, learning would be easy – simply adjust each connection weight to the value that minimizes error. Unfortunately, these error functions are unknown to the learner, and are unlikely to assume the simple, smooth parabola drawn in **Figure 2**. The neural network learner may know the size of the discrepancy between actual and target responses in the training set, but not the exact shape of the error function.

However, this meager information can be used to compute the slope of the error function at each connection-weight value that has been experienced. The slope (or gradient) is the first derivative of a function, evaluated at a particular point. Slope is a measure of how rapidly error changes as a function of changes in a connection weight. Two such hypothetical slopes are shown in **Figure 2** for two different weight values (w_1 and w_2). If the slope at a

given weight value is known, then the direction in which the connection weight should change is also known. If the slope is negative (as at w_2), then the weight should increase; however, if the slope is positive (as at w_1), then the weight should decrease.

However, how much should a connection weight change? If a weight is changed too much, the floor of the error valley could be missed, perhaps creating an oscillation in weight adjustments that never settles near the minimum error. One could make only tiny steps of weight change to avoid passing over the minimum error, but this slows learning. A better solution is to make the amount of weight change proportional to slope. With a steep slope, as at w_1 , a large change in weight is suggested, whereas with a shallow slope, as at w_2 , weight change should be smaller because the error minimum may be close. This technique of using information on the slope of the error function is known as gradient descent because it attempts to slide downhill on the error surface to reach the point of minimum error in weight space. Thus, weight change is a negative proportion (known as learning rate) of the derivative of error with respect to weight.

Relations to the Old Connectionism

Modern connectionism differs from the older connectionism of Thorndike. Thorndike was a founder of behaviorism, emphasizing the idea that organisms learn associations between stimuli and responses. Responses become habitual

Figure 2 A hypothetical function relating network error to the value of a network weight. Slopes of the error function at two weight values (w_1 and w_2) are drawn with dashed lines.

by being rewarded and thus having their associations to stimuli strengthened. As in other versions of behaviorism, learning was explained without recourse to internal states. As in this article, there were applications to educational issues such as reading and arithmetic.

Despite minor historical influence on, and superficial similarities with, modern connectionism, the differences are more profound than is sometimes recognized. Some important differences between old and new versions of connectionism are listed in **Table 2**, most of which are important for applications to education. Whereas behaviorists wrote about single associations between stimuli and responses, modern connectionists deal with large, multilevel, massively parallel networks. Moreover, some modern networks are designed with recurrent connectivity which allows for sequential processing and complex network dynamics, akin to the interesting behavior of differential equations. Following from these differences, the knowledge representations in behaviorist schemes were entirely local. In contrast, modern networks can as well employ distributed schemes in which each unit represents many different ideas and each idea is represented by many different units. Such distributed representations are more efficient and robust and account for many interesting psychological phenomena, along with being more biologically realistic. Behaviorism disavowed interest in mental states, emphasizing a direct association between stimulus and response. Modern connectionists instead invest considerable energy into determining what their networks know at various points in learning. Such knowledge-representation analyses often play an essential role in explaining psychological phenomena.

Thorndike's law of effect emphasized that habit formation was controlled by rewards. Contemporary connectionist models have clearly demonstrated the difficulty of learning from evaluative reward signals that tell the organism that it is doing well or badly, but fail to indicate what is needed for improvement. In contrast, supervised neural networks learn from fully specified target vectors that indicate the correct response to particular inputs, making learning faster and more accurate. All of the foregoing provide modern networks with vastly more learning power than habits. A habit can handle only a simple linear relation between a stimulus and a response, whereas there are now proofs that a network with a single

Table 2 Some key differences between old and new connectionism

Characteristic	Topology	Knowledge representation	Emphasis	Feedback signal	Learning power	Method
Old connectionism	Single association	Local	Behavior	Evaluative	Linear	Vague speculation
Modern connectionism	Massive parallelism	Distributed	Knowledge representation	Informational	Nonlinear	Explicit modeling

layer of hidden units can learn any continuous function to any degree of accuracy if this layer has enough hidden units. There are also proofs that any function can be learned by a network with two hidden layers, provided there are enough hidden units in each layer. Finally, most of the theoretical work in behaviorism was vague and speculative; however, the new connectionism is aided by working computational models that clearly indicate data coverage and predictions.

Models of Reading

Connectionism has been more concerned with establishing a theoretical basis for understanding learning than with developing applications in the field of education. So far, the area of education best modeled by connectionism is that of reading. Reading is an unnatural act for humans that typically requires several years of education. A debate about whether it is better to teach reading by the rules of letter-to-sound correspondence or by learning to visually recognize whole words stretches back to the 1960s. There are hundreds of such phonic rules, but because letter-to-sound correspondence is only somewhat regular, they are not that useful to learn. There is some regularity in reading aloud, as in the pronunciations of the words *lint*, *mint*, and *bint*, but plenty of exceptions, as in *pint*.

A theoretical framework for an influential series of connectionist simulations of reading is pictured in **Figure 3**. The rectangles represent groups of network units encoding information on spelling, sound, or meaning, or hidden units that effect nonlinear transformations between these three encodings. The bidirectional arrows indicate connection weights in both directions. By adjusting these connection weights, the system might learn to transform written words into meanings or pronunciations, meanings into pronunciations or written words, and pronunciations into meanings or written words. So far, research has concentrated on the mapping from written words to pronunciations, that is, reading aloud. These models learned to pronounce the

words they were trained on, such as *gate* and *save*, and generalized successfully to novel words such as *rave*.

Such connectionist models also captured a number of psychological phenomena such as frequency, similarity, and consistency effects. The frequency effect is that common words are read more quickly than rare words. The model correctly predicted that frequency effects are smaller for words with many similar neighbors (e.g., *save*) than for more isolated words such as *sieve*. The consistency effect is that words with regular neighbors are read more quickly than words with irregular neighbors. For example, the word *gave* has a regular pronunciation, but irregular neighbors such as *have*. So words like *gave* take longer to read aloud than words such as *must*, which do not have irregular neighbors. Consistency effects are larger for lower-frequency words and less-skilled readers.

Since all words share the same set of connection weights and neural learning tries to reduce as much error as possible, frequent words, words with high similarity to other words, and words with regular neighbors are read quickly and accurately. Frequency, similarity, and consistency can compensate for each other in that words at a disadvantage in one respect might benefit from another factor. For example, an infrequent word might be read quickly and accurately because of its similarity to other words.

A curiosity of these models is that the network has no explicit representation of lexical entries (words). Not only is it common for language researchers to assume and use a lexicon, but the frequency effect in reading is also customarily explained by storing frequencies within a lexicon. Remarkably, networks exhibit the frequency effect without a lexicon, which shows that a lexicon is not required for this effect.

The recent focus on the mapping from spelling to meaning has enabled connectionist models to address the issue of how to teach reading. In contrast to previous models emphasizing a conflict between visual and phonetic routes, these networks reveal collaboration between the two routes. Early in training, networks relied more on the spelling–sound route (see **Figure 3**); however, with more training, the spelling–meaning–sound route increased in importance, mimicking a psychological progression. As with humans, skilled reading of words involved convergent contributions of both routes from print to sound.

Dyslexia can be simulated in these models by damaging either the network or its training. Reducing the number of hidden units would be analogous to a child with fewer cognitive resources. Limiting the amount of training would correspond to inadequate educational opportunity. Ignoring training in the spelling–sound route would correspond to teaching without phonics. Letting each letter string activate more spelling units could implement a visual impairment. In all of these impaired cases, network learning focuses on the largest current

Figure 3 Theoretical framework for Seidenberg's connectionist models of reading.

source of error, namely that contributed by regular words, thus sacrificing exception words.

Other computational models using symbolic rules have relatively more difficulty accounting for these psychological phenomena. The main implication of connectionist models for reading instruction is to provide students with plenty of examples (not rules) of printed words and their meanings and pronunciations.

Models of Mathematics

Mathematics is another example of unnatural skills taught over several years of formal instruction that have been modeled with neural networks. The two examples considered here are learning of the single-digit multiplication table and prime-number detection.

Multiplication

Learning the 0–9 multiplication table requires 5–6 years of schooling and continues to generate errors even in adults. The most widely studied problem is the production task in which two single-digit multiplicands are presented and the

person is asked to provide their product. Several regularities are evident in the psychological literature:

- Computational procedures such as repeated addition ($m \times n =$ adding m , n times) are gradually replaced by recall.
- Reaction time increases with the size of the multiplicands, except that the 5's table and tie problems (e.g., 4×4 , 7×7) are quicker than expected.
- Adults under mild time pressure make about 8% errors.
- Errors are usually close to the correct product, and often substitute a close multiplicand (see Figure 6 for a breakdown of error types).
- There is a strong positive correlation between errors and reaction time across problems.

Building on the successes and limitations of several earlier models, Dallaway designed a feed-forward network learning with multiplicands 2–9 that captured the last four of these psychological phenomena. The topology of his network is shown in Figure 4, and the nature of his course coding of multiplicands is shown in Figure 5. Target output vectors were designed by turning on one product unit and leaving the others off. The percentage of error types plotted in Figure 6 for adults and Dallaway's

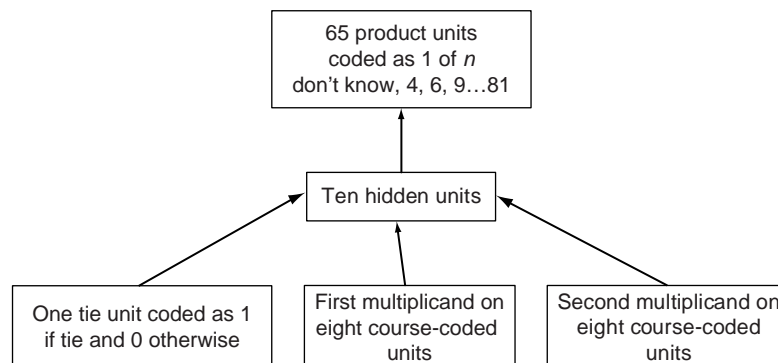

Figure 4 Dallaway's (1994) network for learning the 2–9 multiplication table.

Figure 5 Course coding of the input multiplicands 5, 6, and 7 in Dallaway's (1994) network. Activation representing a given integer is maximal for the unit corresponding to that integer itself and drops off for neighboring values less than or greater than the integer. Only integers from 2 to 9 were included in this simulation; therefore, integer n centers on unit $n-1$.

model indicate a good fit, although the overall error rate was higher for the networks at 14%.

As shown in **Table 3**, operand errors involve changing one of the operands, close-operand errors involve changing to a close operand, and frequent-product errors involve selecting a frequently occurring product. Table errors involve choosing a less-frequent product that is in the multiplication table and does not share any multiplicands with the problem being tested. Operation errors involve adding instead of multiplying. Networks reacted about as quickly to multiplication by 6 as 5, complicating explanation of the 5's speedup. The fit to human data was not as good when the 0 and 1 tables were also trained. Some psychologists believe that multiplication by 0 and 1 is rule governed, rather than being based on connectionist pattern matching; however, it seems possible that the greater regularity of 0 and 1 multiplications just makes them seem rule governed. The fit to human reaction time data worsened when the training sample was not biased in favor of smaller multiplicands.

Applications of this and related models to education remain tentative, but likely would be similar to those made for reading, namely to include many examples of

Figure 6 Percent of multiplication errors of different kinds in adults (Campbell and Graham, 1985) and neural networks (Dallaway, 1994). The values do not sum to 100 because error types are not exclusive.

Table 3 Multiplication table with three error types highlighted^a

x	2	3	4	5	6	7	8	9
2	4	6	8	10	12	14	16	18
3	6	9	12	15	18	21	24	27
4	8	12	16	20	24	28	32	36
5	10	15	20	25	30	35	40	45
6	12	18	24	30	36	42	48	54
7	14	21	28	35	42	49	56	63
8	16	24	32	40	48	56	64	72
9	18	27	36	45	54	63	72	81

correct multiplication that go just beyond the student's current ability. The role of addition in learning and understanding multiplication should be explored in future modeling because of its evident role in children's learning and its possible role in several multiplication errors.

Primality

Prime-number detection is a more advanced mathematical skill that has also been modeled with connectionist methods. The primality of an integer n can be determined by seeing if n is divisible by any integers between 2 and the integer part of \sqrt{n} . It is efficient to test in this order because the smaller the prime divisor, the more composites it detects in a fixed range of integers.

A connectionist system called knowledge-based cascade-correlation (KBCC) learned this algorithm from examples by recruiting previously learned knowledge of divisibility. KBCC is based on a simpler connectionist algorithm called cascade-correlation (CC) that learns from examples by recruiting single hidden units. CC and KBCC have simulated a large number of phenomena in learning and cognitive development. KBCC has the added advantage that it can recruit its existing network knowledge as well as single hidden units. Both CC and KBCC are constructive learners that build their new learning on top of existing knowledge.

For primality, the pool of source knowledge contained networks that had previously learned whether an integer could be divided by each of a range of divisors, for example, a divide-by-2 network, a divide-by-3 network, etc., up to a divisor of 20 (see **Figure 7**). These source networks were trained on integers from 2 to 360. Twenty KBCC target networks trained on 306 randomly selected integers from 21 to 360 only recruited source networks involving prime divisors below the square root of the largest number they were trained on (360). Moreover, they recruited these sources in order from small to large, and avoided recruiting single hidden units, source networks with composite divisors, any divisors greater than square root of

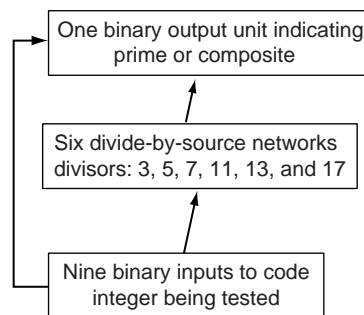

Figure 7 Topology of a KBCC network that learns prime-number detection (Egri and Shultz, 2006).

360 even if prime, and divisor networks with randomized connection weights.

KBCC target networks never recruited a divide-by-2 source network; however, this was because they, instead, used the least significant digit of n , binary coded, to directly determine if n was odd or even. As with people who use the 1's digit of base-10 numbers to check for divisibility by 5 or 10, this is a shortcut to dividing by 2.

The KBCC target networks learned to classify their training integers 3 times faster than did knowledge-free networks, with fewer recruits on fewer network layers, and generalized almost perfectly to novel test integers. Networks without knowledge of divisibility did not generalize better than chance guessing.

As predicted by this simulation, university students testing the primality of integers also mainly used prime divisors below \sqrt{n} and ordered their divisors from small to large. The recommendation for education is not only to use examples, but also to structure curricula so that later learning can build on existing knowledge.

Educational Relevance

As connectionist modeling of learning continues, potential applications to education could become more apparent. Some implications of connectionist models of reading and mathematics were already noted, namely the use of examples with fully specified feedback on what to do with these examples. Teaching with examples is compatible with the long-recognized notion of learning by doing. Since students may vary considerably in their skills, this can be challenging in a classroom, but could be accomplished with materials that vary enough in difficulty to continuously provide at least some examples just beyond the ability of each student.

Accompanying examples with full feedback is more informative than the evaluative feedback provided by rewards or equally vague cues to disequilibrium which were characteristic of the educational recommendations of classical behaviorist theory and Piagetian theory, respectively. Computational results make it clear that having to convert information about being wrong into a useful target vector makes learning both slower and more difficult.

Another educational suggestion stemming from connectionism is that repetition and patience are often required. This stems, in part, from the fact that connectionist learning can be quite slow. Some insight into this slowness has been gained from studying variation in learning-rate parameters. When learning rate is too high, networks may oscillate across error minima. To settle near such minima, it is often necessary to take small steps in connection-weight adjustments. This could also be true of brain networks, and if so, teachers should not rush through difficult material.

Of course, methods for increasing both the speed and accuracy of network learning are under active investigation. Networks learn faster and more accurately if they can recruit relevant existing knowledge. In the case of prime-number detection, successful generalization to untrained integers requires recruiting existing knowledge. This suggests curricula designed to ensure that lessons are optimally ordered. Network simulations might identify the most beneficial lesson sequences.

Another implication of neural modeling is that context is important and that it limits generalization. Connectionist learning algorithms naturally exhibit context effects whenever contextual cues aid learning. However, such contextual effects ensure that generalization may not be as universal as desired. Similar to network researchers, teachers might try to decontextualize learning by varying contextual cues in teaching. Again, exploratory network simulations could help.

Many of these educational suggestions emanating from connectionist research (practice, feedback, prior knowledge, and structured lessons) at first appear more consistent with teacher-centered, rather than child-centered, approaches to education. This seems paradoxical given that constructive connectionist approaches (CC and KBCC) are consistent with a Piagetian approach to knowledge acquisition that is the psychological basis for child-centered education.

Whereas teacher-centered education focuses on structured lesson plans, extensive practice, and feedback, child-centered education emphasizes curiosity, problem solving, and discovery learning. Although these approaches are often portrayed as being opposed, constructivist connectionist modeling suggests a possible rapprochement, with computational demonstrations that effective learning incorporates both methods. In connectionist learning, knowledge representations are constructed and abstracted, rather than memorized. Moreover, this learning is particularly effective when experience is well structured, building more complex ideas on top of earlier simpler ideas, and well practiced, with detailed feedback.

Constructivism and Learning

S Sjøberg, University of Oslo, Oslo, Norway

The Many Faces of Constructivism

The term constructivism is used in different fields and with many different meanings. If one looks it up in an encyclopedia, one gets somewhat disturbing results. In Encyclopaedia Britannica (2008, DVD version) constructivism is discussed in 29 articles. Most of these, including the article with the heading Constructivism, are related to a Russian art movement, and none of them are related to the constructivism we talk about in education. Similarly, Encarta (2008, DVD version) gives 30 entries, none of which are related to education.

Searches on the Internet provide entries in millions, even when limiting the searches by adding education or learning. One also notes that most of the educational entries are related to the teaching and learning of science, technology, and mathematics, although many also relate to other areas. Many hits relate to informal teaching and learning as found in science centers.

The level of precision of the term constructivism has led some critics (e.g., Matthews, 1994) to consider the term to be empty of meaning and its use purely ideological. It seems, according to Matthews, to be used to distinguish the good guys (constructivists) from the bad guys (traditionalists). Many critics say that the label constructivist teaching is used by many authors as more or less synonymous to any teaching that is somewhat child-centered, caring, inclusive, or based on enquiry, discovery, or any kind of active involvement from the learners. The literature abounds with lists of aspects that characterize constructivist classrooms, teachers, curricula and assessment. Most of these articles and books have a low precision on the definition of the term but they all seem to associate the term with something unquestionably positive.

Based on such observations, many critics argue that constructivism as a meaningful concept has lost its power. Some call constructivism a new orthodoxy, a fad and a fashion, a movement (Erickson, 2001), or even a religion with different sects (Phillips, 1995).

However, there is, of course, also serious theoretical writing and research that strongly opposes such characterizations. Many academics claim that there is a strong theoretical underpinning of constructivism. But they also disagree with one another about the epistemological and theoretical status of constructivism.

One should also note that even within the field of education, there are several varieties over the theme of

constructivism. Many scholars use qualifiers when they refer to constructivism. Hence, we find individual and cognitive constructivism (often with reference to Jean Piaget) and social constructivism (often with reference to Lev Vygotsky). Some use the term simple, mild, or even naive constructivism with reference mainly to some interpretations of Piaget, and with a contrast to radical constructivism, used by von Glasersfeld (1984). Other widely used versions include contextual constructivism (Cobern, 1993), sociotransformative constructivism (Rodriguez, 1998), and sociocultural constructivism (Tobin, 1998). The list can be made longer, and many of the above qualifiers are used in new and inventive combinations. It is beyond the scope of this article to go in detail on differences and similarities behind this flourishing terminology. The point is simply to warn the reader about the possibility for misunderstandings, as well as for real and false disagreements.

Constructivism: The Construction of What?

In this article, we discuss constructivism as a theory of learning, hence, we debate on how people construct meaning and knowledge. It is important to distinguish this from epistemology of scientific knowledge, that is, the growth, development, and status of scientific knowledge about the world.

We may ask what is constructed? Is it:

1. our individual knowledge about the world? (e.g., children construct their own knowledge)
2. the shared and accepted scientific knowledge about the world as it exists in established science? (e.g., scientific knowledge is socially constructed) or
3. the world itself? (e.g., the world is socially constructed)

The first of these questions is a problem of psychology and educational or learning theory, while the latter two are part of philosophy and epistemology. Question no. 2 is also addressed by the sociology of knowledge and also science.

Analytically, it is important to keep these questions apart. One may, for instance, be a strong supporter of constructivist learning theories while at the same time reject the two other stances, in particular the last and most extreme one. This latter kind of constructivism is criticized for being a subjectivist and relativist postmodern attack on

the rationality of science (Boghossian, 2006), a stance that certainly runs against any suggestions from, for instance, Piaget and Vygotsky to be discussed later in this article.

Much confusion and disagreements occur because one does not keep the fundamental differences between the nature of these constructivist claims in mind. A recent book title is called *Teaching Constructivist Science* (Bentley *et al.*, 2007). While the book is about constructivist methods of teaching, the title may suggest that the authors claim that science itself is constructed.

Constructivism and Learning – Core Ideas

Within the large family of constructivist-learning theorists, there are some ideas that more or less all subscribe to. Hence, they may be seen to be a mild version of constructivist claims. Here are some of these core ideas, partly based on the analysis of Taber (2006).

1. Knowledge is actively constructed by the learner, not passively received from the outside. Learning is something done by the learner, not something that is imposed on him.
2. Learners come to the learning situation (in science, etc.) with existing ideas about many phenomena. Some of these ideas are *ad hoc* and unstable; others are more deeply rooted and well developed.
3. Learners have their own individual ideas about the world, but there are also many similarities and common patterns in their ideas. Some of these ideas are socially and culturally accepted and shared and are often part of the language, supported by metaphors, etc. They also often function well as tools to understand many phenomena.
4. These ideas are often at odds with accepted scientific ideas and some of them may be persistent and hard to change.
5. Knowledge is represented in the brain as conceptual structures and it is possible to model and describe these in some detail.
6. Teachers have to take the learner's existing ideas seriously if they want to change or challenge these.
7. Although knowledge in one sense is personal and individual, the learners construct their knowledge through their interaction with the physical world, collaboratively in social settings and in a cultural and linguistic environment. (The relative stress on such factors account for the different versions of constructivism earlier alluded to.)

The Many Phases of Constructivism in Education: A Brief History

The following description is based on how these ideas have emerged, with emphasis on the field of science education.

Piaget and Constructivism

Many of the core ideas of constructivism are indeed very old, but it may be fruitful to present a historical account based on the influence of the Swiss psychologist and epistemologist Jean Piaget (1896–1980). Few intellectuals have been so widely used and misused, or understood and misunderstood as Piaget. A main reason for this is that his research and perspectives do not fit well into the established boundaries of academic disciplines.

A brief version of his life story exemplifies this: at the age of 21 he had a PhD in biology, and his specialty was how organisms adapted to their environment. He was also deeply interested in philosophy. For some years he worked in psychoanalysis with CG Jung, and later in testing of intelligence in the behaviorist tradition of Stanford-Binet and Cyril Burt. Piaget was, simultaneously or in succession, professor in several fields: in psychology, in sociology, in the history of science, and in genetic and experimental psychology. Moreover, he used mathematical logic and group theory to express his ideas. He even contributed to the development of this field. Most of his examples of the intellectual development came from observations and clinical interviews with children when they manipulated physical, technical, and chemical objects in experiments that were rather similar to traditional textbook examples (pendulum, balance, etc.).

Piaget's biological background and language, his use of examples from physics and technology as well as his wish to formulate general theories in a mathematical way may explain why Piagetian theory has a strong appeal to science and mathematics educators. He had the greatest admiration for physics as a discipline and considered it to be the most mature and developed of all scientific fields. He also corresponded and met with Albert Einstein, who was fascinated with Piaget's ideas.

As one can understand, Jean Piaget covered several academic disciplines. It is, however, a paradox that the field where he has had most influence in is education. He was not at all an educator, and actually wrote very little on teaching and pedagogy.

Piaget was academically active for more than half a century, and wrote more than 50 books and several hundred articles. Although he remained faithful to his initial research agenda, his theories developed during this period. When one tries to understand (or to critique) Piaget's theories, one must know which age of Piaget one has in mind. The early Piaget is very different from the older, and in many ways he was his own best critic. Some of his books were rather badly translated from his original in French to English, and then translated from English to other languages. Such factors may also have added to the confusion over his ideas. One might say that Piaget's strong interdisciplinary orientation was his strength, but it was also his problem because it made his thinking

difficult to access for people with a more typical (and narrow) academic background.

However, Piaget's basic research problem remained the same all the time. His problem was epistemological and philosophical: What is the nature of knowledge? How does it grow and develop? Piaget's epistemological research agenda is well reflected in the name of the institution that he established in Geneva in 1955: Centre International d'Epistémologie génétique (International Center for Genetic Epistemology.) Here, of course, genetic refers to the genesis and development of knowledge, and not to biological heredity.

The nature of knowledge should, according to Piaget, be studied empirically where it is actually constructed and develops. This can be done either through the historical development of knowledge, as it is found in well-established sciences (in particular, physics and mathematics), or may be studied in the growth and development of an individual. We may therefore say that Piaget's study of the development of children was in effect only to get empirical access to his epistemological research question: the growth of knowledge and the development of logical thinking.

Piaget's earlier writings, from the 1920s on, were on children's conceptions of the world. This was, in fact, also the title of one of his earlier books (Piaget, 1929). Already at that time, he had started to use the term constructivism. A very influential book had the title *La Construction du réel chez l'enfant* (*The Construction of Reality in the Child*). The French original came out in 1937, with the Introduction written as early as 1925. His other writings from the same period (late 1920s to 1940) included detailed studies on how children developed (or constructed) ideas about time, space, causality, logic, numbers, movement and velocity, conservation, and a long list of various natural phenomena.

As we can see, Piaget gave meaning to the term constructivism long before it was used by academics in other fields, like the psychologist George Kelly (Kelly, 1955) and sociologists Berger and Luckman (Berger and Luckmann, 1967).

He remained faithful to this constructivist perspective throughout his long active period. In his last publication, written the year that he died, some 55 years after his first use of constructivism, he summarizes his lifelong program: his task had been to

establish what we have called a *constructivist* theory of knowledge and, at the same time, refute the empiricist and nativist theories. The essential problem of a theory of knowledge is: How is new knowledge constructed? Is it, as empiricism contends, always derived from observing reality, or is it preformed in the human mind, and thus innate? Even our earlier work, I believe, clearly showed the insufficiencies of both the empiricist and preformist theories. (Piaget, 1980: 3)

In this statement, Piaget locates his own constructivist epistemology. He rejects the empiricist and behaviorist stance that knowledge derives directly from sense experiences. He also rejects the rationalist or preformist view that knowledge is innate and develops more or less biologically as we grow and mature. His whole life program consists of showing how both these views are insufficient.

Piaget developed his theory of knowledge based on ideas derived from biology like the process of adaptation, consisting of assimilation and accommodation. Other Piagetian concepts like self-regulation also indicate his basic belief that the development of intelligence and thinking should also be understood as the individual's biological adaptation to the external world.

As noted, Piaget was not very interested in education, let alone in teaching (Solomon, 1994). Nevertheless, his theories have probably been more widely used (and misused) in education than in other fields. As also noted, the main uses have been in science and mathematics education because of reasons explained earlier. But even in these areas, his theories have been used in a wide and often contradictory ways. Let us briefly look at this development.

Piagetian Constructivism Emerges

Piaget's theories were discovered by science educators in the early 1970s. At that time, most attention was given to his stage theory. A recurring theme in Piaget's writing was the description of stages of intellectual development that each individual had to pass. Names like the psychomotor, the intuitive, and the concrete operational and the formal operational stage soon became part of educational terminology.

He asserted, for instance, that an individual at the concrete operational level was able to understand and perform certain logical operations, while the spectrum was much wider at the formal operational stage. At this stage, the individual could reason in a way that is close to ways commonly used in science, like thinking with hypotheses and abstract models, understanding proportionality, and control of variables etc. These stages are described in Piaget's publications (Piaget and Inhelder, 1958). On the basis of these descriptions, educators developed written tests that they used to classify the learners by their Piagetian level. They also developed teaching material that was supposed to match the level of abstraction of the learner. This so-called matching model became very influential for a long period. Numerous studies based on the Piagetian stage theory were published in the journals for science and mathematics education, and large curriculum development projects were carried out. In the US, the Science Curriculum Improvement Study (SCIS) project (SCIS, 1974) was based on Piagetian stage theory. This program was also exported to several other countries and had some success. It is still in use some places.

The British Science 5/13 project had a similar foundation (Science 5/13, 1972).

Some of the strongest supporters of the stage theory claimed that this theory and its practical applications had turned science education into a real science. “Towards a science of science education” was the ambitious title of a book by two of the British pioneers in the field (Shayer and Adey, 1981). This book presented experiences from a large research and development program based on Piagetian stage thinking. They also provided evidence that the development from one stage to the next could be accelerated or enhanced by certain learning experiences and tasks (Shayer and Adey, 1992).

However, although this theoretical stance and the corresponding curriculum projects gave inspiration and positive impetus to science education, the stress on Piagetian stage theory gradually lost supporters and waned in popularity. In short, the approach did not hold what it promised. The theoretical underpinning was also under attack. Most important, however, is probably new and more promising developments.

The new turn in the thinking in science education may be exemplified by a seminal article written jointly by the American Jack Easley and his former PhD student Rosalind Driver from the UK (Driver and Easley, 1978). In hindsight, we may say that this article is a starting point for what we now label the constructivist tradition in science education.

In their article, Driver and Easley reviewed research on children’s ideas and perceptions regarding natural phenomena, and also provided a language and theoretical perspective to talk about the findings and their educational aspects. The article was strongly influenced by Piagetian theory and triggered a new interest for the actual contents of children’s ideas. While the Piagetian stage theory was centered around the more formal and logical aspects of children’s thinking, we now got a new interest for what concrete ideas that children bring. They also anchored their interpretations to Piaget’s constructivist epistemology as well as to his early studies of children’s ideas.

In the following years, the research agenda in science (and mathematics) education changed gradually. There was a growing concern about the ideas that children develop about the phenomena in the physical world (as well as other phenomena), and the term constructivism started to occur frequently. Rosalind Driver was a key person in the development of this constructivist movement. Alone, and in cooperation with colleagues from several other countries, she published academic articles (e.g., Driver and Oldham, 1986) as well as books meant for the classroom teacher (e.g., Driver, 1983). These (and similar) books are probably the main reason why the ideas behind constructivism soon became highly influential, not only in research, but also in teacher-training and in science classrooms.

Constructivism and Children’s Ideas

Although it had been known for a long time that pupils have their own ideas, often at odds with those of established science, about natural and other phenomena, the emergence of constructivism in the late 1970s and early 1980s triggered a virtual flood of such studies. Children’s ideas for all thinkable phenomena (like force and movement, electricity, heat, etc.) were studied in great detail. This also implied a rediscovery of the early Piaget (from the late 1920s and some decades to follow), where he had published many books on these themes. Also Piaget’s research methodology, the clinical interview, got a revival, but was also supplemented by many other research methods, qualitative as well as quantitative.

The many names given to children’s (and indeed adults’) ideas reveal that different researchers understood and interpreted their findings from very different theoretical perspectives. The literature reported on children’s ideas, their alternative paradigms, mini-theories, conceptions, misconceptions, etc. The variety in terminology reflects ambiguity and some confusion over the status of what one observed. This, of course, also has implications on how to act on such observations. If you face a misconception, you can simply try to correct the misunderstanding. If, on the other hand, the child’s explanation has the character of being a paradigm, an alternative way of seeing the world, well integrated with other strongly held beliefs, then the educational task is indeed very different!

However, the status of the ideas that children express may indeed differ from one type of phenomenon to another, and this is an empirical question that may be clarified by research. In some areas, one may find that the expressed ideas are very loose, often *ad hoc*, and even invented in the interview setting. Piaget himself wrote about these challenges in the 1920s. For other types of phenomena, children’s explanations are more deeply rooted, well integrated, and systematically used to understand a wide class of experiences. In this case, they may be very resistant to change, and sometimes one should think twice before embarking on such a project.

The research on children’s ideas, often under the theoretical umbrella of constructivism and/or conceptual change proliferated from the early 1980s. Reinders Duit at IPN, the German Institute for Science Education in Kiel, maintains a bibliography that, according to the Introduction is “an attempt to document constructivist research in science education”. The 2009 version contains 8400 research articles, a clear indication that this is by now a dominant perspective in science education research.

Constructivism: Widening the Perspective

The influence from Piaget is evident in nearly all the written reference to constructivism, especially in

the early phases. But Piaget's own perspective was, as noted, mostly on the general aspects of the development of knowledge *per se*. He was not so much interested in education, let alone teaching or conditions for good and effective learning. Constructivism has, as noted, developed from such a Piagetian perspective, and has drawn on other theorists who put more stress on social and cultural conditions for learning. This may explain why we now have so many varieties of constructivism.

A main contributor to this development has been from a contemporary of Jean Piaget, the Russian Lev Vygotsky (1896–1934) and his students, mainly Luria and Leontiev. Vygotsky's work remained virtually unknown in the West until its rediscovery in the 1960s, when the translation of *Thought and Language* from 1934 was published in English in 1962 (revised edition in 1986). It was not until the end of the 1970s that his works started to get attention, and his collected works were available in English only in the late 1990s.

Many books have been written where Piaget and Vygotsky are seen as more or less as opposites. It may be more productive to note some fundamental similarities. They may both clearly be seen as constructivists. Some of the differences between the two can be explained by the fact that they had rather different research agendas. While Piaget was interested in epistemology and knowledge *per se*, Vygotsky was more interested in understanding the social and cultural conditions for human learning. Hence, his writings may be closer to the concerns of educators.

With his stress on the social and collaborative nature of learning, Vygotsky is often considered to be the father of social constructivism, while Piaget is often classified as a father of personal (or cognitive) constructivism. It may be interesting to note that Piaget and Vygotsky corresponded, and that Piaget acknowledged to have been inspired by Vygotsky's ideas.

Constructivism: Paradigm or Research Program?

We have noted that constructivism is a dominant perspective in fields like science education. How profound is this influence? Some authors write about constructivism as a paradigm in a Kuhnian sense (Kuhn, 1970). Others find it more proper to use the terminology of the philosopher Lakatos (1970). They therefore argue that constructivism represent a so-called research program.

For this author, the term paradigm in the Kuhnian sense seems to be too strong. A paradigm implies that the idea is so strong that it completely dominates an entire field or discipline, and that other ideas practically do not exist (like the paradigm of evolution in biology, or of atoms or quanta in physics). Therefore, the term research

program seems more suitable. Lakatos (1970) has developed these ideas in detail, but here are some basic ideas. A research program is a set of ideas that provide a platform of common assumptions and ideas about certain phenomena. This core of commitment is shared among those working in this research program. (Core ideas of constructivism have been suggested earlier in this article.).

Several research programs may coexist within the same field over time. A research program provides direction and structure of a field of research. It contains a positive heuristic that may generate new knowledge and ideas for further research. When a research program develops, grows, and adds new knowledge, it may be called progressive. When it ceases to do so, it degenerates and may fade away, particularly if other research programs are seen to be more promising for new research.

Many authors have used the concept of research programs on constructivism. Driver and Easley (1978) used the term in their seminal article in 1978. Joan Solomon wrote about the rise and fall of constructivism as a paradigm as well as a research program in 1994. In spite of this, the influence of constructivist ideas and studies continued to grow in the following years. Erickson revisited the theme and strengthened the claim of constructivism as a still progressive research program in 2001, and these ideas are supported in a recent review article of the whole field of teaching and learning science (Taber, 2006).

The core set of ideas of constructivism suggested earlier in this article seem to be widely accepted by many. This is, in itself, a sign of their current dominance. But a set of principles for learning does not directly translate into a set of recommendations for good teaching. One cannot logically deduce a scientifically based pedagogy from a theory of learning.

Many books claim to present constructivist teaching, often in the form of lists of concrete recommendations. Many authors also give detailed prescriptions regarding constructivist curricula and constructivist assessments. It is beyond the scope of this article to enter into an analysis and critique of these widely differing recommendations, but can only advise the reader to exercise some care regarding such assertions.

Cultural–Historical Activity Theory

A Havnes, University of Bergen, Bergen, Norway

© 2010 Elsevier Ltd. All rights reserved.

The cultural–historical activity theory (CHAT) has its origin in the work of Lev Semenovich Vygotsky (1896–1934) and has since been developed, first by his colleagues and students in USSR, and later in the Western world. In USSR, Vygotsky's ideas had been suppressed during the Stalin period, but revitalized in the post-World War II period. Until the publishing of *Mind in Society* in 1978 (edited by Cole, John-Steiner, Scribner, and Souberman), little was known about the so-called Soviet school of psychology in the West. At this time, around 1980, Western scholars had become receptive to the ideas expressed in *Mind in Society*. *Thought and Language* had been translated into English in 1962, but had not attracted much interest until then.

Vygotsky described his approach as cultural–historical. Alexei N. Leontiev (1904–1979) developed the notion of activity. His approach has been termed the activity theory. Later, CHAT had been further developed by Western researchers, on the basis of the conceptualizations of both Vygotsky and Leontiev. Vygotsky's notion of culture, history, and mediation, and his emphasis on speech and thought and self-directed action has been revitalized. As a consequence of these reconceptualizations, the term CHAT is now commonly used.

While Vygotsky, Leontiev, and their colleagues were immersed in psychology – particularly educational psychology – the interest in activity theory has expanded and is now frequently applied in, for instance, educational research, organizational studies, linguistics, and human–computer interaction. This article classifies three main categorizations of CHAT: (1) the initial formulation by Lev Vygotsky in the early history of USSR where the basic principles of the theory were formulated; (2) the further development and reconceptualization of Vygotsky's ideas after his death, where the concept of activity was developed (Leontiev, 1978); and (3) the more recent development of CHAT in the West, particularly in the context of Northern European and American educational and psychological research.

Because of these reconceptualizations and the wide use of CHAT, it is hard to regard it as a strict and conceptually consistent theory. The relationship between Vygotsky's cultural–historical approach and Leontiev's activity theory is problematic, similar to the relationship between Leontiev's activity theory and the recent application of CHAT in diverse research contexts today. It is not easy to state exactly where the boundaries of CHAT go.

CHAT – A Theory in Development

The developmental stages described above are often referred to as three generations of CHAT (Engeström, 1996; Daniels, 2001), which imply that the history of CHAT represents an expansion of the research platform that Vygotsky developed. The expansion has taken place under different social, historical, and political conditions. It would be inconsistent to present CHAT as a thing in itself, detached from its context. The reconceptualizations can, therefore, also be understood in terms of the recontextualizations, as well as development of the internal logic of the theoretical approach. For instance, Kazunin (2005: 112) explains that Leontiev worked under conditions where “Soviet psychologists were expected to derive psychological categories directly from the works of Marx, Engels and Lenin.” While Vygotsky relied on theories and methods from, for instance, psychoanalysis and Gestalt theory and reframed Western European and American psychological and philosophical research, Leontiev and his colleagues relied on Marxist (political) theory in a more direct sense.

In the West, the social, cultural, and political conditions have been different, and Vygotsky's ideas have been revitalized. Researchers in a wide range of fields have come to see the potential of CHAT to improve their research, but generally without adopting the political agenda associated with Marxism. The theory has been a conceptual tool not only for transforming research agendas and methodologies, but also for making changes in institutions and local communities to improve the conditions for children's learning and development – some of which has a political undertone of supporting underprivileged children and families. Parallel to the growing interest in CHAT, the theory has been developed to accommodate the challenges of theoretical and empirical research under the social and political conditions in these researchers' societies. The history of CHAT illustrates that psychological and educational research develops in relation to the society in which it takes place. In addition, CHAT research has developed in a two-way process where the potentials of the theory open up for new ways of doing research at the same time as its theoretical basis is developed and expanded.

The interest in Vygotsky and CHAT has also merged with a broader interest in the social learning theory. These ideas are now often associated with a spectrum of more or

less overlapping approaches, for instance, sociocultural research, cultural psychology, situated learning, and dialogism. While Vygotsky developed his approach in a context where behaviorist stimulus–response psychology and Pavlov’s reflexology dominated – in opposition to the dominant theorizing of his time – the much-later introduction of his ideas in the West followed in the wake of the so-called cognitive revolution and largely in opposition to the individualist and mentalist perspective that has dominated psychological and educational research over the recent decades.

Lev Vygotsky, the Founder – A Mind in Society

In January 1924, the 28-year-old Vygotsky, from the small province town Gomel in western Russia, and unknown in the community of researchers at the conference, gave a presentation on ‘Methods of reflexological and psychological investigations’ at the Second All-Russian Psychoneurological Congress. He contested the dominant reflexology and behaviorism of the time by emphasizing human consciousness as a mediating factor in human functioning. A main point in his presentation was that by ignoring the problem of consciousness the psychology of that time had deprived “itself of access to the study of some rather complex problems of human behavior. It is forced to restrict itself to explaining no more than the most elementary connections between a living being and the world” (Vygotsky, 1925). He also criticized the deduction of human psychological functioning from animal studies: deducting from animal psychology to human psychology is not possible. The director of the Psychological Institute in Moscow appreciated his approach and invited him to take part in restructuring the institution. From this time on, Vygotsky was devoted to developing an alternative approach to psychology in opposition to the two dominant approaches of the time: objective behaviorism and reflexology and subjective–empirical introspection.

Vygotsky established a school of psychology that was founded on two main agendas: one basically theoretical, that is, to develop a psychology in the philosophical tradition of Marxism and another practical, that is, to find concrete ways of dealing with some of the massive problems in his society, he was particularly concerned about problems related to education, special education, illiteracy, and services to homeless (or so-called difficult) children and those who were mentally retarded. Both of these agendas can be seen in the perspective of the social, political, and scientific circumstances in the society where he had his academic life; postrevolution USSR. This was a period of massive social, economic, and political changes in society accompanied with the rethinking of dominant scientific theories and paradigms. These agendas – the

theoretical and practical – not only drove Vygotsky’s psychological research, but also merged with the mandate associated with restructuring psychological research in his contemporary society in line with the new social and political situation in his society. In a wider, international perspective, this was a period of heated scientific debate as well as optimism and progressivism in the progress of scientific knowing. In this respect, Vygotsky’s work represented a particular contribution to psychology at a particular time and place in society, locally and internationally. He was a mind in society, and a remarkable one at that. When he died from tuberculosis, 37-year-old Vygotsky had written about 180 papers and established a number of research collectives and research centers throughout the country.

The Early Phase – Basic CHAT Ideas

Levels of Development

As discussed, Vygotsky’s work was mainly in psychology; however, he was influenced by his background in literature and semiotics, his interests in European and American psychology (e.g., German Gestalt theory), and in new developments by contemporary biologists and evolution theorists in the USSR. Though he opposed applying findings from animal research to human psychology, and emphasized consciousness and higher mental functions, he had a great interest in animal studies, for instance, Köhler’s studies of chimpanzees and their tool use. Evolution was, in fact, one of the three lines of development that Vygotsky emphasized along with sociocultural development (societies and institutions) and ontogenesis (individuals). A basic assumption in Vygotsky’s approach is that there is no single factor or set of explanatory principles that alone can account for these different lines of development. Instead, there are multiple forces of development, each with its own set of explanatory principles.

Higher Mental Functions

In the article ‘The genesis of higher mental functions’, Vygotsky made a distinction between three stages in the development of behavior. “Instinct, or the innate, inherited fund of behavioral modes, forms the first. The second consists of [...] the stage of training or the stage of conditioned reflexes [...]. Finally, still higher, we have the third stage, the stage of intellect or intellectual responses that fulfill the function of adaptation to new conditions” (Vygotsky, 1981a: 154). Each of these three stages requires a specific set of explanatory principles. The intellectual response is of a different class than the mechanical formation of habits taking place through trial and error. The main problem of psychology is to understand the transformation of elementary processes, starting

with the newborn baby's reflexes, into higher mental functions. Vygotsky attributed two main components to the higher mental functions. The first was the making and use of tools and signs as auxiliary means. Tools provide the ability to change the object of an activity as they are externally oriented toward the mastering of nature, while the signs are internally oriented and aimed at mastering oneself. Second, higher mental functions are socially rooted and historically developed activities. The combination of tools and signs constitutes the unique feature of human psychology; it is the basis for the qualitative leap from animal to human psychology. Human practice is fundamentally mediated by tools and signs that have been created and made accessible through history and culture. Consequently, mental functioning is integral to complex social structures.

The Cultural and Historical in CHAT

The starting point for CHAT, then, is that human psychological functioning is embedded in culture and history – hence the term cultural–historical.

In his discussion of the problem of method in psychology, Vygotsky elaborated on the principles of the genetic or developmental approach. He emphasizes process analysis as opposed to object analysis: it is in movement that a body shows what it is. “By a developmental study of a problem, I mean the disclosure of its genesis, its causal dynamic basis” (Vygotsky, 1978: 62). It implies explaining a phenomenon by investigating its origin and its development instead of its appearance. We need to focus on how the higher forms of mental functioning are established. It implies analyzing individual development and learning in the contexts of social contexts and social practices. Individual development is interpreted as a trajectory of the individual's inclusion (or exclusion) in cultural contexts, and the context is interpreted in the perspective of its history and its interrelatedness with other contexts.

The cultural embeddedness implies that human action and interaction cannot be understood without including the social and cultural context in the analysis. It implies that the unit of analysis is person in context. Vygotsky's colleague, Luria, expressed it this way:

In order to explain the highly complex forms of human consciousness one must go beyond the human organism. One must seek the origins of conscious activity [...] in the social and historical forms of human existence.
(Luria, 1981: 25, quoted from Wertsch, 1998: 8).

Vygotsky formulated what he called the general law of cultural development, which states that the development of higher psychological functions implies mastery of processes that in their origin are social – they are external and social before they become internal. Any function in the child's cultural development appears twice, or on two

planes: first on the social plane and then on the psychological plane. First, it appears in social interaction and subsequently as an individual achievement. From this general law, Vygotsky formed the well-known theses that learning emerges as a consequence of the zone of proximal development:

It is the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers.
(Vygotsky, 1978: 86)

Tool-Mediated Action

As discussed, CHAT takes as a starting point that human practice is mediated by tools or signs, which Vygotsky (1981b: 136–137) described as “devices for mastering mental processes [...]”. They are directed toward the mastery or control of behavioral processes – someone else's or one's own – just as technical means are directed toward the control of processes of nature” (Vygotsky, 1978: 55). They are partly externally oriented (changing an external object) and partly internally oriented (mastery of oneself). A variety of terms is used more or less synonymously: tools, signs, mediational means, and recently (cultural) artifacts is commonly used. Vygotsky particularly emphasized the meaning of psychological tools (signs) like language, models, and theories, as well as material tools like hammers, pens, and computers. By using psychological tools, the possibilities for behavior are immeasurably extended. Bateson's example of how the blind man extends his tactile space by using the stick illustrates the point that tools extend the capacity of the user. Wertsch (1998) emphasizes the irreducible relationship between agent and mediational means by defining the unit of analysis as the individual operating with mediational means.

Coming back to the cultural–historical aspect of CHAT, artifacts are seen as cultural tools often offered to the user by someone; mediational means are also ways of conveying the culturally given. Through the use of artifacts, we are linked to culture. Artifacts represent and constitute culture. When we learn to the use of artifacts, we are, in fact, introduced to the activities of prior generations. “Cultural mediation implies a mode of developmental change in which the activities of prior generations are cumulated in the present as the specifically human part of the environment” (Cole, 1996: 145). This means that signs and tools manifest cultural practices and, through their use, human practice and mental representations are linked to these cultural practices.

The first generation or conceptualization of CHAT is illustrated in **Figure 1**. The left part of the **Figure 1** illustrates Vygotsky's initial illustration which reframed

the stimulus–response approach: the simple stimulus–response process is replaced by a complex, mediated act. The relationship between a stimulus and a response goes through the use of mediational means. The right part illustrates the more recent conceptualization. It highlights the triangular interdependent relationship between (1) artifacts, tools, or mediational means; (2) the object or target of activity; and (3) the subject as tool operating and object oriented. The focus of Vygotsky’s conceptualization of CHAT is the genesis of higher mental functions in the perspective of ontogenesis, but with the intention to solve the individualism/social dualism: individual action and development emerge from social and cultural practice; they are an integral part of social practice.

The Notion of Activity in Chat

A. N. Leontiev, who worked with Vygotsky from 1924 to 1930 before being appointed to a position in Kharkov, Ukraine, developed the concept of activity. What does the term activity in CHAT mean?

First, activity includes, but is not identical with, the actions of individual agents. Leontiev differentiated between activity, action, and operation. To illustrate the distinction between activity and action, Leontiev used the example of the role of the beater in primeval collective hunt. The task of the beater was to frighten the animals and send them toward other hunters that were hiding in the ambush. His individual task ended with that, and the rest was completed by the (other) hunters. However, the meaning of his task can only be understood in the context of the collective task and actions, including the beater and the other hunters. “We can say, for example, that the beater’s activity is the hunt, and the frightening of the game his action” (Leontiev, 1981: 210). The activity is constituted by the joint and coordinated actions of more than one actor, often a wide range of persons with diverse roles and expertise. The frightening of the animal did not in itself lead to the satisfaction of the beater’s need for food, but it was needed both for the beater and the other hunters to be able to satisfy their needs. The object of the

coordinated activity was the hunt (which provided meat, skin, etc.) in which object the motive of the activity resided. At the action level, the beater’s intention was to drive it in the direction of the other hunters whose action was to kill the animal.

The second point, then, is that while the actions relate to the intentions of the actors, the activity is driven by a collective motive. To discover the true motive of the participants in the hunt, we need to address the complex coordinated and joint activity of actors with different roles, tasks, and goals. Taking schooling as another, more familiar example of an activity, the coordinated actions of many individuals constitute the activity: in particular, the actions of a number of different subject teachers and the students’ actions in and out of the classroom. “Consequently, it is the activity of the others that provides an objective basis for the specific structure of individual activity” (Leontiev, 1978: 281). It is the activity that attributes the overall meaning to the series of diverse actions.

The third point is that, in an activity, actors also perform a series of more or less automatic operations. Teachers respond immediately to situations or conditions that occur in the classroom, and students write without consciously reflecting on how to hold the pencil or having any present intentions about how to form letters. Such operations represent the third level of an activity. **Table 1** illustrates these different levels of an activity.

Leontiev did not emphasize semiotic mediation – Vygotsky’s point that, through signs and psychological tools, the subjects can master not only the world, but also oneself and others’ relationships to the world. Instead, he emphasized the direct relationship of psychological functioning with reality. Thus, “the subject assumed in [Leontiev’s] categories is the social–historical subject rather than the psychological–individual” (Kazulin, 2005: 117).

Activity System

Engeström (1987) took Leontiev’s approach further, and included the role of semiotic mediation and the mediated act in his reinterpretation of CHAT. His conceptualization of CHAT is frequently referred to in scientific publications (Roth and Lee, 2007). Following Leontiev, he regards activity as the most adequate object of study, but introduced the notion of an activity system. An activity system is a unit of analysis that includes both the active, participatory role of individuals and the impact of the

Figure 1 The mediate act and its recent reconceptualization. Modified from <http://www.edu.helsinki.fi/activity/pages/chatand.dwr/chat/>, with permission from the Centre for Activity Theory and Development Work Research, the University of Helsinki.

wider social system in which the agents operate. It incorporates the core mediating components of action and activity (Figure 2). The model integrates Leontiev's focus on object-related activity and collective object-driven motive with Vygotsky's emphasis on material and psychological tools and the mediated act.

As participants, we are engaged in social systems (communities) where certain rules apply and where the action and interaction between participants are regulated to some extent (division of labor). The upper part of the triangle is, thus, just the tip of the iceberg. Actions are anchored in social conditions and requirements that are not so clearly visible. The model depicts what we mean when we say that actions are culturally, institutionally, and historically situated and opens up paths for empirical research based on a contextual approach to learning. First, the core component of the activity system is the object of activity, which includes the outcome the system is directed toward. For instance, in studies of health systems, the object can be depicted as the sick patient and the outcome of the activity as the same person healthy again. Second, the model implies that the improvement of the activity presupposes changes in the diverse components of the activity system. Which component(s) that needs to be addressed to initiate change is an empirical question; it

will vary from one activity system to another. The model conceptualizes the genesis of social practice, the development of activity – social transformation rather than individual development, and it has led to the development of a strand of research called developmental work research.

Third Generation of CHAT

The reconceptualization of Leontiev's version of CHAT in the Western multicultural, democratic societies took place under other social and political conditions than the ones in USSR. CHAT has appealed to researchers who question the way institutions and societal practices are organized. However, the theory entered a multicultural and multivoiced social and academic context where diversity, dialog, and confrontation between various perspectives and viewpoints were prevalent. Second, while Leontiev, from his focus on psychological processes, stated that “the human individual's activity is a system in a system of social relations”, Engeström made the point that an activity system is also a system within a system of other activity systems. The principle that an individual is not an independent and isolated unit of analysis was applied on activities. To understand the meaning of an activity, we need to take into consideration its interrelatedness with other activities. It means, for instance, that the activity of schooling should be analyzed from the perspective of how it interrelates with, for instance, play, work, family life, or kinship relations out of school. Consequently, the minimal unit of analysis should include the system studied and one or more activity systems with which it interacts. In their interaction, a potentially shared object might occur and, thereby, a shared motive for both collective activity and individual actions (Figure 3). In healthcare, for instance, the focus might be on how primary and secondary health care institutions interact in the treatment of a sick patient.

In the third generalization of CHAT, where transformation of activities and organizational development are in focus, the potential tensions between activities and

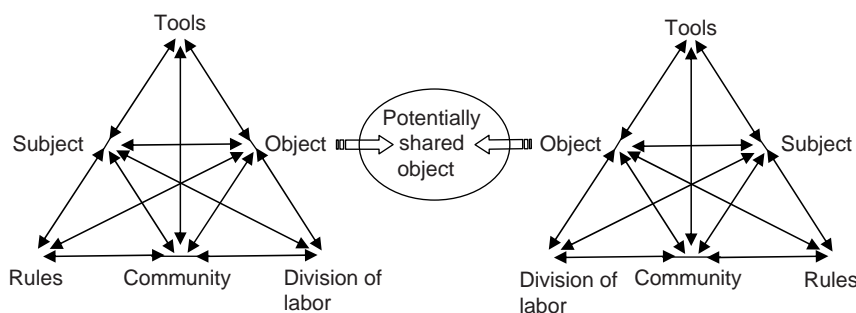

Figure 3 Third generation of CHAT. Modified from Engeström, Y. (1996). Developmental work research as educational research. *Nordic Educational Research Journal* 16, 131–143.

activity systems emerge as objects of study. It can be questioned if the emphasis on collective activity, activity systems, and social transformation has led to undercommunication of individual's practices and development. Stetsenko (2005: 72), for instance, suggests that the major challenge today "is to conceptualize psychological processes avoiding the extremes of reducing them either to a separate individual mental realm [...] or, alternatively, to the essentially sociological realm of collective discourses and practices."

Summing Up

As mentioned, CHAT is an approach that has been, and still is, in a process of development. Its development is not a linear process in the meaning of one continuous movement toward new stages where the next stage or conceptualization takes over from the previous. First, new conceptualizations did not follow directly from the previous. For instance, Leontiev's activity theory diverted, to some extent, from Vygotsky's emphasis on sign-mediated action and the mediating role of language. Second, new developments have also implied reinterpretations of core elements of the earlier versions of the theory. Thus, Vygotsky's initial ideas about, for instance, the social origin of individual development, the zone of proximal development, and mediational means are still under development and subject to reinterpretation. Wertsch (1998) has elaborated on and expanded Vygotsky's notion of mediational means, and Cole (1996), on the role of culture on mental functioning. Leontiev's notion of object-oriented activity has been developed by, for instance, Engeström (1987) and, in a recent special issue of the journal *Mind, Culture and Activity*, the interpretation of the object of activity has been reconsidered by Kaptelinin (2005) and Stetsenko (2005), among others.

It should be stressed that the philosophical and theoretical underpinnings of CHAT did not start with Vygotsky. For instance, Valsiner and van der Veer (2000) have elaborated on the influence on Vygotsky by his contemporaries in USSR, US, and Europe. From the very beginning, CHAT has itself been developed and applied in various cultural-historical phases and conditions. To understand the development of CHAT, it is needed to address both its external relationship to social, cultural, and political conditions and the internal dynamics of the theory – its potentials as a research platform and its inner tensions and dilemmas.

In applying CHAT as a platform for research, it is essential to understand that it is not straightforward and consistent. The three conceptualizations that have structured this presentation of the theory illustrate not

only how it can be applied in studies of both individual development and organizational development, but also how these developmental lines interact.

Learning in a Sociocultural Perspective

R Säljö, Göteborg University, Göteborg, Sweden

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Issues of learning and development were at the heart of the attempts by Vygotsky (1896–1934) to take psychology out of what he described as its ‘crisis.’ He developed his ideas by dialoguing with the theoretical perspectives presented by many of the distinguished scholars who were active during the rich and dynamic period of psychology of the early twentieth century: Piaget, Janet, Thorndike, Pavlov, Freud, Bühler, and others who we now conceive as Grand Theorists. He was also eager to challenge the basic ideas of the influential schools of psychology of the time, such as behaviorism, pragmatism, and Gestalt psychology. Vygotsky carefully and critically scrutinized the conceptions of learning and development, underpinning these diverse traditions, and pointed to where they, in his opinion, were flawed. Some of these traditions he saw as idealistic and speculative rather than scientific; others he accused of being too reductionistic and failing to address the fundamental problems of consciousness and how the human mind develops and is transformed through social experience. (Informative accounts of the development of Vygotsky’s ideas have been written by Bruner, 1985; Kozulin, 1986; and Leontiev, 1997).

One way to understand some of Vygotsky’s revolutionary ideas on learning and development is to listen to his critique of the dominant tradition of his day in the Soviet Union: pavlovian reflexology. Reflexology, like behaviorism, represents a view of learning which from a philosophical perspective can be described as associationism. The core idea is that learning can be reduced to understanding the associations between stimuli and responses, the so-called $S \rightarrow R$ connection. This link between a stimulus (the presence of food) and a response (salivation by the dog in Pavlov’s famous experiments) was conceived as the atom of learning. Through the principle of conditioning, which implies that a new stimulus (in Pavlov’s case, a bell) is introduced to elicit a response, learning takes place. What was previously a natural response is now a conditioned, that is, learned response. In this tradition, more advanced behaviors can be understood as chains of increasingly complex connections between stimuli and responses. Vygotsky viewed this experimental approach to the study of psychological phenomena, although scientific, as insufficient for understanding how human beings learn and develop. Indeed, the adherence to this perspective on human psychological functioning was a significant part of the ‘crisis.’ This approach is only relevant for explaining what he referred to as the ‘lower psychological functions,’ that is, those

elementary processes which are largely biological and given to us by nature, as it were. A genuinely psychological understanding of phenomena such as learning and development must grapple with specifically human modes of thinking and acting, where language and other cultural tools play a decisive role. These are the “higher psychological functions” (Vygotsky, 1978), which are social, historical, and cultural in their origin and nature.

The Sociocultural Approach

Vygotsky formulated his ideas during a short and hectic period of about ten years. His style of writing and the richness and originality of his ideas led the philosopher Stephen Toulmin to refer to him as the Mozart of psychology in a review of *Mind in Society* when it was published in 1978. Together with his colleagues A R Luria (1902–77) and A N Leontiev (1904–79) he formed the famous troika that was to have a profound influence on psychology and allied disciplines. The history of the sociocultural tradition is also fascinating. The research and the ideas were dormant during the dark ages of political oppression in the East and the intellectual hegemony, even monotony, of behaviorism in the West. The interest resurfaced in a major way in the 1970s and 1980s, thanks to the efforts of Luria and Leontiev and scholars in the West such as Jerome Bruner, Michael Cole, and Jim Wertsch. Today, the influence of the legacy of Vygotsky is stronger than ever and his writings form a rich and inspiring source for developing our understanding of human learning.

One important clue to understanding the pillars on which Vygotsky tried to build a new, and in his view more productive, approach to the study of learning and development can be found in the terms which have been used by his followers to characterize his approach. Some authors refer to it as a sociocultural approach, while others use the terms cultural–historical or sociohistorical. Cole (1996) uses Vygotsky’s ideas as a foundation for what he refers to as cultural psychology. All these expressions communicate something significant about Vygotsky’s original intellectual project: he wanted to study the relationships between the sociocultural and sociohistorical development of human activities and societies on the one hand, and, on the other, what these transformations imply for learning and development of individuals during ontogeny (i.e., their life span). In other words, he wanted to understand how a biological being becomes a sociocultural being equipped

with language and a range of cultural and intellectual skills relevant for social life – skills that have no counterpart in any other species.

Mediation and Cultural Tools

One of Vygotsky's core ideas is that human beings, unlike animals, learn and develop by using cultural tools. Such tools, "language, different forms of numeration and counting, mnemotechnic techniques, algebraic symbolism, works of art, writing, schemes, diagrams, maps" (Vygotsky, 1997: 85) are the products of the development of practices in society over time. They are sociocultural also, in the sense that the nature of these tools may vary between societies. For instance, in some languages one uses some kind of phonetic alphabet for writing, others have syllabic and/or logographic writing systems. These writing systems are different cultural tools, each with their own particularities when it comes to how reading and writing are carried out. In a historical perspective most societies have not used writing at all. Growing up in the latter kind of environment implies that many human activities have to be done differently from what we are used to. For example, one cannot make notes to remember and there can be no such thing as a book of law as an element of legal practices.

Cultural tools develop through an evolutionary process, that is, they have a sociogenesis (de Graaf and Meier, 1994). This idea of the sociogenesis of tools, and of psychological processes, is central to a sociocultural perspective. Vygotsky made a distinction between intellectual/mental (although he used the term psychological) tools and technical or physical tools. Mental tools are symbolic systems used for activities such as writing, counting, measuring, and so on. Examples of physical tools, that is, artifacts, would be rulers, computers, hammers, compasses, etc. (Säljö, 1999). However, and as Cole (1996) argues very convincingly, the distinction between these two kinds of tools is difficult, maybe even pointless, to uphold; a mini-calculator or an abacus is an artifact but both these artifacts, although in different manners, incorporate intellectual tools such as number systems and rules for performing calculations. This ability of externalizing intellectual tools into physical tools is another example of a unique human talent of considerable significance for learning.

At the level of individual action, cultural tools serve as instruments of thinking and acting, to use Vygotsky's own expression. They enter into the flow of human actions and transform the manners in which we reason, communicate, and carry out all kinds of activities. From a psychological point of view, it is one thing to carry out multiplications of four-digit numbers with two decimals as mental arithmetic, another to do it with paper and pencil, and yet another to do it with a mini-calculator (Säljö *et al.*, 2006).

The manners in which we perform such operations differ radically in these situations. What is impossible to do as mental arithmetic becomes almost trivial when there is a calculator present.

In the language of sociocultural theory, cultural tools mediate the world for us in social practices. This notion of mediation is one of the most central concepts in the sociocultural approach. By learning to use cultural tools, we appropriate (Wertsch, 1998) portions of the accumulated experiences and knowing of our society. When learning how to make calculations using decimals or learning how to use a compass, we take over some of the insights and practical knowing that have emerged in our society. These tools are not the inventions of the individual; rather, we come to know and master them because they are used in the society in which we are socialized – and we use many such tools without knowing where they came from or how they emerged. Thus, all readers of this text are familiar with intellectual tools such as percent, decimals, and the = sign, but we may have no idea of their sociogenesis. We take them over as they are, and in this sense the world is pre-interpreted for us. When tools change, such as when we begin to use calculators for complex multiplications, remediation takes place.

For Vygotsky, language is the prime mechanism for mediating what happens in the world, it is "the tool of tools" as he puts it. The relationship between language and thought was one of his most prominent interests, and there are many reasons for this focus on language. One reason why language is so significant for learning and development, both at the collective and the individual level, is that it simultaneously serves as the link between people in interactive settings, and as a tool for thinking. This is how our thinking is socialized or, to put it even stronger, humanized. One of the most quoted passages from Vygotsky's work is the following, where he makes this point:

Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first *between people (interpsychological)*, and then *inside the child (intrapsychological)*. This applies equally to voluntary attention, to logical memory, and to the formation of ideas. All the higher functions originate as actual relationships between human individuals. (Vygotsky, 1978: 57; italics in original)

This formulation indicates how Vygotsky attempted to solve the problem of creating a link between the inner world (thinking) and the outside world (interaction with others). Through language, cultural tools are appropriated (or in Vygotsky's terms: internalized) by individuals in social interaction. Thus, in a sociocultural perspective, thinking is seen as a kind of inner speech carried out by means of cultural tools that we first encountered in communicative practices (Vygotsky, 1986). To think is to engage in internal dialogs with semiotic tools.

Language is also the prime mechanism of semiotic mediation, that is, thinking by means of signs. Sign-mediated communication is another uniquely human phenomenon which, for instance, behaviorist interpretations of learning are unable to deal with. Learning as conceived in behaviorism implies that the organism (be it a human being or an animal) responds directly to stimuli in the external world, that is, in an unmediated manner. Sign-mediated communication instead implies that people think in a roundabout way (Vygotsky, 1994: 61) by means of cultural tools. We, metaphorically speaking, engage with the world via cultural tools when we communicate and perform physical activities.

In passing it should be pointed out that Vygotsky in no way denied the significance of the biological basis of human cognitive and psychological functioning. In fact, in many of his writings, he explores various features of animal cognition, in particular the thinking of primates, and he had a strong interest in such comparative research. But he was adamant in his insistence on the fact that human thinking and learning cannot be reduced to biological processes. Humans are unique in the sense that they think, communicate, and work through cultural tools, and it is at this level that we have to study learning and development if our interest is in human psychological functioning. The sociocultural development is “not a simple continuation” of the biological one. On the contrary, when people begin to appropriate cultural tools through communication with those around them, the “*nature of development itself changes, from biological to sociohistorical*” (Vygotsky, 1986: 94; italics in original). In this sense, “animals are incapable of learning in the human sense of the term,” since “*human learning presupposes a specific social nature and a process by which children grow into the intellectual life of those around them*” (Vygotsky, 1978: 88; italics in original). The evolutionary psychologist Donald (2001) expresses this idea of the relationship between biology and culture even more strongly when he argues that the human brain is a biological structure which has been ‘hi-jacked’ by culture for cultural and interactional purposes.

Learning and Development: the Zone of Proximal Development

Another idea which is central to the sociocultural tradition, and which differs from other perspectives, is the focus on the change and dynamics of psychological processes. In fact, Vygotsky argued that when studying human beings, one always studies change. This idea he developed as a critique of the research of, among others, Piaget and his stage theory and of the representatives of traditional intelligence testing such as Binet. An assumption of such theories is that “learning trails behind development” (Vygotsky, 1978: 80). This implies that “[d]evelopment

or maturation is viewed as a precondition of learning but never as a result of it” (Vygotsky, 1978). From the point of view of educating children this implies that development is seen as a more fundamental process; children can only learn it when they are at the required stage of maturation. Instruction, thus, should be adapted to the developmental level of the child.

For Vygotsky, and from a sociocultural perspective, the opposite assumption, that is, that learning is constitutive of development, is more productive. It is by appropriating cultural tools that children develop and become familiar with the accumulated knowing and skills of their community. When children begin to appropriate the basics of addition and subtraction, they become familiar with specific cultural tools and “this provides the basis for the subsequent development of a variety of highly complex internal processes in children’s thinking” (Vygotsky, 1978: 90). Expressed differently, through learning the development of the child is set in motion in a specific direction. However, learning is not identical with development; rather, it is a necessary prerequisite for the child to develop “culturally organized, specifically human psychological functions” (Vygotsky, 1978).

These ideas of the dynamics of human thinking, and that learning contributes to development, are incorporated into the famous concept of the zone of proximal development (ZPD). Throughout his short life, Vygotsky had a strong interest in education and wanted to offer an alternative way of thinking about pedagogical practices to the ones offered by, for instance, stage theories and behaviorism. Instead of seeing maturation as a necessary prerequisite for learning, one should consider the manner in which children (or adults) appropriate cultural tools. This is done gradually and through the support the learner receives in social interaction by more expert partners. Thus, for the individual there is a ‘zone’ in which his or her familiarity with how to use a cultural tool is still at an early stage. Vygotsky (1978: 86) defined ZPD as:

the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers. (italics in original)

What this idea implies at a very concrete level is that when people are allowed to cooperate with more capable peers, their performance is usually much better than when they work alone. When a child is struggling with understanding the basics of addition and subtraction, support by a teacher or a parent will assist the child in understanding how to proceed when dealing with specific problems. These hints and suggestions may be indirect and subtle but when the adult and the child share a certain interpretation of the task, the child can make productive use of the skills of the more expert person. More capable

partners will thus ‘scaffold’ (Wood *et al.*, 1976) the activities of less experienced members of an activity.

The ZPD can be conceived as a developmental path in which the child’s appropriation of a cultural tool is still partial, and where external support will be necessary to accomplish a task such as tying a knot (Nilholm and Säljö, 1996) or solving a puzzle (Wertsch, 1985). But it can also be seen as the zone in which a child is particularly sensitive to instruction from a more knowledgeable partner. It is within this zone that the child is able to profit from the assistance provided by the adult in order to develop a more independent understanding of the cultural tool and how to use it in a specific setting.

The ZPD has served as an inspiration for important developmental work in education in many contexts. The attempts to develop reciprocal teaching and guided cooperative learning by the late Ann Brown and her colleagues (Brown, 1993) is one example of this. In reciprocal teaching, the role of the teacher is “to scaffold the involvement of learners in the discussion by providing the explanation, modeling, support, and feedback that will – in time – enable full participation of students” in activities such as understanding texts and other cultural tools. The idea of the ZPD has also been used as an underlying notion for the view of learning as a process of increasing participation in social practices emphasized by scholars such as Rogoff (1990). In much of this work there is also a critique of the rather one-sided view of the adult–child relationship that Vygotsky presents, where the child is always the dependent part and the adult is in control of the progress of the activity. Several of these scholars, for instance, Rogoff in her analyses of guided participation, instead emphasize the joint efforts by all parties of maintaining mutual understanding and shared perspectives on the world when engaging in conversations. This critique also draws inspiration from the more dialogical interpretations of learning and social interaction which have emerged during recent years when Vygotskian ideas have been combined with the dialogical perspective on language and interaction that is at the heart of Bakhtin’s approach to human communication (Wertsch, 1991).

Language, Learning, and the Formation of Mind

The most well-known publication by Vygotsky is his book *Thought and Language*. It was originally published in the final year of his life and has appeared in a number of English translations. The first English version, a highly abbreviated one, appeared in 1962 and more extended versions were published in 1986 and 1997 (the latter one with the title *Thinking and Speech*). In this volume, which undoubtedly is one of the most influential books in the fields of learning and development, Vygotsky explores fundamental problems

of the relationships between thinking, communication, and the formation of mind. His ambition is to scrutinize the role that language and communication play in human ontogeny, and he touches on several significant issues that pertain to how the mind is shaped by social experience.

Vygotsky’s emphasis on the role of linguistically mediated communication is rooted in his conviction of the role that semiotic mediation plays in the formation of human thinking and social interaction. It is through semiotic mediation that we develop the abilities characteristic of higher psychological functioning. We learn conceptual knowledge, how to remember, how to monitor our own activities and put them under conscious control, and a range of other sociocultural skills. Much of what we learn would in modern psychological parlance be described as meta-cognitive or meta-communicative skills; we learn to structure our own activities and the world through language (Rommetveit, 1985). The emphasis on these kinds of skills reflects Vygotsky’s conviction that as human beings we not only live in the world; rather, we are also able to reflect on it and develop knowledge about what we do (cf. Cole, 1996: 120). Language is the most significant tool in such processes.

From the educational point of view, one particularly interesting analysis concerns that of the distinction between the acquisition of spontaneous concepts and scientific concepts, respectively. We appropriate spontaneous concepts (brother, sister, and family) in everyday interaction, that is, we learn them from below, metaphorically speaking. Other concepts (one example that Vygotsky uses is Archimedes’ law) we have to learn through some form of explicit instruction or guidance. Somebody has to explain to us what the term and the concept mean, and appropriation then proceeds in a top-down fashion; we descend from the abstract to the concrete (cf. Kozulin, 1998: 48). Thus, understanding them implies learning to contextualize a particular class of phenomena by means of an abstract principle. Supporting this specific type of learning is the responsibility of schooling and the teacher. This is one of the reasons why schooling is so important, and why the specific learning practices of schooling are different from what we find in other settings. Thus, Vygotsky objected to Piaget’s view that children, when engaged in self-directed learning and experimentation, will come to master scientific concepts. Such learning, Vygotsky argued, presupposes guidance by someone who masters the relevant discourses. A significant role for schooling is to introduce children to those parts of the accumulated knowledge of our society that is not available through everyday practices.

Vygotsky and the Development of Education

In the debates on learning and development Vygotsky’s sociocultural approach has become central. The theory

has become part of many introductory books in psychology and education, and has found its way into discussions about pedagogy. An interesting dimension of the legacy of Vygotsky concerns his impact on education. Already in the Soviet period there were many who attempted to develop pedagogical practices that were rooted in Vygotsky's thinking. The success of these experiments is not convincing. In fact, many of these attempts now strike us as highly problematic. The notion of a scientific approach to education often resulted in a kind of scienticism with what appears to have been rather sterile, even authoritarian, teaching patterns dominated by adults. Children were, to some extent, treated as objects of teaching rather than active participants and contributors to their own learning. In recent developments in educational research, however, Vygotskian ideas have become important for approaches to teaching and learning that emphasize the situated nature of knowing and the necessity of actively engaging learners in the process of appropriating knowledge and skills in cooperation with adults and in various kinds of learning communities. The work by Brown and Rogoff and their colleagues mentioned earlier are but two examples of many contemporary attempts to take Vygotskian ideas into educational practices. This is also an important reminder of a point that John Dewey repeatedly made: theoretical principles are not enough for creating successful educational practices. This move from theoretical insights to pedagogical practices *per se* requires extensive work. But for anyone struggling with these important issues, the sociocultural approach is a rich and promising companion.

Glossary

Agency – The human capacity to choose and act on choices.

Coregulation – The temporary sharing or distributing of self-regulated learning between a learner and a more capable other (peer or teacher) to help the learner advance toward more effective self-regulated practice.

Enactive learning – Learning by doing or practicing.

Metacognition – The thought about cognition and the products of cognition usually involving monitoring and choosing among tactics and strategies.

Scaffolding – The dynamic interaction between a learner and an other in which the kind and degree of support is carefully matched to the goal of learning and the learner's current level of mastery relative to that goal.

Self-regulated learning – The intentional and strategic adaptation of learning activities to change cognition, motivation, and behavior outcomes.

Sociocognitive theory – A theory that acknowledges the joint roles of cognitive factors, self-beliefs, and environmental factors in human learning; an extension of social-learning theory.

Sociocultural theory – A theory that emphasizes social interactions and participation as central in enculturating learners into the practices of their learning communities.

Strategy – A carefully selected set of tactics coordinated to achieve a learning goal.

Tactic – A basic technique for learning that is initiated under specific conditions and produces a well-defined result.

Vicarious learning – Learning by observing others.

made to learning processes and strategies; to conditions, like motivation or factors in the learning environment, that affect learning activities or to learning outcomes and products.

For example, after writing a paragraph, I typically pause to read it. I check it against at least two standards; whether it is (1) clear and (2) presents content I intended it to. If the paragraph falls short of these standards, I adjust the words or phrasing (products), then reexamine the paragraph to judge whether these adjustments are sufficient to meet the standards I set.

I often write without making a written outline. However, when the topic is particularly complex or relatively new to me, past experience in producing less-than-satisfactory products leads me to adjust my writing process. In these cases, I begin by creating an outline, then writing to fill in its sections. I also add a third standard to be used when pausing and reviewing my writing, namely, examining the match between what I have written and the outline.

These examples of regulating my writing are instances of self-regulation because I, rather than some external person or source of feedback (e.g., a computer beep) initiated and performed the regulating activity. I determined the standards to use in monitoring whether adjustments were necessary, and I decided whether the product and processes met those standards. If instead, my coauthor read my draft and made changes to it, that is regulation by an external source or other-regulation. If my coauthor modeled the development of a concept map as a method for improving my writing, that adjustment to my typical writing process also is other-regulation. If my coauthor asked me questions that prompted me to reflect on and adjust my writing process or product, this would be considered coregulation because rather than doing the regulation or changes for me, she encouraged me to metacognitively reflect upon and regulate my own writing.

In sum, regulation occurs when learners adjust products they create or methods they use to create products. Adjustments are made in relation to standards that characterize ideal or sufficient products and processes. Regulation is metacognitive because the monitoring examines prior cognitive activities that were methods by which the person engaged in a task. When regulation is initiated and managed by one's self, that is self-regulation. When people regulate processes they use to acquire new knowledge – to learn – they engage in SRL.

What Is Self-Regulated Learning?

Self-regulated learning (SRL) refers to intentionally and strategically adapting learning activities to achieve goals of learning. Learners self-regulate by applying learning tactics they predict will be successful. They monitor how well tactics achieve goals and, when differences exceed a threshold, they make adjustments. Adjustments can be

Models of SRL

The number and scope of models of SRL make it impossible to address all of them here. We select models that are prevalent in the research literature and provide context for considering sociocognitive aspects of SRL.

Boekaert's Model of Adaptable Learning

Boekaerts' model of adaptable learning focuses on students in classrooms. A basic premise is that learners strive to balance two priorities: (1) extending knowledge and skills to enhance their personal resources – a mastery mode of learning – and (2) preserving what one knows and believes to avoid injuring the self – a coping or well-being mode of learning. Corresponding to these two modes, the learner draws on constellations of: (1) learning strategies that build resources and (2) coping strategies that protect resources. Thus, Boekaerts' model, like others, blends cognitive and motivational elements. Success in this depends on the learners' capacity to appraise the overall situation and, on that basis, control their approach to learning as well as elements in their task environment.

When learners participate in learning, they draw on three main sources of information. The first is their perception of the task environment. This is an amalgam of the task they are assigned, the teacher's (or textbook's) instructions, and features of the physical and social context in which the task is situated. The second source of information is a spectrum of knowledge and skills specific to the domain of the task that comprise an action plan. The plan includes: prior declarative and procedural knowledge, tactics and strategies they have successfully used before, plus metacognitive knowledge. The third source of information concerns the student's hierarchy of goals, motivations, and values.

Boekaerts' model emphasizes learners' goal setting and ways they apply control to deal with successes and failures. Productive self-regulating learners plan for how they can receive feedback about goals. When goals are not met, learners seek to balance goals relating to mastery and those of coping in ways that adapt to maintain a satisfactory balance and sense of self.

Winne and Hadwin's Model of Recursive Self-Regulation

Winne and Hadwin developed their model to describe occasions when learners study, as in doing homework or preparing for an oral presentation. They postulate that SRL unfolds over four flexibly ordered and recursive phases.

In phase one, learners identify what they perceive to be conditions that define the assigned task. Conditions fall

into two main categories. Task conditions are features of the assigned task such as objectives the teacher (or textbook) set, time available, whether peers are involved, social structure (e.g., cooperative vs. competitive, or whether responsibility is individual or shared), resources available to start and then support work on the task, and guidance or scaffolding. Cognitive conditions are internal to the learner. They include the scope and relevance of prior knowledge, motivational orientation, epistemological beliefs, known study tactics, and other qualities that make the learner a unique individual.

In phase two of this model, learners construct a perception of what the task is and, on that basis, set their own goals. In phase three, learners begin engaging with the task, taking steps to reach goals. In phase four, large-scale changes to preceding phases may be made, including changing metacognitive knowledge, to enhance success in the present and for future tasks.

Within each phase, Winne and Hadwin hypothesize that learners engage in metacognitive monitoring. For example, in phase one, learners may reexamine external resources or what they know about the task to revise their description of the assignment. When metacognitive monitoring in later phases reveals gaps of the kinds the learner perceives to be too great, learners retreat to a prior phase to make adjustments – this is the recursive property of their model.

Zimmerman's Social-Cognitive Model

Zimmerman's model extends Bandura's social cognitive theory. It also is a phased model. In the forethought phase, learners undertake two main activities. One couples an analysis of the task the learner perceives to be assigned to planning that identifies what the learner forecasts are optimal techniques for succeeding at the task. The other facet of the forethought phase is where learners survey their self-motivational beliefs, specifically: self-efficacy, expectations they have for the outcome(s) of the task, their intrinsic interest in the task and its value to them, and goals they seek to achieve.

In the second phase, learners engage in the task and simultaneously apply control processes to stay on track toward goals. One key component is applying self-control, for which there are four main elements: (1) self-instruction, where learners overtly or covertly describe what they are to do; (2) imaging, where learners mentally picture their activities; (3) attention focusing, where learners change their external and cognitive environment to screen out distractions; and (4) applying strategies that decompose a complex task into parts that can be managed. The second key component, self-observation, sets the stage for applying control. Learners record mentally or materially (e.g., in a personal log) what they do and how well it works, and

engage in cycles of self-experimenting to explore whether variations in their approach will lead to greater success.

In the third and final phase, learners self-reflect. This has two components: self-judgment, where learners determine the extent to which goals are achieved; and self-evaluation, where learners compare their achievements to standards. Standards have four forms: mastery, one's prior performance, normative expectations, and in collaborative task environments, whether one's expectations were successfully fulfilled.

Commonalities across Models of SRL

Task Environment

Whenever SRL occurs, it occurs in the context of a task the learner is pursuing. Tasks may be assigned by teachers, textbooks, or peers in a collaborative work group; or, tasks may be self-generated, as when a learner pursues knowledge and skills related to a hobby. Tasks are multifaceted and there is great variety among typologies for characterizing tasks. Common facets include time available, resources at hand, whether standards are explicit or implicit, and characteristics of feedback the learner can access (e.g., timing, topic, and guidance).

Agency

To have capacity to self-regulate learning, learners must be able to make choices and, within relatively wide limits, to act on their choices. Without such latitude of behavior, learning is other-regulated rather than self-regulated. Agency is the common term used to describe this capacity to choose and act on choices. Sociocognitive theory emphasizes the role of individual agency on human learning. Bandura proposed that human agency involves four core features including: intentionality, forethought, self-reactiveness, and self-reflectiveness. These features of agency are cornerstones in most models of SRL and account for the perception that self-regulation is a sociocognitive process. As such, every model of SRL rests on the assumption that learners can exercise agency although it is recognized that, for practical and other reasons, agency is not boundless. For example, expressions of agency are strongly prescribed by social conventions.

Goals

Making adjustments to products of learning or processes used in learning might sometimes be trial and error. Notwithstanding a universal assumption tacit in some models of SRL is that learners are purposeful and oriented to particular goals. Goals define standards for judging the adequacy or sufficiency of products and processes. Formally, a standard is a description of an observable

feature of a product or process that can be measured at least nominally, that is, present or absent. Goals also can have features that are measured at finer distinctions, such as ranks and intervals.

Goals have two characteristics. One is purely informational. In this sense, standards that constitute goals are just descriptions of products or processes. The other characteristic of goals is what they mean to people. In this sense, goals matter because they have *qualia*—feelings, emotions, motivation, and values. Some models of SRL give different prominence to the informational features and the *qualia* of goals.

Monitoring

Goals play roles in SRL across time. First, goals are information learners consider as they shape their approach to tasks, including whether the task is accepted as presented, accepted but modified, or rejected. Second, learners may consider goals in the midst of engaging in a task. Some tasks have explicit subgoals. Third, learners can examine products and processes used in learning at point of completion. In all three instances, standards inherent in the goals are compared to attributes of the products and processes at each point along the timeline. Monitoring is the cognitive process responsible for making this comparison and generating a description of the match between goals and events. In this sense, all models of SRL are metacognitive models because this monitoring is inherently metacognitive.

Memory and Reasoning

New situations are never exactly the same as prior experiences. Thus, learners interpret each new situation in relation to what they remember about previous situations they deem similar. In this way, all SRL is integrally dependent on what a learner can remember about previous situations, as well as what that knowledge permits them to perceive about new situations. In matching history to the present, learners interpolate or interpret.

When learners adjust a product or process, models of SRL assume learners do this with an intention that making that particular adjustment, as opposed to some other adjustment, will align the product or process with standards defined in goals. Having this intention entails that learners reason about the likelihood the adjustment will have intended effects.

Sociocognitive Accounts of SRL

When is Cognition Social?

From a sociocognitive perspective, learners are agents who can choose how they will behave. Bandura's triadic theory describes learners' choices as shaped by reciprocal

interactions among: (1) past behaviors; (2) personal variables, such as interest in a task and beliefs about whether they have efficacy to complete a task; and (3) environmental variables, such as instructional supports they can draw on, material resources, and task contexts. The reciprocity involving environment, particularly peers and models, in learning represents cognition as fundamentally social. As learners work on tasks, they generate new information that updates any or all three factors. In addition to reciprocal influences between personal beliefs and behavior, social and environmental factors mediate learning. Environmental factors include things such as social modeling, feedback, and instructional conditions. Each can influence on personal variables and behavior before, during, or after a task. Each can, in turn, be shaped or regulated by behaviors and personal variables. For example, my coauthor, who initially thought he would easily complete his writing task, might revise that belief after several unsuccessful attempts to generate an outline. Personal beliefs about the writing task might be influenced by the fact that the deadline is approaching. Collectively, these beliefs about his person and the environment might lead him to adopt a different strategy for writing, such as abandoning the preliminary outline, writing an introductory section, and using that introduction as a vehicle for collaboratively generating an outline with his coauthor.

Sociocognitive theory recognizes that learners can learn in two ways. They can learn by doing, called enactive learning; and by observing, called vicarious learning. Both kinds of learning are social because the activities of learning are embedded in a task environment that is reciprocally influenced by: (1) others directly (e.g., modeling and feedback), (2) memories of others' behaviors (e.g., attention to what is observed), and (3) tools others created (e.g., instructions and examples).

Sociocognitive Learning and SRL

Vicarious learning is central to sociocognitive accounts of SRL because regulation is described as a developmental trajectory moving from observation, through emulation of others usually involving guided practice, to self-control, and finally to self-regulation. Observation is fundamentally social because it involves attending to actions of a proficient model, participating in guided practice, and learning in relation to instrumental feedback. Through these social processes, students develop competence with the task, content, and context; as well as their capabilities to self-regulate learning.

From this perspective, SRL is a developmental process assisted by observing models, trying out the behavior, and receiving feedback from others. There is a tacit assumption in most sociocognitive descriptions of SRL that social supports are prominent while SRL proficiency develops

and become less prominent afterward. In fact, however, environmental factors such as instructional sequence and classroom context continually exert a reciprocal influence on self-regulatory behaviors and beliefs.

The three models of SRL introduced earlier share two features with sociocognitive perspectives of learning. First, they emphasize the role of individual agency. Second, they acknowledge the role of task environment in shaping self-regulatory activity.

Alternatives to Sociocognitive Theories of SRL

More recent perspectives of learning reveal increased interest in explaining the role of social and contextual influences on SRL.

Sociocultural influences on SRL

Sociocognitive perspectives of SRL emphasize self-regulation as developing within the individual and assisted by external modeling and feedback. In contrast, sociocultural perspectives of SRL emphasize it as a fundamentally social process wherein students learn to internalize language, signs, and activities existing first in the sociocultural practices of their communities. This shift in perspective changes the emphasis from self- to coregulation.

From a sociocultural perspective, SRL is a stage occurring as children are socialized into speech patterns and practices. Coregulation is the temporary sharing or distributing of self-regulatory processes and thinking between a learner and more capable other (peer or teacher), while the learner transitions toward self-regulatory practice.

Three basic concepts characterize coregulatory aspects of self-regulation. First, rather than focusing on the individual learner, the focus is on the relationships among individuals, objects, and settings. Second, regulating learning involves coordinating and negotiating social contexts as well as self and social expectations and goals. Third, instructional supports afford opportunities for learners to experiment with and learn motivation as well as strategies and self-evaluations central to SRL.

Informed by Vygotsky's notion of internalization, regulation is seen as a social process because it appears first on the intrapsychological plane and then later becomes part of a child's understanding, appearing on the interpsychological plane. Borrowing from partners in learning and joint problem solving are considered core coregulatory processes in the social exchange between learners and more capable others. From this perspective, the mark of SRL is when the activity and practice appears in a learner's own performance, and when those activities are internalized and automated.

Coregulation

From the sociocultural perspective, coregulation is a central transitional process in a learner's development of more

productive SRL. Coregulation is an interactive process whereby ownership of self-regulatory activity and thinking is first shared among participants, then gradually taken up or appropriated by the individual learner. During coregulation, student and teacher regulate together, sharing thinking and decision making and developing a shared or intersubjective task environment where each brings expertise and control to the task. Slowly, as knowledge and control are transferred to the learner, self-regulation emerges and students begin to develop realistic self-evaluations. Hence, this process is referred to as emergent interaction. Finally, the student independently engages behaviors, actions, and thinking associated with SRL.

In contrast to a sociocognitive perspective of SRL that emphasizes self-regulation developing within the individual in reciprocal interaction with external modeling and feedback, coregulation emphasizes a shifting in who shapes the regulation. Through scaffolding, cognitive demands arising from engaging in a task are eased by sharing the demands of metacognitively monitoring, evaluating, and regulating task processes. For example, rather than a mother modeling her own steps and thinking while tying a shoe lace, she takes on the regulation of her child's tying shoe laces by metacognitively monitoring and evaluating with the child. The mother might ask questions like: "What do you know about how to connect those two laces?" "How do you know when you have completed the first step properly?" "What do you need to do now?" In this way, the child focuses on task enactment while the mother supports metacognitive engagement and regulatory control of learning.

Research on SRL and Sociocognitive Models

Several core social components appear in theoretical and empirical accounts of SRL. We provide a snapshot of findings.

Feedback and SRL

Feedback provided by others is a social tool that exerts powerful effects. An important distinction about feedback is whether it is targeted at tactics and strategies, called process feedback, or at products, called knowledge of results. The distinction is somewhat artificial in the case of SRL because, when a learner is attempting to regulate processes, these are products of metacognition that are being affected by feedback describing how processes were carried out.

The small amount of research on how feedback affects SRL and products generated in tasks is quite consistent. When learners face challenging tasks for which their current tactics and strategies are not sufficient for success, performance in the long run can be improved by

providing feedback about processes in the short run. What occurs in this case is that, while the learner is shaping up tactics and strategies, there is little success in meeting the goals of the task *per se*. Delaying gratification, in the sense of postponing progress toward task goals, often frustrate learners and their teachers but overcoming this pays off in the end.

Modeling and SRL

Modeling is considered an important antecedent of self-regulation. When students observe models, they acquire knowledge and strategies for successfully completing a task. Under productive conditions of modeling, they also develop beliefs regarding their efficacy for that task. Models can display mastery of the task or methods for coping with the challenges of a task not yet mastered. Research shows both kinds of models are beneficial under different circumstances. When children have experienced failure or challenges, coping models enhance self-efficacy and skills better than mastery models. Observing multiple peer models is more effective. Modeling has been shown to improve self-regulation of academic skills in domains such as mathematics and writing, motor skills, strategy knowledge, and metacognitive strategies.

Models are effective when observers perceive them as competent, regardless of model age. Children are more influenced by models they perceive as similar in ability to themselves.

Scaffolding and SRL

Scaffolding is a dynamic interaction between the learner and another. The other provides support that is carefully calibrated to the goal of the task and the learner's current level of mastery relative to that goal. Through scaffolding, learners can achieve something that would not be possible by themselves. With effective scaffolding, the learner gradually assumes full regulatory control of cognition, metacognition, motivation, and behavior.

Research has yet to systematically examine the role of diagnosis, calibration, and fading on specific subprocesses of cognition, motivation, metacognition, and behavior associated with SRL. The picture that is beginning to emerge suggests that scaffolding takes time. It involves forms of coregulatory dialog. The teacher requests information, confirms the learner's results or interpretation, restates results, and models thinking or requests judgments about learning or performance. In coregulatory dialog, students request information, confirm interpretations of the teacher's activities, elaborate on features of the task and goals, and request evaluations of performance and learning. Furthermore, when scaffolding is adapted, timely and targets specific aspects of SRL such as planning,

monitoring, and using strategies, students experience shifts in their mental models, use more strategies, and regulate their learning by planning, activating prior knowledge, and monitoring their progress toward goals.

General Background

Australia is a large island continent. With an area of 7.7 million square kilometers and a population of 21 million, it is one of the most sparsely populated countries on earth. The continent's first inhabitants arrived about 46 000 years ago. Most Australians are of European descent, but large-scale migration since World War II has produced a culturally diverse society.

Australia is a constitutional democracy based on a federal division of powers. Its basic political, legal, and administrative structure derives mainly from Britain. British colonization of the country began in 1788 and by the 1850s, six colonies had been established across the country. In 1901, the Commonwealth of Australia was established as a federal system, the former colonies becoming states. Retaining its constitutional ties with the United Kingdom, Australia is a member of the Commonwealth. However, it now enjoys substantial independence.

The first schools in Australia were private, but by the 1870s, each colony had established a public education system. Under the 1901 federal constitution, the six states retained responsibility for education. Australia also has two territories with similar education powers to the states. While there is no single national system as such, education and training operate within frameworks set by the Ministerial Council on Education, Employment, Training and Youth Affairs (MCEETYA) and the Ministerial Council on Vocational Education and Training (MCVET).

The population of Australia grew rapidly in the 1950s and 1960s when substantial numbers arrived from southern and northern Europe. Since then, population growth rate has slowed. Two-thirds of Australians live in the major capital cities. Almost 25% of Australians were born outside the country, and one in three is either a first- or a second-generation migrant. In the past decade or so, Asia and the Middle East have been prominent sources of immigration and overseas students.

Despite the diversity of languages and cultures, English continues to dominate all activities in daily life, including education. Given the number of immigrants coming from non-English-speaking countries, extensive provision has been made for the teaching of English as a second language, and most children study a language other than English as part of their general education.

For many years, the Australian economy has been dominated by agriculture and mining. These industries remain important, but now employ relatively few people. In 2006, there were 10.7 million people aged 15 years or over in the workforce, 70% working full time. Unemployment is low (under 5%) and concentrated among those with the least education. Over the years, there has been a significant upward movement in the occupational and educational structure of the labor force. More than half of the population aged 15–64 has at least one nonschool qualification, over 36% have completed year 12, and about 20% have a university degree.

With average yearly earnings at A\$28 400, Australia is a relatively wealthy country. Strong economic growth since the beginning of the twenty-first century has led to a skills shortage and the continuing growth and diversification of post-compulsory education. There has also been a strong push for reforms aimed at equipping workers with the competencies seen to be essential to improving productivity and competitiveness in the global knowledge society.

Goals of the Education System

For most of the twentieth century, there has been a broad agreement about the basic goals of the education system and the responsibilities of government. These are generally set out in legislation and are supplemented by more detailed policy documents. The goals of:

- the school sector are reflected in the national goals for schooling, and focus on developing the capacities and

talents of all young people so that they have the necessary knowledge, understanding, skills, and values for a productive and rewarding life;

- the vocational education and training (VET) sector focus on giving industry a highly skilled workforce to support strong performance in the global economy; and
- the higher education sector include a focus on advancing and applying knowledge and understanding to benefit the Australian economy and society.

National goals for schooling have been set by MCEETYA. In addition, it was agreed in 1999 that the curriculum in the compulsory years should encompass the arts, English, health and physical education, languages other than English, mathematics, science, technology, studies of society and environment, and most recently, history. Schools are required to develop computer, vocational, and enterprise skills, and an understanding of Aboriginal and Torres Strait Islander cultures and the value of cultural diversity.

High-quality outcomes for postschool education are critical for both individual welfare and national development. The focus in VET is on supporting the growing and changing Australian economy. Goals are set jointly with Australian industry and employers, and aim at ensuring the availability of a highly skilled and mobile workforce. Higher education institutions have more flexibility in defining their mission and managing themselves. But at the same time, government is pushing for a stronger focus on contributing to economic growth and social development, and on increasing enrolments in science, mathematics, and engineering.

Structure and Operation of the Education System

Figure 1 outlines the formal education system. Key statistics on enrolments and resources in the major education sectors are provided in Table 1.

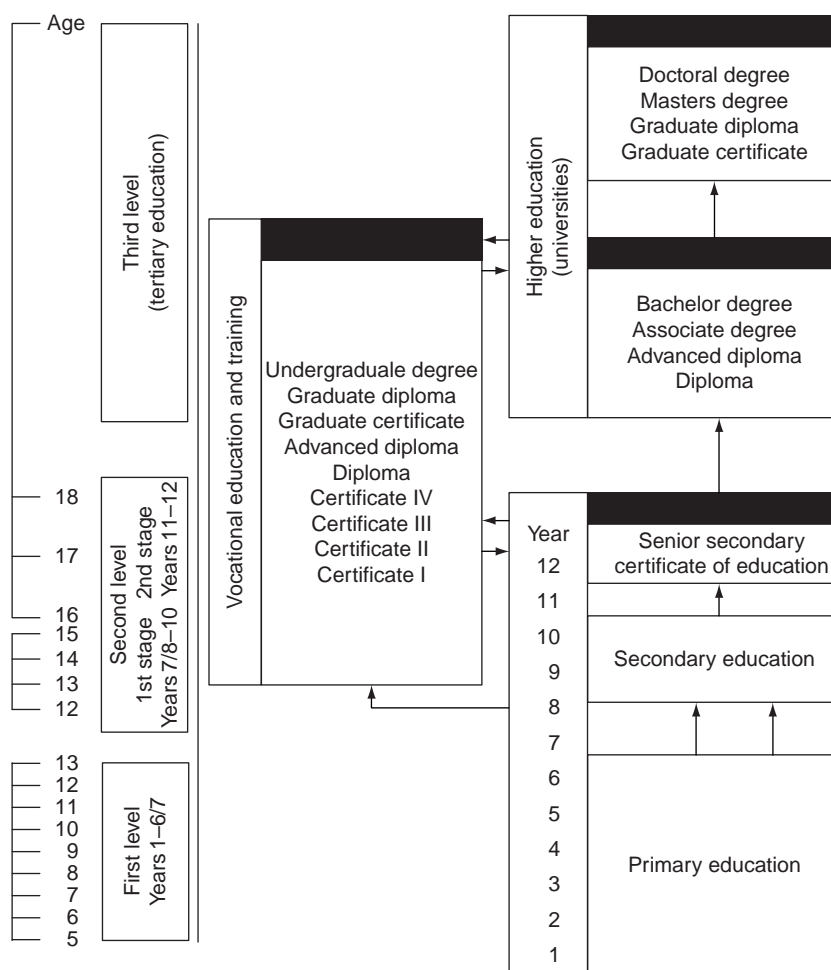

Figure 1 Outline of the Australian education and training system. Providers deliver qualifications in more than one sector. Schools, for example, are delivering certificates 1–2, universities are delivering certificates 2–4, and VET providers are delivering undergraduate degrees, graduate certificates, and graduate diplomas (higher education qualifications in some jurisdictions, but in others also VET), all subject to meeting relevant quality-assurance requirements. Adapted from National Offices of Overseas Skills Recognition (2000).

Table 1 Educational providers, students, and teaching staff, 2005–06

<i>Provider</i>	<i>Institutions</i>	<i>Students '000</i>	<i>Teaching staff '000</i>
Schools	9612	3375	239
Government	6902	2257	158

Males	.	432	44
Females	.	513	47

^aThese figures are for 2006 and do not include combined primary–secondary schools (1181 schools) and special schools (395 schools).

^bNote VET institutions include both government and private providers in 2005.

^cOf the 1.6 million people participating in VET in 2005, 1.2 million were in government-funded programs.

^dThe higher education sector includes 37 public universities, private, and other self-accrediting institutions, and higher education providers accredited by state and territory authorities. Adapted from Australian Bureau of Statistics (2007). *Australian Yearbook*. Canberra: Australian Bureau of Statistics Australia Department of Education, Science and Training (DEST) *Annual Reports 2005, 2006*. Canberra: Australian Government Publishing Service.

Preschool and Early Childhood Care

Many Australian children attend an early childhood center prior to formal education, this sector being increasingly privatized. In such centers, the focus is generally on structured play and social development. In 2006, over 217 000 4-year-olds (62% of the age group) were attending a public or private full-time preschool, kindergarten, or preparatory-year program. Subsidies and tax rebates are provided to support families of children in private childcare and preschool programs.

Primary (Elementary) and Secondary Education

Schooling in Australia is compulsory for children from the ages of 6–15 (16 in South Australia and Tasmania). In 2006, there were 9612 schools, of which 72% were government schools and 28% were nongovernment schools. Over 70% of schools were primary, 16% secondary, and the rest were combined primary/secondary schools. There were 3.4 million full-time school students and over 265 000 teachers. The number of students in nongovernment schools is now over 1.1 million, making up one-third of all students, up

from 26% in 1986. The number of indigenous students rose from 42 000 in 1986 to over 140 000 in 2006 (the total indigenous population being about 500 000).

Primary education lasts either for 6 or 7 years, depending on the state or territory concerned. Children who are 5 years old at the beginning of the year normally enter at that stage. The scattered rural population has necessitated a relatively large, but declining, number of small primary schools. The primary school day normally contains about 5 h of tuition, and comprises around 200 school days per year. Overall, the average number of students per full-time teacher equivalent (FTE) in primary schooling was 16.0.

Secondary education is normally for either 5 or 6 years depending on the duration of primary education in the state. The secondary year operates for around 200 days, with about 5.5 h of teaching per day. Twenty years ago, less than 50% of all students stayed in school to year 12, but now three-quarters of all students remain in school to year 12. Completion rates are significantly higher in independent schools and for girls than boys. The average number of students per FTE in secondary schools in 2006 was 12.2.

Each state or territory has established a statutory authority responsible for curriculum development and assessment. Some systems (e.g., Queensland) use moderated school-based assessments, while others combine school-based assessment with external examinations at year-12 level. Given increased retention rates, the curriculum at upper secondary level has been increasingly vocationalized. There are now over 210 000 secondary students enrolled in VET in school programs, most of which are industry-specific courses accredited within the Australian Qualifications Framework.

Other Schooling Arrangements

During the compulsory years, the goal in Australia is for inclusive schooling. But not all students of school age can attend a regular school. Thus, extensive use is made of a variety of delivery mechanisms (e.g., School of the Air, distance and open learning), and the children of some indigenous groups in remote areas receive schooling in homeland learning centers. An estimated 2% of children in Australia have disabilities requiring special education. Wherever possible, children with disabilities are integrated in regular schools, but some do attend special schools (397 in 2005) provided by government or nongovernment authorities.

Technical and Further Education

In recent years, considerable efforts have been made to effectively engage and retain young people in learning and to provide them with opportunities to develop the competencies expected of them in the workplace and to

improve their employability. All governments are seeking to develop smoother, more diverse, and flexible vocational and educational pathways.

In Australia, around 2000 registered training organizations operating in almost 10 000 locations deliver VET programs to 1.6 million students. The participation rate in VET programs exceeds 8% of 15–64-year-olds, and 34% of adults hold a VET qualification. Currently, over 25% of VET units completed are in the management and commerce, 18% in engineering technologies, 10% in health, and the rest in fields like society and culture, food and hospitality, architecture and building, and agriculture. In 2006, there were 389 000 apprentices and trainees, males dominating construction, automotive, electrical trades, the only trade with a majority of females being hairdressing.

Technical and Further Education (TAFE) colleges administered by state and territory governments provide a wide variety of technical and vocationally relevant courses, apprenticeship partnerships, and adult and continuing-education programs. MCVET assures harmonization of the national system of standards, performance assessment, and accreditation with goals agreed in a Commonwealth-State Agreement for Skilling Australia's Workforce. One of the guiding principles for the training scheme is that industry and business need to drive training priorities and delivery, and industry-skills councils have been created for this purpose.

Higher Education

The Australian higher education system is made up of 39 universities (37 public and two private) and other higher education providers recognized under Australian, state, or territory law. All universities are autonomous, self-accrediting institutions responsible for their own governance, under guidelines set by the Department of Education, Science and Training (DEST). There is now also an Australian branch of an overseas university and there are four other self-accrediting higher education institutions. The higher education sector includes over 150 providers that are accredited by state and territory authorities. The non-self-accrediting providers form a diverse group that ranges from theological colleges to those offering courses in areas such as business, information technology, and health.

In 2006, total higher education enrolments were over 843 000, the equivalent full-time student load being almost 430 000. About one-quarter of enrolments are in postgraduate programs. Over 70% of students are studying full time, and most (83%) are internal students, although external students continue to be an important feature of the higher education in Australia. About 40% of year-12 graduates enter higher education within a year or two of successfully meeting entry requirements. But there

are now many pathways for entry to higher education, and in most institutions, mature-age students outnumber those entering directly from school.

Despite rapid expansion in the systems in the past 20 years, students are still drawn disproportionately from urban areas and professional and managerial backgrounds. About 18% of students come from rural or isolated communities, one in seven from a socioeconomically disadvantaged background, and in 2005, there were 8370 indigenous students.

The major shift in the composition of the student body has been created by the enormous growth in the numbers of overseas students that began in 1986 when public institutions were first permitted to enrol overseas fee-paying students. There were some 345 000 overseas students enrolled in 2005, the proportion rising from 8% in 1996 to around 25%. Many Australian higher education providers have established joint-venture agreements with their counterparts in Asia, and about one in four overseas students enrolled in Australian programs is studying offshore.

Adult and Nonformal Education

Adult participation in formal education has increased significantly with the recognition of the need in the knowledge society of the twenty-first century for all to continue to learn through life. Enrolments in the non-formal (i.e., nonaward) sector are difficult to estimate, but almost 600 000 persons were enrolled for study not leading to a qualification in 2005. Programs provided in the nonprofit adult and community-education sector include vocationally oriented courses, secondary school completion, basic skills, personal development, and leisure activities.

The Teaching Profession

In 2005, there were 156 000 FTE teaching staff in government schools (67% of all teachers) and 79 200 employed in nongovernment schools. As a whole, school teaching is a highly feminized profession. Many people with teaching qualifications leave the profession or are not employed as teachers. In VET, there were 14 800 full-time and 7600 part-time teachers. Most (63%) full-time VET teachers are male, and most (65%) part-time teachers are female. There were about 39 000 academics and 51 500 nonacademic staff working in higher education institutions, 53% higher education staff being female. At all levels, teaching is an aging profession.

The training of teachers and specialist-educational personnel is undertaken by universities, and is normally 3 years for primary and 4 years for secondary school teachers. Australia is experiencing a shortage of teachers in rural and remote areas and in mathematics, science,

technology, and languages other than English. To cope, educational institutions at all levels are making increased use of part-time, contract teachers. Education authorities, teachers' unions, and professional organizations (such as the Australian College of Educators) are exploring ways to recruit more teachers into the profession and to improve retention. At the national level, the National Institute for Quality Teaching and School Leadership (now Teaching Australia) and the Carrick Institute for Learning and Teaching in Higher Education have been established to support efforts to make teaching more extrinsically attractive and to establish professional standards.

Administrative and Supervisory Structure

Government schools in Australia operate under the direct responsibility of the relevant state or territory minister, while nongovernment schools are established and operate under conditions determined by government registration authorities. State education departments recruit and employ teachers for government schools; supply buildings, equipment, and materials; and provide some discretionary funding for use by schools. Responsibility for the day-to-day administration of schools has been increasingly devolved to regional offices and the schools themselves.

Private education and training have always been an important part of the Australian education system. Most nongovernment schools have a religious affiliation. Each state has a substantial system of Catholic schools, and over 20% of all school students are enrolled in a Catholic school. Around 900 schools are independent, that is, they do not belong to a system. These schools vary from established, prestigious schools to relatively new, religious, and alternative-education schools. Aside from having to meet prescribed standards for registration and funding purposes, private schools are largely free from government direction, and governed by school boards.

In the tertiary sector, decision making, regulation, funding, and governance are shared among the Australian government, state, and territory governments and the institutions themselves. TAFE colleges are operated by state governments and governed by boards. Higher education institutions are autonomous bodies established under state legislation, each with their own independent governing body. Since 1974, the primary responsibility for higher education has rested with the Australian government, with DEST administering government funding, policy, and programs. While higher education institutions are autonomous, they are accountable to the Australian government through an institutional assessment framework, and their self-assessments are audited by the Australian Universities Quality Agency.

Educational Finance

Total expenditure on education has two components: public and private. For the financial year 2004–05, total government education and training operating expenses were A\$47 billion (5.3% of gross domestic product (GDP)). Private household expenditure on education was A\$18.2 billion (2% of GDP).

Government expenditure on primary and secondary education was A\$26 billion or almost 56% of total government expenditure on education. Government expenditure on preschool, special, and other education was A\$2 billion; VET A\$4.6 billion; and higher education A\$13.9 billion. Nongovernment schools receive the highest proportion (about 70%) of Australian government direct funding, while the states and territories provide over 90% of the funds for government schools.

Income sources for nongovernment schools include Australian government grants (53%), state/territory grants (19%), and private income – predominantly fees (28%). VET providers in receipt of public funds receive 48% of their recurrent funding from state and territory governments, 33% from the Australian government, and the remainder comes mainly from fee-for-service activities (11%) and student fees (4%).

Government funding for higher education comes mainly from the Australian government. It contributes toward the cost of an agreed number of government-supported places, and provides grants for research and other purposes. In 2005, the operating revenue of government-supported institutions amounted to A\$13.9 billion, of which 42% came from government grants. Competition for research grants administered by the Australian Research Council and the National Health and Medical Research Council is highly competitive. DEST also administers government formula-driven research and development.

In addition to government funding, institutions receive research grants from the private sector and revenue from student fees. Most Australian students contribute to the cost of their education through the Higher Education Contribution Scheme (HECS). In 2005, 15% of the operating revenue was raised from HECS, and other fees and charges accounted for a further 23% of operating revenue. In 2007, the fees for full-time HECS students range from about A\$4000 to A\$8400 (for fields such as medicine, law, and dentistry). Charges for full fee-paying students depend on the faculty and institution, and range between A\$14 500 per year for arts, and A\$38 200 for medicine. The revenue from fees paid by overseas students totaled A\$2.1 billion. In the 2007 budget, the Australian government announced funding increases for higher education of about 8% and an increased number of scholarships for overseas students.

Performance Monitoring, Evaluation, and Research

The performance of the education system is monitored by the national, state, or territory authority responsible, using data collected by agencies like the Australian Bureau of Statistics. Most educational research is undertaken by Australian Council for Educational Research, the National Center for Vocational Education Research, and universities. Partnerships are being forged linking university researchers, policymakers, and industry via government initiatives such as the cooperative research centers and collaborative university ventures such as the recently established Eidos Institute. Professional organizations like the Australian Association for Research in Education also play an active role in support of research in their field of expertise.

Increasingly, overall system performance is judged using international and national performance indicators. For example, overall education-participation rates in 2005 were 96% for 15-year-olds, 78% for 17-year-olds, 58% for 19-year-olds and 25% for 24-year-olds. School retention rates from years 7/8 to year 12 were 69% for males and 80.6% for females. Young people who are neither studying nor in the labor force are of particular concern, and are deemed to be at risk: 14% of 15–19-year-olds and 22% of 20–24-year-olds fell into this category.

The Australian Qualifications Framework indicates the level of knowledge, skills, and competencies associated with qualifications issued by accredited education and training authorities and include year-12 certificates, VET and higher education degrees, diplomas, certificates, and awards. In 2005, 51% of the 15–64-year-old age group held at least one nonschool qualification as their highest qualification, and half had completed year 12. The percentage of Australians aged 25–34 with a tertiary qualification (36% in 2002) was above the Organization for Economic Cooperation and Development (OECD) average (29%), but below that of countries like Canada, Japan, and Korea.

In addition to participation rates, performance indicators include learning outcomes. The National Assessment Program includes regular assessments of reading, writing, and numeracy performance at years 3, 5, 7, and 9, and of areas such as scientific literacy, information technology, civics, and citizenship. In 2005, the proportion not reaching national benchmarks in numeracy was 6% for year 3, rising to 9% for year 5, and 18% for year 7. At the international level, Australia consistently ranks among the highest performing countries in the OECD Program for International Student Assessment (PISA) and the Trends in International Mathematics and Science Study (TIMSS).

The performance framework for VET revolves around objectives established under the national strategy for 2004–10. For example, most VET students (84%) and employers

(79%) are satisfied with the training provided. Higher education performance is assessed by institutions using international and national indicators and benchmarks of the quality of teaching, research outputs, graduate employment, and other outcomes set out in the national institutional-assessment framework. These assessments are audited by the Australian University Quality Assurance Agency.

Major Changes and Issues since the 1990s

The major changes and issues facing the Australian education system since the 1990s stem from the processes of globalization and the dominance of market economic theories in shaping policy. Education is big business, contributing an estimated 4.6% to Australia's GDP, and accounting for 7% of its workforce. International education is now Australia's fourth-largest export.

The application of market principles generally leads to policies designed to deregulate the education market. The Australian government has encouraged greater choice and diversity at all levels of education, and promoted cost sharing between participants in the education system and the society as a whole. The ultimate goal has been to increase competitiveness by improving the quality of education while containing or reducing its cost to government.

In most OECD countries, public investment in education actually increased between 1995 and 2002, regardless of changes in private spending. Australia is the main exception. The shift toward private expenditure has been accompanied by a fall in the level of public expenditure in real terms (especially in higher education). Critics of higher education policies of the national government claim that Australia is at risk of falling behind as the global knowledge economy gathers momentum. Efforts to increase Australia's share of the international education market have also led to criticism from abroad.

Successive national governments have encouraged state governments to adopt common approaches on issues such as school-starting age, teachers' registration and salaries, curriculum and assessment reform, quality assurance, and standard setting. A consensus has been reached on many issues such as the measures needed to improve early childhood education, literacy and numeracy outcomes, retention and participation levels, the attractiveness and quality of teaching, and education for indigenous children. Reforms at the state and territory level have focused on priority areas agreed at MCEETYA meetings, notably those set out in the National Goals for Schooling and Skilling Australia's Workforce. The Australian government has used its funding mechanisms to realign education in accordance with its national human capital reform agenda, which includes privatization and vocationalization of

education; standards and accountability mechanisms; partnerships with industry; science, engineering, and information technology; and history, civics, and citizenship education.

National intervention in areas for which the states are responsible has not always been welcomed, and, so on occasion, national initiatives (such as performance-based remuneration, and national year-12 curricula and examinations) have met with strong resistance from state and territory governments. However, the financial power of the Australian government and global pressures for reform mean that a more cohesive national approach to education and training seems inevitable. In 2008, the Australian Government established a National Curriculum Board to develop a nationwide K-12 curriculum in English, mathematics, science, and history.

While it is accepted that national and state governments must assume their responsibility to ensure that education systems and institutions meet their goals and are accountable, how this is to be done and by whom remains an issue. Those who believe that critical thinking, creative independence, and innovation are vital if we are to meet future challenges, argue that education and research in Australia are overregulated and underfunded. It is also likely that in an unequal, conflicted, and environmentally threatened world, there will be a renewed emphasis on education for sustainable development, and on what United Nations Educational Scientific and Cultural Organization (UNESCO)'s International Commission on Education for the 21st Century insisted are the key issues for the future – learning to live together and learning to be.

Description of the Educational System

Education Population and Language of Instruction

In the academic year 2004/05, approximately 57% of the population under the age of 30 were in education, and there were 848 000 young people of compulsory education age. The language of instruction is predominantly German but, in regions with a linguistic minority, instruction at primary schools is divided between German and Slovenian, respectively, and Hungarian or Croatian in bilingual institutions.

Administrative Control and Extent of Public-Sector Funded Education

In the academic year 2004/05, nearly 88% of students attended state-funded educational establishments. Private institutions accounted for the remaining 12%.

Responsibilities for legislation and its implementation are divided between the federation (*Bund*) and the *Länder* (where it is executed by the *Länder* parliaments and the *Ämter der Landesregierungen*).

In specific matters enumerated in the Constitution, the federation sets the framework, while detailed legislation is implemented by the *Länder* parliaments (*Landtage*).

The Federation has an overwhelming responsibility for the educational system, including virtually all areas of school organization, the organization of school instruction, private schools, as well as the remuneration and retirement law governing educational staff.

As regards administration, the Federal Ministry of Education, Science and Culture is responsible for primary, secondary, and nonuniversity tertiary education, as well as for *Fachhochschulen* and universities. The Ministry of Economic Affairs and Labour has responsibility for in-company apprenticeship training. The *Länder* are mainly responsible for the provision of public-sector compulsory education. They support the local communities in establishing and maintaining these schools via school-construction funds that are administered by the *Länder*. The *Länder* have sole responsibility for crèches and kindergartens. Schools enjoy some autonomy in budgetary management and – up to a point – are free to adapt the curriculum to local needs. Province school inspectors in each of the nine Austrian *Länder* (assisted by district school inspectors for compulsory schools, and subject

inspectors for the intermediate and upper secondary levels) are responsible for inspections.

The 2002 *Universitätsgesetz* (University Act) transformed universities from federal institutions to public law entities which are no longer under federal administration. Federal funding consists of 3-year global budgets based on public-service agreements; universities are free to tap other sources of funding by virtue of their full legal capacity. Territorial entities and private legal entities may operate *Fachhochschulen*. At present, *Fachhochschule* study programs are mainly funded by the federal government in line with authorized study places.

Preprimary Education

Up to the age of 3, children may attend a crèche (*Krippe*), if available (Table 1). They may attend a kindergarten, when they are in the age range between 3 and 6. The training programs for kindergarten teachers have been aligned to take account of the growing number of children younger than 3 years who attend kindergarten. The provision of these facilities and decisions with regard to fees are the responsibility of the *Länder* or private institutions (providers). In 2005/06, 66.3% of all 3-year olds, 89.8% of all 4-year olds, and 91.9% of all 5-year olds attended pre-compulsory education (Figure 1).

Compulsory Education

Phases

Education is compulsory for 9 years and starts at the age of 6 (Table 2).

Sonderschule (special school; 6–15 years of age is described in section 7).

Admission criteria

Primary school pupils must have attained 6 years of age by 1 September in the year of admission. Children who have not yet attained the age of compulsory schooling and will be aged six by 1 March of the next following calendar year may be admitted earlier, if they are sufficiently mature and have the required social skills for attending school.

Transfer to lower secondary schooling requires successful completion of grade 4 of primary school. Admission to *Allgemein bildende höhere Schule* depends on achievement or is conditional on an admission test. With the exception of education in private schools, compulsory schooling is free of charge.

Length of the school day/week/year

The school year comprises 180 days (5 days a week) and lasts – according to a staggered schedule depending on the *Land* – from the first or second Monday in September to the Saturday between 28 June and 4 July, or between 5 July and 11 July.

Schools open 5 or 6 days a week.

The number of lessons per week ranges from 20 (primary school) to 35 (in secondary higher technical and vocational colleges). A lesson lasts 50 min. The minimum number of hours taught each year is around 630 for children of age 7, 750 for those aged 10, 870 at lower secondary, and 960 at the upper secondary level.

Class size/student grouping

The maximum class size is 30, while the minimum is 10 in primary school and 20 in secondary general school (*Hauptschule*) and the prevocational school. Pupils are grouped by age, but there is some grouping by ability in

German, mathematics, and modern foreign language at secondary level (secondary general school and prevocational school). At pre-vocational schools, pupils may be grouped in these subjects also by interest (or subject areas). As a rule, primary school pupils are taught by one teacher in all subjects except for religion and crafts; in secondary education, instruction is provided by subject teachers.

Curricular control and content

On the basis of proposals drafted by curricular task forces, the Ministry for Education, Science and Culture establishes a curricular framework in a consultation process that includes district and province educational bodies and organizations of teacher representatives.

The Ministry also approves textbooks. Schools are free to make their choice and enjoy some freedom to adapt the curriculum to the local context. Primary school compulsory subjects include religion, early science, German, reading, writing, mathematics, music, arts, textile/technical work, exercise and sports, modern foreign language, and road safety (without grading).

As of the school year 2003/04 onward, a modern foreign language has been taught on a mandatory basis at all primary schools – starting in grade 1. At the lower

Table 1

Krippe	0–3 years
Kindergarten	3–6 years

Allgemein bildende höhere Schule (secondary academic school – lower level)	
Grade 9	From 14 years of age
Polytechnische Schule (pre-vocational school)	
Or any other upper secondary school	

secondary level, pupils continue these subjects, in addition to science and technical subjects.

A special committee composed of teachers and parents (and – at secondary, intermediate, and higher level – students also) exercises an advisory and decision-making function in defined matters that are laid down in law.

Assessment, progression, and qualifications

There is no formal external testing during compulsory education. Teacher-generated assessment is based on classroom participation and oral, written, practical, and graphical work. Primary school pupils have to sit for written exams (school tests) in German and mathematics in grade 4.

As a rule, progression to the next higher form depends on achievement in all subjects (with exceptions at primary school level or unsatisfactory achievement in only one subject).

Pupils receive reports at the end of each term and at the end of the academic year.

In German and mathematics, pupils may attend instruction in the next lower or next higher form – if this is more appropriate for their individual learning situation.

Upper Secondary Education and Postsecondary Level

Types of education

*Although students start courses at these schools at the age of 14, compulsory education ends when they are 15 (Table 3).

Admission criteria

Following grade 8, students may opt for one of the many different courses in either the general or technical and vocational education (TVE) sector offered at secondary level II. Transfer requires successful completion of grade 8 and is also based on achievement.

Candidates failing to meet the achievement criteria must undergo admission testing.

Pupils without a leaving certificate following grade 8 may attend a pre-vocational school. The aim is to convey the best-possible support and skills for transfer

Table 3

<i>Upper secondary education</i>	<i>Age</i>
Allgemein bildende höhere Schule (secondary academic school – upper level)	14*–18
Polytechnische Schule (pre-vocational school)	14*–15
Berufsbildende mittlere Schule (technical and vocational school)	14+*
Berufsbildende höhere Schule (technical and vocational college)	14*–19
Bildungsanstalten für Kindergartenpädagogik/ Sozialpädagogik (schools for the training of kindergarten teachers and nonteaching education staff)	14*–19
Berufsbildende Pflichtschule (part-time vocational school)	15+
Post-secondary education Kolleg	18–20

to vocational training later on (dual system of training) or a higher-level school. Transferring back from secondary higher general or technical and vocational school to a pre-vocational school is possible only until 31 December of the current school year.

For some training routes at secondary higher technical and vocational schools or colleges, or colleges for kindergarten teachers and nonteaching education staff, candidates must prove their physical or artistic aptitudes as well as social and communication skills.

Following completion of 9 years of compulsory schooling, pupils may enter into an apprenticeship contract with an employer, minors require parental consent. Apprentices – at the same time – become pupils of a compulsory part-time vocational school.

Curricular control and content

Curricula at this level of education depend on the course chosen, although German, mathematics, and a modern foreign language are part of the general mandatory syllabus.

At pre-vocational schools, the emphasis lies on vocational orientation and basic vocational training in specialist areas according to widely scoped occupational fields such as technical-commercial occupations, commerce-clerical occupations, as well as service – industry and tourism.

TVE schools and colleges offer a wide variety of courses and special emphases. Consultation with the social partners is important, as curricula also include technical theory and practical instruction.

Teachers are free to select methods. The curricula emphasize student-centered learning, project work, cross-curricular activities, and the opportunity to acquire key skills.

In addition, in this area, textbooks and other materials are selected by the school.

Assessment, progression, and qualifications

Students who pass the examination at the end of an Allgemein bildende höhere Schule receive a matriculation certificate (*Reifeprüfungszeugnis*).

Apprentices receive a certificate on completion of their part-time course at school.

They may sit for an end-of-apprenticeship examination.

The *Lehrabschlussprüfungszeugnis* gives access to certain trades, foreman or master craftsman courses, professional diploma examinations, and courses for 'working adults', as well as to the *Berufsreifeprüfung* and the *Studienberechtigungsprüfung* (access to higher education).

Students on courses lasting 1–2 years receive pre-vocational training certificates.

Students at 3–4-year TVE schools take a leaving examination (written/practical and oral). The certificate entitles them to exercise certain regulated occupations or trades and provides access to upgrading or to the *Berufsreifeprüfung* examination.

Students of 5-year higher-level TVE courses may take the *Reife- und Diplomprüfung* – which includes written/practical and oral parts – and leads to double qualifications comprising general higher education access and professional qualifications for immediate entry into employment at middle-management level (EU diploma-level recognition).

Students of post-secondary courses (e.g., *Kollegs*) take a *Diplomprüfung* which is evidence of the acquisition of professional qualifications.

Higher Education Structure, Admission Criteria, Qualifications Awarded

Types of institutions

Higher education is offered at:

- Public universities including the arts universities;
- *Fachhochschulen* (institutes of technical/vocational higher education);
- the *Krems University of Continuing Education* (Danube University Krems);
- Private universities (following accreditation);
- *Pädagogische Akademien and Berufspädagogische Akademien* (general and vocational teacher-training colleges; as of October 2007 *Pädagogische Hochschulen*, Universities of Education);
- *Akademien für gebobene technisch-medizinische Dienste und Hebammenakademien* (colleges for higher-level medico-technical professions and midwifery colleges);
- Moreover, there are a number of educational institutions which offer university-type courses.

Access

Applicants to university (and to the *Akademien*) must have the *Reifeprüfungszeugnis* (or a *Reife- und Diplomprüfungszeugnis*) from a secondary higher school, or, alternatively, a *Berufsreifeprüfungszeugnis* or *Studienberechtigungsprüfungszeugnis* for the particular course of study. Depending on the course chosen, they may have to appear for supplementary examinations.

In 2005, there was a major change in the access requirements. Admission testing was introduced for those study programs which are affected by eight *numerus clausus* – study programs in Germany. This measure will last until 2007 and allows the restriction of access to university studies, mainly for medical study programs.

At the teacher-training colleges for vocational schools, the *Reifeprüfung* may be replaced by a *Meisterprüfung* (master-craftsman examination; the *Reifeprüfung* is, generally, required to access the future Universities of Education).

All applicants to universities of art and music have to pass an entrance examination. Candidates for a *Fachhochschule* – which, normally, requires an entrance exam – may either have a *Reifeprüfungszeugnis* or equivalent, or relevant vocational qualifications, as well as additional examinations, as the case may be.

The general tuition fees for university programs amount to € 363.36 per term for students from Austria and other EU – and EEA – countries, and to € 727.27 for other foreign students (exemption and reimbursement regulations apply to students from developing countries or to students in mobility programs). An amount of € 363.36 may be collected for *Fachhochschule* study programs.

Qualifications

Students at teacher-training study programs at *Pädagogische und Berufspädagogische Akademien* graduate as '*Diplompädagogin/Diplompädagoge*.' The teacher-training study programs at the future universities of education will lead to graduation as bachelor of education.

Students at colleges for higher-level medico-technical professions graduate as follows:

'*Physiotherapeutin/Physiotherapeut*'
 '*Biomedizinische Analytikerin/Biomedizinischer Analytiker*'
 '*Radiologietechnologin/Radiologietechnologe*'
 '*Diätologin/Diätologe*'
 '*Ergotherapeutin/Ergotherapeut*'
 '*Logopädin/Logopäde*'
 '*Orthoptistin/Orthoptist*'

Studies at midwifery colleges lead to graduation as a midwife.

As of the academic year 2006/07, training for higher-level medico-technical professions and midwives is also offered at *Fachhochschulen* in the form of bachelor-study programs.

University studies end with the following degrees:

Regular programs

- Diploma (after 8–12 terms)
- Bachelor (6–8 terms)
- Master (2–4 terms after the bachelor)
- Doctor (4 terms following the master or diploma degree)

- University programs ending with an international master degree, for example, master of business administration (MBA);
- University programs ending with the designation of *akademischer* . . . (at least 60 ECTS).

Fachhochschule programs end with a diploma degree – since 2002 – also with a bachelor and master degree similar to the classification for the universities. *Fachhochschule* graduates are allowed to enter doctoral programs at universities.

Special Needs

Pupils with special educational needs may be educated either in special schools or in inclusive settings in primary and lower secondary schools. Parents have the right to choose the kind of schooling they prefer for their child. Special curricula and/or adapted mainstream curricula are applied in response to pupils' individual needs. During the school year 2002/03, over 50% of all pupils with special educational needs attended integration classes.

Compulsory education

To be admitted to a special school, a pupil's special educational needs must be determined by way of official decree (Table 4).

Class size/student grouping

The maximum class size is as follows:

- special school for blind, deaf, and severely disabled pupils – 8;
- special school for visually impaired, hearing impaired pupils and remedial schools – 10;
- others – 15.

Curricular control and content

Pupils are taught according to the curricula of primary school or secondary general school or of the lower cycle of secondary academic school, if they are, generally, able to attain the objectives of instruction without being overtaxed. In all other cases, the curriculum of a special

school – geared to their disability – is to be applied. There are special curricula for general special schools (for performance-impaired pupils or pupils with learning difficulties), for the special schools for blind children, the special schools for deaf children, and the special schools for severely disabled children.

Assessment, progression, and qualifications

Pupils with special educational needs at general schools are entitled to transfer to the next higher form if this provides better opportunities for the pupil's overall development; the class conference decides on such transfers.

In the absence of pertaining statutory provisions, inclusive settings during the last (9th) year of compulsory schooling are, at present, provided in pilot projects only.

Specific programs for the transition period between school and the labor market are funded by the Ministry of Social Security, Generations and Consumer Protection and implemented in cooperation with schools.

Vocational training options for disabled or disadvantaged young persons

The Vocational Training Act was amended in the summer of 2003, adopting the integrative vocational training model. This amendment created a basis for young people with disabilities or at a disadvantage for better employment opportunities. Ever since, the number of young persons in integrative vocational training has risen steadily.

In addition, the Apprenticeship without Barriers campaign was launched to inform the public, companies, as well as the young people affected and their parents with regard to the opportunities of integrative vocational training. This media campaign, moreover, aims at raising awareness and understanding of the public at large for encouraging even more companies to accept apprentices for integrative vocational training.

Teachers

Kindergarten teachers complete 5 years of training from the age of 14 onward or a 2-year post-secondary course.

Primary and lower secondary school teachers must have completed a 3-year course at a teacher-training college (as of October 2007 *Pädagogische Hochschulen*, Universities of Education).

Teachers at an *Allgemein bildende höhere Schule* must complete a university study program of at least 4.5 years leading to a degree.

Depending on their subject area, teachers for the TVE sector are trained either at universities or at vocational teacher-training colleges (as of 2007, at universities of education). A relevant professional background and experience is required for teaching technical theory and practice at TVE schools and colleges.

Table 4

<i>Sonderschule</i> (special school): General special school consists of levels I and II and of an upper cycle.	6–15 years of age
Specialized branches for physically disabled children, for children with linguistic disabilities, for hearing impaired, deaf, visually impaired, blind, severely disabled, and maladjusted children.	
Pupils may attend special school during the entire period of compulsory schooling	

Primary school teachers do not specialize, whereas lower and upper secondary school teachers specialize in two subjects (at TVE schools and colleges, they may also specialize in a group of subjects or a subject area).

Teachers are employed by the federation or the *Länder* (civil servants).

Teachers at colleges for higher-level medico-technical professions and midwifery colleges are trained in specialist courses (following general training).

Current Reforms and Priorities

Reforms in Primary, Lower, and Upper Secondary Education

Afternoon childcare

Nearly 80 000 pupils have enrolled for afternoon childcare as per the autumn of 2006. This is more than 10% of a total of 760 000 pupils for whom afternoon childcare arrangements are available.

Every child in need of afternoon care should have a right to attend. Providing afternoon childcare to meet the given needs is an important task to be jointly fulfilled by the federation, the *Länder*, and the local authorities.

Nearly 10 h of afternoon childcare are allocated for 15 children each by the federation to the *Länder* at compulsory school level. Afternoon-childcare groups may be set up across classes, years, or different schools.

In early 2006, the schools informed the parents regarding afternoon childcare programs and identified existing needs. In the school year 2006/07, afternoon childcare will be offered wherever needed, while respecting parental freedom of choice.

Five-day week

As of the autumn of 2006, Saturdays at schools catering to the 6–14 age range will be free. Pupils should not work on more days of the week than their parents and will now have more time to spend together with their families.

Early language learning

Allocation of 1964 teaching posts as of the school year 2006/07 has made for a swift integration in primary school. The existing 1600 posts will be stepped up by an additional 330. Children at primary school who do not know German can henceforth be taught up to 11 h per week in small groups.

Learning German even earlier is better still. This is why the federal government sponsors language-learning courses at municipal and local nursery schools and has invested a total of € 640 000.

In recent months, 8000 children benefited from language-learning courses that are to ensure a good start of their school careers.

Expanding support for specially gifted pupils

Dispensation provisions (premature admission to primary school) and the possibility to skip a class (even at the primary/secondary transition) will take better account of the needs of highly gifted pupils. Reflecting their specific talents and skills, children should be able to terminate their school careers earlier.

Upgrading of class heads

Class heads have an important role to play in terms of furthering and assisting talented as well as underachieving pupils. This includes the early detection of strengths and weaknesses to make sure that children and adolescents can be supported in the best-possible manner through accompanying educational measures. They are also responsible for effectively implementing the early-warning system in cooperation with the school partners (parents, pupils, etc.), ensuring the target- and needs-driven use of remedial instruction, coordinating the educational and recreational activities during afternoon childcare, assuring high-quality teaching, and participating in evaluation. As of autumn 2006, class heads at compulsory school level will receive an additional € 70 per month as a performance-linked remuneration for these activities.

Schools now starting on Monday in the first school week

Instruction guarantee: No more than 2.5% of all classes may be canceled.

Monday and Tuesday in the first school week are days of familiarization. In order to ensure that classes start on the Wednesday of that week in line with the timetable, examination resits may be held on Thursday and Friday of the last week of the main holidays as of autumn 2006/07. The final dates will be determined by the school-partner forums.

Blocking of teaching units

According to an amendment to the School Periods Act (*Schulzeitgesetz*), teaching units may now be blocked. Classes can, therefore, be organized more flexibly and modern teaching methods – such as project work or interdisciplinary instruction – can be used.

Higher Education Reforms

University reform

The 1999 amendment to the *Universitäts-Studiengesetz* (University Education Act) introduced the three-tier system of universities studies, excluding teacher training, human medicine, and dental medicine studies – which are only offered as diploma programs. In the mid-range, diploma studies will, generally, be replaced by bachelor and master study programs. In the winter term of 2006,

211 bachelor and 277 master study programs existed alongside 179 diploma study programs.

The 2002 *Universitätsgesetz* (Universities Act) gave full legal status to the universities as of 1 January 2004. Newly recruited university staff is now employed under private law contracts. Universities are funded via a global budget which is set up for 3-year periods based on public service agreements which define the services to be rendered by the Federal Ministry and the university by way of negotiation. The first public service agreements between the universities and the Federal Ministry of Education,

Science and Culture will be concluded in the autumn of 2006. The first period for public service agreements is 2007–09. Following that time, every university must submit an annual performance report on the state of implementation of the public service agreement as well as an intellectual capital report. Budget reporting is done via the financial statements based on a commercial system of accounting. Twenty percent of all university budget allocations are formula-linked. This formula covers indicators on teaching, research and development, on the development of the arts, as well as on social objectives.

Glossary

General stream of education – This is the mainstream at all stages of education: primary, secondary, and higher. The curriculum of general education at all levels contain arts, science, and business subjects forming substreams at different stages.

Madrasah – Islamic religious schools.

Madrasah education – Refers to the religious stream of education at all the three stages of education: primary, secondary, and higher education.

Stream – Streams are different courses of study at a particular stage of education.

Structure – Structure of education refers to the organization of the education system in terms of successive cycles of education along with their duration.

Upazila – Subdistrict.

Zila – District.

General Background

Introduction

Bangladesh emerged as a sovereign country in the world map in 1971. It lies in the northeastern part of South Asia. Having an area of 147 570 km² and inhabited by 139 million people, the country has the highest population density in the world. Bangladesh has a per capita gross domestic product (GDP) of US\$456 and the GDP growth rate is 5.38%. The adult literacy rate is 62.6% and the average life expectancy at birth is 65 years. Categorized as a low-income country (World Bank, 2006), the country ranks 137 in the list of 177 countries of the world in terms of Human Development Index (UNDP, 2006).

The territory constituting Bangladesh was a part of the Indian subcontinent which was under the Muslim rule from 1201 to 1757. In 1757, the British defeated the last Muslim ruler of Bengal and established British rule which lasted up to 1947, over the whole subcontinent. The British rule ended in 1947 through the partition of the subcontinent into India and Pakistan. Pakistan comprised two parts – East and West. The present Bangladesh was the

eastern part of Pakistan and was known as East Pakistan. Pakistan existed for 24 years. In 1971, East Pakistan won freedom through a 9-month War of Liberation.

The country is bounded on three sides by India and Myanmar and by the Bay of Bengal on the South. It is mostly constituted of plain fertile land composed of alluvial soil having some hilly regions in some parts of the country. The major rivers of the country, along with their 230 tributaries, form a river network which, covering the whole country, flow down to the Bay of Bengal. In the south-western part of the country along the coast, stands the Sunderbans – the world's largest mangrove forest. The total forest area covers about 14% of the land area. Bangladesh has a subtropical monsoon climate.

Poverty remains the critical issue to resolve. The national poverty rate based on the cost-of-basic-needs (CBN) method (using upper poverty line) is 40.0. The health situation has improved over the years in terms of safe drinking water users, and child (1–4 years) and maternal mortality rates. Over the period 1995–2005, the road network has enhanced by 34%. Bangladesh has recently been connected with high-speed submarine cable consortium.

Bangladesh has, according to the 2001 census, a population of 130.0 million. The population projected for 2006 stands at 139 million. The population density is 928 persons per square kilometer. The population growth rate is 1.48%. Bangladesh is a Muslim-majority country, having 89.6% Muslims, 9.2% Hindus, 0.7% Buddhists, 0.3% Christians, and 0.2% other ethnic minority groups. The sex ratio of the population is 105.4 males per 100 females. Twenty-five percent of the population are urban dwellers, while 75% live in villages. The total civilian labor force of the country is estimated at 44.3 million, of which 34.5 million are males and the rest females.

Bangladesh has a parliamentary form of government, with the prime minister as the head of government, while the president is the head of the state. The prime minister is assisted by a council of ministers. The National Parliament of the country is a uni-cameral legislature consisting of 345 members.

The country has six administrative divisions each of which comprises a number of districts (*zila*). Each district consists of a number of subdistricts called *upazila*, which is the lowest administrative unit. There is a local government covering both urban and rural areas. The local government is entrusted to bodies elected by the people.

Bangladesh is a linguistically, religiously, and culturally diverse country. The Bangla-speaking group accounts for 98% of the population. The remaining 2% consists of about 45 ethnic minority groups speaking their own languages and have their own religions.

These diversities in religion and languages have made the country own a checkered culture.

Bangladesh is an agrarian country with 52% of the labor force engaged in agriculture. Agriculture and fisheries contribute about 21% to the GDP. Although the economy is agro-based, industrialization is taking place at a slow pace. The industrial sector is contributing about 17% to the GDP. Other sectors having notable contribution to the GDP are construction, trade, and services sectors. Coal deposits are there awaiting exploration. The country has a considerable deposit of natural gas. Other mineral resources include hard rock, limestone, and silica sand.

Legal Frame Under Which the Education System Operates

Article 15 and 17 of the Constitution contains the national directives regarding education. Article 15(a) recognizes education as the basic need of the people and also describes fulfillment of this need as a state responsibility. The nation's vision regarding education has been articulated in Article 17 of the Constitution. Article 17 reads as follows:

The state shall adopt effective measures for the purpose of

- (a) establishing a uniform, mass-oriented and universal system of education and extending free and compulsory education to all children to such stage as may be determined by law.
- (b) relating education to the needs of society and producing properly trained and motivated citizens to serve those needs.
- (c) removing illiteracy within such time as may be determined by law.

Besides, Bangladesh is a signatory to World Declaration on Education For All and the Dakar Framework for Action adopted in Jomtien, Thailand in 1990 and at Dakar, Senegal in 2000, respectively. In the context of these constitutional and international obligations, acts, laws, rules, and regulations have been framed for different levels of education.

Background of the Education System

In Muslim India, there were two levels of education: primary and higher. However, the levels were not very

structured or organized. The primary-level institutions were of two types based on languages: Persian and indigenous (mainly Sanskrit) language. Higher education institutions also had two major types: *madrasas* for Muslim students and *tolls* for Hindu students.

Many schools were situated in the houses of people or private lands and were funded by the head of the family, community people, rich men of the locality, and, in some cases, the local rulers. Teaching was mainly a mission. The curriculum included literature, logic, religion, grammar, mathematics, astrology, and medicine. A learner generally needed 10–12 years to complete higher education.

During the early years of the British rule, this system of education continued. The first document relating to education, popularly known as Wood's dispatch, was published in 1854 by Mr. Charles Wood, an officer of the East India Company. This document included recommendations regarding primary to higher education levels.

Immediately after the publication of Wood's dispatch, in 1855, a few universities at different places of India were established for facilitating higher education. However, primary and secondary education were not given due importance. Thereafter, an Education Commission, under the leadership of William Hunter, was constituted. The commission's report was published in 1882. On the basis of this report, primary and secondary education were organized. The British rule in India ended with the division of the subcontinents into two sovereign nations – Pakistan and India. The education system in Pakistan was a continuation of the British system. Bangladesh inherited this system.

Goals/Objectives of Education System

In order to fulfill the constitutional obligations, the government of the country constituted education commissions/committees and task forces at different times. Educational goals set in these documents are reflected in the development plans and the curricula. Summarized, these goals are as follows:

- to accomplish learners' overall growth and development and to enable their creativity to flourish;
- to introduce work-oriented, value, and need-based education;
- to ensure equality in terms of gender and educational opportunities at all levels of education;
- to extend the foundation for science and technology education and creating a knowledge society; and
- to create conscientious, patriotic, and productive citizens capable of contributing to the overall development of the country.

Structure and Operation of the Education System

The Structure of Education

Education in Bangladesh has three major stages: primary, secondary, and higher education. Primary education is a 5-year cycle, while secondary education is a 7-year cycle having three substages: 3 years of junior secondary, 2 years of secondary, and 2 years of higher secondary. Higher secondary is followed by higher education in different streams (general, *madrasah*, technology, and medicine), which require 3/4/5 years to obtain a first degree and another 2/1/1 years to obtain a master's degree.

In the general stream, after the higher secondary, a learner needs 3 years to get a first degree with pass and 4 years for a first degree with honors. The pass and honors degree holders need 2 years and 1 year, respectively to get the master's degree. For a first degree in engineering and business, 4 years of schooling is necessary, while for a first degree in medicine and architecture, the requirement is 5 years.

The entry age for primary is 6 years. The corresponding age groups for primary, secondary, and tertiary education cycles are 6–10, 11–17, and 18–22.

There is a preprimary system run by many primary schools, English medium schools, kindergartens, and nursery schools mainly located in urban areas. Mosque-based institutions, such as *maktabs* also offer preprimary along with religious teaching. This stage is prior to primary and extends from 1–3 years. This preprimary stage is not recognized by the government (Figure 1). However, government is planning to include the preprimary stage into the formal education structure.

Stream

Primary education has two major streams – general and religious – while secondary education has three major streams: general, technical–vocational, and religious. Higher education has four streams: general (inclusive of pure and applied science, arts, law, business, and social science), religious (*madrasah* education), medicine, and technology (engineering, agriculture, textile, and leather) education. Teacher education forms a separate stream.

Another stream of education is running parallel to the general stream at the primary through secondary levels. This is the English medium schools located in city areas and offering the English system of 'O' (ordinary) and 'A' (advanced) levels. Mostly, city-dwelling and children of well-off people are enrolled in these schools. The learners of this system constitute a negligible portion of the total strength.

Institutions and Courses of Study

Primary

On the basis of ownership and management, primary-level institutions may be classed under four major heads:

1. government primary schools (GPSs),
2. registered nongovernment primary schools (RNGPSs),
3. nonregistered nongovernment primary schools (NRNGPSs), and
4. others.

The last category includes experimental schools, community schools, kindergartens, nongovernmental organization (NGO)-run schools, *Ebtedayee madrasahs*, and satellite schools. The total number of institutions, teachers, and

Grades	Cycles and corresponding ages	Cycles and corresponding ages
17	Master's degree 21–22 years	Master's degree 22 years

pupils in the primary education subsector are presented in **Table 1**.

Female teachers and students account for 36% and 50% of the total numbers, respectively. The average pupil–teacher ratio stands at 47:1. It is the highest in government primary schools and is almost double of that in the other primary-level institutions in which it is 29:1. Government primary schools account for 47% of the total strength and form the mainstream.

Secondary: General stream

The total number of educational institutions at the secondary level (general stream) is 20313. This number comprises:

1. junior secondary schools, all of which are non-government;
2. government-owned and managed secondary schools;
3. nongovernment secondary schools; and
4. government and nongovernment higher secondary schools.

Statistics related to the number of institutions, teachers, and students in these institutions is presented in **Table 2**.

A vast majority of the secondary-level institutions – 98% – are nongovernment.

Secondary: Technical and vocational stream

Technical vocational education and training (TVET) offers certificate and diploma courses to the learners. The certificate courses prepare skilled workers in different

vocations and trades spread over 1–2 years after completion of the junior secondary level in the general education stream. The diploma courses offer diploma in different branches of engineering. This is a 3-year course, and the minimum requirement for admission into these courses, is secondary-level (grades 6–10) completion certificate, that is, the Secondary School Certificate (SSC).

There is a variety of institutes in the area of TVET. The total number of institutions in 2005 stands at 2722 and that of the trainers/instructors thereof, at 17140. The enrollment comes to 241336. The pupil–teacher ratio is 14:1. Females account for 19% and 26% in the trainer and student categories, respectively.

Secondary: Religious stream (madrasah education)

For the secondary-level *madrasah* education, there are Dakhil and Alim *madrasas*. The major focus of *madrasah* education is on the Holy Quran and Al-Hadith. Courses in Bangla, English, arithmetic, science, and social science, as prescribed in the general education stream, are also taught. The total number of secondary-level *madrasas* is 8000. Teachers and enrollment are 123757 and 2786838, respectively. Females account for 9% and 48% in the teacher and pupil categories, respectively. The pupil–teacher ratio is 22:1.

Higher education

Higher education is imparted by two sets of institutions: colleges (all streams; public and private) offering first and

Table 1 Number of primary schools, teachers, and enrollment

Table 2 Number of secondary (general stream) schools, teachers, and enrollment (2005)

Sl. no.	Type of school	No. of schools	No. of teachers	Enrollment	Pupil–teacher ratio
1.	Junior secondary	4322	36 122(20%)	910 914 (58%)	25:1
2.	Govt. secondary	317	7452 (31%)	221 887 (47%)	30:1
3.	Nongovernment secondary	13861	194 584 (19%)	6 265 751 (52%)	32:1
4.	Higher secondary (both govt. and nongovernment)	1813	35 408 (20%)	261 229 (48%)	7:1
	<i>Total</i>	20 313	273 566(20%)	7 659 781 (52%)	28:1

Figures in parenthesis indicate the percentage of females.

From Bangladesh Bureau of Educational Information and Statistics (BANBEIS) (2006). *Bangladesh Educational Statistics, 2006*, Dhaka.

master's degree courses and universities (general and specialized; public and private). Colleges offering general education are affiliated to the National University (NU) and colleges for other streams are affiliated to the respective specialized universities. There are general universities for the general stream and specialized universities for studying medicine, agriculture, and technology. For higher-level *madrasah* education, there are Fazil and Kamil *madrasahs*. The universities also offer MPhil and PhD courses in selected subjects. Besides, there is an Open University which offers secondary to higher education level courses (mainly general stream) through distance mode. **Table 3** shows the number of institutions offering first and master's degrees in general, *madrasah*, technology, and medical streams:

Nonformal Education

The Ministry of Primary and Mass Education (MOPME) executes the nonformal education (NFE) policies through the Bureau of Non-Formal Education (BNFE) at the national level. The BNFE is headed by a director general. The organizational structure provides for 64 offices in 64 districts of the country. The NFE programs are disseminated through continuing education centers (CECs) and learning centers.

NFE covers disadvantaged groups, including children and youth with physical and mental disabilities, ethnic minorities, people living in ecologically difficult locations, street and working children, and people living in especially difficult circumstances.

Initially, the NFE programs were designed to impart literacy to illiterates of the 11–45 age group. At present, the employment-oriented Post-Literacy and Continuing Education (PLCE) project is being implemented, which covers 1.6 million neo-literates with a 9-month course. The other project run by this Bureau is the Basic Education For Hard To Reach Urban Working Children (BEH-TRUWC) which targets 0.2 million urban working children aged 10–14 years with 40 months of basic education program.

Teacher Education

There are 54 primary teacher training institutes popularly known as PTIs offering Certificate in Education (C-in-Ed). These are all public institutions and spread all over the country. For secondary school teachers, there are 99 (14 public and 85 private) teacher training colleges (TTCs) offering Bachelor of Education (BEd) degree. The Institute of Education and Research (IER) of the University of Dhaka also offers BEd courses. The Open University, through the distance mode, imparts BEd course to secondary teachers. There are training institutes for technical–vocational, *madrasah*, and physical education teachers and also for higher secondary teachers. The total number of teacher-training institutes, trainers, and enrollment (trainees) for all-level teachers are 188, 2123, and 36265, respectively, for the year 2005. The trainee–trainer ratio is 17:1. Besides, there are two national academies – National Academy for Primary Education (NAPE) and National Academy for Educational Management (NAEM) – for imparting educational management training to teachers and administrators of primary and secondary subsectors, respectively.

Although it is a precondition for entry into the teaching profession to have the requisite pedagogical training, a large proportion of teachers in the system are still untrained. The relevant training for a primary teacher is C-in-Ed, while that for a secondary teacher is BEd.

Operation of the System

The net enrollment ratio at the primary is 87%. The repetition rate at this level is 11.2% and as a percentage of the relevant age group, the completion rate is 73%. The survival rate to grade 5 is 53.9% and the years input per graduate is 8.2. The pupil–teacher ratio for all types of schools is 47:1. Taken individually, it is the highest in the mainstream government primary schools which is 58:1. Only 12% of the GPSs and 9% of the RNGPSs run single shift, while the rest run double shift. The contact hours for single shift and double shift schools are 900 h and 600 h, respectively, per academic year. The percentage of trained

Table 3 Number of institutions, teachers, and students at the higher education level (2005)

No.	Institutions by stream and level	No. of institutions	No. of teachers	Enrollment
1.	First-degree (pass and honors) college (general stream)	1248	48 069	719 524
2.	Master's degree college (general stream)	89	6924	386 493
3.	Medical, engineering, and other (dental, law, textile, leather) technology colleges/institutes	127	3460	42 507
4.	Madrasah (higher education level: Fazil and Kamil madrasahs)	1214	28 292	669 256
5.	University (public and private; general and specialized universities)	74	10 339	207 577
	<i>Total</i>	2752	97 084	2 025 857

From Bangladesh Bureau of Educational Information and Statistics (BANBEIS) (2006). *Bangladesh Educational Statistics*, 2006.

teachers at the primary is 73% and the transition rate from primary to secondary is 83.3%.

With the 58:1 pupil–teacher ratio in the mainstream primary schools, contact hours of 600 per annum in most of the schools, and 27% of teachers being untrained, the primary-level institutions are striving hard to ensure quality.

In the secondary (general), the net enrollment ratio is 48%. The dropout and completion rates in the secondary cycle are 80% and 20%, respectively. In the general, technical, and madrasah streams of secondary education, the pupil–teacher ratios are: 28:1, 14:1, and 22:1, respectively. The contact hours at this level, on an average, is 5 h a day. The number of working days is 228. With a very high dropout ratio and almost half of the teaching force being untrained, and even trained teachers mostly following the teacher-centered method of teaching, ensuring quality poses a problem. This is reflected in the success rates at the SSC and Higher Secondary Certificate (HSC) results which are 59% and 64%, respectively, in 2006.

At the primary level, there is no general public examination. There is a system of continuous pupil assessment (CPA) for grades 1–3. At the end of grades 3 and 4, there are annual examinations for promotion to the next grade. At the end of the cycle, there is the school-leaving examination conducted by the respective schools.

At the junior secondary level also, there is no public examination. The most important public examination is held at the end of grade 10. This is the SSC examination. For internal evaluation, pupils of each grade from 6 through 10 have to take three term examinations.

Those who complete the secondary level, have to take a 2-year higher secondary course and sit for a public examination titled HSC examination. The SSC and HSC are organized, conducted, and controlled by the Board of Intermediate and Secondary Education (BISE). For Madrasah and Technical Education, there is the Madrasah Education Board and Technical Education Board.

At the tertiary level, student evaluation is the responsibility of the universities.

Teacher Management

Recruitment of government primary school teachers is carried out through a competitive written examination conducted by a central committee headed by the Director General of the Directorate of Primary Education (DPE). For nongovernment schools, it is the School Managing Committee (SMC) that appoints teachers in accordance with the nongovernment Teacher Recruitment Rules. The minimum qualifications required for the primary teacher is the SSC for females and HSC for males, with a preservice training titled C-in-Ed.

Teachers of government and nongovernment secondary schools, colleges, *madrasahs*, and other institutions are recruited through competitive examinations. Government teachers are recruited by the Directorate of Secondary and Higher Education (DSHE) and nongovernment teachers by Nongovernment Teacher Registration and Certification Authority (NTRCA), respectively. After recruitment by the NTRCA, the Appointment Board constituted at the institutional level concerned and headed by the chairman of the SMC, selects and appoints teachers in nongovernment institutions. The eligibility requirements for a secondary teacher are a first degree from a university and a preservice training/degree, that is, BEd.

The pay scale for both government and nongovernment teachers are the same, but there are differences in salary-payment practices. The government pays the salary, including the allowances of government teachers, but for nongovernment teachers, the government pays only the basic pay, and not the allowances. The allowances have to be collected from other sources, including tuition fees from pupils.

The career prospects for teachers at both the government and nongovernment primary and secondary levels, are not bright. In course of time, assistant teachers become senior teachers and their possibility of becoming headteachers is bleak, as the positions of headteachers are few in relation to the number of teachers.

Teachers in government institutions are evaluated annually through the criteria set in a format called the Annual Confidential Report (ACR). Teachers in nongovernment institutions are evaluated informally. The evaluation has a direct link with their promotion.

Teachers at all levels of government institutions are transferable on completion of 3 years of service in one station. Teachers in nongovernment institutions are not transferable.

Administration and Supervisory Structure

The education system of Bangladesh functions under two separate ministries: MOPME, responsible for primary and mass education, and the Ministry of Education (MoE), responsible for secondary and higher education.

Administration

Administrative structure: Primary

The MOPME is the policymaking body for primary and mass education. The ministry is headed by an adviser with the status of a state minister, under the direct supervision of the prime minister. The adviser is assisted by the Secretariat headed by a secretary of Primary and Mass Education.

The principal executing body for the Secretariat is the DPE. The directorate is headed by a director general who

has six directors heading six units. These units are: training, finance, operations, monitoring and evaluation, planning and development, and administration. A number of deputy directors (DDs) and assistant directors (ADs) assist the directors of the six units. This is the national level. The directorate has structures at the zone, district, and subdistrict levels.

At the zonal level, the Zonal Primary Education Office is headed by the zonal DDs who are assisted by the ADs. Zonal DDs are under the direct control of the director of administration located at the national level.

At the district level, there is the district primary education officer (DPEO) and assistant district primary education officer (ADPEO). The subdistrict structure is manned by *upazilla* (subdistrict) education officers (UEOs). Each UEO in the 481 *upazillas* of the country is assisted by one assistant *upazilla* education officer (AUEO).

Alongside the DPE, there is a Compulsory Primary Education Implementation and Monitoring Unit (CPEIMU) for implementing and monitoring the programs and activities undertaken for executing the provisions of the Compulsory Primary Education Act enacted in 1990 and for ensuring education for all (EFA).

Administrative structure: Secondary and higher education (imparted by colleges)

The (MOE) is the policymaking body and also the apex body for educational administration, management, and planning for secondary and higher education. The MOE is headed by a minister who is assisted by a state minister. The ministry executes its functions through the secretariat which is headed by the education secretary.

The secretariat is assisted by two administrative directorates: Directorate of Secondary and Higher Education (DSHE) and Directorate of Technical Education (DTE) which have the key roles in the administration and management of postprimary education subsectors for the general and technical education streams. The government policy and planning for general secondary and higher education is implemented by the DSHE, while those for the technical education (secondary level) is implemented by the DTE.

The DSHE is headed by a director general who is assisted by 4 directors at the center, who head the four units of the directorate: (1) planning, (2) secondary education, (3) college education and administration, and (4) training. The directorate has substructures at the zonal, district, and subdistrict levels. The zonal offices are headed by DDs who are assisted by ADs and school inspectors. The district offices are headed by district education officers (DEOs) who are assisted by the respective assistant district education officers (ADEOs). At the subdistrict level, there are *upazila* (subdistrict) secondary education officers (USEOs) and assistant *upazila* secondary education officers (AUSEOs).

Likewise, the DTE is headed by a director general who has the requisite support offices at the central and lower levels.

There are some staff organizations located at the center which extend support to the administrative functions of DSHE. The National Curriculum and Textbook Board (NCTB) develops curricula for the primary and secondary (general streams) subsectors. There are six education boards called the Board of Intermediate and Secondary Education (BISE), one Madrasah Education Board (MEB), and one Technical Education Board (TEB). These boards are responsible for the accreditation of nongovernment secondary and higher secondary education institutions (general, *madrasah*, and technical-vocational streams) and the administration of public examination at the secondary- and higher-secondary levels (SSC and HSC examinations). MEB and TEB are also charged with the responsibilities of developing the curricula for Madrasah and technical-vocational streams of education, respectively. For administering public examinations of higher education imparted by colleges, there is the National University. The Directorate of Inspection and Audit (DIA) is engaged in inspecting the schools to ensure mainly the financial accountability of the schools.

The Bangladesh Bureau of Educational Information and Statistics (BANBEIS) is responsible for collecting data and furnishing information. Infrastructure support to the postprimary education subsectors is provided by the Education Engineering Directorate (EED). There are two apex bodies for providing professional support to MOE and MOPME. The support is provided through management training to education managers and administrators and research support to the two ministries for policy and decision making. These are (i) National Academy for Primary Education (NAPE) and (ii) National Academy for Educational Management (NAEM). The former is for primary education and the latter for secondary and higher education subsectors.

The above structure applies to both government and nongovernment institutions. One important feature of the administration and management of nongovernment primary, secondary, and higher-level educational institutions is the school-based management through the school managing committees (SMCs). For the college-level institutions, which impart higher education, these bodies are called the governing bodies. These are elected bodies having representatives from the community and parents. These bodies are responsible for all in-school management issues in the nongovernment schools, except academic matters. The heads of schools and colleges are the member secretaries of these administrative bodies.

Educational planning of the country is mainly a top-down process. The Planning Commission, an organ of the Ministry of Planning (MOP), is the principal authority for formulating the national-level plans of the country. The education wing of the Planning Commission formulates

the education plan. The planning cell in the MOE and MOPME, and the planning units of the DPE, DSHE, and DTE provide inputs to the education wing for planning primary, secondary, and higher levels of education.

Administrative structure: Higher education imparted by universities

There are 74 universities in the country. Of these, 21 are public universities and the rest 53 are private. These include general, medical, agricultural, engineering, and technology universities. Universities are autonomous bodies having their own set of rules and principles to govern themselves. However, there is the University Grants Commission (UGC), a supervisory body which provides operational regulations and allocates fund to the public universities.

Teacher Supervision and Support

Primary

At the primary level, the inspectorate comprises mainly the UEOs and AUEOs who work at the field level. The main functions of the UEOs and AUEOs are to visit schools which aim at both teacher supervision and school inspection. There are supervision guidelines, reporting formats, and also provision for follow-up actions. There is a regular monitoring system of the supervision staff.

The AUEOs have to organize subcluster (one subcluster comprising 15–20 schools) training for in-service teachers every month. The other in-service training methods that are imparted to the teachers include subject-based training, training on teaching methods, and management training for headteachers. Supply of teaching aids, learning materials, and teacher guides are the other forms of teacher support.

Secondary

Supervision of secondary schools and teachers are particularly the job of regional, district, and subdistrict offices of DSHE. Each of the nine DD's office is manned, so far as the supervisory staff is concerned, by two inspectors of school (ISs) and two assistant inspectors of schools (AISs). At the district level, the DDs are supported by DEOs who form the pivot of academic inspection and supervision activities. Each DEO is assisted by an ADEO. The USEOs and AUSEOs are the school supervisors at the subdistrict level. Besides, there is a body of academic supervisors (ASs) who have school supervision as their major responsibility.

The DIA and the BISE have responsibilities of inspecting and supervising schools for various purposes but not specifically for the purpose of academic supervision.

Despite the prevalence of a body of academic supervisors, academic supervision remains a weak area of secondary-education management mainly due to the high school-supervisor ratio. If the DEOs, who form the main body of academic supervisors, are considered, then the ratio is 314:1.

Financing of Education

As a percentage of gross national product (GNP), expenditure on education during the years 2000–04 was 2.2% which compares favorably with an average allocation of 1.8% during 1993–94.

The allocation to education in the revenue and development budgets of the government accounts for 15.03% and 12.8%, respectively, of the total allocations in 2005–06 (BANBEIS, 2006). The primary and mass education subsector is given the highest allocation of 61.51% in the development budget for education for the year 2005–06, followed by secondary and higher (general stream) education – 27.7%. In the revenue budget for the same year, the share of primary and mass education stands at 32.7%, while that for secondary and higher education stands at 52.5%. The rest goes to technical, university, *madrassa* education, teacher training, administrative and subsidiary services, etc.

The development budget for education is financed from two major sources – government and aid, grant, loan from development partners. The 2005–06 development budget has been shared at a 60:40 proportion by the Government of Bangladesh (GOB) and development partners. The other sources of financing education include parents and the community. NGOs also finance education development but mostly for primary and adult-literacy programs.

Nongovernment institutions at the primary and secondary levels account for 53% and 98%, respectively. The government pays only the basic salary of teaching and nonteaching staff of nongovernment institutions. The rest of the cost is borne by the private sector. In nongovernment institutions that account for 53% and 98% of the primary- and secondary-level institutions, respectively, the major share of the costs of primary and secondary education is borne by the private sector.

Performance Monitoring, Evaluation, and Research

The performance of each level of education is monitored by the administrative agencies concerned. The monitoring and evaluation of primary education is done by the monitoring and evaluation unit of the DPE. As there is no specific unit or cell for monitoring and evaluation in the DSHE, this responsibility is discharged by the secondary and college and administration units of the directorate. The performance indicators that are used are: literacy rate, participation rate (gross and net enrolment rates), and indicators of internal efficiency such as repetition, dropout, survival rates, the success rates, and the like.

Educational development programs and projects are undertaken on the basis of feasibility studies. Research studies prior to educational reforms are also practiced. These studies are conducted by different national agencies

under the MOE and development partners in collaboration with national agencies. The linkage between education research and education reforms and decision making is not yet well established. There is no central agency to undertake education research to extend research support to educational policy and decision making on a regular basis. However, public research institutions, such as the Institute of Education and Research (IER) of the University of Dhaka, the National Academy for Educational Management (NAEM) working under the MOE, and the Bangladesh Institute of Development Studies (BIDS), are organizations and agencies that are doing the needful in this respect at present.

Major Changes, Challenges, and Issues since 1990

Changes

The educational sector has undergone remarkable changes since 1990. In 1990, the Compulsory Primary Education Act was enacted. Children's Stipend Programme was introduced for retaining poor children in schools. This yielded a notable improvement in enrollment. Over a period of 10 years (1990–2000), enrollment enhanced by 46%. During the period 1990–2005, girls' participation enhanced from 45% to 50%.

For ensuring better administration and management of primary and mass education, a separate ministry titled Ministry of Primary and Mass Education, was established.

Another change that deserves mention in the primary education arena is the change in curriculum. From a traditional one, the curriculum was changed to a competency-based one in 1992. The curriculum containing 50 terminal competencies to be achieved by learners, was implemented phase-wise during the period 1992–97.

In order to enhance access and gender parity in secondary education, financial support in the form of stipends for girls through a number of female secondary stipend projects (FSSPs), was introduced in 1994, and this is still continuing. This resulted in enormous growth in girls' participation in secondary education, enhancing gender parity.

Because of very low girls' participation in technical education, the government has established six new polytechnic institutes for girls to support a wider coverage of girls.

In the secondary-education subsector, changes occurred in learner assessment. Previously, learners were assessed on the knowledge aspect of education only. With the introduction of school-based assessment (SBA), where 30% marks have been earmarked for assessing learners' behavioral aspects, the psychomotor and affective domains have come under the purview of assessment. The other reform in learner assessment is the introduction of the grade point average (GPA) system in 2001 in place of the absolute marking system. This has ensured more effective assessment of learners' merit and achievements.

A very major intervention in the quality arena is the enactment of the Nongovernment Teacher Registration and Certification Authority Act in 2005, aimed at recruiting and appointing quality teachers for the nongovernment educational institutions of all postprimary subsectors which constitute 98% of the total strength. The other objective is to bring them under the fold of registration which was never done in the past. Now, nongovernment teachers are needed to be registered with and certified by the authority for entry into the teaching profession.

In the higher education arena, the enactment of the Private University Act in 1992 had been a great step forward toward privatizing higher education and enhancing access to higher education. At present, 53 out of the 74 universities are privately owned.

Challenges and Issues

Till today, the major challenge is ensuring the participation of all in the education system. Despite remarkable achievements in enrollment and gender parity at both the primary and secondary levels, 13% of the primary-, 52% of the secondary-school-age children are still out of school.

Apart from this, the prime concern is quality. The internal efficiency is low as demonstrated by a high dropout and low completion rates both at the primary and secondary levels. Years input per student at primary is 8.2 years. In the secondary cycle, the dropout rate is 80%, the completion rate is 20%, and the repetition rate is 10%. Fifty percent of children at the primary level fail to achieve more than 50% of basic competencies. Improving this situation is the major challenge to the government and the education actors.

Low instructional time, ineffective teaching–learning, characterized by no lesson plan, and a weak learner–assessment system, are the major issues at the primary- and secondary-education subsectors.

The success rate at the public examination at the secondary- and higher-secondary levels (SSC and HSC) ranged between 42–53% and 39–59%, respectively, during the period 2000–05. All these point to the quality issue. The relevance of the curriculum is questionable as it is oriented toward higher education and examination, and not to practical skills. The assessment system has drawbacks. The common criticism against the system is that it encourages rote learning and not the understanding of the learners.

Improving the quality of secondary teachers is a challenge. Only 53% of the teachers have the requisite professional qualifications.

Enhancing the participation of women as both teachers and students still remains a challenge despite the fact that gender parity has been achieved at the pupil level at both the primary and secondary subsectors. Female teachers account for 36%, 20%, 19%, and 9% in the primary, secondary (general), secondary (technical), and secondary (*madrasah*) streams.

In the TVET arena, the major challenges are to establish linkage to the job market and to improve the effectiveness of training support and delivery.

The challenges facing higher education are improving the external efficiency, making higher education need-responsive, and establishing linkages to national and global markets.

General Background

Barbados is a small, island country of 166 square miles with a population of over 270 000 people. Most Barbadians are of African descent.

The first inhabitants of Barbados were Amerindians, who arrived here from Venezuela. The island was taken over by the Spanish in 1492. Spain, however, left Barbados in favor of the larger Caribbean islands. This left the island open when the British came to colonize it. The first English ship came to the island on 14 May 1625, under the command of Captain John Powell. The island was, therefore, claimed on behalf of King James I. On 17 February 1627, Captain Henry Powell landed with a party of 80 settlers and ten slaves to occupy and settle on the island. This expedition landed in Holetown, formerly known as Jamestown. The colonists established a House of Assembly in 1639. It was the third ever parliamentary democracy in the world.

The earliest attempts at formal education were introduced in approximately 1686, when a charity school was established for the education of poor white children. With the further efforts of private individuals, more charity schools were established for poor white children; however, it was only in 1818 that the first school for colored boys was established. In 1827, an elementary school for colored girls was established. By 1844, there were 215 schools – with a total enrolment of 7452 students – operated by churches, as well as private individuals throughout the island.

The first Education Act was passed, in 1850, and it provided for the establishment of an Education Committee with a part-time school inspector as its executive officer, who was also simultaneously, the head of the Central School for Boys. The committee was given responsibility for the educational policies and the administering of the annual grant of £3000, to be distributed to the schools in proportion to the average attendance of pupils and the amount raised in school fees.

In 1858, a second Education Bill was passed. The Inspector became a full-time officer and the subjects of the curriculum were determined. The pupil–teacher system was introduced and payment by results was initiated. Elementary education developed rapidly during this period and government grants were increased, annually, to £9200 by 1874.

The first serious attempt to organize higher education came in the early 1870s. During 1874–75, two important events occurred in education. The first was the affiliation

of Codrington College to Durham University and the establishment of a Classical Facility. The second was the appointment of a Commission – headed by Bishop Mitchinson – to study the system of education in the island and make recommendations for its improvement.

The Report of the Mitchinson Commission was completed in 1876. It found favor with the authorities who embodied the recommendations in the 1890 Education Act, which remained the principal Education Act until 1983. This Act resulted in many far-reaching consequences for the educational system. An Education Board – consisting of four members of the House of Assembly, three of the Legislative council, and two others, all of whom were appointed by the governor – replaced the former Committee. An inspector and an assistant inspector served as its officers.

The Board had general control of elementary education and could require the vestries (local parish authorities) to provide and maintain elementary school buildings.

Under the 1878 Act, two schools were designated First Grade Schools with governing bodies and received annual grants. Provision was also made for Second Grade Schools, (between First and Elementary) to be established. By the end of the nineteenth century, there were three First Grade Schools and five Second Grade Schools. There were 169 elementary schools receiving financial support from government with an enrolment of 24 145 students: 134 were Anglican, 19 Wesleyan, and 16 Moravian. School fees were charged at all schools.

Although education was provided from public funds, there was no distinction between government Elementary Schools and Church Schools. The Education Board with the Bishop as president made the rules and regulations for elementary schools. Teachers were appointed by the local Board of Managers and approved by the Education Board. Buildings were maintained by the vestries.

Many private schools were in existence at the time, but there was “no inspection or notice taken of them.” The number of children being educated in these schools – at that time – was in excess of 10 000.

During the first 25 years of the twentieth century, the educational system came in for severe criticism. It was reported that the Board lacked a definite policy and had lost control through decentralization. Elementary school buildings were unsuitable for educational purposes and grossly overcrowded. Elementary education was described as removed from the needs of the children, which rendered them unemployable to a large degree. Education in the

First Grade Schools was described as being severely academic and having little contact with reality. The Second Grade Schools were also described as unsatisfactory. Without adequate facilities, they tried to imitate the First Grade Schools and, as a result, they provided neither culture nor technical skill.

The Marriott–Mayhew Commission was appointed, in 1932, “to make a comprehensive investigation into the educational services of the colony.” The report – published in 1933 – drew attention to the need for the appointment of a Director of Education, and the necessity of improving the facilities for teacher-training, at the Rawle Training Institute attached to Codrington College. The Commission also advocated a reorganization of the schools and a review of the curriculum to bring education into closer touch with the needs of the students and the times. An important recommendation was the introduction of the modern Secondary School. Very few of the recommendations could be implemented during the years following the report because of social unrest in the region and the outbreak of World War II.

In 1943, the first recommendations of the Marriott–Mayhew Report came into force. A Director of Education was appointed and the Education Board became an advisory body. Several changes were immediately put into effect in the teaching service. Teachers in elementary schools became civil servants; the regulations for the award of certificates of competency were revised in relation to a new salary scale; secondary teachers’ salaries were also improved but they were not granted civil servant status.

The Rawle Training Institute, opened in 1912, was closed in 1945, with plans to open a new institution nearer to Bridgetown. Other changes taking place were the introduction of age-grouping in elementary schools, strengthening of the administration and inspectorate by creating the posts of assistant director, inspector, and assistant inspector of schools and three specialist posts for Handicraft, Domestic Science, and Infant Methods. A new Housecraft Centre was opened for training women in domestic science, in 1945.

Another milestone in educational history was reached with the creation of a separate Ministry of Education in 1958. The Minister’s responsibility for policy and development of education was more clearly recognized. The establishment for the teaching staff in primary and secondary modern schools was increased and provisions made for more acting staff.

The most significant step in the field of education was made in 1962, when school fees were abolished in all government secondary schools. This meant that all persons of ability would have free access to secondary education. In 1962, the Department of Education was integrated with the Ministry of Education and the Director of Education was re-designated the Chief Education Officer.

In 1963, a school Meals Pilot Scheme was introduced in three primary schools. During the same year, the College of Arts and Science at the University of the West Indies was opened. Erdiston College reintroduced the 2-year program while the 1-year course was continued for experienced, unqualified teachers.

A new Education Act was proclaimed in 1983. Its main objective was the democratization of education and the regularizing of the management and operation of all secondary schools. Under this Act, all teachers have become members of the civil service.

The Act is very comprehensive and covers all aspects of education from school attendance, registration of private institutions, duties of teachers, to management of primary and composite schools, and provision of special education.

Administration of Ministry of Education

The Ministry of Education was established in 1954, under the portfolio of the Premier. In 1958, a separate ministry was established with its own staff of administrative and technical officers to assist the minister in the execution of government policy.

The Ministry is divided into two main sections – technical and administrative. The Chief Education Officer, who heads the technical staff, is the Chief Professional Advisor while the Permanent Secretary is the Chief Administrative Officer with responsibility for finance. This dual system functions rather effectively, but can be a bit intricate where roles are not clearly defined.

The administrative section has responsibility for personnel, financial, and general administrative matters while the technical section has responsibility for specific educational matters.

For administrative purposes, the two main sections were subdivided into four divisions namely:

1. The Schools Division
2. The Planning and Development Division
3. The Personnel Management and Services Division
4. The Finance Division

In 1997, there was a restructuring of the Administrative and Technical sections to meet the new reform process initiated by the White Paper on Education Reform (1995).

The divisions have now been renamed:

1. Schools Supervision and Management Division
2. Planning, Research and Development Division
3. Human resources Division
4. Education – Management Information System Division
5. Finance Section
6. Student Services Division
7. Curriculum Division

8. Testing and Measurement Division
9. International Relations Division
10. Higher Education Award Division
11. Office Management
12. Parent Volunteer Support Division

The Technical Division

The Technical Division is headed by the Chief Education Officer who has two Deputy Chiefs to assist her/him. This Division has responsibility for schools, educational planning, and development.

The Schools Division

The schools division is made up of two subunits and is supervised by a deputy chief education officer. Each section in the schools division has administrative personnel to assist the technical teams in carrying out their duties. These administrative persons include administrative officers 1 and 11, senior clerk, and clerical officers.

The subunits are (1) School Supervision and Management, and (2) Student Services.

The schools supervision and management unit

This embraces the primary and secondary schools and is, at present, managed by a senior education officer. The main functions of this subunit include the supervision of public and private assisted schools, registration, selection of teachers for appointments (at primary level), and advising schools on educational and administrative matters. The public primary and private assisted secondary schools are divided into five districts – each district being supervised by an Education Officer.

The main goals of the Ministry are:

- To ensure high-quality, free education for all from preschool to tertiary level
- To provide a wide range of higher education and training opportunities to enable those best able to avail themselves of the facilities to develop the professional, technical, and other skills they can use to further their careers and contribute to the development of the Barbadian economy and society.
- To promote gender equality, which will produce citizens who are well-balanced, disciplined, industrious, creative, self-reliant persons who can think critically and function effectively in a modern society.

Early-Childhood Education

The Government of Barbados is committed to the achievement of the United Nations' Declaration on Education for All – Expansion of Early Childhood Care and the CARICOM Plan of Action to address early-childhood

issues. To this end, the Ministry has embarked on a program to facilitate the expansion of early-childhood education that would ensure universal educational access for children between the ages of 3 and 5. This program was started in the academic year 2005/06 and 825 new students have been enrolled since the commencement of the Nursery Expansion project. By September 2007, 6560 3–5-year olds or 91.15% of the cohort were enrolled in pre-primary education. There are, at present, seven public nursery schools and many private nursery schools.

The curriculum at this stage focuses heavily on the oral language development of the students. The Early Childhood Education (ECE) program seeks to assist these young children in developing oral competence in standard English before they are called upon to demonstrate literacy in it. In addition, the program – at this level – seeks to develop the natural curiosity of children and pave the way for them to be critical and creative thinkers from an early age.

As specified by the Ministry of Education, any ECE program should strive to enhance the following characteristics of the students:

- Ability to talk freely
- Innate curiosity and desire to learn
- Playful activity
- Ability to imitate and interact with each other, as well as adults
- Ability to use concrete and multisensory material and tools
- Ease in simultaneously acquiring knowledge and skills in multiple areas
- Capacity to learn at different rates
- Ability to distinguish right from wrong
- Need for success to build a sense of security and self-confidence

Observation is a critical assessment procedure employed by early-childhood teachers. Teachers observe the children throughout the school day, paying special attention to their progress in terms of physical growth, social growth, as well as the evolving of their literacy, mathematical, and practical abilities.

Primary Education

In Barbados, primary education is provided for children between the ages of 3+ and 11. At present, there are 71 public primary schools and 20 private primary schools; together, they cater to approximately 28 000 students.

Modes of Assessment at the Primary Level

With the introduction of flexible transfer in 1996, children as young as 9+ can appear for the Barbados Secondary

School Entrance Examination (BSSEE) to gain admission to secondary schools if they are ready. Conversely, those who reach age 11+ and have not fully covered the primary syllabus can postpone appearing for the BSSEE for 1 year.

As a means of ensuring that pupils reap optimum benefit from their primary education, the Ministry of Education has introduced a number of innovations in the area of testing and assessment. One such innovation is the Criterion – Referenced Test (CRT), which is administered at the end of Infants B (~6-years old) and Class 2 (~8-years old). This test provides teachers with information on the strengths and weaknesses of students.

Secondary Education

Secondary Education is provided for students between the ages of 10+ and 16+ at 22 public secondary schools. Four of these schools – Harrison College, Queen's College, Combermere, and Lodge – provide sixth-form education. In addition to the public secondary schools, there are eight assisted private schools that offer secondary education.

Admission to secondary schools is based on the BSSEE. Students take the examinations of the Caribbean Examination Council (CXC) at the basic and/or general proficiency levels between the ages of 15 and 17 years. Most students write four or more subjects and, those whose performance is deemed to be excellent, may write the Advanced Level Examination of the Caribbean Examinations Council, the Caribbean Advanced Proficiency Examination (CAPE) 2 years later at 17–19 years of age. Excellent performance in this examination may result in the award of scholarships or exhibitions to pursue studies at colleges or universities, local or overseas.

Students at most of the newer secondary schools still appear for the Barbados Secondary School Leaving Certificate, Stage 1.

Tertiary Education

Education, at the tertiary level, is provided at vocational and technical colleges as well as at the university. Admission to these institutions varies from the possession of a Barbados Secondary School Certificate Stage I to a Caribbean Examinations Council Certificate to G.C.E A Level qualifications. Possession of these qualifications represent completion of secondary education. The institutions for tertiary education are the Samuel Jackman Prescod Polytechnic, Erdiston Teachers' College, the Barbados Community College, and the University of the West Indies.

University of the West Indies

Qualified Barbadian students are eligible to enter the University of the West Indies – a regional institution

with campuses at Mona in Jamaica, St. Augustine in Trinidad, and Cave Hill in Barbados. The University of the West Indies has faculties of medicine, science, arts and general studies, social sciences, agriculture, engineering, and education and law.

The campus at Cave Hill was established in 1965; however, classes were started at a temporary site near the Bridgetown Harbour, in 1963. Courses offered at the Cave Hill Campus lead to the bachelor's degree in arts and general studies, law, natural sciences, theology, social sciences, and education. In addition, a number of certificate, diploma, and graduate-degree programs are offered.

Erdiston Teachers' College

Erdiston Teachers' College is a nonresidential institution providing a basic 2-year teacher-education program for nongraduate teachers of primary and secondary schools. In addition to general teacher-education courses, the college cooperates with the Samuel Jackman Prescod Polytechnic and the Barbados Community College to provide certification in technical and vocational areas such as business education, industrial arts, and home economics. These courses are mainly for teachers at the secondary level. The college also offers a number of post-basic and continuing-education courses designed to meet the special needs of teachers and the public. Among these are 1-year in-service part-time courses in the teaching of reading and remedial education along with 1-year full-time courses in early-childhood education and physical education.

Barbados Community College

The Barbados Community College – established in January 1969 – is an institution designed to improve the facilities available to the community for training in a wide range of skills at the technical para-professional, middle-management, and preuniversity levels.

The college offers courses in the divisions of liberal arts, fine arts, health sciences, sciences, commerce, hospitality studies, technology, general and continuing education, the language centre, and the departments of computer studies and physical education. In addition, the college offers a wide range of evening and summer courses as part of its service to the community. The courses of studies are of 2 years' duration and lead to the associate degree in arts or applied arts, and sciences or applied sciences.

Nursing education was transferred from the Tercentenary School of Nursing of the Ministry of Health to the Division of Health Sciences of the Barbados Community College – with effect from April 1986.

Samuel Jackman Prescod Polytechnic

The Samuel Jackman Prescod Polytechnic – an institution offering a wide range of trade courses – was officially

opened in January 1970. Craft-level training – which had been offered at the Barbados Technical Institute, since 1953 – was reorganized and expanded in scope within this new institution. Its objectives are to develop trade skills and occupational competencies up to the level of skilled craftsmen, as well as to prepare students for entry into the Division of Technology of the Barbados Community College.

The Housecraft Centre – formerly located at Bay Street – has been incorporated into this institution as the Division of Human Ecology.

The types of training offered include:

1. training for students about to enter the labor market;
2. training for persons who wish to improve their skills; and
3. re-training for those desirous of changing their occupations.

The courses of training are offered either on a full-time, part-time, or evening basis and may lead to either local certification or qualifications of the City and Guilds of London Institute or CXC.

Government-Aided Programs in Schools

There are several programs designed specifically to assist the disadvantaged students so as to ensure that they can take advantage of the educational system. Some of these programs are described below.

Textbook Loan Scheme

The TextBook Loan scheme was established by the government to ensure that all secondary students have easy access to the texts required for the study of programs offered in schools. Each student – on payment of an annual rental fee – is issued with the required textbooks. Provision has been made for the waiver of the rental fee when this is justifiable.

The monies collected as rental fees are used for the management of the scheme. Government provides the funds, annually, to replenish the stock.

School Uniform Grants

A scheme for the provision of uniforms for school children was introduced in 1980. The scheme provides a one time grant to each qualified student entering a secondary school, the senior department of a composite school, or a senior school for the first time.

School Lunch Programme

In 1963, a Schools Lunch Pilot Programme was introduced under which children attending primary schools were provided with a cooked lunch every day. The facility was

gradually expanded until all primary, composite, and senior schools became involved in the program. In addition, two private schools are benefiting from this program.

The Teaching Profession

In 2006, there were 2912 teachers in government schools from the pre-primary to the secondary levels. Of this number, 2082 were female and 830 were male; these figures clearly show that the teaching profession is highly feminized. The minimum qualification for a teacher is certification from the CXC at the general level in at least five subjects – including English language and mathematics. Teachers' salaries are determined based on qualifications. The salaries range from \$22 551.60 per annum to \$59 575.00 per annum for teachers and, for principals, from \$79 608.72 per annum to \$98 505.24 per annum.

Education Sector Enhancement Project

The central goal of the Education Sector Enhancement Programme (ESEP) is to comprehensively reform the entire primary and secondary school system in Barbados so that its output will reflect an increase in the number of young persons who can significantly contribute to the sustainability of the social, cultural, and economic development of Barbados. The implementation of the reform initiative is being done through the execution of civil works activities, teacher training, curriculum reform, and the introduction and integration of technology into the school environment.

The Programme Coordinating Unit manages and coordinates all matters pertaining to the planning, implementation, and monitoring of the program in conjunction with other ministry sections, departments, and institutions. The Education Project Implementation Unit has special responsibility for the management and execution of civil works, project accounts, and some aspects of procurement in the program. In addition, the Curriculum Section is responsible for curriculum reform, while the Erdiston Teachers' Training College is responsible for teacher training under the human resource development component of the program.

Functions

The functions of the abovementioned units involved in the implementation of the program include:

- Liaising with the program's international funding institutions (IFIs) – the Caribbean Development Bank (CDB) and the Inter-American Development Bank (IDB).
- Negotiating and preparing contracts relevant to the procurement of goods and services for the program, and preparing relevant Cabinet Papers.
- Preparing budgets and reports for internal and external users/purposes.

- Coordinating and monitoring all civil works and activities related to the rehabilitation of schools in the program.
- Coordinating the procurement of technological equipment and software, technical assistance, and general professional services for the ESEP.
- Coordinating teacher training relevant to the program as well as the training of the ministry's technical and administrative personnel in program-related areas.
- Coordinating the preparation and implementation of revised curricula for the primary and secondary schools.
- Communicating and working with the schools to ensure the effective implementation and management of the reform program at the school level.
- Coordinating the evaluation of the program.
- Preparing and disseminating information on the program – including publications and multimedia presentations – for education stakeholders and for the general public.

Education Financing

The Government of Barbados is committed to the development of an educational system, which will enable all persons to reach their fullest potential. Education – at all

Table 1 Government expenditure on education

<i>Year</i>	<i>Education as a % of total government expenditure</i>
1933–34	10%
1940–41	13%
1950–51	16%
1960–61	12%
1970–71	20%
1979–80	19%
1982–83	18.40%
1997–98	16.39%
2000–01	18.55%
2004–05	16.98%
2007–08	16.68%

levels – is free for all Barbadian Nationals. In the pre-independence era, the expenditure on education fluctuated between 10% and 16% of the total government expenditure, and with independence came an increase in expenditure on education.

The education budget averages between 16% and 20% of the total annual budget of the country. This reflects the government's policy of using education as an instrument of social change. **Table 1** reflects the percentage of government expenditure on education from the 1930s to the present day.

Glossary

Asparuh or Isperih – was ruler of a Bulgarian tribe in the second half of the seventh century and is credited with the establishment of the First Bulgarian Empire in 680/681. He is the most famous Bulgarian ruler. The accuracy of the Turkic title *khan*, commonly applied to him and his successors, is a subject of some dispute.

Old Great Bulgaria or Great Bulgaria – was a term used by Byzantine historians to refer to Onoguria during the reign of the Bulgarian ruler Kubrat (father of khan Asparuh) in the seventh century north of the Caucasus mountains in the steppe between the Dniester and Lower Volga.

The Bulgars – (also *Bolgars*, *Bulghars*, *Huno-Bulgars* or *Proto-Bulgarians*) were originally semi-nomadic people, probably of Turkic descent, originating in Central Asia, who from the second century onwards settled in different parts of Europe.

General Background

The Republic of Bulgaria is a country in Southeast Europe, a European Union (EU) member state (01 January 2007) and a member of the North Atlantic Treaty Organization (NATO) (02 April 2004). Up to the year 2007, the population of Bulgaria was 7 679 290. According to the 2001 census, 83.9% of the people in the country are Bulgarian, 9.4% are Turkish, and 4.7%, Roma. The official language in the country is Bulgarian, spoken by 84.5% of the people, Turkish is spoken by 9.6%, and Roma is used by 4.1%. Most Bulgarians are Orthodox (82.6%), 12.2% Muslim, 1.7% Roman Catholics, 0.8% Jewish, and the remaining 1.6% are Protestants or other.

The first Bulgarian state existed on the Balkan Peninsula, and its adjacent parts, of Southeast Europe from 680 until 1018. It was founded by Khan Asparuh, who, after the dissolution of Great Bulgaria, brought a part of the proto-Bulgarian tribes, subjected the local Slavs, and entered into a peace treaty with Byzantium in 681. In 864, Bulgaria converted to Orthodox Christianity and, in 866, the Slavic alphabet and writing were introduced.

The second Bulgarian state (1186–1393) was founded by the brothers Asen and Peter after the period of the Byzantine rule (1018–1186). In the twelfth century, following the military success of Tsar Kaloyan over the crusaders, the country grew stronger and during the rule of Ivan Asen II, there was extension of territory, economic, and cultural development, as well as reestablishment of the Bulgarian patriarchy. In 1396, Bulgaria fell under the Ottoman rule which continued for almost five centuries.

After the Russian Turkish war for liberation (1877–78) the San Stefano peace treaty was signed in 1878 and it reestablished the Bulgarian state and marked the beginning of the third Bulgarian state. The Berlin Treaty, signed in 1878, partitioned Bulgaria and established an independent Bulgarian Principality and an autonomous region Eastern Rumelia. The unification of Bulgaria was achieved in 1885. In 1908, following the proclamation of the independence of the state, the kingdom of Bulgaria was established.

After World War II, Bulgaria fell into the Russian sphere of influence and in 1946 it became a people's republic. The Bulgarian Communist Party (BCP) headed the country and its governing role was provided for in the Constitution. In 1898, following the resignation of Todor Zhivkov as the secretary general of the BCP and as the Chairperson of the State Council (head of state), the transition of Bulgaria from socialism to market economy began.

The Bulgarian education developed during three periods: capitalistic (1878–1944), socialist (1944–1989), and transition (after 1989), wherein each one of them is characterized by specifics which are conditioned by the particular political, social, economic, ideological, and cultural conditions. During the first period of its establishment, the educational system had a three-tier structure: primary school with a 4-year tuition course; junior high school with three grades; and high school with five grades of tuition, separated into three profiles – classical, semiclassical, and real. After 1944, the high school period was reduced by 1 year, but the structure was retained – primary school, junior high school, and high school. A new three-stage educational model was affirmed in 1979. According to this model, the general education is received in a unified school and it lasts for 10 years (grades 1–10); after that there are two 1-year grades (11 and 12) in which the students receive broad profile professional training in special educational professional complexes. After the democratic changes in 1989, the educational system also changed.

Legislative Foundations

Public Education

Public education act (1991)

The Public Education Act (1991) being the first democratic law in the recent Bulgarian history, includes the following basic aspects:

- All limitations and privileges are abolished.
- School education begins at the age of 6 or 7 by choice of the parents or the guardians.
- The parents are granted the right to choose the district and the school according to their preferences and opportunities.
- There is permission to open private kindergartens and schools both by Bulgarian and foreign individuals.
- State educational requirements are introduced.
- Simultaneously with state subsidy, the schools and kindergartens may provide their own funds.

After passing the Act, numerous changes have been made, wherein the most significant ones were between 1998 and 2002.

An act for amendment and supplementation of the public education act (1998)

This act introduces significant changes with reference to more than 30 articles of the previous act. The most significant ones are:

- School education begins at the age of 7 for pupils turning 7 in the year of starting the first grade.
- Bulgarian is regulated as the official educational language.
- Two degrees of school education are introduced – primary and secondary (7)8 + (5)4.

An act for amendment and supplementation of the public education act (2002)

This act introduces the following significant changes:

- A compulsory preschool education is introduced which may be conducted both at school or kindergarten.
- The number of the state matriculation exams is reduced to two, wherein one of them is obligatorily Bulgarian language and literature and the other is chosen by the pupil.
- The number of textbooks to be approved by the Minister of Education and Science is limited and they may not be more than three for a school subject for each school year.

An act for amendment and supplementation of the public education act (2006)

The amendments in the act are minor and they are related to the pending accession of Bulgaria to the EU. In this respect, the following provisions are made:

- Pupils, whose parents are citizens of EU member states and work in Bulgaria, may join the educational system.
- The admission of pupils after grade 7 in the state and municipal schools is done by test-format exams.

An act for amendment and supplementation of the public education act (2008)

The amendments refer to the state matriculation exams, which were introduced for the first time in 2008, as well as to the regulation of the so-called protected schools (if such a school is closed, this will prevent access to education) and central schools (a school which is located in the closest inhabited area in the territory of the municipality, where pupils from the areas without a school are educated). In particular, this means:

1. With reference to state matriculation exams:
 - State matriculation exams are assessed by a national commission, which includes school teachers and university professors.
 - The pupils who have not passed the matriculation exams receive only a certificate for completed education degree.
2. With reference to the protected schools:
 - They may not be closed and they receive additional subsidy.
 - The list of schools is being updated every year.
3. With reference to secondary schools:
 - The list of secondary schools is accepted by an act of the Council of Ministers following a proposal of the respective municipal councils.
 - Funds are provided for additional financing of the education of traveling students.

Educational degree, general educational minimum, and study curriculum act (1999)

The 1999 Act is a separate law which regulates the study-curriculum structuring and the preparation of the study content. School subjects in the general-educational preparation are grouped into eight cultural and educational spheres: (1) Bulgarian language and literature; (2) foreign languages; (3) mathematics, informatics, and information technologies; (4) social studies, civil education, and religion; (5) natural sciences and ecology; (6) arts; (7) manner of life and technologies; and (8) physical education and sport. The Act establishes the portion of the compulsory preparation (CP) and compulsory optional preparation (COP), where CP represents 90% of the compulsory classes for primary school, 80–90% for junior high school, and 45–80% for high school. The freely chosen preparation (FCP) for all grades is four classes per week.

In 2002, 2004, and 2006, the Act underwent some amendments which refer to the matriculation exams and to the ways for receiving secondary education.

Professional education and training act (1999)

The Act provides for the functioning of professional training and the implementation of the entire professional training system in Bulgaria. It complies with the European trends in this sphere even though many of them are difficult for implementation under the Bulgarian economic and financial conditions. This necessitated a number of amendments in the course of its passing. The most significant aspects of the law are:

1. introduction of four stages of professional qualification;
2. introduction of six programs (categories) for professional training;
3. establishment of state educational requirements for professional education and training; and
4. establishment of new structures for management and financing of the professional training system.

Higher Education**The higher education act (1995)**

After the political, economic, and social changes, which were implemented in Bulgaria in 1989, the higher education is regulated by the Academic Autonomy of the Higher Education Institutions Act, which was passed as early as 1990, whereby higher education institutions were granted academic freedom with reference to tuition, structure, and organization of the study process as well as with reference to scientific and research activity.

After the passing of this Act, there were a number of amendments and supplementations, referring to both the structure and organization of the study process and to financing, academic autonomy, professors, and regulation of the functions of the state in the management of the higher education institutions.

The key aspects of the Higher Education Act are as follows:

- Higher education shall be received at higher education institutions which have been accredited by the National Agency for Evaluation and Accreditation, as well as established under the terms and conditions of the Act.
- The higher education institutions are both state owned and private.
- Higher education institutions shall be universities, the specialized higher education institutions and the independent colleges, which award only a bachelor's degree.

Unlike the Public Education Act which also includes rules for application and which refers to all schools in the Republic of Bulgaria, there are no unified rules in the sphere of higher education and each higher education institution develops its own rules which comply with the requirements under the Act.

After the accession of Bulgaria to the EU, there were a number of legislative changes with a view to harmonize the

higher educational system, the focus being on student and professor mobility, introduction of a system for transferring credits, and an European diploma attachment being added to the diploma on completion of an educational qualification.

Academic degrees and titles act (1972)

The Academic Degrees and Titles Act was passed in 1972 and a number of amendments and supplements thereto were passed, particularly after 1990 – 1992, 1995, 1996, and 2000. This Act regulates the procedure for awarding academic degrees and titles, which is unified and applies to all who wish to obtain them.

The academic degrees in Bulgaria are two:

- educational and academic degree PhD and
- academic degree – DSc.

The academic titles are: assistant, senior assistant, chief assistant, associate professor, and full professor.

The academic degrees PhD and DSc, as well as the academic degrees associate professor and professor are awarded by special academic councils and approved by academic commissions. The final say is of the Supreme Attestation Commission, which is appointed by the Prime Minister. Thus, the academic degrees and titles have state value.

This makes the procedures hard and slow – it takes about a year, which hinders the academic growth of the specialists considerably. In recent years, there have been proposals for amendment of this Act but up till now (2008) these have not been implemented.

Promotion of scientific research act (2003)

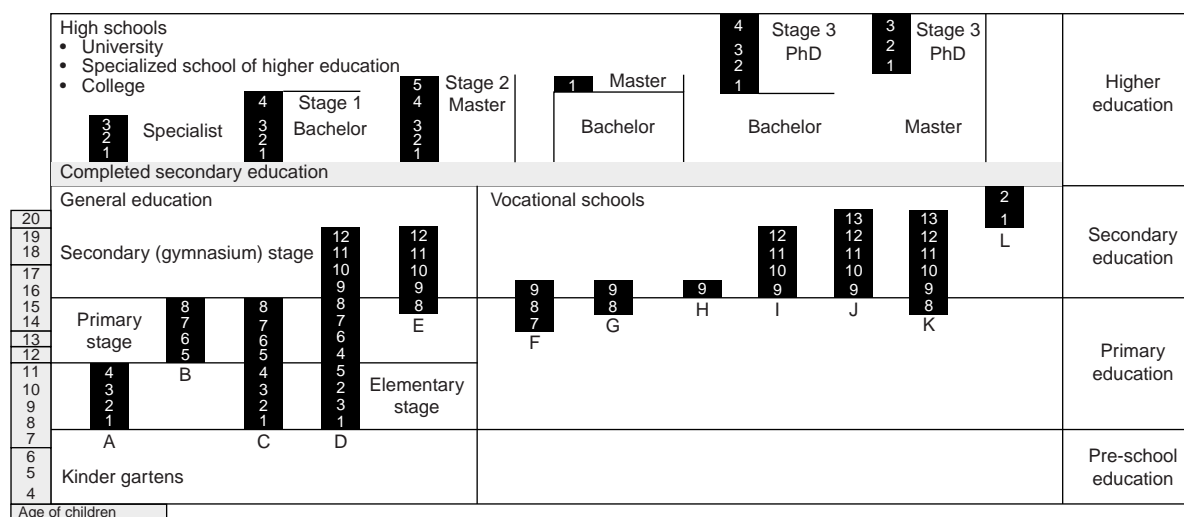

Currently, this Act has more of a theoretical scope rather than a specific practical value. It regulates the principles and mechanisms for the state policy for promotion of scientific research. There is an underlying national strategy for stimulation of the scientific research in the Act, in view of its significance for the economy, the social processes, and the human resources.

Structure of the Educational System

The educational system in Bulgaria includes the following degrees (see **Figure 1**).

Preschool Education

It is designated for children between the ages of 3 and 7 and it is implemented in kindergartens, which may be municipal and private. After amendments in the Public Education Act (2002) CP for children was introduced 1 year prior to starting first grade.

- A – Elementary (basic) school
 - B – Junior school
 - C – Primary school
 - D – Secondary school (general education)
 - E – Specialized secondary school
 - F,G,H,I – Vocational training school
 - J,K – Vocational secondary school
 - L – Vocational college
- 1 - 13 - Grades
1 - 5 - Duration of the education (years)

Figure 1 Structure of the educational system in Bulgaria.

School Education

In the Republic of Bulgaria, school education is compulsory until the age of 16.

According to the degree of education, the school education includes:

1. Primary education – with duration of 8 years (grades 1–8), which is subdivided into two stages:
 - elementary stage of the primary education (elementary education) – (grades 1–4), and
 - junior high school stage of the primary education (junior high school education) – (grades 5–8).
2. Secondary education – with duration of 4 or 5 years (grades 9–12), which is implemented into just one stage – high school. The profile (language, mathematics and sciences, and mathematics) and the professional high schools admit pupils after grade 7 (grades 7–12).

According to the contents of the preparation which are received in the two stages, the schools are:

- a. general educational schools;
 - elementary school (grades 1–4),
 - junior high school (grades 5–8),
 - primary school (grades 1–8),
 - high school (grades 9–12),
 - profile high school (grades 8–12),
 - secondary general education school (grades 1–12), and
 - secondary general education school (grades 5–12).
- b. Vocational schools;

- vocational high school (grades 7/8/9–12/12/13),
 - vocational trainings school (grades 9–12),
 - vocational college – 2 years after completion of secondary education.
- c. sports schools (grades 5/7–12);
 - d. art schools (grades 5/7–12);
 - e. special schools – for children with special educational needs – (grades 1–8/12); and
 - f. culture schools – two national schools (grades 8–12).

School education may be obtained in private schools as well, which have the same structure as the state and municipal schools.

There are also theological schools which are opened by the respective religious institutions in the country. Education there is implemented after completion of primary education and it may be equated to secular education if the state requirements for the respective stage have been observed.

Higher Education

Higher education is implemented at:

1. Universities – having the following degrees:
 - bachelor – 4 years,
 - master – 1–2 years, and
 - PhD – 3–4 years.
2. Special higher education institutions – having the same degrees.
3. Independent colleges:
 - specialist – 3 years, and
 - bachelor – 4 years

Education and Qualification of the Teachers

The education of teachers in Bulgaria is implemented according to the regulation for unified state requirements for acquisition of professional qualification as teacher (1997). According to this regulation the professional qualification teacher is obtained in higher education institutions which comply with the requirements of the Higher Education Act. This may be implemented simultaneously with the preparation for acquisition of the respective education qualification degree, as well as after graduation. The training includes a unified educational minimum for theoretical and practical preparation during full-time studies and 40% of it during part-time studies. The theoretical preparation is implemented by obligatory, optional, and elective study subjects. The minimum number of obligatory study disciplines and the minimum number of their classes are:

1. pedagogy (theory of bringing-up and didactics) – 60 h;
2. psychology (general, age, and pedagogical) – 45 h;
3. audio-visual and information technologies in tuition – 15 h; and
4. teaching methods – 60 h.

The optional study disciplines with the number of hours not less than 15 h for each one is distributed depending on the nature of the major into two groups, where the students obligatorily choose one or two study disciplines out of each of the stated groups:

- first group – pedagogical, psychological, and methodological; and
- second group – interdisciplinary and applied experimental disciplines, related to the professional pedagogical realization of the teachers.

The practical preparation is implemented under the following forms of training with a minimum number of hours as follows:

1. lesson observation – 30 h;
2. continuous pedagogical practice – 45 h; and
3. pre-graduation pedagogical practice – 75 h.

The training for obtaining a professional qualification as teacher ends with an integrated practical-applied state exam, comprising delivering and defending a lesson prepared by the student. The state exam is passed before a state-exam panel whose members are appointed by order of the head of the higher education institution.

The conditions for improvement of the qualification of the pedagogical professionals in the system of the public education and the order to obtain pedagogical professional qualification degrees is regulated by Order No. 5 (1997 and supplemented in 1999). The training for

improvement of the qualification of the pedagogical professionals is implemented within the structure of the higher education by Bulgarian higher education institutions, established under order, stipulated by the Higher Education Act and by the Information and Teacher Qualification Improvement Departments with the higher education institutions. In 2008 they were three in number.

Main forms of improvement of qualification are:

- a complex course – duration of attendance at least 3 weeks with a training program comprising current problems according to the functions of the position of the people trained;
- a thematic course – duration of up to 2 weeks with a training program comprising theoretical and practical preparation on a specific professional pedagogical issue;
- an instructive course – duration up to 1 week with a training program comprising the preparation of new study content, specific professional functions, etc.;
- professional pedagogical specialization;
- specialization in a specific scientific field;
- training for acquisition and improvement of professional pedagogical skills; and
- seminar, practice, problem group, conference, etc.

The improvement of the qualification is implemented at three levels:

- school – the head of the school or kindergarten organizes or coordinates it;
- regional – by the regional inspectorates of the Ministry of Education and Science (MES); and
- national – by the MES.

Depending on the level of their professional competence during their professional realization, the pedagogical professionals may obtain the following professional qualification degrees, which are awarded by the specialized institutes for improvement of qualification of the teachers with the universities in Sofia, Varna, and Stara Zagora:

1. fifth professional qualification degree – teachers should have at least four subsequent years of pedagogical experience and pass an oral exam according to a questionnaire with at least 4.50;
2. fourth professional qualification degree – teachers should have at least fifth professional qualification degree and should pass a written exam with at least 4.50 on an issue of the specific professional field of the candidate;
3. third professional qualification degree – teachers should have fourth professional qualification degree and should complete 1-year professional pedagogical specialization with an average score of at least 4.50;
4. second professional qualification degree – teachers should have third professional qualification degree and they should defend a written paper with at least

- 4.50, related to analysis of the results of a diagnostic procedure applied by the candidates; and
5. first professional qualification degree – teachers should have second professional qualification degree and they should defend successfully a written paper of research and innovative nature, related to the pedagogical practice of the candidate.

Management of the Educational System

Management of Public Education

The management in preschool education is implemented at four levels: national, regional, municipal, and internal.

The management in school education is implemented at three levels: national, regional, and internal.

The activities at the specified levels are implemented by different institutions, as follows:

1. *National level – the MES.*

The MES forms the national policy and coordinates the overall work for the functioning and development of the educational system by developing strategies, priorities and programs, state educational standards, and programs for qualification and specialization of the pedagogical professionals; it proposes, prepares, and confirms agreements for international cooperation. The stated activities are implemented by different departments which report to the minister of science and education.

2. *Regional level – regional education inspectorate (REI).*

The REIs are 28 in number and correspond to the administrative division of the country. The REIs are managed by heads who take the position after they win a competition and the operational activities are implemented by experts, where all of them have the status of civil servants. The structure of the REI is separated into general administration with administrative legal, financial and economic, and information services departments, and specialized administration, which makes inspections and performs organizational methodological activity.

3. *Municipal level – education department with the municipal administration.*

The activity of the education department comprises securing the obligatory school education, maintenance of the necessary equipment of the schools and kindergartens, providing funds for support, repairs, furnishing, facilities for recreation, canteen feeding, sports facilities, boarding houses, and transport for pupils and teachers.

4. *Internal level – headteacher and pedagogical council.*

The headteachers of the state and municipal kindergartens and schools are appointed after a competition, organized by the MES and by the regional inspectorate

respectively. The headteacher organizes, manages, and takes charge of the entire activity of the school or the kindergarten. He or she disposes budget and nonbudget funds on the principle of delegated budgets. The headteacher appoints the entire school staff and controls its activity, organizes the admission of children and pupils, keeps and maintains all school records, and represents the school before organizations and persons.

The pedagogical council is a special collective body for management of the kindergarten or school, which is convened by the headteacher at least once in 2 months. The pedagogical council accepts the strategy for the development of the educational institution, frames rules for the activity of the school and ensures their implementation, discusses and takes decisions about the education results.

The school board is an independent volunteer association for assistance in the development and the material support of the kindergarten or school. It is established by the initiative of the headteacher, the parents, teachers, and public figures.

Management of the Higher Education Institution

Higher education institutions are managed on two levels – national and internal.

1. *National level – the National Assembly, the Council of Ministers, the Ministry of Education and Science and the National Evaluation and Accreditation Agency.*

The National Assembly pursuant to decision, opens, restructures, renames, and closes the higher education institutions and determines the state budget subsidy for each higher education institution annually.

The Council of Ministers has broader functions related to opening, restructuring, and closing faculties, institutes, branches, and colleges in the state higher education institutions; it affirms the classification of the higher education spheres and the professional streams; the state requirements for educational qualification degrees; the number of students and postgraduates admitted annually; the list of the regulated professions, etc.

The MES is the state body for implementation of the national policy in the field of higher education; it maintains a register of the higher education institutions, organizes the acknowledgment and legalization of the diplomas of the people who have graduated abroad, and exercises control over the higher education institutions for compliance with the Higher Education Act.

2. *Internal management – management authorities of the higher education institutions are the general meeting, the academic council and the rector.*

The general meeting of higher education institutions is held once in 4 years during which it elects the rector,

the academic council, a chairperson, a deputy chairperson, and members of the control council by secret vote; it also accepts and amends the rules for the activities of the higher education institutions, as well as the annual report of the rector.

The academic council consists of 25–45 members and includes representatives of the academic staff, students, postgraduate students, and employees on a quota principle. It is within the powers of the academic council to elect the deputy rectors, to take decisions for opening, closing, and restructuring of chairs and departments, to approve the study curricula for the individual majors, to approve and control the implementation of the budget of the higher education institution, to approve a system for evaluation and maintenance of the quality of education and the quality of the academic staff.

The rector is elected for a 4-year term and represents the higher education institution; he or she enters into or terminates the employment agreements on all levels, takes final decisions on matters with reference to admission, deregistration, and movement of students, postgraduate students and specializing postgraduate students, and prepares reports about the activity of the higher education institution.

Financing of the Educational System

Financing of the Public Education System

The financing of the state and municipal kindergartens and schools is provided by the state budget, by the municipal budget, by sources under other laws and acts of the council of ministers, and by private sources. The financing is implemented in a manner provided for under the Public Education Act and the amendments and supplements thereto, as follows:

- The MES in coordination with the Ministry of Finance sets the annual subsidy for each child or pupil in the state and municipal kindergartens and schools.
- After approval of the funds in the state budget by the National Assembly and after approval of the municipal budgets, the MES relocates budget funds for investments, scientific research subsidizing, and for qualification of the teachers.
- The funds for support and salaries are stipulated separately in the municipal budgets and the MES budget. These funds are provided to the state and municipal kindergartens and schools and on the basis thereof the headteachers form their budgets.
- The MES controls the spending of funds for support and salaries both for state and municipal schools.
- The mayors control the manner for spending the funds provided to the municipal kindergartens and schools.
- The municipal budgets, including the one for education, are formed from state-budget proceeds and from their own proceeds from local charges and taxes. Therefore, the more their own proceeds they obtain, the fewer subsidies from the budget.
- The kindergartens and the schools are entitled to provide their own funds from rents, fees, donations, inheritances, produce realization, qualification and creative activity, and educational and other services.
- The ministries and the municipalities may not reduce the subsidy at the expense of the private proceeds, gathered from the abovementioned sources and activities.
- The construction, maintenance, repairs, reconstruction, and modernization of the material and technical equipment of the kindergartens and the schools are implemented with funds from the state budget or from that of the municipalities or with funds from other sources.

The delegated budgets were introduced in January 2007, which may provide greater effectiveness in the utilization of the funds, as well as differentiated payment for teachers. The principle that money follows the pupil was introduced and this applies to private schools as well.

Financing of the Higher Education System

The state higher education institutions are financed by the state budget on an annual subsidy, through financial aid from the municipalities, from donations, wills, sponsorships, inheritances, and with their own proceeds from different activities – research and scientific, arts and creative activity, healing and sports activity, and from proceeds from application and tuition fees, postgraduate qualification, administrative services, etc.

Under the Higher Education Act, financing is implemented according to the following principles:

- The state subsidy provides funds for: tuition support, scientific or creative activity, publishing study and scientific works, accommodation expenses, and for capital investments.
- The tuition support is estimated on the basis of: differentiated norms into professional streams for a single student, number of students and postgraduate students, and the results from the accreditation of the higher education institution.
- The funds for scientific studies are stipulated by norms for the tuition support.
- The council of ministers stipulates the rates for the remuneration of the people working in the higher education institution.
- The students and postgraduate students are entitled to apply for grants from the state budget.
- The students, the postgraduate students, and the specializing postgraduate students pay tuition fees, which are stipulated annually by the council of ministers.

Control and Assessment of the Educational System

School Education

In 2003, the MES published an order which determines the state educational requirement for the assessment system. Under this normative document, the assessment is done at these junctures: in the process of school education; upon completion of secondary education; upon completion of professional education; and upon completion of professional training. The assessment is both internal and external. In internal assessment, the teacher is the assessor, and in external assessment the assessors may be: the school panel, appointed by the headteacher of the school; officers or commissions, appointed by the minister of education and science, the head of the REI, or by the directors of the control and assessment units servicing the public education.

In 2005, the center for control and assessment of the quality of school education was established by the MES. It is in charge of the development of national tests, and currently there are such tests for grades 4, 5, 7, and 12. Some of them are the basis for a future external assessment at the end of the study stages – those for grades 4, 7, and 12. There is an ongoing process of standardization of school-education assessment and when the methodology of the tests becomes clear, there will be a system for independent assessment of the knowledge and skills of the students from the entire year at the end of each educational stage. Then the tests will be done by a real structure with nationwide coverage, which is external both to the ministry and the educational network; however, this has not been implemented yet. This year (2008) the tests for grade 5 were approved, next year there will be such a test for grade 6, and may be for some of the junior high school grades, and this should be the skeletal framework for the future annual internal assessment based on national criteria. This should remain a task of the school and its purpose it to standardize the outgoing assessment at the end of the year, which the school is obliged to do now as well.

Higher Education

A special state authority for assessment and accreditation of the quality of the activities of the higher education institutions is the National Agency for Assessment and Accreditation with the council of ministers. Its activities are related to:

- approval of criteria for assessment and accreditation in compliance with the state requirements;
- approval of procedures for assessment and accreditation and the documentation related to them;
- evaluation of projects for opening and restructuring of higher education institutions, basic units, branches, professional streams, and majors;

- approval of criteria and procedures for post-accreditation observation of the higher education institutions, the basic units, branches, professional streams, and majors;
- evaluation of the activity and the quality of the education in the higher education institutions on the basis of which accreditation is awarded or refused; and
- setup and maintenance of an informational system with data about the accredited higher education institutions, basic units, branches, professional streams, and majors.

Statistic Data

General Educational System

Tables 1–3 show the number of general educational schools, the number of students in the general educational schools, and the number of teachers in the general educational schools, respectively.

Special schools

Table 4 shows the number of special schools.

Professional educational system

Tables 5 and 6 show the number of professional schools, and the number of students in the professional schools, respectively.

Table 1 Number of general educational schools

General

Education in England is compulsory for all children aged between 5 and 16 years of age. The government provides free education to all children up to the age of 19 via state primary and secondary schools and further-education colleges. Some parents, however, prefer to pay to send their children to private independent schools: these may be residential schools or pupils may live at home and attend on a daily basis. There are around 2300 independent schools in England and around 7% of the pupil population attend independent schools. Furthermore, although most parents educate their children at school, under UK law, parents are allowed to educate their children from home if they choose to do so.

The first 6 years of education are known as primary education and the remaining 5 years as secondary education. Between these ages, the subjects that children study and the way in which they study them are set out by the government according to the National Curriculum.

The National Curriculum has been established to allow all children the opportunity to learn the skills needed throughout their lives. The curriculum consists of the core subjects of English, Maths, and Science together with the foundation subjects of design and technology, information and communication technologies (ICT), history, geography, modern foreign languages, art and design, music, physical education (PE), and citizenship. It is flexible and allows teachers the freedom to set suitable learning challenges for all pupils, taking into account their needs, abilities, and interests.

The responsibility for the education service in England lies with:-

- The Department for Children, Schools and Families (DCSF), which brings together all aspects of policy affecting children and young people. The government's aim is to ensure that every child gets the best possible start in life, receiving the ongoing support and protection that they – and their families – need to allow them to fulfill their potential.
- The Department for Innovation, Universities and Skills (DIUS) which is responsible for investing in science, research, and innovation. It also takes responsibility for ensuring that UK has the skilled workforce it needs to compete in a global economy.

School Governors

All local authority (LA)-maintained schools in England must have a school-governing body. Set up by law as corporate bodies, responsibility lies with the whole governing body rather than individual members. Each school has an Instrument of government which specifies the constitution of its governing body.

Governing bodies are made up of key stakeholders:-

- *Parents.* Parent governors are elected by other parents at the school;
- *Staff, including the headteacher.* Staff, that is, teaching and other staff, governors, that is, members of the community;
- *The LA.* The LA appoints one or more local education authority (LEA) governors; and
- *Foundation governors.* For some schools, the foundation or relevant religious body appoints foundation governors.

The main responsibilities of the governing body are:

- Setting strategic direction, objectives, targets, and policies;
- Reviewing progress against the budget, plans, and targets;
- Approving the school budget;
- Acting as a critical friend to the headteacher by providing support and challenge; and
- Appointing a headteacher.

In practice, the governing body delegates much of the responsibility for the day-to-day management of the school to the headteacher, while retaining its strategic role in developing and monitoring the implementation of policy at the school.

Inspection of Schools and Higher Education Institutions

The Office for Standards in Education (Ofsted) was first set up on 1 September 1992. The new Ofsted, which came into being on 1 April 2007, is a nonministerial government department which brings together four formerly separate inspectorates. Ofsted inspects education and training for learners of all ages. Its main aim is to raise aspirations and

contribute to the long-term achievement of ambitious standards and better life chances for service users.

The Quality Assurance Agency for Higher Education (QAA) was set up in 1997 to provide an integrated quality-assurance service for UK higher education institutions. The agency is an independent body, funded by subscriptions from universities and colleges of HE, and through contracts with higher education funding bodies. Its board of directors comprises 14 members: four are appointed by the representative bodies of the heads of higher education institutions; four are appointed by the funding bodies in HE, and six are independent directors who have wide practical experience of industry, commerce, finance, or the practice of a profession.

Preprimary Education

For children aged 3 months to 3 years, provision is largely in the private and voluntary sectors, and parents pay fees. For children aged 3–5 years, places are in state-maintained nursery schools and classes in primary schools, and in voluntary and private settings.

The government has, in recent years, set targets to expand and develop publicly funded early-years education and childcare in cooperation with the private and voluntary sectors. Free part-time nursery provision is now available for all 3- and 4-year-olds. It is a statutory requirement that children at this stage of education work toward early learning goals, which cover six key curricular areas.

Primary Education

In England and Wales, the primary school normally has 7-year groups and comprises two key stages. Infant schools are for children aged 5–7, junior schools are for those aged between 7 and 11. Some primary schools have a nursery attached for children aged between 3 and 4.

Key stage 1 provides for children aged between 5 and 7 and key stage 2 provides for children aged 7–11. At the end of key stage 1, all pupils have to take classroom-based tests in English and Mathematics. The tests are marked by the class teacher, but set and audited by an outside agency.

At the end of key stage 2 (age 11), pupils take written tests in English, Mathematics, and Science. These tests are set and marked by an external agency which is appointed by the Qualifications and Curriculum Authority. National tests at the end of key stage 2 are not used to assess the ability or aptitude of pupils for the purpose of selection for secondary schools. Selective secondary schools (which exist in some areas of England only, and are commonly

known as grammar schools), set their own tests for this purpose, and these are usually administered earlier in the school year than the key stage 2 tests.

Secondary Education

Most secondary schools, which are maintained schools, are mainly nonselective and accept pupils regardless of their ability. These are known as comprehensive schools. Parents have an element of choice in choosing a secondary school and it is not uncommon, especially in towns and cities, for students to travel some distance to a school of their choice.

There has been a recent drive to designate comprehensive schools as specializing in particular areas, for example, technology, modern foreign languages, performing arts, physical education, or sport, etc. The government achieved its target to increase the number of specialist schools to 2000 by the year 2006, over a year early. The current target for the program is that 95% of all schools will be specialist by 2008.

The School Standards and Framework Act 1998 allows the admissions authority for a school with a specialism in certain prescribed subjects to give priority to up to 10% of pupils on the basis of aptitude in those subjects. This does not apply only to schools in the specialist schools program; any admissions authority may decide to give priority in this way.

There are still some schools which select all their pupils by ability; these are grammar schools.

In England, the first 3 years of secondary education, catering to pupils aged 11–14 years, are known as key stage 3 and the remaining 2 years of compulsory education, for pupils aged 14–16, as key stage 4.

Pupils are organized into year groups with a senior teacher as head of year.

Depending on the policy of the school, within the year group, pupils may be divided into classes or tutor groups with a designated teacher who has organizational and pastoral-care responsibilities. Tutor groups in some schools may include pupils from different year groups. The organization of teaching groups is also determined by the school. In secondary schools, teachers usually teach one or more specialist subjects.

Pupils may be grouped by their general ability (a practice known as streaming), taught in mixed-ability groups or, more commonly, grouped according to their ability in a particular subject (a practice known as setting). Most schools use setting for some subjects only, such as mathematics and languages, and teach other subjects in mixed-ability groups. Other schools use a combination of these teaching groups/methods. Pupils are placed in a class according to their age.

The first formal academic qualifications, which are taken by school children, are the General Certificate of Secondary Education (GCSE). Generally, these are taken by students at the end of their final year. Students are taught on average eight GCSE subjects comprising a mix of compulsory subjects, plus others which they have chosen to study. GCSEs are available in more than 40 subjects in total, including humanities (such as English literature and history), sciences (including biology and physics), social sciences (including health and social care and economics), technology (including ICT and engineering), creative subjects (including art and music), and many modern and ancient languages. GCSEs are awarded in a series of grades from A* the highest to G the lowest.

The National Curriculum and its key stages do not apply to pupils in postcompulsory schooling. The final 2 years of (postcompulsory) full-time secondary education for those aged 16–18+ (in years 12 and 13 of school education) are usually known as the sixth form. Pupils are taught by specialist subject teachers, normally in smaller groups than younger pupils. There are no regulations covering class sizes.

14–19 Education and Skills Reform

The White Paper 14–19 Education and Skills outlined plans to meet the government's ambition to ensure that post-16 participation rates rise from the current 76% to 90% by 2015. These reforms will give all young people the opportunity to choose a mix of learning which motivates, interests, and challenges them, and which gives them the knowledge, skills, and attitude they need to succeed in education, work, and life. The aim is to develop an education system where all young people have the opportunities to learn in ways that motivate and stretch them – a system where, through their own hard work and that of their teachers and tutors, young people are able to qualify themselves for success in life.

As part of its proposals to improve secondary, further, and HE, the government is introducing 14 specialized diplomas covering all sectors of the economy. From 2008, the first five diplomas will be ready for teaching.

Private Education

In general, private education is that which is provided in institutions which are largely privately funded, receiving most of their income from tuition fees, usually paid by parents. In some cases, private schools also receive some funding from donations and grants received from benefactors.

Six hundred and fifteen thousand children attend some 2500 independent schools in the United Kingdom. In

England, this represents about 7% of the school age population; it is lower in Wales.

Over 80% of these children are in 1283 schools regulated by membership of an association represented by the Independent Schools Council (ISC).

At present, under transitional arrangements, some existing pupils may have part or all of their fees (depending on parental income) paid by the government through the Assisted Places Scheme. This scheme was originally set up in 1981 under the provisions of the Education Act 1980, but was brought to an end by the Education (Schools) Act 1997.

The Music and Ballet Scheme (MBS) was also set up in 1981, to provide government grant aid with fees at seven independent specialist schools in England for children with exceptional talent in either music or dance. In 2002, the scheme was renamed the Music and Dance Scheme and another school added. The Aided Pupil Scheme, which operates within the scheme, is similar to the Assisted Places Scheme, but it also provides additional funds to cover the costs of specialist tuition and boarding fees. The grant is means tested. There are over 800 children participating in the scheme, which remains unaffected by the Education (Schools) Act 1997.

There is private provision at all levels of education. Private schools are often known as independent schools. Some long-established secondary private schools are known as public schools. Apart from city technology colleges and academies, independent schools receive no public funds (except for the financial advantages, e.g., tax relief, conferred by their charitable status). They are financed through fees, donations, and endowments.

Sixth Forms and Sixth-Form Colleges

The legal school-leaving age is 16, although many schools have provision for their pupils to stay on until they are 18. In these cases, students will most usually take 2-year courses of AS- and A-level.

A-levels are awarded at five grades, from A (the highest) to E (the lowest), and each A-level scores between 40 and 120 points on the Universities and Colleges Admissions Service (UCAS) tariff. The UCAS is the single clearinghouse for applications for admission to full-time first degree, foundation degree, and first-diploma courses at universities and other higher education institutions in the United Kingdom. A new UCAS tariff has been developed to provide a point-score system for expressing entry requirements to higher education. The new system was introduced in 2002 as the first cohort of applicants with the new post-16 qualifications (introduced in September 2000; see 5.17.2. and 7.14.) entered HE. It makes provision for a wide range of qualifications, including Scottish qualifications and the new Welsh Baccalaureate. However, use of the tariff is not obligatory.

A student who scores three grade As or more has an unlimited choice of where he/she can progress after their A-levels. The lower the score, the more limited the choice. Realistically, a student will find it difficult to be accepted for a degree course with a UCAS score of less than 180 points (equivalent to three A levels at lower grades or two at medium grades). The average score achieved by students on degree courses is around 240 points.

GCE A-level and GCE AS qualification passes are graded on a scale of A to E. The grade U denotes a fail. Pupils have a right of appeal if they are not satisfied with the grade they receive. Appeals (from the pupil's school or examination center) must be addressed in the first instance to the appropriate awarding body. Grades can be lowered, raised, or confirmed as a result of an appeal. The Examinations and Appeals Board (EAB) hears appeals which have failed to be resolved by an awarding body's own procedures.

Pupils can have access to their marked examination papers, on request. Requests can be made by schools, colleges, or examination centers or by students via their school, college, or examination center. A charge is made for this service. About 75% of UK students remain in full-time education beyond the age of 16.

Further Education

After the age of 16, students are free to remain in full-time education, to leave education and enter the workplace, or to undertake a mixture of part-time education and part-time work. Education undertaken at this stage is known as further education. It includes courses that expand on the knowledge learned at school, and courses that offer a second chance or new direction to students who have not obtained the results needed to progress to the next level (generally those who did not achieve five GCSEs at grades A* to C or equivalent). Courses may be 1 or 2 years long.

The 75% of 16-year-olds who choose to enter full-time further education undertake their studies either in the sixth-form college or at a college of further education. They choose from a wide range of education and training opportunities and, from this stage onward, most will specialize in a general direction, such as science, arts, or humanities, or train for a specific career or industry sector such as health and social care, engineering, or tourism. Education falls into two broad categories, academic and vocational.

Higher Education

After successfully completing further-education qualifications, many students progress to HE. Students usually need to be at least 18 years of age to begin a higher education course. HE includes academic courses, such

as diplomas of HE (Dip HE), bachelor's degrees, and, at the postgraduate level, master's degrees, masters of business administration (MBAs), and PhDs. Vocational higher education is covered by Higher National Certificates (HNCs) and Diplomas (HNDs) and Foundation Degrees, which are offered by HE colleges and universities, and some further-education colleges.

Students who opt for HE will usually begin their course at the age of 18 or 19. Courses can be anything from 1 to 4 years long and students may choose to stay on as postgraduates into their 20s. Adult education is increasing in popularity and many colleges and universities now have a growing number of mature students who are aged over 21. They have usually worked for a few years and now want to improve their career prospects.

Most students progress smoothly from compulsory school education to further education to HE. A government commitment in the White Paper *The Future of HE* was to increase participation in HE toward 50% of those aged 18–30 by 2010. Alongside this, the government wants to widen participation so that more people from nontraditional backgrounds have the opportunity to participate in HE. They are doing this through a number of initiatives focusing on raising the aspirations and attainment levels among groups currently underrepresented in HE; by improving the financial packages available to students and by improving progression routes into HE.

We are doing this through a number of initiatives focusing on raising the aspiration and attainment levels among groups currently underrepresented in HE; by improving the financial packages available to students and by improving progression routes into HE. Entry requirements for degree courses vary, depending on the reputation of the institution and the popularity of the course. Approximately, 180 UCAS points from A levels or the equivalent is the minimum acceptable for a course.

Bachelor's Degrees

Honors degrees form the largest group of HE qualifications. Typical courses last for 3 years (if taken full-time) and lead to a bachelor's degree with honors, having a title such as bachelor of arts (BA(Hons)) or Bachelor of Science (BSc(Hons)). Moreover, at this level are short courses and professional conversion courses, based largely on undergraduate material, and taken usually by those who are already graduates in another discipline, leading to graduate certificates or graduate diplomas.

Honors degrees are normally classified into first, second, and third class. Second-class degrees are further divided into two divisions, upper and lower, also known as 2i and 2ii. Students who do not achieve a high enough standard for an honors degree may be awarded a pass (or ordinary) degree.

Master's Degrees

Master's degrees are awarded after the completion of taught courses or programs of research, or a combination of both. Longer, research-based programs often lead to the degree of MPhil. Most master's courses last at least 1 year (if taken full time), and are taken by persons with honors degrees (or equivalent). Some master's degrees – in science and engineering – are awarded after extended undergraduate programs that last, typically, a year longer than honors degree programs. At this level, there are also advanced short courses, often forming parts of continuing professional development programs, leading to postgraduate certificates and postgraduate diplomas.

Doctorate Level

Doctorates are awarded for the creation and interpretation of knowledge, which extends the forefront of a discipline, usually through original research. The titles PhD and DPhil are commonly used for doctorates awarded on the basis of original research. Doctoral programs that may include a research component, but which have a substantial taught element, lead usually to awards that include the name of the discipline in their title (e.g., EdD for doctor of education). A doctorate normally requires the equivalent of 3 years full-time study.

Professional Qualifications

Some institutions offer professionally accredited courses in subjects such as engineering, accountancy, teacher training, librarianship/information science, and medical studies. The Chartered Institute of Library and Information Professionals (CILIP), for example, is a professional body which accredits degree courses in librarianship and information science offered by universities.

Qualifications specific to a profession and required for its practice, which may be taken at a university or after initial studies at a university are completed, are more often obtained through the successful completion of examinations set or accredited by professional bodies such as the Chartered Institute of Public Finance and Accountancy and the Inns of Court School of Law.

Finance

Undergraduate students apply for financial support to their LA, or Education and Library Board in Northern Ireland, which then carries out an income assessment. A notice is sent to the student advising how much support will be available in terms of grants and loans, and how much, if anything, the student or his/her family are expected to contribute. Some funds are administered by individual institutions.

Loans

Students entering HE can apply for an income-contingent loan which is repayable through the tax system through their LA. Loans are available to full-time students up to the age of 54. Part-time higher education students on low incomes become entitled to avail of student loans to manage the costs of their course.

Seventy-five percent of the maximum loan is available to all eligible students regardless of any other income they have. The remaining 25% depends on the student's income and that of his/her family. This is assessed by the student's LA.

The government's policy is that loans should be available to students on favorable conditions, which require borrowers to repay, in real terms, broadly the same amount as that borrowed. Thus, interest rates are indexed to inflation rates and adjusted each year in line with the retail price index. Students make payments at the rate of 9% of their income above a certain threshold.

Teacher Training

In England and Wales, teachers employed in maintained schools, including nursery schools, must have qualified teacher status (QTS) or be otherwise licensed or authorized to teach by the Secretary of State for Education and Skills, the Training and Development Agency for Schools, or the National Assembly for Wales.

Teachers of classes of pupils with hearing or visual impairments must, in addition, obtain a recognized specialist qualification within 3 years of appointment.

Persons training to teach in the postcompulsory education sector can work in further education, tertiary colleges, or sixth-form colleges. The sector also includes agricultural and horticultural colleges, and there are also opportunities to work in adult and community education and in private training organizations. Maintained schools may also have postcompulsory age students (16+) in sixth-form classes; regulations concerning teacher training and qualifications for those teaching in these schools are covered by those for the school sector.

HE institutions are autonomous corporations. Each determines its own requirements concerning staff and there is no single legislative provision in this area. Increasingly, institutions provide training for their teaching staff, especially those who are new to the profession. The admission requirements for teaching staff, curriculum content, and method, and the evaluation and certification of any professional development offered to staff, vary from one institution to another. However, national professional standards for teaching in HE are currently under development.

Estonia

M Keränen and J Kõrgesaar, Ministry of Education and Research, Tartu, Estonia

General Information

The Republic of Estonia is located in northern Europe. Estonia is the northernmost of the three Baltic countries, situated on the eastern shore of the Baltic Sea and is bordered by the Gulf of Finland in the north, Russia in the east, and Latvia in the south. The official language in Estonia is Estonian which is closely related to Finnish. Along with Finnish, English, Russian, and German are also widely spoken and understood. Estonia has a population of 1 342 000 inhabitants spread over 45 000 km² making it quite a sparsely populated country in Europe. The capital of Estonia is Tallinn. Estonia is a member state of the European Union (EU) and the North Atlantic Treaty Organization (NATO).

The Estonian education system started with cathedral and monastery schools established in the thirteenth and fourteenth centuries. In 1583, the first Estonian Gymnasium was opened for a short period in Tartu by the Jesuits, followed by the gymnasiums established by King Gustavus II Adolphus of Sweden in 1630 in Tartu, and in 1631 in Tallinn. Tartu University, the first university of Estonia was founded in 1632. The Lutheran Church had an impact on Estonian culture and education from the sixteenth century onward, competing with pietist movement since the late eighteenth and, with the impact of freemasonry, in the beginning of the nineteenth century. The first peasants' schools were established in the seventeenth century, along with the 2-year college for training native teachers for peasants' schools from 1684. According to the 1881 population census, about 90% of Estonians were literate. Since the thirteenth century, Estonia has been dominated by Danes, Germans, Poles, Swedes, and Russians. Estonia was established as a modern nation-state on 24 February 1918. Since then, Estonian has been the dominant language of instruction in schools and universities. Before and after World War II, Estonia was occupied by the Soviet Union. Independence was regained in 1991 and the new constitution came into effect from 1992.

Prior to 1940, 90% of the population was Estonian. Between 1944 and 1998, intensive migration from different areas of the Soviet Union changed the structure of the population. According to population census in 2000, 68.6% of the population are ethnic Estonians (922 000) and 25.6% are ethnic Russians (345 000). This ethnic structure remains reflected in a language-based semidivided education. There are quite a few Russian-language or mixed-language

kindergartens, general education and vocational schools, and higher education institutions functioning in Russian-dominated or mixed-population areas along with prevailing Estonian-language and some English- or Finnish-language schools.

In a geopolitical sense, Estonia's change from Russia's west into Europe's east was formally adopted with the turn of millennium as Estonia became a member state of the EU and the NATO in 2004. Until 2008, Estonia's economic development has been very intensive. Estonian gross domestic product (GDP) per capita was US\$702 in 1992 and US\$20 300 in 2007.

Politics and Goals of the Education System

Estonia has done remarkably well in two major international comparative studies: Trends in International Mathematics and Science Study (TIMSS) 2003 (assessing eighth-grade students) and Programme for International Student Assessment (PISA) 2006 (assessing 15-year-olds).

Between 1940 and 1991, despite adoption of the over-politicized and formally unified Soviet educational structure and curricula, the Estonian educational system was able to maintain instruction in the Estonian language on all levels of education, to develop a relatively widely differentiated secondary education, even to secure 1 additional year of secondary education.

The political renaissance at the end of the 1980s also stimulated Estonians' sense of national identity in educational matters. This was a big moment, since, in Estonia, education has traditionally been highly valued. Estonians connected their hopes with education. A depoliticized form of child-centered humanistic education was highly valued by politicians.

The Republic of Estonia Education Act from 1992 provides legal basis for the formation, functioning, and development of the education system. This act was followed by the laws on adult education (1993), on universities (1995), on vocational education institutions, on private schools, on applied higher education (all three in 1998), and preschool education (1999).

The long-term goal of the Estonian education policy has been to raise the living standard of citizens. Education has a major role in further improving the economic competitiveness of Estonia. By the year 2007, there were policy documents for managing all areas and levels of

education, research, language, and youth. In order to increase the coherence and coordination between the fields, in 2006, the Ministry of Education and Research prepared and approved the development plan *Smart and Active People 2007–10*. The goals of all the relevant strategies have been summarized as follows:

- everyone has equal opportunities for lifelong learning following their abilities and interests;
- the quality of teaching and instruction is high;
- Estonian continues to be developing cultural language, while linguistic diversity is highly valued;
- youth work supports the development of the personality of young people; and
- research and development are of high quality and sustainable.

The Estonian education system expects to be positioned to benefit from international cooperation. Exchanging experience across national borders is a vital condition on decision-making processes. Estonia participates in a large number of international cooperation activities in EU, Organization for Economic Cooperation and Development (OECD), United Nations Educational Scientific and Cultural Organization (UNESCO), Council of Europe, and Nordic Council of Ministers.

The Formal System of Education

There is a 9-year compulsory basic school, which replaced the compulsory secondary school in 1988. There are 3–4-year professional higher education institutions introduced along with universities. There are private, municipal, and public educational institutions. The formal structure of education is shown in **Figure 1**. Education has the following levels: preschool education, basic education (first level of education), secondary education (second level of education), and higher education (third level of education).

Primary, Secondary, and Tertiary Education

Children who turn 7 years of age by first of October of the current year are obligated to attend school. The compulsory schooling obligation applies to children until they acquire basic education or turn 17 years of age. Basic education can be acquired in primary schools (grades 1–6), basic schools (grades 1–9), or predominantly in comprehensive schools with grades 1–12.

Basic school is divided into three stages of study:

- stage I: grades 1–3;
- stage II: grades 4–6; and
- stage III: grades 7–9.

In the 2007–08 academic year, there were 121 405 pupils acquiring basic education. It can be acquired on the basis of three national curricula: the national basic school and upper secondary school curriculum, the simplified national basic school curriculum, and the national curriculum for students with moderate and severe learning disabilities.

There are two main options after the basic school: upper-secondary general school (grades 10–12) and vocational school. The certificate confirming secondary education gives students the right to continue their education either in universities or in other tertiary educational institutions.

Attendance of state schools and general-education schools of local governments is free of charge. There were approximately 155 000 pupils in general-education schools in the 2007–08 academic year, 12 606 of them were in the first grade. There were 589 general-education schools (primary schools, basic schools, secondary schools or upper-secondary schools, and adult upper-secondary schools) in the 2007–08 academic year. The number dropped by 12 when compared to 2006–07. Local governments have established catchment areas for all municipal schools. Schools must admit all children who live in their catchment area obligated to attend school. There are also schools which recruit their students from all over the town area or even all over country. There are only a limited number of seats and so candidates have to pass entrance tests to get into such schools.

The provision of basic education on all levels of education is carried out on the basis of common curricula irrespective of the language of instruction, that is, any language may be the language of instruction. In the upper-secondary school stage, from the year 2011, 60% of the curriculum should be taught in Estonian in Russian-language schools. Any other language may become the language of instruction in the upper-secondary stage of municipal schools and in specified classes of municipal school, by the permission by the Government of the Republic.

Schools elaborate their curricula on the basis of the national curricula.

General and upper secondary education are provided pursuant to the national curriculum which is used by each school as the basis of their own curriculum. There are 35 study weeks in daytime study. One study week must include at least 32 lessons. Pupils in upper-secondary schools can acquire extensive knowledge in certain fields of study within the framework of elective subjects (in arts, science, natural sciences, etc.) or learn a profession taught in vocational schools. At the end of the 3-year study period, pupils take five graduation examinations, of which at least three are state examinations. In the 2007–08 academic year, 33 666 were studying in upper-secondary schools. Approximately 6300 pupils are acquiring basic and general secondary education in the form of evening study and

Age study period

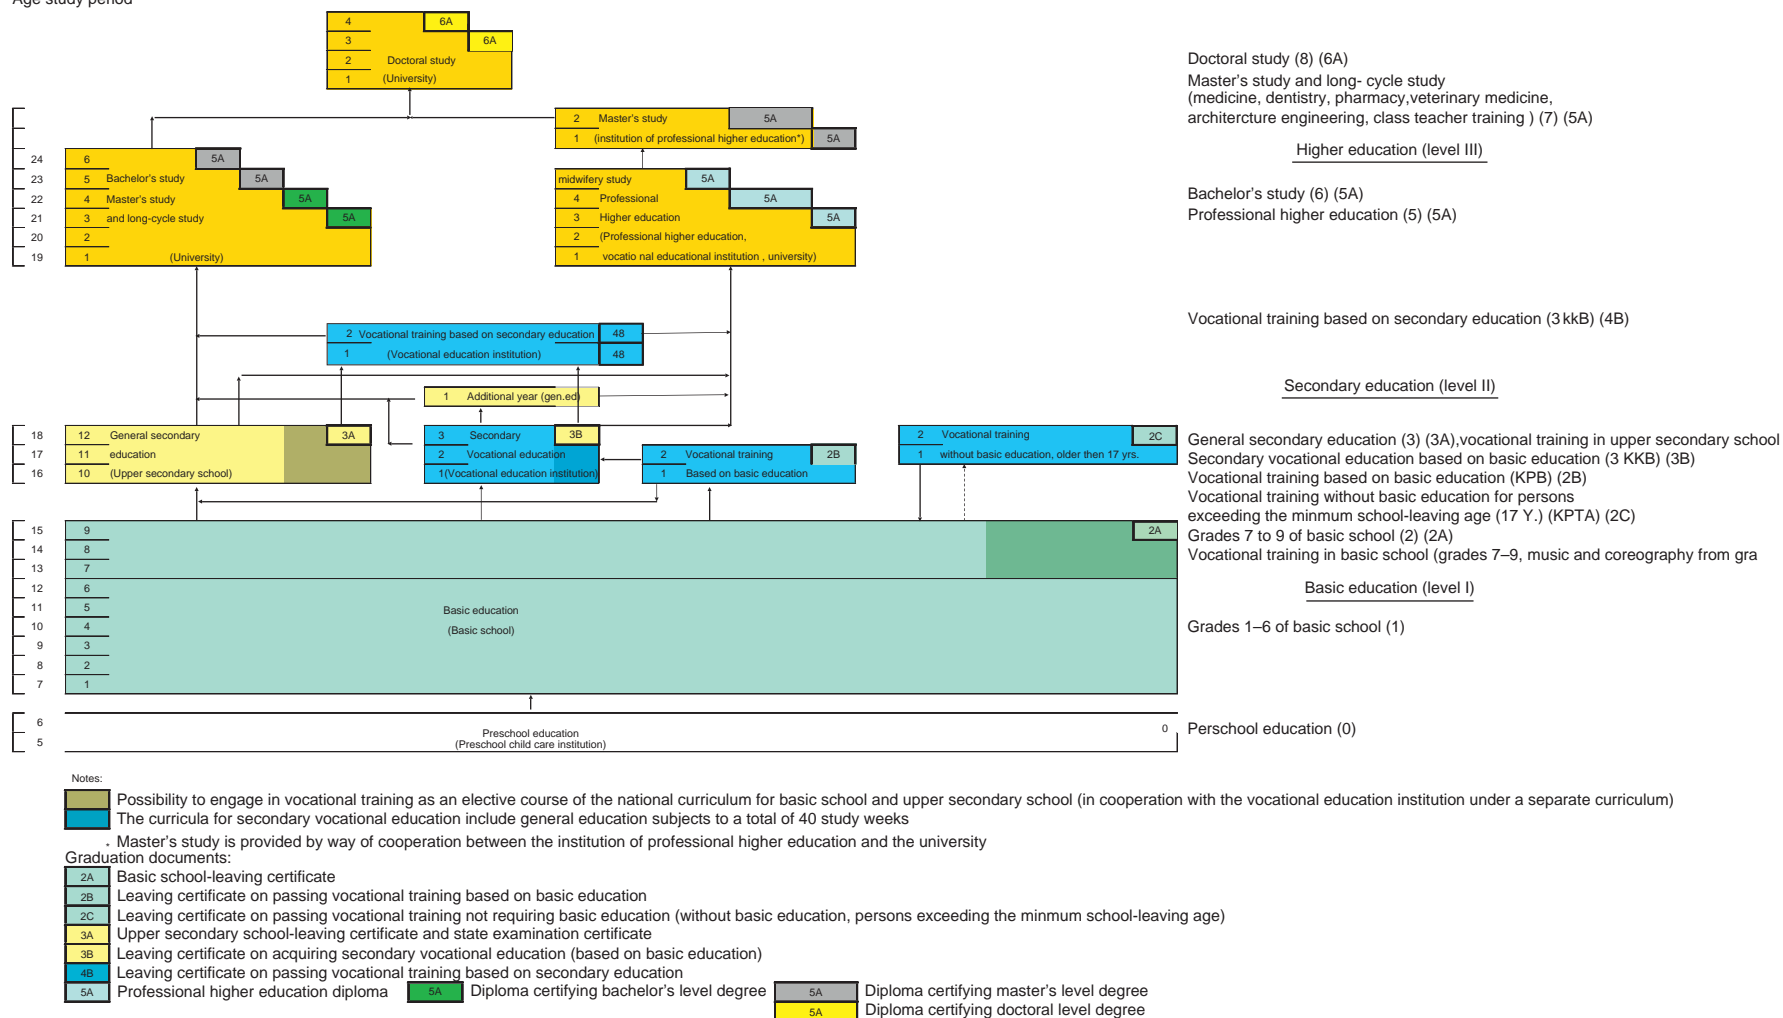

Figure 1 Structure of formal education and graduation documents in Estonia in 2006.

distance learning, and 5000 of them are acquiring general secondary education.

In vocational education, providing specialist knowledge and skills, one can acquire secondary vocational education after graduating from basic school or upper secondary school. There is an option to take up vocational studies without the requirements of basic education, in which case only professional skills are targeted. In the 2007–08 academic year, there were 47 different vocational training institutions enrolling 27 000 students.

Acquisition of general secondary education and secondary vocational education is free, while higher education can be either free of charge or tuition-fee based.

Estonia has a two-tier system of higher education. Universities are institutions of research, development, education, and culture; one of their duties is to offer research-based doctoral studies. Institutions of professional higher education prepare motivated specialists with good professional skills on the first level of higher education, meeting the needs of the labor market. Thirty-four educational institutions offer higher education in Estonia, as of 30 June 2008. There were six universities as legal persons in public law, four private universities, 10 state higher schools, 11 private higher schools. In addition three vocational education institutions provide applied higher education in a limited number of programs.

Students can choose between two types of curricula at the first level of higher education:

- theory-based bachelor-study curricula where professional skills are developed on the basis of theoretical principles; and
- practice-based professional higher education curricula where theoretical knowledge is developed primarily on the basis of practical needs. The curriculum contains at least 30% practical work.

The standard period of bachelor and master's study is at least 5 years and the study load specified in the curriculum is 200 credit points (300 credit European credit transfer system).

At the beginning of academic year 2007–08, 68 168 students were acquiring higher education. The number of students studying according to higher education curricula has increased 2.7 times in the 2007–08 academic year, when compared to 1994–95, when the number of students was 25 483.

Forty-six percent of the students enrolled obtain higher education at state-commissioned and 54% at nonstate-commissioned study places in the academic year 2007–08.

Sixty-two percent of students are women. The fields of study of national priority and with increasing employment are engineering, production and processing, information technology sciences, biosciences and environmental protection (environmental technology), physical natural sciences, and healthcare.

Preschool Education

According to the Education Act and the national curriculum of preschool child-care institutions, preschool education is acquired either in a preschool child-care institution or at home and thus, the acquisition of preschool education is the responsibility of the child's parents or guardians. Parents of children who go to child-care institutions or who stay at home have the right to receive advice about educating and raising their children from the teacher of the child-care institution in their region.

There are four types of preschool child care institutions – day nurseries (for children 1–3 years of age), nursery schools (for children 1–7 years of age), special nursery schools, and nursery primary schools. Most child-care institutions have the first three groups and such institutions are mainly located in rural areas. Child-care institutions with up to 12 groups dominate in cities. Local governments must provide all their resident children between 1 and 7 years of age the opportunity to attend child-care institutions in their catchment areas, if this is requested by the parents. Still, the need for nursery school places is very high in certain regions such as the capital city of Tallinn and its surroundings and university town Tartu.

Rural municipality or city governments provide children with physical, speech, sensory, or mental disabilities, and children who need special assistance or special care, the opportunity to grow and develop in the adaptation groups of the child-care institutions in their places of residence.

Rural municipality or city governments create special groups or establish special nursery schools if it is impossible for local child-care institutions to create an adaptation group. Children are admitted to adaptation or special groups on the basis of a written application of a parent and the decision of the counseling committee.

Preschool child-care institutions or schools have opened preparatory groups for children who do not attend nursery schools, and children can participate in these groups free of cost.

Special Education

Children with special needs have the right to learn in schools of their residence like all other children.

Pupils with special educational needs are pupils whose outstanding talent, learning or behavioral difficulties, health problems, disabilities or long-term absence from studies creates the need to make changes or adaptations in the content of studies, the study processes, or the learning environment (study aids, classrooms, language of communication, including alternative communications, specially trained teachers, support staff, etc.), or in the work plan prepared by the teacher for work with the relevant class.

The task of schools is to involve pupils in the study process and adapt the learning environment in such a manner that every pupil would be able to learn according to their abilities and to develop their abilities to the maximum.

Disabled children or children who need special care have the right to study in the nearest school that complies with requirements if the school of their residence does not have the possibilities and conditions for accommodating children with special needs.

Pupils in Estonian schools can study on the basis of different curricula. A simplified national basic school curriculum, which is used to teach children with slight mental retardation, exists in addition to the national basic school and upper-secondary school curricula. There is also the national curriculum for students with moderate and severe learning disabilities.

Adult and Nonformal Education

Adult education is divided into formal education, work-related training, and popular adult education.

Flexible study opportunities have been created for adult students to participate in formal education: distance learning and evening courses, learning as an external student, or in part-time study. It is possible to acquire basic and secondary education, to study in a vocational educational institution or higher education institution.

Popular adult-education institutions and several other training institutions offer nonformal training. Popular training courses, which primarily focus on the hobbies and interests of people, offer the opportunity to develop one's creativity, talents, and social skills.

There are 7% of learners in lifelong learning among people aged 25–64 in Estonia in 2007 according to the data of the Statistical Office. The goal set by the EU is to achieve a level where at least 12.5% of the working-age population participate in lifelong learning by 2010. Estonia plans to reach 10% by 2008.

Administrative and Supervisory Structure and Operation

The parliament establishes the principles, budget, and general structure of the educational system. The government is responsible for the establishment and maintenance of the state programs of education and regulates the governance of universities and other higher education institutions. The Ministry of Education and Research is responsible for the development and implementation of state educational programs and standards. It also grants licenses to private educational institutions.

Local municipalities establish and finance local municipal educational institutions. Local self-governments form

the structural units to administer preschool, primary, secondary, and vocational educational institutions. Determining of the national curricula for public educational institutions is in the jurisdiction of the government or the Ministry of Education and Research. Each school designs its own curricula on the basis of the national curricula.

Educational Finance

In recent years, 14–15% of the total public expenditure in Estonia has been invested in education each year, and in 2007 this amount was over 11 billion kroons. Expenditures on general education comprise 56% of the total public expenditure on education (in the second-half of the 1990s, expenditure on general education comprised 62–64% of the total public expenditure on education). The share of pupils on the general-education level has also decreased in the same period. The state pays for ongoing teacher training, some reconstruction and building costs, nationwide student fairs, hobby schools, and adult education. Local governments pay for the salaries of preschool teachers. Instruction at school is free. At basic school, the teaching materials are free. Meals are subsidized.

Vocation education expenditures now comprise 12% of total expenditures. Higher education expenditures amounted to 18% in 2007. The number of students has more than doubled when compared to the middle of the 1990s, but this has mainly occurred on account of students studying in nonstate-commissioned student places. Thirteen percent of the public expenditures on education are classified under other education costs – this covers costs that cannot be tied to any concrete level of education, including education projects that combine several levels of education, the expenditures in the areas of language and youth, and preschool education.

Education expenditures comprised approximately 4.7% of GDP in Estonia in 2007.

The EU has been supporting the areas of education, research, and development in Estonia through the European Social Fund (ESF) and the European Regional Development Fund (ERDF) since 2004.

Approximately 1.1 billion kroons of assistance was directed in the area of responsibility of the Ministry of Education and Research from 2002 to 2006. The largest share of the total costs was directed at vocational education.

Supplying Personnel for the Education System

The number of preschool teachers was 7111 in the beginning of 2007. The average age of teachers is 45 and the share of male teachers is 0.4%. The number of teachers who worked in general-education schools in the academic

year 2007–08 was 15 039; 1.073 of these worked in state schools and adult upper-secondary schools. The average age of teachers is slightly over 45. Fourteen percent of all teachers are men; 2214 teachers work in vocational educational institutions; 34% of them are men and 66% are women. The average age of vocational teachers has increased to 47.9 years. Approximately 2500 teachers work in hobby schools.

Teachers' standard of professional competence was approved in 2005. Teacher training is provided in universities and their colleges. The duration of the training program for class and subject teachers is 5 years, and basic school teachers acquire the competence for teaching several subjects within the framework of this training. Initial training of preschool teachers is primarily based on professional higher education and bachelor study curricula.

Since 2004, all teacher-training graduates need to undergo an induction year where they are supported by their colleagues/mentors and where they can also take part in the support program offered by institutions of higher education.

Teachers must also undergo at least 160 h of in-service training in 5 years. Professional in-service teacher training takes place in the form of independent work or in state and municipal institutions, private schools with training licenses, or by legal persons or sole traders governed by private or public law if their activities comply with the taught subject or specialty.

Curriculum Development and Teaching Methodology

Curricula, having been developed during the Soviet occupation, had to follow the general principles of the Soviet school ideology. Despite the strict demand to unify the curricula, Estonia was able to maintain some of its educational traditions. For example, instruction was carried out in the native language and a number of textbooks were written by Estonian authors. These are the potential factors, why the results of Estonian students in 2006 PISA comparative study on education turned out to be very good (fifth on natural sciences). The other reason may lie in the fact, that Congress of Estonian Teachers held on 1987 started the necessary process of restructuring the system. The curriculum was depoliticized, many syllabi modernized, factual material diminished, the time allocated to optional subjects and to foreign languages was increased, and new subjects were introduced. In 1996, the Estonian government approved the new national curriculum for basic and secondary education. The overarching vision was forward-looking, but not all subject syllabi managed to embrace changes. The revised state curriculum was adopted in 2002. It provides more freedom for schools in

choosing the direction of studies, makes it possible to consider the students' interest and abilities, coordinates the development of the system of external evaluation, decreases the study load, leading to the implementation of knowledge into practice, and emphasizes the importance of the integration of different subjects and the importance of competencies, as the basis of lifelong learning.

English, French, German, and Russian are taught as primary and secondary foreign languages, the choice of which is up to the school (taking into account the school's possibilities and students wishes). Students have to study at least two foreign languages, the choice of which is up to them. In grade 3 the first foreign language is introduced and in grade 6, the second foreign language.

The curriculum is nationwide for the core subjects but allows choices for the school and students in some subjects. According to the 2007–08 timetable, the number of classroom hours per week was 20 h in grade 1, 23 h in grade 2, 25 h in grades 3 and 4, 30 h in grades 6 and 7, 32 h in grade 8, and 34 h in grade 9. The length of the school year is 175 school days.

The System of Examination, Promotion, and Certification

The evaluation of students' achievement, the transfer of students from grade to grade, and graduation from school are administrated by the National Examination and Qualification Centre. The students' achievement is numerically evaluated on a five-point scale. In basic schools, verbal evaluation is also used. The reports given at the end of each grade at basic and secondary school levels monitor the student's progress. The first formal certificate is received at the end of basic school (grade 9). The next certificate is received at the end of secondary school.

The state exam in the mother tongue in the form of an essay is obligatory for all students graduating from secondary school; in schools where instruction is in a language other than Estonian, an exam in Estonian as a second language is also obligatory.

The mathematics state exam is obligatory to all. The rest of the state exams can be chosen from Russian language and literature; English; German; French; Russian; biology, chemistry, and physics; and geography, history, and civics.

The evaluation commission for state exams evaluate the state exams on a 100-point scale.

Since 2002, the passing minimum for graduation has been 20 points. Secondary education certificate does not confer any automatic right of admission to tertiary educational institutions or universities. The applicant must pass the examinations of the higher education institution in compliance with their admission requirements.

Educational Assessment, Evaluation, and Research

Estonian Education Information System (EHIS) is a web-based national register, which provides information about schools. All the information regarding the Estonian education system is entered into this online state register. System includes data about educational institutions, students, teachers, study modules, as well as education licenses and educational certificates. It was launched in 2005 and now there are also subregisters for kindergartens, juvenile committees, and hobby schools. System is obligatory for education institutions. Every school-leader nominates 1–2 responsible school administrators to update school data in the register. All the governmental statistics and financing decisions are made according to register data. This register is a tool not only for schools, but also for local governments and other state institutions.

In 2006, the compulsory internal assessment of preprimary child-care institutions, general-education schools, and vocational-educational institutions was introduced and altered the system of state supervision. The changes served to support the development of internal quality-assurance system in educational institutions. This is in line with the general-educational political trends toward promoting the independence and self-management of educational institutions. State consulting will be introduced to ensure the effective implementation of internal assessment.

The Research and Development Organisation Act provides the structure and functioning of Estonian research and development (R&D) system. The Government of the Republic establishes national R&D plans, submits them to the Parliament, obtains the approval for the programs, ensures the cooperation between the ministries, and enacts legislation. Research and Development Council provides consultation to the Government of the Republic on the matters of R&D. The Ministry of Education and Research implements national research policy, organizes the financing and evaluation of the activities of R&D institutions, and coordinates international research cooperation on the national level. The Ministry is also responsible for the planning, coordination, execution, and monitoring of the research policy related to the activities of universities and research institutes.

Estonia has been cooperating with the (OECD) since the beginning of the 1990s. In autumn 2006, Estonia joined the International Conference on Intelligent Engineering Systems (INES) program. On 16 May 2007, Estonia received an invitation to accession negotiations with the organization.

Current Topics

The impact of a drastic decrease in the number of children for the education system, labor market, and also for

the state is discussed by the education community and general public. There were approximately 155 000 pupils in the daytime form of study in general-education schools in the 2007–08 academic year: in 2004–05 there were 184 038 pupils. Closing municipal educational institutions particularly in peripheral areas has made many parents decide to send their children at an earlier age to schools at larger centers. Such a decrease in the number of students according to school stages has a direct influence on the school network, state-commissioned teacher training, the need for in-service training and retraining of teachers, the whole higher education system and also on the labor market.

Developing efficient financing models, which would ensure the quality and accessibility of education, is an urgent issue at all levels of education. Much progress has been made with renewing the financing system of general education-schools, which was approved by the government coalition in 2007. The principles agreed upon foresee replacing the per-capita financing model with a per-class model. The aim of the proposal is to retain small rural schools and to reform school network in order to guarantee basic schools and upper-secondary schools the implementation of the agreed availability and quality criteria and to offer assuredness to parents and teachers as regards the development of local schools. Financing of vocational training has been a national priority in recent years. Bearing in mind the relative stagnation of vocational training and the notable support of employers' central organizations, the goal related to vocational training is reaching the price of a study place, 1.5 times higher than the price of a study place in general-education schools in 2008. With the support of European structural funds, investments in the vocational training system infrastructure have also been increased in the recent years, the study support system has been implemented, and the government has approved the new curriculum-group coefficients, which, compared to earlier, take better account of the price of studies in different professional spheres. The financing-system reforms are also prepared in higher education where, according to the approved higher education strategy, the 3-year result-based contracts will be implemented latest by the year 2009.

Increasing dropout rates in basic school and the decreasing educational level of younger age groups sets challenges for decision makers. The ratio of early school-leavers in the 18–24-year age group was 14.3% in 2007 (the respective ratio being 14.2% in 2000). Public debates focus on the need for strengthening social support structures more than in previous times and for this purpose, a boarding school program has been launched, and eligibility for free school lunch has been broadened to basic school students and to students acquiring vocational education after basic school. The curriculum development process is of principal importance in this context.

In the academic year 2007–08, a transfer of municipal upper-secondary schools with Russian as the language of instruction to partial subject study in Estonian has begun. The goal of the transfer is to ensure that students whose mother tongue is other than Estonian get equal opportunities to attain higher education and scope in the labor market. The goal is to achieve a situation where at the upper-secondary level, at least 60% of compulsory courses are taught in Estonian.

In the context of a changing labor-market environment, it is necessary to bring enterprises' needs and the structure of higher education curricula quickly into compliance. At all levels of education, raising young people's interest in natural and exact sciences and technology is being debated. As measures to amend the situation, the following have been proposed: supporting respective hobby groups already at basic-school level, making digital study aids available to schools, and offering various e-study materials. Launching of special scholarship programs, enhancing the role of employers in rendering respective professions more popular, and better organization of practical training are also deemed important.

Background

Fiji lies in the heart of the Pacific Ocean; its exclusive economic zone (EEZ) covering about 1.3 million square kilometers, contains nearly 330 islands of which a third are inhabited. Fiji was ceded to Great Britain, in 1874, and remained a crown colony until it achieved independence, in 1970. When Europeans first arrived in the country, they began to claim large tracts of land in order to engage in plantation agriculture, initially growing cotton and later sugarcane. However, the British colonial government moved to prohibit any further alienation of native land by foreigners. As a result, at least 83% of the country's land still belongs to the Fijian population, being communally – rather than individually – owned.

With the need for manual labor in the sugar industry in its early years, the first group of Indian indentured workers was brought into the country, in 1879, under the then-Governor Sir Arthur Gordon, and their recruitment under indenture continued until 1916 – by which time, ~60 000 had arrived in Fiji. On completion of 10 years of contractual labor, there was an option to return to India at the expense of the colonial government. Approximately, two-thirds of the workers decided to make Fiji their home.

Political

A former British colony, it became a republic, in 1987, following two *coup d'etats*. Fiji was – until the December 2006 military coup – a sovereign democratic state. Fiji's Parliament prior to this, largely followed the procedures and customs of the British where there was an elected House of Representatives and a nominated senate. The senate complemented the work of the House of Representatives through the scrutiny and revision of Bills coming to it.

Fiji's Pacific interests focus on membership of the South Pacific Forum where it was a founding member – on bilateral relations – membership of the Melanesian Spearhead Group, and those with other regional agencies. Fiji has always strongly opposed Pacific nuclear tests and the use of driftnet fishing. While supporting the promotion of Small Island States (SIDS) sustainable development, it has continued to draw attention to the special environment threats relating to the small islands of the Pacific.

On the international front, the increased effectiveness of the roles of Fiji's 11 missions abroad will continue to be reinforced, to align their roles more toward trade promotion and securing market access for its export products.

The government has continued to strengthen the embassies and high commissions in Asia to maximize benefits – particularly in enhancing trade and economic relations, especially with China and India. Since 1978, Fiji has played a prominent role, and will continue to maintain a high priority in international peacekeeping by the United Nations (UN).

Early Schools

It is well documented that, by 1874 – when Fiji became a crown colony – there was a fairly well-established network of small village schools, most of them under the control of the Methodist church offering a 4-year program in which Fijian teachers taught basic numeracy and literacy using materials printed in the dominant *Bauan* (a Fijian) dialect. There were also a few centrally located Roman Catholic schools run by Marist missionaries offering a more academic education with European teachers and English as the medium of instruction. During the first decades of colonial rule, the British administration's approach to education for the indigenous people was one of nonintervention, although they did establish and support schools for European children in Suva and Levuka. Fijian aspirations for education were such that, by 1900, there was a school in almost every village and general acceptance of school attendance as a norm of Fijian childhood.

Population

Fiji is becoming increasingly urbanized as internal migration to urban areas continues. Extension of urban boundaries has contributed to this trend. In 1996, nearly 46% of the population were living in urban areas – up from 39% in 1986. At least 41% of Fijians and Rotumans now live in urban areas. Figures for the year 2006 showed that the capital Suva is the most populated with 1 67 975 persons, followed by Lautoka with 43 274 and Nadi at 30 884.

Language and Culture

While English is the official language, Fijian and Hindi are taught as part of the curriculum. Fijians and Indo-Fijians have their own dialects while the latter, generally, speak a distinctive Fiji–Hindi dialect; people of other nationalities who have made Fiji their home, include Europeans, Chinese, and other Pacific islanders.

Economy

Across 4 years, up to the end of 2006, Fiji experienced strong and continuous economic growth and, for 2004, it was estimated at 4.1%. Tourism then, continued to be the main foreign-exchange earner, followed by garments, sugar, fish, gold, and mineral water. Economic growth, for 2005, was projected at 1.4% and, for 2006, 0.8%. A significant proportion of Fiji's population continues to be involved in the natural resource sector. The sugar industry – on which ~200 000 people are dependent – has been the principal export for the past 100 years; it continues to occupy a dominant position in the economy.

The distribution of economic power in the country comparing the size of the major sectors shows that the primary-resource-based sector – encompassing agriculture, fisheries, forestry, and mining – has declined in its share of gross domestic product (GDP) since 1986, from 25% to 18%. It has been surpassed by wholesale and retail trade, restaurants, and the hotel sector. Economic growth, for 2005, was around 1.4% and, for 2006, 0.8%.

Goals of the Education System

The core function of the ministry is to ensure that all students – from kindergarten, compulsory school age group to Form 7, and including vocational education students – have access to quality education. The ministry is also charged with the responsibility of ensuring that standards in education are met and maintained, and that the human, physical, and financial resources allocated to education are appropriately directed and expended.

The ministry had set its plan for 2006–14 to target resources and support to allow all students to achieve full benefit from educational services. For social justice and equity, all Fiji students must have the opportunity to achieve their full personal best, and the opportunity to make a positive contribution to society.

Structure/Operation of Education System

Over the last decade, the government's efforts in partnership with the community have focused on increasing access to quality education for all. Significant progress has been made in making education accessible, especially to the rural and urban disadvantaged.

Nearly one-quarter of the entire population is of school-going age and, although education is not compulsory at any stage, over 98% of children between 6 and 14 years of age are attending school. In 1996, ~70% of the population had already received some secondary education (74% Fijians and 66% Indians), and nearly all children 6–8 years of age were enrolled in schools. In the same year, the literacy rate was 92.9% and was higher

among Fijians (92.9%) than among Indians (89%). The rate was higher among males (94%) than among females (91%).

In the year 2007, Fiji had a population of 8 35 230 of which 36 190 children were 4–5 years old (of preschool age) – 1 35 724 children were of primary school age (between 6 and 13 years of age), and 78 196 in the secondary school age group (between 14 and 18 years of age).

Fiji is guided by the goals of the South Pacific Forum's Basic Education Plan which, in turn, re-affirms the support for the global initiative Education for All. All major examinations have been localized and are conducted by the Ministry of Education. The government is planning to set up a semi-autonomous Fiji Schools Examinations & Assessment Board in the Ministry of Education to enhance transparency and improve on the quality of assessment and certification procedures.

The Education Summit document produced, in 2006, for the 10-year-period 2006–15 contains the platform for education reform in Fiji and looks at six themes that have been chosen as the most encompassing key educational aspects, with the child at the center of the whole education process; it is also the key theme. Included, as the other five themes, are the curriculum, the school, technical and vocational education and training (TVET), human resources, and the community.

The recently established Teacher Registration Board will monitor teacher quality and professionalism, and the Ministry of Education will closely monitor the development of teachers to improve discipline and performance. Recently, the teacher–pupil ratio has improved slightly, declining from 1.31, in 1992, to 1.27, in 2003, for primary education, and declining from 1.20, in 1992, to 1.17, in 2003, for secondary education; the teacher–pupil ratio in both primary and secondary education is higher for urban than rural schools.

Early-Childhood Education

There are 899 preschools in Fiji and all of them are non-governmental. Most of the early kindergartens were established in the late 1940s to early 1950s by qualified expatriate wives, initially for their own expatriate children. While many of the Fiji communities have shown initiative in setting up and maintaining some form of early-childhood education at the village or community level, there needs to be a consistent effort to ensure the sustainability of such programs. It is evident that preschool centers exist more in the urban than in the rural areas. Some centers offer awareness and support programs for parents and families.

Primary Education

In 2007, there were 720 primary schools of which, only two were government run; the others were run by a committee

of private schools. Primary schools offer education for classes 1–6 or 1–8. In the 6th year, students appear for the Fiji Intermediate Examination. A new test – the Fiji Islands Literacy & Numeracy Assessment (FILNA) – is, at present, offered to more than 50% of schools in Fiji at classes 4 and 6 in place of the Fiji Intermediate Examination.

Over 160 years of development have ensured that primary schooling is well established throughout Fiji. It is well documented that, by 1874, when Fiji became a British colony, there was a fairly well-established network of small village schools – most of them under the Methodist church offering a 4-year program in which Fijian teachers taught basic numeracy and literacy using materials printed in the dominant *Bauan* dialect. There were also a few centrally located Roman Catholic schools run by Marist missionaries, offering a more academic education with European teachers and English as the medium of instruction. During the first decades of colonial rule, the British administration's approach to education for the indigenous people was one of nonintervention, although they did establish and support schools for European children in Suva (capital) and Levuka. The introduction of the indentured labor from India to Fiji, between 1879 and 1916, saw – at the turn of the century – the establishment by the missions of some schools for Indian students, with more being provided by Indian religious organizations, laying the foundation for strong Indo-Fijian community provision of – and involvement in – the education of young people.

In the decades following 1969, education initiatives in the primary sector responded to the concerns about quality and relevance. Much curriculum revision was undertaken, in the 1970s, with the objectives of improving quality and standardizing the primary system, as well as making the system relevant to an independent Fiji. The recommendation to reduce the primary school years from 8–6 – thus moving from an 8-year primary/4-year secondary structure to a 6-year primary/6-year secondary one – was implemented in the early 1970s; although not made compulsory, many schools restructured accordingly.

Only two of the 731 primary schools are state owned, at present, with most run and managed by school committees or religious and cultural groups.

Secondary Education

Up to 2000, all areas of curriculum have been modified to better fit the local context, and all external examinations had, by then, been localized. There, then, were 169 secondary schools as compared to 57 in 1969; 12 of these were government run; and 55 were boarding schools. A total of 69 230 students attended secondary school in 2007, of which 6409 were boarders. Secondary schools have Forms 1–6 (or 7) or Forms 3–6 (or 7), junior secondary schools have Forms 1–4. In 2007, there were 11 junior secondary schools. At the end of Form 4, students sit for the Fiji Junior Certificate

(FJC) examination which assesses 2 years of work in Forms 3 and 4. At the end of Form 6, students sit for the Fiji School Leaving Certificate (FSLC Examination – which assesses work on Forms 5 and 6. Following the successful completion of Form 6, students can either continue in secondary school in Form 7 or pursue Foundation level at a university. At the end of Form 7, students sit for the Fiji Seventh Form Examination.

The Ministry's National Substance Abuse Advisory Council focuses on raising awareness on the effects of misuse and abuse of substances. Value education inculcates, in students, stronger feelings of national consciousness and respect for others as well as an appreciation of Fiji's rich multicultural heritage.

Other Schooling Arrangements

There are 17 special schools which look after the special needs of children. All these schools are nongovernmental and are run by the communities.

The 1996 census recorded nearly 12 000 people as being disabled, some suffering from more than one disability, having important implications for care, service, administration, and policy concerning the disabled. Special education delivery commenced in Fiji in the early 1960s. As awareness of disability grew, a handful of nongovernmental organizations were formed. Special schools were established, in the 1970s and 1980s, to take care of children with a variety of disabilities. There are, at present, 17 special education schools catering to over 1200 disabled children at various centers; there is a rehabilitation center for older students. All the schools are managed by societies and they operate in partnership with the government.

In the existing special education schools, there is provision for teaching and learning in the areas of early intervention from birth to 8 years. Services are also provided for those beyond these years right up to vocational training. Primary education is provided for children with visual, hearing, intellectual, and physical impairment in these special schools. The integration of students into regular primary and secondary schools and tertiary institutions is one of the more recent initiatives in the effort to embrace an inclusive educational practice.

At present, the approved establishment of civil servant positions is inadequate to meet the demands placed on the special education school, in terms of the needs of children who require greater teacher-time than children in the mainstream classes.

The Curriculum Development Unit continues in its efforts to provide a well-balanced, effective, and applicable curriculum in the formal education system. One of its major tasks, to date, is the revision of the whole school curriculum under the National Curriculum Framework initiative.

Technical and Further Education

Technical and vocational education is offered in secondary schools in the form of technical/vocational subjects. It is part of the secondary curriculum. Some secondary schools also offer vocational programs. Vocational education is also offered in some primary schools as enterprise education.

The institutions outside the formal school system, including the University of the South Pacific, University of Fiji, Fiji School of Medicine, Fiji College of Agriculture, the Fiji Institute of Technology, and the Training and Productivity Authority of Fiji, have continued to progress with growth in infrastructure developments, student enrollment numbers, diversification of programs, and a marked increase in the introduction of new delivery modes. With continued varied requirements in technical and further education, the government keeps abreast and ensures the provision of academic and practical courses to develop and equip Fijian youth in a rapidly changing society; scholarships are based on merit.

Higher Education

The cabinet recently endorsed the establishment of an independent advisory body, to be called the Higher Education Advisory Commission, whose role will be to regulate the higher education sector in Fiji. The present lack of regulation in higher education is a concern because there is no control over standards and quality, as these may severely compromise its national and international standing. The Commission will manage the accreditation and approval processes. Higher education is offered at technical institutes offering certificate, diploma, and degree programs. There are two universities – the University of the South Pacific, jointly owned by the Pacific Country Forum members, and the University of Fiji, established in 2004 and based in Lautoka. There are also two main vocational training centers.

Adult and Nonformal Education

Nonformal education (NFE) has existed in Fiji, in various forms, for almost as long as its formal counterpart. NFE has included programs in areas such as primary healthcare, literacy, vocational skills, farming, recreation, and income-generating projects. While the provision of NFE has been – and still is – the domain of nongovernmental organizations (NGOs), government ministries have played a part in NFE programs, such as through the Women's Interest Office and extension services of agriculture and fisheries. While NFE is for all communities, it is, often, associated with the rural population, as it is often located in rural areas and frequently caters to out-of-school youths; the target group is, however, broad and inclusive.

The Teaching Profession

Fiji recognizes the centrality of the teacher's role in improving the quality of education offered in schools in developing countries such as Fiji. Up to 2000, remuneration for teachers absorbed approximately 90% and 85% of the budget for primary and secondary schools, respectively. While the core function in primary education in Fiji is to provide, facilitate, and promote excellence in the teaching, learning, administration, and management of primary education, secondary education's core function is to provide optimal staffing resources for all secondary schools, and to promote a committed and competent workforce that will enable the ministry to maximize the use of its budgeted resources. The government operates two of the five teacher-training institutions.

Administrative and Supervisory Structure

There are four Education Divisions and each division is managed by a Divisional Education Officer; a division consists of one or more Education Districts. There are nine education districts, each administered by a District Senior Education Officer.

Educational Finance

The education budget for 2007 amounted to \$F320 678 400 – an increase of about 1% compared to that for the previous year. The funding of education in Fiji is a joint enterprise among the government, NGOs, and local communities. The initial funding of education was largely undertaken by NGOs, particularly religious organizations. The colonial government did not provide any financial assistance for the education of the community until about the beginning of the twentieth century, although it established schools in Levuka and Suva for European children. Since independence, the government has substantially increased public funding for education in all levels of the system. Schools are allowed to charge levies for various school activities such as admission and administration and administration, hiring of books, purchase of stationery and school equipment, extracurricular activities, and parent-teacher levy. School committees manage and control the finances of their schools.

The funding of education at the primary and secondary levels represents a more active partnership among the government, NGOs, and local communities. A formula for government funding of aided schools, based on school rolls, is being used at present. The government provides grants to assist in the construction and repair costs of facilities. The ministry meets the cost of teachers' salaries according to a formula in all registered schools, with exception in the case of a few schools.

The government continues to support fee-free primary education for classes 1–8 and tuition-free secondary assistance for Forms 1–6. Several new policy initiatives were introduced, since 2002, and these include the payment of premiums required by the Native Land Trust Board for new leases to nongovernment-owned schools on native leased land. Boarding school assistance is being extended to all rural boarding schools as well as secondary boarding schools. The normal fees for the three public examinations in secondary schools have all been abolished.

Performance Monitoring, Evaluation, and Research

The performance review and standards monitoring policy for schools was recently approved by the government and was formulated with assistance from AusAID; Phase 1 implementation has begun in 2008.

Standards monitoring in schools is an important element of the process of continuous improvement and critical to achieving the purpose of the Ministry. This policy is to provide a framework that will enhance and facilitate continuous improvement of student achievement through quality teaching and learning. This is enhanced and supported by the recognition of the rights of the child and a child-centered approach to growth and development.

Major Changes and Issues Since 1970

As Fiji approached independence in 1970, there was a clear need to assess the education system and plan for its future. A Royal Commission was established in 1968 and its Sherlock Report (1969) made 81 recommendations in three major areas: the quality and number of teachers, disparities between geographical and racial groups, and the curriculum. While not all of its recommendations were implemented, it was significant as the first substantive and critical review of the entire education system.

In 1970, Fiji had a very uneven situation of educational provision. As most schools were owned and run by communities and civil society, the poor rural communities had schools that were, often, small and ill-equipped. Communities with more resources were able to put in more for their schools. There was an overwhelming move, in the 1990s, for more technical and vocational subjects to be included, rather than maintaining the academic focus. The distinguishing partnership between the state and the wider community evolved out of historical circumstances and social demand – not conscious choice. The school inspection system was terminated, in the 1970s, and the Ministry's Curriculum Development Unit staff visits schools in an advisory capacity.

The government introduced fee-free education in 1973 and, by 1981, the first 8 years of school were tuition free and this was subsequently extended to 10 years.

From 2000, tuition-free assistance had been extended to Form-5 students and children from low-income families could claim fees remission in the remaining secondary school years. In 1997, the education ministry decided to revert back to the 8-year primary cycle with the change being linked to the compulsory education initiative as well as access and equity. As primary schools are much more widespread, children's chances of completing at least 8 years of schooling are optimized. The political crisis of mid-2000 had a profound effect on the education system.

International Programs

Fiji is part of the global community and, by virtue of this link, it has international responsibilities. Fiji has made commitments to international bodies such as the UN, AusAID, and EU. At the regional level, the country holds close ties with organizations, such as the Pacific Islands Forum, through bilateral and multilateral agreements. Fiji is also part of the EU/NZAID Pacific Regional Initiatives for the Delivery of Basic Education (PRIDE). It has commitments with United Nations Educational, Scientific and Cultural Organization (UNESCO)'s Education for All (EFA) and the Fiji Education Sector Programme (AusAID and EU). Of importance also is the government's commitment to the UN Millennium Declaration and the achievement of the eight Millennium Development Goals (MDGs). Fiji's new education plan features the commitment by government to the Decade of Education for Sustainable Development (DESD) 2005–14.

Fiji and Papua New Guinea (PNG) are the two Pacific countries among nine other African, Caribbean and Pacific (ACP) countries where the International Labour Organization, in cooperation with the EU, has launched a major project aimed at tackling child labor through education. The overall goal of the partnership is to accelerate the fight against poverty and work toward the achievement of the MDGs.

The Future

Fiji's education system is confronted by new and complex issues. Educating the Fijian child of the twenty-first century becomes a more challenging task than ever before. Social problems and tensions in schools placed added pressure on the system as a whole – challenging the curriculum, the teachers, the community, the school environment, culture, and ethos. Another serious issue is the continued rise in unemployment and school dropouts, challenging the relevance of the curriculum and programs in schools. As a result, there is a demand for relevance from all segments of society and the nation as a whole.

In conclusion, there will always be the need for the education system to continue to prioritize the child, and that the educational programs should be structured to

accommodate the needs of the child. Greater attention must continue to be directed to inculcating values and aesthetics. For a peaceful and prosperous Fiji, the country will need a generation of citizens who have been educated in a holistic manner.

Glossary

Licenciate – A 2-year post-master's, predoctoral degree which may be taken as complete set of studies on its own, or may be extended to lead to a doctoral qualification.

Lukio – An upper secondary school.

Matriculation – The national final school examination and accreditation process.

Polytechnic – A postschool professional training institution.

Sámi – An ethnic minority group, distributed throughout the northern regions of Finland, Sweden, Norway, and Russia.

General Background – National Context of the Education System

Finland is a country of 5.3 million people living in an area of 338 000 square kilometers between Sweden and Russia. In a land of severe winters and mild summers, the Finns and the Sámi people have carved a living from a land of dense forests, multitudinous lakes, and islands. Finland has a relatively low average population density of 17.4 people/km². The south of the country is more densely populated, with densities up to 218 people/km² (Uusimaa), whereas in northern Lapland, the population drops to 2.0 people/km². Finland's population mostly consists of Finnish-(91.24%) and Swedish-speaking (5.46%) Finns, with the Sámi-(0.03%) and Russian-speaking (0.85%) groups being the largest minorities (2007 figures).

Finland is a democracy, with a president and a national parliament. She achieved her independence from Russia in 1917 and, although she suffered badly in wars both before and during World War II, she has maintained her independence and democratic government since then. Her economy has been transformed from an agricultural base to a leading knowledge-based economy.

Both adults and school children value education very highly. Thus, strong community support and high expectations for education are evident in Finland. This was already demonstrated in 1852, while Finland was an autonomous region of Russia, by the establishment of the first professorial chair in education at the University of Helsinki. The community support has enabled Finland to reform its

education system, most recently in three phases from 1960s to late 1980s, during the recession in the early 1990s and in a continuing phase since then.

In the early 1960s, the educational reform concentrated on changing the two-track system of school education to a comprehensive common schooling. In the two-track system, the students at the end of grade 4 in primary (elementary) school elected to continue to either an academic stream consisting of eight further grades leading to matriculation and university entrance or a civic stream of three to five grades, which led to employment or vocational schools. The reform goal was for Finland to become internationally and economically competitive by producing a better-educated population and improving educational equity.

All students now participate in a common compulsory comprehensive schooling for the first 9 years. After this period, they can choose between upper general schooling with nongraded, modular curriculum, typically completed in 3 years (84% complete it in 3 years, less than 1% in 2 years, and 16% take 4 years to complete it), or a 3-year basic vocational school, or not to continue formal school education any further. Although it is possible to combine the vocational and general tracks, very few do so.

At the end of the upper general schooling, the students may sit for their matriculation examinations, the only high-stakes national testing conducted in Finnish schools. Based on these results, they can then take up higher education studies. After the education reform in the 1960s through the 1990s, some vocational secondary school students can also enter universities. A few places are reserved for them. However, they usually enter the polytechnics if they need further education to handle the increasingly knowledge-intensive trades and professions.

Aims of the Education System

The Finnish education system aims to promote quality, efficiency, equity, and internationalism. It is intended as a means to achieve and improve the competitiveness of the Finnish society, while maintaining its strong welfare and equity focus. Finland's constitution and laws guarantee equal opportunity for every resident of Finland to get comprehensive school education irrespective of their financial standing or location in the country. Thus, education is free throughout the country, from primary to higher education.

Structure and Operation of the System

Characteristics and Basic Statistics for Levels and Types of Education and Training

The Finnish education system consists of 1 year of an optional free preprimary education, which students can enter at the age of 6 years. It is followed by a compulsory 9-year common basic education phase for students aged 7–16 years. The common 9-year stage of schooling does not include streaming or other forms of separation of students to different ability or gender groups. This is followed by two streams of further school education, one general and the other vocational, with a possibility of combined general and vocation track, leading to university or vocational, polytechnic studies. The intention of the Finnish education system is for students to be able to continue their studies as far as they wish, irrespective of the pathways they choose along the way. Therefore, even though the upper general secondary school is the main pathway to the university, students can also get to the university through the vocational education institutes.

The 20 universities and 30 polytechnics are located throughout the country, allowing easy access to free post-school education. Traditionally, university education has provided a pathway to ever more sophisticated levels via

bachelor's degrees, master's degrees, licenciate, and doctoral level studies. The master's degree, not the bachelor's, is the typical initial university exit point for students in Finland. The polytechnics award polytechnic bachelor's degrees and polytechnic master's degrees. The structure of the program is shown in **Figure 1**.

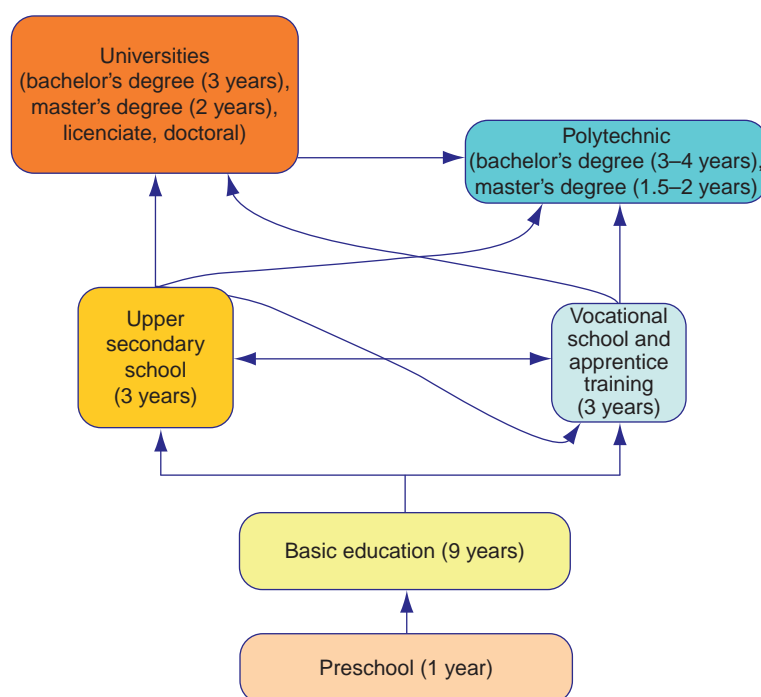

The numbers of schools, polytechnics, universities, and students are given in **Table 1**.

The school class sizes are smaller than the Organisation for Economic Co-operation and Development (OECD) average.

Preschool and Early Childhood Care

The first kindergartens were established in the nineteenth century, funded by donations, for example, the profits from the state-owned alcohol company. In 1927, a state subsidy for kindergartens was introduced. In 1973, state subsidies were granted to all forms of day care, including day-care centers, provision of family day care, and play activities.

The objective of preschool education is to support children's growth toward civilized human beings who are ethically responsible members of society and to provide

Note: Specialist vocational qualifications, further vocational qualifications, and contributing work experience are not shown for clarity.

Figure 1 Schematic structure of the Finnish education system. Aadapted from the Education System Chart on the Finnish National Board of Education Website.

Table 1 Educational Institutions and Students^a

<i>Type of educational institution</i>	<i>Number</i>	<i>Students</i>
Comprehensive schools	3067	547 500
Comprehensive school level special education schools	159	8300
Upper secondary general schools	406	122 600
Comprehensive and upper secondary general level schools	37	24 400
Vocational institutes	161	164 900
Special needs vocational institutes	12	4900
Specialized vocational institutes	37	28 900
Vocational adult education centers	32	42 700
Fire, police, and security service institutes	2	1400
Military vocational institutes	15	–
Polytechnics	30	143 300
Universities	20	176 300
Military academies	1	–
Music schools and colleges	89	62 600
Sports institutes	14	1600
Folk high schools	89	14 500
Adult education centers	234	506 900
Study circle centers	11	53 800
Summer universities	20	32 500
Other educational institutions	7	600
Total	4443	1 937 700

^a2007 figures, based on Statistics Finland information. Note that 49% of the pupils in the comprehensive school were girls and 51% were boys.

them with the basic knowledge and skills necessary in life. Preschool education aims to improve children's learning capabilities and to even out the individual differences in children's readiness to start school, to prevent growth in undesirable differences. The preschool curriculum is based on language and interaction, mathematics, ethics and philosophy, environmental and natural studies, health, physical and motor development, and art and culture.

Approximately 98–99% of 6-year-old children participate in preschool education (2007–08 school year estimate). It consists of at least 700 h per year, that is, about 18 h per week. However, there are no detailed national specifications of the school year, the number of school days, the length of school days, or the duration of periods of preschool teaching; instead, the practical arrangements of preschool education are decided by each local authority. The education providers adopt a curriculum for the education, prepared separately for instruction in the Finnish, Swedish, and Sámi languages and, where necessary, for instruction in other languages. Based on the curriculum, the education providers need to devise their own annual educational programs.

The students are grouped on the basis of achieving the curriculum objectives. During the preschool education, the necessary schoolbooks, learning materials, work equipment, and materials are free for children. Children are also provided free daily meals.

Basic Education

The students normally study their 9-year basic education in comprehensive government schools in their localities. There are also a few private schools. The regular comprehensive schools (about 3226 catering for 555 800 students in 2007) are funded by the local councils, with subsidies from the national government. The basic education is free to all students. The school sizes vary from less than ten students to schools with over 900 students. During the first 6 years, they are taught by classroom teachers for most of their subjects; however, in the last 3 years, they are generally taught by subject specialist teachers. Nevertheless, schools are increasingly deploying the subject specialist and generalist teachers across the 9 years of the basic education in order to create better continuity across the primary–secondary divide. Similarly, primary and secondary school phases are often integrated at the same physical sites and co-located buildings. On satisfactory completion of basic education, the students are entitled to enter the upper secondary school. Almost all (99.7%) of children in Finland complete their basic education.

Upper Secondary School

There are about 443 upper secondary schools, either established as separate schools or co-located with basic schools but functioning as distinct operating entities, with about 147 000 students. The typical length of upper secondary schooling (*lukio*) is 3 years, but may vary from 2 to 4 years. The age range of students is typically 16–19 years. Some of these schools may specialize in music, physical education, fine arts, languages, or natural science. The matriculation certificate entitles a student to enter university. The main aims of upper secondary education are to assist in students' moral development, in order that they become balanced and educated individuals and members of society, and to provide them with skills and knowledge needed in further studies, employment, recreational activities, and overall personal development. This stage of education is intended to develop them into life-long learners who will undertake self-development throughout their lives.

The studies in the upper secondary school are divided into courses of about 38 lessons each. The school year is usually divided into five or six stages, where the timetable focuses on particular subjects in each of these stages. The students' subject choices determine their progress and their study groupings. There are no year classes and the classes are nongraded. The progress throughout this stage of schooling is individually determined. Overall, the upper secondary syllabus consists of a minimum of 75 courses,

which are composed of compulsory, specialized, and applied courses approved by the Finnish National Board of Education.

Vocational Schools and Apprenticeship Training

The vocational schools or institutes provide 3-year studies after basic education. There are 161 vocational institutes with about 164 900 students (2007 figures). These studies authorized by the Ministry of Education and based on the national core curriculum from the Finnish National Board of Education lead to either higher education in polytechnics or universities or directly to employment. The key aims are vocational competence and entrepreneurial capability, as well as meeting the same general aims as the general upper secondary schools.

Students can select from 52 qualifications and 116 study programs. The core subjects in all courses are mother tongue, second national language, a foreign language, mathematics, physics, chemistry, social studies, entrepreneurship, workplace studies (a minimum of 6 months of workplace training outside the school is included in all vocational programs), physical and health education, and arts and cultural studies.

These qualifications may be obtained through school-based education or an apprenticeship training where an employment contract is set up between the student and an employer and confirmed by an education provider. The qualifications can also be gained by competency testing.

Polytechnic Education

There are 30 polytechnics with 143 300 students (2007 figures). They provide education in humanities and education; cultural studies; natural sciences; tourism; catering and domestic services; social services; health and sports; technology, communication and transport; social sciences; and business and administration. The students usually enter polytechnics after completing either a general or vocational secondary school, or with relevant work experience, for which they gain credit. They can complete their degrees in 3.5–4.5 years of full-time study. The polytechnic degrees have a professional emphasis and include a 6-month job placement.

University Education

The 20 universities cater to 176 300 students (2007 figures). Ten are multidisciplinary universities, three are technical universities, three specialize in economics and business administration, and four are art academies.

Approximately one-third of the possible national age group studies at a university. The universities provide courses in 20 fields of study, with the largest student numbers being in science and technology, humanities, and natural sciences.

The first level of study is a 3-year bachelor's degree followed by 2-year master's programs. Beyond the master's degree, further studies are provided at the licentiate and doctoral levels. The licentiate degree is a 2-year predoctoral degree which may be taken as complete set of studies on its own, or may be extended to lead to a doctoral qualification by about 2 more years of study which includes independent research culminating in a thesis incorporating a formal public defense. Licentiate degrees are accepted as sufficient qualification to practice medicine, veterinary medicine, and dentistry; however, many continue their studies to the doctoral level.

Adult and Community Education

In addition to the university and polytechnic education providers, various forms of adult education are provided in Finland by about 750 other institutions. These institutions are operated by the government, local authorities, collaborative municipal groups, private associations, foundations, and companies. Some programs are free, whereas others charge fees to cover the costs not wholly borne by the national government or other levels of public administration. Liberal adult education is provided in 258 adult education centers, 91 folk high schools, 11 study centers, 20 summer universities, and 14 physical education centers. General adult education is provided in 54 upper secondary schools for adults and vocational training at the upper secondary level is provided in 220 initial vocational education provider sites, 54 specialized vocational institutions, and 45 vocational adult education centers. The participants in these programs may study for qualifications or partial qualifications and train to prepare for competency-based examinations. A significant portion of the adult education is intended to upgrade existing competencies.

Teaching Profession

The Finnish teachers' high quality is based on thorough teacher preparation. This is a distinctive feature of the Finnish education system. A master's degree is required for permanent employment. They participate in school management, curriculum design and interpretation, resource materials selection, etc., in addition to classroom teaching. Studies in these areas during their extensive preservice education period prepare them for these wide-ranging responsibilities.

The Finnish school students receive special assistance with learning difficulties. Thorough teacher preparation through explicit teacher-education programs develops the teachers' capabilities to assist struggling students. The teacher-education programs have integral components helping them to identify and deal with learning problems. For example, in the basic preparatory program to become a primary classroom teacher, significant studies on dealing with learning difficulties are included. These studies are based on the premise that 15–20% of the children will experience developmentally significant learning problems during their schooling and, in fact, 21% of the Finnish basic school students accessed learning support services and 6.7% of the students were assigned to special needs education programs in 2003–04.

The high esteem of education in Finland means that teachers have high community regard. Thus, teaching as a profession attracts the best students in Finland as it is as highly valued as other high-status professions, such as medicine and information and communications technology. It is quite difficult to enter a teacher-education course in Finland. For example, only the top 10–15 % of the applicants are typically selected for primary school teacher-education programs. They are highly motivated and multitalented, with successful progression in academic disciplines as well as in art, music, and sport. The interview-based selection of students into university teacher-education courses takes into account more than their academic performance. This creates a highly capable teaching force that is strongly committed to their profession and finds a high degree of satisfaction and community support. However, as in many other countries, Finland finds it most difficult to attract the best students into mathematics and science teacher-education programs.

The teachers identify with the upper social strata in the community and are mostly politically conservative. For example, in the Finnish teacher-education politics, very few teachers hold radical or extreme Left positions. Instead, they have consistently strived for professionalism, seeking university-level teacher education for primary teachers since 1890. This has been achieved in stages; for example, in 1930s, the first University College of Education was formed at Jyväskylä and, since then, others were developed. All teacher education became a university-level provision as part of the national 1973–79 *Teacher Education Reform*.

Administrative and Supervisory Structures

The Finnish education system is governed by national acts of parliament and consequent regulations. Among other things, the regulations cover the core subjects taught to everyone and the number of hours of instruction. The core subjects comprise mother tongue and literature,

in either Finnish or Swedish, the second official language, one foreign language, environmental studies, health education, religion or ethics, history, social studies, mathematics, physics, chemistry, biology, geography, physical education, music, art and crafts, and home economics. Guidance counseling is also stipulated and some optional subjects may also be provided based on local decisions. The general curriculum is mandated at the national level; however, the details of its implementation are left to the municipalities, schools, and teachers. The national curriculum also defines cross-curricular themes, which integrate the various facets of the school programs. The core curriculum also specifies how special needs education, student welfare, student evaluation, and school–home collaboration should be conducted, but the implementation is decentralized.

Educational Financing

The primary and secondary schools in Finland are predominantly owned and operated by the municipalities. However, they receive substantial support from the national government in lumpsums not tied to particular funding requirements, allowing the schools and the municipalities to allocate their education budgets as they wish.

Education in Finland is free for the students and includes many forms of assistance. During the compulsory education phase, the textbooks and school transport and other facilities are also free, but not in the upper secondary or vocational schools. Students with learning problems can access a number of legally mandated support services. For example, schools have counselors (assisted by school nurses, psychologists, and doctors) to help in diagnosing learning problems; remedial teachers to work with individuals or small groups who are having difficulties; or class teachers who are paid for extra hours of work outside the normal class times with students who are having learning problems. The publicly funded school lunches at schools constitute an important factor in Finnish school resourcing, ensuring that, irrespective of the home environments, all students are fed relatively well at school with good cooked food.

Special needs assistants are employed to help the comprehensive school teachers if their students need extra care, for example, when special education students are integrated into general classes. Many of the school assistants proceed to teacher training programs after personal experience in schools.

Similarly, dental and health services are provided free to Finnish students. Thus, good physical health and dental basis for education is not out of the reach of any students because of cost, as the physical impediments to education receive early and continual attention and help. However, these service costs are causing community concern and some communities find it difficult to supply even the minimum standard provisions.

The cost of educational institutions in Finland as a share of the gross domestic product (GDP) is 6.0% (2002 figures). The cost of education as a share of total public funding is 12.7%. The expenditure per student in the lower basic school is US\$5090, in the upper level of the comprehensive school is US\$8200, in upper secondary school US\$6460, and in higher education US\$7330 (excluding research and development costs).

Performance Monitoring

Student testing in Finnish schools consists almost wholly of school-based assessments, which are mainly diagnostic in nature and lead to interventions to assist students with learning as described above. The main form of external testing is the matriculation examination at the end of the upper general education (*lukio*). About half of each age group participates in these examinations.

The student assessment in Finland is intended to guide and encourage student learning and help to develop students' self-assessment capabilities. The students' schoolwork, their total learning process, and conduct are assessed. The students are provided end-of-year reports and they may receive intermediate reports throughout the year. In the first 7 years of the basic compulsory school, the reports may be verbal or numerical, but later the assessments must be expressed in numerical terms. However, they may be accompanied by verbal assessment comments. Elective subjects have greater potential of assessment variability.

The scales used in the reports range from 4 to 10; 4 = fail, 5 = adequate, 6 = moderate, 7 = satisfactory, 8 = good, 9 = very good, and 10 = excellent knowledge and skills. The subject assessments are provided by the subject teachers and conduct and schoolwork assessment is jointly marked by all the teachers of a given student. The national curriculum provides criteria for the good (8) grades for all subjects. These are the fundamental tools used by the teachers to determine student grades.

The secondary school students may sit for the final national matriculation examinations in up to three consecutive stages. These examinations are held twice a year, in spring and autumn. Everyone must sit for a minimum of four examinations, depending on the students' pattern of study, but students may choose to attempt more examinations. Every student must sit for the mother tongue examination and a selection of three tests selected from the second national language, one foreign language, mathematics, sciences, and humanities.

Evaluation and research

In Finland, the education and training providers primarily evaluate their own activities. Evaluation is conducted

to provide the basis for educational policy decisions and information and performance management. The evaluation of education at local, regional, and national levels is coordinated by the Finnish Education Evaluation Council. School evaluations are primarily conducted through a regular sampling program; however, schools not scheduled to be included in a sample may also ask to be included. Finland also participates in international educational evaluations, for example, in the Programme for International Student Assessment (PISA) of international comparisons conducted by the OECD, and International Association in the Evaluation of Educational Achievement (IEA) studies, for example, in civic education (International Civic and Citizenship Study (ICCS)) and mathematics and science (Trends in International Mathematics and Science Study (TIMSS)). University and polytechnic evaluation is carried out by the Finnish Higher Education Evaluation Council. General, vocational, and adult education evaluation is the responsibility of the Educational Evaluation Council.

Educational research in Finland is mainly carried out by universities and, to a much lesser extent, by the polytechnics, or as part of national priority programs, through agencies such as the National Strategy for Education, Training and Research in the Information Society. Specialized research centers in educational research have been established at some universities; for example, at the University of Jyväskylä, there is the Institute for Educational Research, which has conducted a number of the PISA studies in Finland, and at the University of Helsinki, there is the Centre for Educational Assessment, which has conducted numerous school evaluations as well as the 2006 PISA study in Finland. The national surveys of educational outcomes in various subjects are mostly conducted by the National Board of Education.

Major Changes and Issues since the 1990s

The reform of the 1960s, discussed earlier, continued throughout the 1970s, 1980s, and the 1990s. The 1990s phase of the process coincided with a severe recession in Finland in the early 1990s, resulting in huge unemployment. However, Finland persisted in the reform of education and the recession gave added impetus toward reducing educational expenditure, reducing centralized control, and increasing regional educational autonomy. Thus, a number of functions specified centrally for the whole country were handed over to the municipalities who owned the schools and operated them. Instead of the previous systems of centrally specified detailed syllabuses, inspectorial visits, and selection of textbooks, the new system was based on trust that the local municipality in collaboration with school principals, teachers, and

the community could best decide on how to implement a much briefer form of centrally mandated syllabus and ensure the funds provided by the municipality and the National Education Department were used to the best effect.

This has led to an education system with nationally agreed direction, but implemented at the local level, with significant amount of professional discretion vested in teachers, schools, and local communities. The results have been very pleasing, with excellent student academic performance demonstrated in rigorous international comparisons and a remarkable level of equity in school performance across the country.

Glossary

Adaptation and integration school (AIS) – Since the 1970s, a policy to help special-needs children to adapt and to integrate into regular schools.

Baccalauréat – A diploma (equivalent A-levels) obtained at the end of secondary school and required for access to higher education.

Decentralization – It transfers powers and responsibilities of the State to local authorities or institutions, run by elected boards and managers.

Priority education zones (ZEPs) – Created in 1981, ZEPs are designed to provide additional means for the education of the most disadvantaged pupils by giving more for those who have less. Means are concentrated in social and economically disadvantaged areas.

Qualification – All learned competences (knowledge, know-how, and social skills) that people can mobilize in a job.

Recteur – A chief education officer appointed by decree by the President of the Republic, on proposal of the Minister of National Education. Responsible for primary, secondary, and higher education, he or she represents the Minister of National Education in an academy (there are 30 for 26 regions).

School life of the education community – All actions and reflection indissolubly linked to school as a complex system within an environment.

Secularism – Pupils and families have freedom of conscience: School as an institution must respect all political, philosophical, and religious choices although it recognizes none.

Technical education – It prepares pupils for different technical baccalauréats in secondary schools for general and technical education (LEGT) in the second cycle.

Vocational education – It prepares pupils for diplomas that enable immediate professional insertion. Today, students can opt for vocational high schools (LP) in the second cycle or for centers for apprenticeship (CFA). Both combine teaching vocational programs with training in enterprise.

French Context

France is a European country with its capital in Paris. The French Republic (official name) comprises metropolitan France as well as various overseas territories. Its total surface area is 675 000 km² (metropolitan France, 551 500 km²). In January 2008, the population was 64 473 000 (metropolitan France, 61 876 000), that is, 1% of the world's population. France's demographic growth is one of the fastest in Europe, combining a birth rate higher than the European average with a positive migratory balance.

The unification of France was achieved by its kings who, from Hugues Capet (987–996) to Francis I (1515–1547), gradually established their authority over the whole country. French, the language of the king, became the official language of the kingdom in 1539. The French Revolution of 1789 put an end to the Ancien Régime and reorganized French society on a new basis, which remains that of the Republic today. France has been a member of the European Union since its inception (Treaty of Rome, 1957).

Among the economic powers of the world, France ranked fifth or sixth (depending on the calculation method) in 2008. Although it is basically capitalist, the country's economy has been characterized by strong State intervention since Colbert (a Minister of Louis XIV in the seventeenth century). Two major problems plague the French economy today: its unemployment rate, which is one of the highest in Europe (7.5% in May 2008), particularly among women, people over 50 and the youth; and the size of the national debt and budget deficit, which put France in a difficult situation regarding the requirements of the Stability and Growth Pact adopted in 1997 by the Member States of the Euro zone.

In terms of the 1958 Constitution (which founded the Fifth Republic), France is an indivisible, secular, democratic and social Republic. Although it is a parliamentary democracy, the Constitution grants far-reaching powers to the President of the Republic, who is elected by direct universal suffrage.

The French Revolution laid the foundations for the edification of the Nation. One of its objectives was to ensure that education, until then provided largely by the Roman Catholic Church, was entrusted to the State and based on principles grounded in the Declaration of Human Rights and Rights of Citizens adopted in 1789, that is, public education, secularism, freedom, and equality. Secularism,

based on the separation of Church and State (the Law of 1905), stipulates that the State must respect all religions, although it recognizes none. A school quarrel has nevertheless raged for nearly two centuries between State education and private schools, most of them religious. The public education system is characterized today by its pluralism. It includes schools operating under contract, most of them Roman Catholic, which provide education for approximately 17% of all pupils – a rate that has remained stable since 1959.

Metropolitan France is divided into three tiers of local government authorities, namely, 36 568 communes, 96 departments (instituted by the Revolution), and 22 regions (since 1982). The State, which traditionally concentrated far-reaching powers at central level, has since 1980 introduced measures that have increased decentralization to local authorities, in particular in the field of education. In the past, several key events marked the intervention of the State in this respect: the organization of secondary education, by Napoleon; that of primary education teaching for boys (Guizot Law, 1833); and the institution, under the Third Republic (1870–1940), of free and compulsory schooling for boys and girls aged 6–13 years (Jules Ferry Laws, 1881–82). The system was completed under the Fourth (1946–58) and Fifth Republics.

Objectives of the Education System

The objectives of the French education system are set out in Section 1, Paragraph 1, Article L111-1 of the Education Code, which guarantees every citizen the right to education to enable them to develop their personality, to improve their level of schooling and further education, to participate fully in social and professional life, and to exercise their rights and responsibilities as citizens.

The 23 April 2005 framework law for the future of schooling added the following amendment to this first paragraph: “in addition to imparting knowledge, the main mission of schools, as established by the Nation, is to transmit the values of the Republic to pupils.” The public school system must allow access to all children, without exception, and strive to ensure their success.

The 11 February 2005 law on the equality of rights and opportunities for disabled persons reaffirms the right of special-needs children to education. The education system is now legally obliged to accept disabled children at the school closest to their home, which is their reference school. The parents of these children must be involved in the development of a personalized schooling project for their child.

The obligation to enrol children in school applies likewise to new immigrants who have been in the country

for less than a year (i.e., 3.9% of the total school population). These pupils are entitled to specific measures to facilitate their integration.

The role of schools is to contribute to equal opportunities for pupils to acquire knowledge, skills, and qualifications, on which their access to the labor market, especially in France, will depend. France is strongly attached to the principle of equal opportunities and the offer of the same quality of teaching for everyone throughout the country. It is only since the 1980s that priority education zones (PEZs) have been created to provide additional means for the education of the most disadvantaged pupils.

The Law of 23 April 2005, in the attached report, assigned quantitative objectives to the education system, to continue the democratization policy, and to meet France’s European commitments. “This is why the Nation has set the objectives for the education system to guarantee that, when they leave school, 100% of pupils have obtained a qualification, and to ensure that 80% of pupils in every age-group (i.e., born in the same year) reach the *baccalauréat* [equivalent A-levels] level.” The law also set the objective of ensuring that 50% of pupils in every age-group obtain a higher education degree or diploma.

Presentation of the Education System

In 2006–07, education was provided for 14 972 849 young people (pupils and students), in State and private schools, accounting for 23.5% of the total population in France. Schooling is compulsory from ages 6 to 16 years.

Pupils in Primary Education

In 2006, French primary schools provided education for 6 644 100 pupils, including 111 100 disabled pupils.

Nursery or pre-elementary education precedes the years of compulsory schooling (which begins at age of 6 years). In 2006, nursery schools, of which 87.6% were in the public sector, accommodated 2 578 445 children. Characterized by their strong and original identity, nursery schools fulfill an educational mission of which France is very proud. They provide education to all 3-year-old children and 23.4% of 2-year-old children.

Elementary schools, beginning at age 6, provide education to all French children (4 016 900 in 2006) for 5 years, from the preparatory course (CP) to the end of the intermediate course (CM2).

Special-needs children in the special schools/classes (AIS) set up to help them to adapt and to integrate into regular schools account for 3.5% of enrolments annually and total 48 700 pupils.

Pupils in Secondary Education

In 2006, a total of 5 418 100 pupils attended secondary school in France, 79.3% of them in public schools. Up to 44 300 were special-needs children who received individual or collective, part-time or full-time schooling. There were 201 100 students of foreign nationality in secondary schooling (no figures are available for primary schooling), that is, 3.7% of the total. Some 155 300 students, 2.9% of the total, were enrolled in schools falling under the Ministry of Agriculture and Fisheries.

Secondary schools in the first cycle

In the French system, the first cycle of secondary schooling (called *collège*, equivalent to junior high school) lasts for 4 years, theoretically from ages 11 to 15 years. The principle of secondary schooling for all was enshrined in a law passed in 1975 and has been applied since then. At the end of these 4 years, students sit for a national examination, *diplôme national du brevet* (DNB). In 2006, 57% of students (with or without the DNB) furthered their education in high schools for general and technical education, *lycées d'enseignement général et technologique* (LEGT) and 26% went on to vocational high schools, *lycées professionnels* (LP). Six percent of those who failed repeated the year and 11% left the system of schooling delivered under the Ministry of National Education (some continued with sandwich courses or training delivered by institutions falling under other ministries, while others exited the educational system altogether).

Secondary schools for general and technical education (LEGT) in the second cycle

The LEGT covers the last 3 years of schooling (*seconde*, *première*, and *terminal*). The first year of this cycle is decisive as students choose the main subjects that they are going to carry through to the end. Slightly under two-thirds of all students opt for the general stream, and just over one-third for the technology stream. At the end of the cycle, they sit for the national general or technical *baccalauréat* examination.

Vocational high schools (LPs) in the second cycle

The LPs offer 48 different specialities in which teaching at school is combined with training in enterprise. They prepare pupils for diplomas that qualify them for immediate professional insertion: *certificat d'aptitude professionnelle* (CAP); and *brevet d'études professionnelles* (BEP) or what is known as the *bac pro* (*baccalauréat professionnel*). Of the 26% of students who opt for an LP, 22% take up a BEP and 4% a CAP. The dropout rate at the end of the first year is high: about 16.5% in CAP and about 12.5% in BEP either drop out of schooling completely, or enter apprenticeship, or else move on to another training system.

At the end of the second year, 41% of students doing the BEP and 10% of those enrolled for a CAP choose

to continue for a further two years and to prepare a vocational *baccalauréat* (*bac pro*, created in 1985). Theoretically, this qualification is obtained 4 years after the DNB (although obtaining it in 3 years is currently under consideration).

Apprentices

Apprentices (385 859 in 2006) are young people in the 16–25 age group preparing for a vocational or technical diploma under an employment contract involving training in a company and vocational education programs conducted in a center for apprenticeship, a *centre de formation d'apprentis* (CFA). Most of these students (59%) follow a low level of training (leading mainly to the CAP and the BEP).

Students in Higher Education

In 2006, 2 254 000 students (of which 11.7% were foreign students) were registered in higher education institutions in France, among them 79.2% of the *baccalauréat* graduates from the previous year continuing their studies at university. Students registered in the universities that do not apply selection criteria at entry (62%) can do a 3-year degree called a license (equivalent of a bachelor's degree), a further 2 years to obtain a master's degree and, in a further 3 years, a PhD, following the European pattern (B/M/D).

Ten percent of students do a 2-year post-*baccalauréat* higher technical diploma, a *brevet de technicien supérieur* (BTS) delivered at high schools. The 76 160 students selected for preparatory classes for the prestigious *grandes écoles*, the *classes préparatoires aux grandes écoles* (CPGE), spend 2 or even 3 years on this preparation, as entry to these schools is highly competitive (e.g., the *Ecole Normale Supérieure* or the *Ecole Polytechnique*). This is a French particularity. Engineering degrees account for about 5% of all university degrees, which is considered insufficient to meet the country's needs.

Adults in Continuous Education

Despite being mandatory for firms, local authorities, and the State, since the Law of 16 November 1971, continuous and ongoing education concern only a limited number of people. In 2005, they accounted for 446 100 trainees in the National Education system.

Teaching Staff and Other Educational Personnel

In January 2007, the Ministry of National Education paid the salaries of 1 065 327 employees in the public education sector and another 144 501 in the private education sector under contract with the government. Four out of five

employees were teachers, that is, 982 678. In the public sector, 97.7% of teachers are civil servants with permanent posts, and their average age is 41.8.

Primary school teachers and all secondary education teachers are trained at university in *instituts universitaires de formation des maîtres* (IUFM). New recruits, who must have a license, study for 1 year to prepare for a competitive examination for entry into teaching. In the second year, if they are successful, they follow 1 year of practical training as paid trainee teachers. In 2006, teachers in the first stage of training numbered 13 404 (less than 15% of applicants in 2005), while those in the second stage of training numbered 9584 (less than 12% of applicants). Teaching as a profession seems to be suffering from a malaise and attention is being given to this as a general problem.

In 2007, 227 150 individuals had administrative, technical, or educational positions in the education system.

Administrative Organization and Management

For a long time, the political and administrative organization of France was characterized by the pre-eminence of central State authority, the heritage of an absolute monarchy. Until the end of the 1970s, the administration of education was characterized by a pyramidal system where all the decisions were made at the top by the Ministry of National Education. Corresponding to this administrative organization was a centralized trade-union structure.

The decentralization laws of 1982, 1983, and 1985 profoundly changed this configuration. A significant share of the State's responsibilities was transferred to local authorities: Communes (primary schools), departments (*collèges*), or regions (*lycées*), depending on the level of the educational institution concerned. Although autonomous since 1968, the universities have remained under national authority.

Decentralized powers concern the construction, maintenance, and functioning of educational institutions. As provided for by the Law of 13 August 2004, enrolment, catering, accommodation, general maintenance, and personnel management have fallen within the province of the departments – for *collèges* – and the regions – for *lycées* – since 1 January 2005.

In practice, local authorities have not allowed themselves to be confined to a strict management role. They are involved in pedagogical choices and the school life of the educational community and have, in particular, multiplied initiatives to support pupils in difficulty.

In parallel, many management decisions were transferred from national level to the *recteurs d'académie* (chief education officers, of which there are 30, for 26 regions in France), to the *inspecteurs d'académie* (directors of

departmental services, of which there are 100 in France), and to the principals of secondary schools (11 410 schools, public and private).

The State has nevertheless maintained important prerogatives: responsibility for national programs, the awarding of diplomas and degrees (including the *baccalauréat*), recruitment, remuneration, the management of most staff, including teaching/lecturing staff, the allocation of funds, and the control and evaluation of educational policies.

Overall, higher education remains within the exclusive domain of the State but receives substantial grants from local authorities. Primary schools (of which there are 55 667) have been a service delivered and managed by the communes since the nineteenth century (although the teachers are employed by the State). In secondary education, the State and local authorities have shared responsibilities and must work together.

To steer changes in the education system, which was traditionally regulated according to bureaucratic procedures, France is endeavoring to move toward a form of management-by-results and a new system of educational governance.

The country has an excellent system of statistics and of quantitative and qualitative evaluation, as well as tools for forecasting and reflection. In 1987, it set up a department of evaluation, forecasting, and performance, the *Direction de l'évaluation, de la prospective et de la performance* (DEPP) within the Ministry of Education. The government has entrusted the mission of evaluating all educational institutions, as well as the education system as a whole, to two general inspectorates: 159 IGEN, a general inspectorate of national education, and the 93 IGAENR, a general inspectorate of the administration of national education and research. A significant number of inspectors of primary and secondary schools (3237) are responsible for the quality of teaching. For higher education and research, an evaluation agency, the *Agence d'évaluation de la recherche et de l'enseignement supérieur* (AERES) was created in 2007 to replace the national evaluation committee, the *Comité national d'évaluation* (CNE). In 2005, the higher council for schools, the *Haut Conseil de l'Ecole* (HCE), replaced the higher council for the evaluation of schools, the *Haut Conseil de l'évaluation de l'école* (HCEE) that had been created in 2000. Every year, the HCE delivers a public report on the results of the education system to the President of the Republic. This report is submitted to Parliament.

A new evaluation culture has thus developed which, paradoxically, seems to be used far more at the level of the system as a whole than at that of individual schools.

With the *Loi organique relative aux lois de finances* (LOLF) the organic law relating to finance laws, passed by the Parliament on 1 August 2001, France obtained a new financial constitution. Since 1 January 2006, the Parliament has been able to discuss policy and budget

priorities and objectives concerning education, to which the government is then committed. On this basis, it votes on the required means for meeting those objectives and evaluation results. France is currently experimenting with this new mode of political steering of education.

The Cost of Education

In 2006, France devoted 121.4 billion euros to its education system, that is, 6.8% of its gross domestic product (GDP) and the equivalent of 1920 euros per capita, or 7160 euros per pupil or student. Excluding adult continuous education, this level of investment situates France above the average of the Organisation for Economic Co-operation and Development (OECD) countries (6.1% against an OECD average of 5.8% in 2004).

The share of expenditure on education in the national budget was appreciably increased in the early 1990s, reaching 7.6% in 1993 against 6.4% in 1980. Since then, levels of expenditure on education have continued to increase, but less quickly than the growth of national wealth. This growth in expenditure is explained less by the increase in the number of pupils and students than by the rising cost per pupil.

The State is the main source of funding of public education (63% in 2006, of which 55.9% was funded by the Ministry of National Education). The Ministry's budget is primarily used for salaries. Local authorities now foot 20.6% of the total bill (against 14% in 1980), while households contribute 8% and companies 6.4%.

At the time of writing, in 2008, due to financial constraints, a policy of not replacing one out of two teachers leaving on retirement is under consideration.

Results of the Education System

The French education system made important progress, from both a quantitative and qualitative point of view, during the three decades up to the mid-1990s. Since 1994, the rate of schooling in nursery schools of children from the age of 3 has been 100%, compared with 36% in 1960. During the 1960s and 1970s, access to secondary education was generalized. From the mid-1980s, pupils who graduated from *collège* massively opted for the second cycle to do a general, technical, or vocational *baccalauréat* (the latter was created in 1985), and then to go on to higher education.

The progress of a generation currently engaged in the French education system or which has just left it can be summarized as follows: almost all young people today complete the first cycle of secondary school (81.1% pass the DNB), 70% reach the level of the *baccalauréat*; 64% actually obtain their *baccalauréat*, 50% go on to higher education, and a little more than 40% obtain a higher education degree.

The objective announced in the mid-1980s and included in the Law of 2005, to ensure that 80% of a generation reached their final year of *lycée* –that is, *baccalauréat* or equivalent – may not have been achieved, but it has led to a spectacular rise (over 30 points) in the rate of access to the *baccalauréat* level in just one decade, from under 40% in 1985 to 70% in 1995. School has thus made it possible for young generations to reach much higher levels of education than those of their elders. At the end of the 1990s, slightly over 40% obtained a higher education degree, against 30% at the end of the 1960s, and 20% at the end of the 1950s.

Seventeen percent of young people (approximately 130 000 per generation) leave secondary school without any diploma. This proportion was close to 50% for the generation now aged 55–64. Out of that 17%, close to 6% leave the education–training system without a professional qualification (i.e., without having reached the level of the CAP or the BEP, and without having been accepted in an LEGT).

The rapid development of schooling has definitely supported the democratization of the education system, but all national evaluations show that school results depend strongly on the social origin of the pupils at all levels of schooling. Difficulties and inequalities persist, especially in the level of basic skills acquired, and these have serious consequences for young people's schooling and job opportunities. This is why the Law of 23 April 2005 now requires every young person at the end of the first cycle of secondary school (i.e., *collège*) to acquire a common basic level of knowledge and skills.

France still needs to make an effort to achieve the goals set by the European governments at the Summit of Lisbon in 2000 with respect to the generalization of the second cycle of secondary education, the reduction of dropouts, the development of adult education, the improvement of basic reading skills, and the increase in the number of graduates in science and technology.

The Major Issues Debated since 1995

The development of comparative studies at international level (OECD, EUROSTAT, and UNESCO), and, in particular, the Programme for International Student Assessment (PISA), have made it possible for France to continue its reflection on education.

Since 1995, several OECD indicators have shown no further improvements for France (e.g., the rate of access to the *baccalauréat* level continues not to exceed 70% of a generation). The education system appears to have reached a threshold that it is unable to exceed.

Whereas half of the pupils in France obtain excellent results when compared with students internationally, the other half's scores are among the worst of the developed countries. This suggests that the school system works

successfully for the pupils who adapt to it, but does not manage to meet the needs of pupils in difficulty, especially the needs of the 130 000 young people who leave school every year in France without any diploma and are very likely to find themselves unemployed.

After *collège*, 40% of pupils are directed (in certain cases, against their will) to a short period of vocational training to obtain a certificate or diploma. This is a very high percentage by comparison with the other countries, and explains the insufficient number of graduates in higher education.

Among the students who continue their studies, only 20% of a generation obtain a higher education degree equal to or higher than the license (*baccalauréat* + 3 years). This is not enough to meet France's needs.

This low rate is alarming because France seems to be one of the Western countries where the link between the qualifications obtained at school and at work is the strongest, not only at entry into the workforce but throughout life. It is difficult to compensate for the low level of initial training later in life because adult ongoing education is developing very slowly.

Although the school system has effectively been democratized over the past 20 years, it still reproduces social elites rather than guaranteeing equal opportunities for all. These results are not only contrary to the goal of equity at which the education system aims; they also seem to be counter-productive as regards the needs of the economy.

The 50% of pupils who obtain good results in the PISA assessments, tend to be those who have made it without having to repeat a year, whereas the other half consists of those pupils who obtain weak results even after repeating at least 1 or 2 years – as if repeating compounded their difficulties. Although requiring pupils to repeat a year is a practice that is decreasing, it remains deeply entrenched in the French education system which, in this respect, holds the worst record of European countries (up to 38% of pupils have repeated at least once at the end of the first cycle of secondary school). These extra years are a heavy social and financial burden for the country.

The pattern of boys' and girls' schooling tends to differ: more girls than boys obtain their *baccalauréat* and enter higher education. However, girls are overrepresented in the humanities and training for the service sector, to the detriment of the scientific and technological fields.

Of all these key issues open to debate, the most important and unquestionably the most difficult to solve, remains the evaluation of teaching and nonteaching staff. There is all-round agreement that good management of human resources (the term itself is controversial) appears necessary, but the need to establish a link between pupils' success and teachers' teaching practices, or even the management approach of a school principal, has been formulated only recently.

Because of the contrasting results obtained by the education system and its historical role in the construction of the Republic, the school system in France is a subject of

constant and impassioned debates, which makes any reform difficult to implement.

Germany

A Hüfner and K Hüfner, Berlin, Germany

© 2010 Elsevier Ltd. All rights reserved.

General Background

Since the unification of the two German states on 3 October 1990 which marked the end of over 40 years of division, the new Federal Republic of Germany covers a total of 357 thousand square kilometers. It lies at the heart of the European Union (EU) and shares its borders with nine neighboring countries. Except Switzerland, all of them are also members of the EU. With a population of over 82 million, Germany is one of the most densely populated countries in Europe. In 2005, 6.8 million were of foreign nationality, of which the Turks represented with 26% the largest group. It continues to be a major challenge for the educational system to integrate the children of migrant workers and to offer them adequate opportunities for study, training, and work.

Germany is a democratic and social federal state made up of 16 Länder (states) since 1990. The political, economic, social, and cultural integration process of the former two states takes longer than originally anticipated; the necessary changes from a socialist planned economy of the former German Democratic Republic toward a new type of social market economy are still underway. For the people living in the five new Länder of the eastern part of Germany, these transition processes from security without freedom toward freedom without security implied big problems of adjustment toward unknown market-oriented demands of flexibility. In the areas of culture, education, and science, the Unification Treaty (*Einigungsvertrag*) of 31 August 1990 contained basic provisions in order to establish a common and comparable basic structure in the school system and a common, though differentiated, higher education and research system in the 16 Länder of the new Federal Republic of Germany, primarily according to the model of the former Federal Republic of Germany.

Germany is not rich in natural resources. Therefore, the country is heavily dependent on imported goods (40% of gross national product (GNP) in 2006) and the export of finished products and services (45% of GNP in 2006). GNP per capita reached US\$35 000. Two percent of the 39 million employed work in agriculture, 26% in industry, and 72% in the service sector. Between 2005 and 2007, the unemployment rate went down from over 10.0% to 8.4% remaining high by Organization for Economic Cooperation and Development (OECD) standards. Until 2007, Germany enjoyed economic recovery after a long phase of stagnation since the end of 2004.

In its most recent economic survey of 2008, OECD has included a special chapter on educational policy stressing that improving education outcomes is important for the country's long-term economic performance and social cohesion. This analysis must also be seen in the light of the Lisbon goal of 2000 when the EU heads of state declared their ambition to make the EU "the most competitive and dynamic knowledge-based economy in the world by 2010, capable of sustainable economic growth, with more and better jobs and greater cohesion."

Institutions at the National Level

According to the Basic Law (*Grundgesetz*), the cultural sovereignty (*Kulturbobkeit*) implies the predominant responsibility of each of the Länder for education, science, and culture. Each Land is responsible for its educational and cultural policy. Educational and cultural legislation is primarily, the administration of education and culture almost entirely the responsibility of the 16 Länder. Therefore, one could also argue that Germany consists of 16 educational systems which can be characterized as highly differentiated systems (cf. **Figure 1** and especially the annotations as published by the Secretariat of the Standing Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany).

However, within the Federal Government (*Bundesregierung*), it is the Federal Ministry of Education and Research (BMBF) that is responsible for policy, legislation, and coordination with regard to out-of-school vocational training and continuing education, financial assistance for students, admission to higher education institutions and the degrees they confer. Furthermore, the BMBF shares with the Länder, joint tasks (*Zusammenwirken*) according to Article 91 b of the Basic Law. In order to coordinate cooperation among the Länder and with the Bund, the Länder established in 1948 the Standing Conference of the Ministers of Education and Cultural Affairs (*Ständige Konferenz der Kultusminister der Länder; Kultusministerkonferenz; KMK*).

The General Structure of the Education System

Although German is the normal language of instruction and training at general education and vocational schools as well as higher education institutions, some exception must be mentioned. Those include bilingual schools and

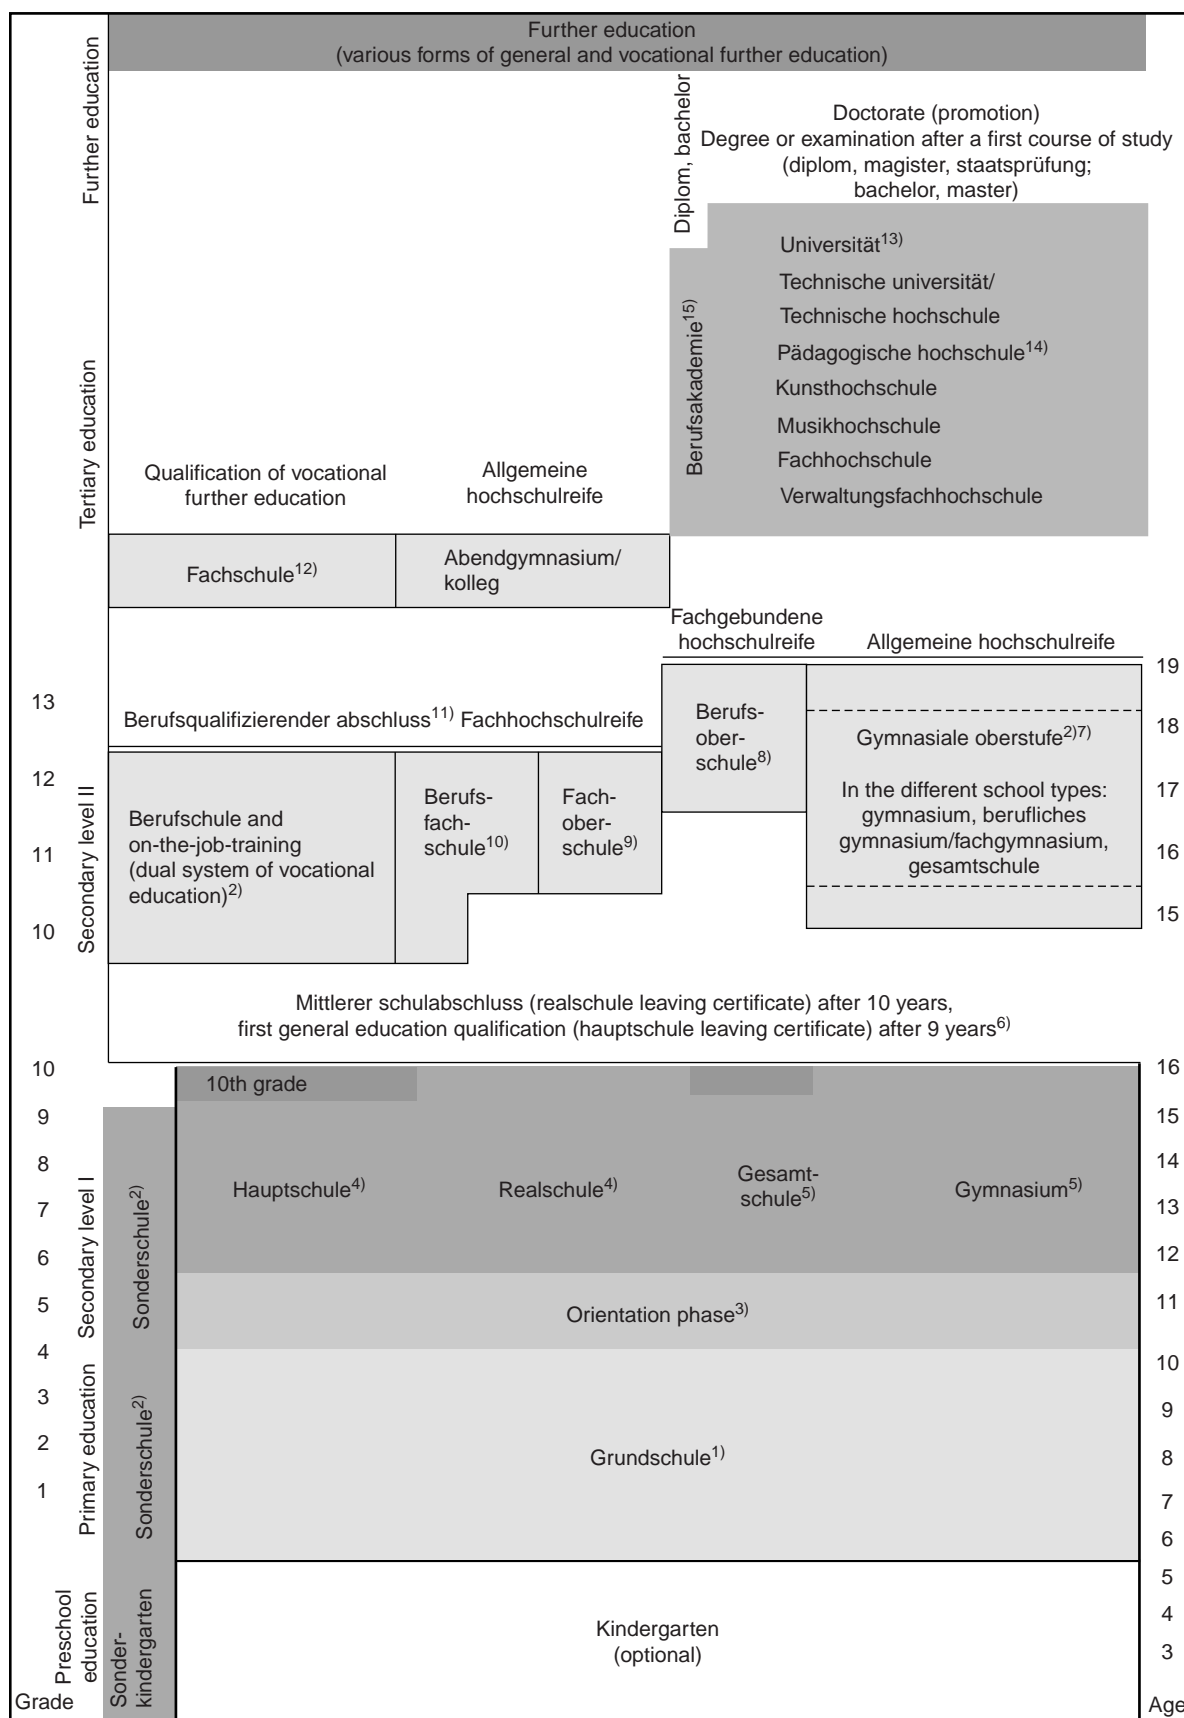

Figure 1 (Continued)

Annotations

Diagram of the basic structure of the education system. The distribution of the school population in grade 8 as per 2005 taken as a national average is as follows: *Hauptschule* 22.5%, *Realschule* 25.8%, *Gymnasium* 30.9%, *integrierte Gesamtschule* 8.5%, types of school with several courses of education 6.3%, special schools 5.3%.

The ability of pupils to transfer between school types and the recognition of school-leaving qualifications is basically guaranteed if the preconditions agreed between the Länder are fulfilled. The duration of full-time compulsory education (compulsory general education) is 9 years (10 years in four of the Länder) and the subsequent period of part-time compulsory education (compulsory vocational education) is 3 years.

1. In some Länder special types of transition from pre-school to primary education (*Vorklassen*, *Schulkindergärten*) exist. In Berlin and Brandenburg the primary school comprises six grades.
2. The disabled attend special forms of general-education and vocational school types (partially integrated with non-handicapped pupils) depending on the type of disability in question. Designation of schools varies according to the law of each Land (*Sonderschule/Schule für Behinderte/Förderschule/Förderzentrum*).
3. Irrespective of school type, grades 5 and 6 constitute a phase of particular promotion, supervision and orientation with regard to the pupil's future educational path and its particular direction. In some Länder, the orientation stage (*Orientierungsstufe* or *Förderstufe*) is organised as a separate school type.
4. The *Hauptschule* and *Realschule* courses of education are also offered at schools with several courses of education, for which the names differ from one Land to another. The *Mittelschule* (Sachsen), *Regelschule* (Thüringen), *Sekundarschule* (Bremen, Sachsen-Anhalt), *Erweiterte Realschule* (Saarland), *Integrierte Haupt-und Realschule* (Hamburg), *Oberschule* (Brandenburg), *Verbundene* or *Zusammengefasste Haupt-und Realschule* (Berlin, Hessen, Mecklenburg-Vorpommern, Niedersachsen) and *Regionale Schule* (Mecklenburg-Vorpommern, Rheinland-Pfalz), *Regionalschule* (Schleswig-Holstein), *Gemeinschaftsschule* (Schleswig-Holstein) as well as comprehensive school (*Gesamtschulen*) fall under this category.
5. The *Gymnasium* course of education is also offered at comprehensive schools (*Gesamtschule*). In the cooperative comprehensive schools, the 3 courses of education (*Hauptschule*, *Realschule* and *Gymnasium*) are brought under one educational and organisational umbrella; these form an educational and organisational whole at the integrated *Gesamtschule*. The provision of comprehensive schools (*Gesamtschulen*) varies in accordance with the respective educational laws of the Länder.
6. The general education qualifications that may be obtained after grades 9 and 10 carry particular designations in some Länder. These certificates can also be obtained in evening classes and at vocational schools.
7. Admission to the *gymnasiale Oberstufe* requires a formal entrance qualification which can be obtained after grade 9 or 10. At present, in the majority of Länder the *Allgemeine Hochschulreife* can be obtained after the successful completion of 13 consecutive school years (9 years at the *Gymnasium*). Yet in almost all Länder the gradual conversion to 8 years at the *Gymnasium* is currently under way, where the *Allgemeine Hochschulreife* can be obtained after a 12-year course of education.
8. The *Berufsoberschule* has so far only existed in a few Länder and offers school-leavers with the *Mittlerer Schulabschluss* who have completed vocational training or 5 years' working experience the opportunity to obtain the *Fachgebundene Hochschulreife*. Pupils can obtain the *Allgemeine Hochschulreife* by proving their proficiency in a second foreign language.
9. The *Fachoberschule* is a school type lasting for two years (grades 11 and 12) which admits pupils who have completed the *Mittlerer Schulabschluss* and qualifies them to study at a *Fachhochschule*. Pupils who have successfully completed the *Mittlerer Schulabschluss* and have been through initial vocational training can also enter the *Fachoberschule* directly in grade 12.

Figure 1 (Continued)

10. *Berufsfachschulen* are full-time vocational schools differing in terms of entrance requirements, duration and leaving certificates. Basic vocational training can be obtained during one- or two-year courses at *Berufsfachschulen* and a vocational qualification is available at the end of two- or three-year courses. Under certain conditions the *Fachhochschulreife* can be acquired on completion of a course lasting a minimum of 2 years.
11. Extension courses are offered to enable pupils to acquire qualifications equivalent to the *Hauptschule* and *Realschule* leaving certificates.
12. *Fachschulen* cater for vocational continuing education (1–3 year duration) and as a rule require the completion of relevant vocational training in a recognised occupation and subsequent employment. In addition, the *Fachhochschulreife* can be acquired under certain conditions.
13. Including institutions of higher education offering courses in particular disciplines at university level (e.g. theology, philosophy, medicine, administrative sciences, sport).
14. *Pädagogische Hochschulen* (only in Baden-Württemberg) offer training courses for teachers at various types of schools. In specific cases, study courses leading to professions in the area of education and pedagogy outside the school sector are offered as well.
15. The *Berufsakademie* is a tertiary sector institution in some Länder offering academic training at a *Studienakademie* (study institution) combined with practical in-company professional training in keeping with the principle of the dual system.

As at July 2007

Source: Secretariat of the Standing Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany. Documentation and Education Information Service.

Figure 1 Basic structure of the educational system in the Federal Republic of Germany.

classes as well as instruction and extra classes in the mother tongue for pupils whose mother tongue is not German. Furthermore, the Länder concerned apply the European Charter of Regional Minority Languages of the Council of Europe to those speaking Danish, Frisian, Sorbian, Romany, and Low German. In the higher education institutions, increasingly English is also used as a language of instruction and as working language. This is also in line with the Bologna Process leading to a European Higher Education Area.

School attendance is compulsory for children between the ages of 5–6 and 18 years. Depending on the Land, full-time schooling is mandated for either 9 or 10 years; it may be followed by part-time attendance at a vocational school, complemented by an apprenticeship (dual system). All compulsory schooling is free of charge.

In principle, the education system is divided into the following levels:

- pre-primary education,
- primary education,
- secondary education, and
- tertiary education.

Pre-Primary Education

Pre-primary education is provided by institutions catering for children from a few months to 5–6 years when they

usually start school (*kindergarten* being the traditional form for children from 3 to 5–6 years). Traditionally, those institutions are not regarded as part of the educational system; they are run by the nonpublic and public child and youth welfare services, for example, by churches, welfare associations, local authorities (*Kommunen*), and parents' associations. In most Länder, the legal and administrative competence lies with the ministries of social affairs.

All children having reached the age of 3 years have the legal right to be admitted to a kindergarten until school entry. The main responsibility is with the *Kommunen* which are obliged to provide places in day-care centers to all children from 3 years until they start school. Parents must pay fees for the attendance of pre-school institutions. The amount depends, *inter alia*, upon parents' income and family size. Parents can apply for full or partial reimbursement by the local youth welfare office if they cannot afford to bear the costs. Whereas in 1960 only 25% of the age group attended pre-school institutions, its share increased to 87% by 2006.

Primary Education

Primary education is compulsory for all. Deferment of school attendance is only possible in exceptional cases. In the majority of the Länder, those children must attend *Schulkindergarten* or preschool classes (*Vorklassen*) in order

to reach the necessary level of individual development. Earlier, compulsory schooling started on 1 August for all children having reached their sixth birthday. Nowadays, a general tendency can be observed to set the statutory qualifying date for starting school on 31 December. Berlin started in 2004, Bavaria and North-Rhine-Westfalia followed. This implies that compulsory education starts between the age of 5 and 6 years.

For the first 2 years of primary education (*Grundschule*), school work is not graded; instead, teachers provide evaluations of the pupils' strengths and weaknesses. Foreign language instruction often begins as early as third or fourth grade. By fifth grade, all students are learning a foreign language, in most cases English. Other subjects are German, mathematics, science, art, music, and physical education. The *Grundschule* lasts for 6 years in the Länder of Berlin and Brandenburg and for 4 years in all the other Länder.

Secondary Education

Upon completion of the *Grundschule* at which all children attend mixed-ability classes, the secondary school system is characterized primarily by three school types which divide the students of age 10–12 into various educational paths with different leaving certificates and qualifications: *Hauptschule*, *Realschule*, and *Gymnasium*. Despite all attempts to increase the horizontal mobility, this differentiated system at the secondary level is still the characteristic feature of German education. Apart from these three types, all Länder have *Gesamtschulen* (comprehensive schools), although highly differing in number (in 2003, e.g., two institutions in Bavaria and 217 in North-Rhine-Westfalia). Several Länder introduced types of schools in which the traditional courses offered by the *Hauptschule* and the *Realschule* are combined under one organizational umbrella. Names, however, differ from Land to Land (cf. **Figure 1** and the annotations).

Secondary education breaks down in lower secondary level (*Sekundarschule I*) from grades 5 to 9/10 and upper secondary level (*Sekundarstufe II*) from grades 10 to 12/13. Transition from *Grundschule* to one of the school branches at secondary level depends on legislation in the Land concerned. The decision is either taken by the parents

or the school or the school supervisory authority, based on an assessment made by the *Grundschule*.

Whereas *Hauptschulen* provide its students with a basic general education preparing them for an apprenticeship afterward, *Realschulen* offer a more extensive general education. The *Hauptschule* normally covers grades 5–9/10, the standard *Realschule* grades 5–10. A *Realschule*-leaving certificate qualifies for a transfer to a school that provides a vocational or higher education entrance qualification.

The *Gymnasium* provides an intensified general education; it comprises both the lower and the upper secondary level and covers grades 5 or 7–12/13; its leaving certificate (*Abitur*) provides a general higher education entrance qualification. In almost all the Länder, the reduction from 9 to 8 years at the *Gymnasium* is currently underway. As mentioned above, in addition to the three school branches, there are *Gesamtschulen* in the majority of Länder. Two types can be distinguished. Whereas the cooperative one combines the *Hauptschule*, *Realschule*, and *Gymnasium* in one organizational unit and offers instruction in classes designed for the achievement of various certificates, the integrated one forms one organizational and educational unit, differentiating classes in some of the subjects according to the level of proficiency.

Table 1 shows how the students in grade 8 were distributed over time. Whereas the share of students at the *Hauptschule* decreased from 72% in 1960 to 24% in 2005, a clear increase can be observed in the attendance at *Gymnasium* and *Realschule* moving from 17% and 11% to 33% and 27%. Since the *Hauptschule* tends to become a kind of left-overs school (*Restschule*) with a disproportionately high percentage of students from migrant families, presently alternative solutions are discussed or even started ranging from an integration (cf. **Table 1**) to its full abolition.

The vocational training system has enjoyed a high reputation based on its success in producing the necessary skills through the dual system of education, a combination of part-time vocational schooling and part-time on-the-job training, which is open to all lower secondary school leavers. It is organized for some 340 professions. In all economic fields, training regulations (the workplace element) are nationally coordinated and framework curricula are established by the Länder (the school element).

Table 1 Distribution among students in grade 8 according to school branch, 1960–2005 (in percent)

Year	Gymnasium	Realschule	Hauptschule	Gesamtschule	Integrated Haupt-und Realschule
1960	17	11	72	–	–
1970	23	21	56	–	–
1980	27	28	41	4	–
1990	30	29	34	7	–
2000	31	26	23	10	10
2005	33	27	24	10	7

From Bundesministerium für Bildung und Forschung (2008). *Grund-und Strukturdaten 2007/2008*, p. 25. Bonn, Berlin: BMBF. p. 25.

Students pass a final examination before an examination board composed of representatives of the chambers concerned. Concomitantly, they receive a second leaving certificate from the vocational school (*Berufsschule*) if they have achieved the necessary results.

Higher Education

The tertiary sector encompasses higher education institutions which include universities and equivalent institutions, for example, for teacher training (*Pädagogische Hochschulen*), theology, art, music, sport, and universities of applied sciences (*Fachhochschulen*) (cf. Table 3). In 2003, Germany had a total of 366 institutions of higher education of which 99 were private institutions (17 universities, 16 institutions for theology, 7 for art and 59 *Fachhochschulen*).

In 2007, 1 979 043 students were registered in German higher education institutions. 246 369 (= 12.4%) of them were foreign students. 57 933 of them were enrolled as students of foreign nationality who gained their higher education entrance qualification at a German school (*Bildungsinländer*). China headed the ranking of countries of origin, followed by Bulgaria, Poland, and Russia. Turkey which ranked first 10 years ago reached rank 5. As a host country for foreign students, Germany ranks third after the United States and the United Kingdom.

In 2006, students had an average monthly income of 770 Euros, 27% of them had less than 600 Euros per month. In a breakdown, 52% of the monthly income came from the parents, whereas 24% were earned. Since 2005, the Länder can impose study fees on students. Some Länder made use of this option for the first time in the winter-semester of 2006/2007 by imposing up to 500 Euros per semester. No matter under what conditions, the imposition of fees is highly controversial among the political parties in Germany.

The internationalization of German higher education shows different features. The Bologna Process is supposed to lead toward a European Higher Education Area, thus enhancing its competitiveness and attractiveness to other parts of the world. In this context, a new graduation system of bachelor's and master's degrees has been adopted for implementation in all higher education institutions since 1998. In addition, a European credit transfer system (ECTS) has been introduced facilitating an increase of student mobility.

In Germany, the speed of the reform process in higher education is accelerating, which indicates that competition is becoming an integral feature both among higher education institutions and among the Länder. In general, a move from detailed input-oriented Länder control mechanisms to highly flexible, output-oriented institutional budgets can be observed. Performance indicators will be introduced, also influencing the amount of salary supplements for professors.

Ongoing Debates about Future Developments

Currently, education receives highest political priority in Germany. Although without legal competences in education, the Federal Chancellor, Angela Merkel, proclaimed "education for all" as the message for the twenty-first century, thereby referring to "welfare for all" as postulated by the father of the concept of social market economy, Ludwig Erhard, in the 1950s. In the following, some of the major issues in education are summarized.

Pre-School Education

In all Länder, the development of educational concepts and the preparation and implementation of plans can be observed which deal with the pre-school sector of day-care centers for children between 3 and 5–6 years, thereby attaching particular importance to improving the linguistic competence of children with migrant background. In about half of the Länder, those measures also include their parents. In order to organize the school entrance phase in a more flexible way, cooperative links between pre-school institutions and primary schools had to be improved. In 2004, the KMK and the Conference of Ministers of Youth adopted a framework for early education in the pre-school sector and a recommendation to strengthen and further develop the overall relationship between education, upbringing, and supervision. Furthermore, the Day-Care Expansion Act of 2004, which came into force at the beginning of 2005, provides for an expansion of the day-care for children under the age of 3 years which should be extended by 2010 in such a way that it meets the actual needs of parents and their children.

Primary Education

Since the 1990s, teaching became more pupil oriented, enhancing their self-initiatives. Furthermore, all Länder have introduced foreign language teaching mainly for grades 3 and 4, in some Länder even for grades 1 and 2. In October 2004, the KMK adopted binding educational standards for the subjects German and mathematics. These determine the competences and knowledge students should have attained by grade 4.

Secondary Education

Germany is participating in several international comparative studies of student achievement. Among them is the OECD project entitled Programme for International Student Assessment (PISA) which provides Germany with indicators concerning the knowledge, skills, and abilities of 15-year-old students in reading, mathematics, and

sciences. The survey covers three thematically overlapping cycles (PISA 2000, PISA 2003, PISA 2006). After the publication of the results of PISA 2000 which focused on reading literacy, the KMK named seven areas in which the Länder and the KMK will undertake measures in order to

- improve linguistic competence as early as pre-school education,
- strengthen the link between the pre-school and primary school sector with the aim of an early school entry,
- improve reading literary and basic understanding of concepts in mathematics and sciences in primary education,
- support more efficiently educationally disadvantaged children, especially those from families of migrant workers (cf. **Table 2**),
- develop and assure the quality of teaching based on binding educational standards and result-oriented evaluation,
- improve the performance of teachers, and
- expand the provision of all-day activities and care aiming to increase educational opportunities.

According to the 2006 OECD, PISA study education achievement of 15-year-olds in Germany has been above the OECD average in science ranking eighth position among OECD countries. Their achievement has been average in reading and mathematics. Students from families of migrant workers had made lower scores in the three subjects than native students. Given the relatively large share of foreign students (cf. **Table 2**), their performance had a large negative impact on Germany's ranking.

Higher Education

Modernization and internationalization are the key efforts in Germany. This implies, *inter alia*, a higher degree of deregulation in the Länder, thus increasing the institutional autonomy and creating financial incentives via the use of performance indicators. The responsible authorities intend to enhance the international competitiveness of higher education institutions. One example is the Excellence Initiative of the Bund and the Länder for the

promotion of science and research in German institutions of higher education funding three areas, namely research schools for the promotion of scientific talent, excellence clusters for the promotion of leading science, and future concepts for top-class research at universities (total amount until 2011: 1.9 billion Euros).

Conclusions

In sum, it can be concluded that the issue of quality assurance through educational standards and educational reporting received the necessary attention after the PISA shock. As a consequence, the KMK had adopted the necessary measures step by step in 2003 and 2004. As a result of this and for the first time, quality development in the general education of all Länder can be checked against jointly agreed criteria. In order to guarantee a central comparative review of the achievement of educational standards, the KMK founded in 2004 the Institute for Quality Development in Education (IQB) which was set up at the Humboldt University Berlin. The comprehensive strategy for educational monitoring of the KMK is indeed a completely new approach in educational planning, thus replacing input-oriented approaches by output-oriented strategies. One step in this direction is the first joint educational report of June 2006, of the Bund and the Länder on education in Germany, which has been drawn up by an independent scientific consortium. This educational report will be published every 2 years and present a set of core indicators, informing the German public about education in the course of life, that is, from early education up to continuing education taking into account the necessity of lifelong learning.

In its second report of 2008 the group observed, *inter alia*, that

- the female students are increasingly successful at all levels of the German education system – a success story which is not yet reflected on the labor market;
- the demand for higher education remains relatively low, although the proportion of students qualifying for higher education increased;
- the socioeconomic background of parents has a stronger impact on student participation in secondary and higher education than in other OECD countries.

Over the last years, a broad spectrum of reforms related to all levels of the education system has been started in Germany. Whether the reform processes will actually lead to the desired results remains an open question.

Educational Finance

The Bund, the Länder, and Kommunen spent altogether 86.7 billion Euros in 2005 (in 1995: 75.9 billion Euros), among

Table 2 Share of foreign students according to educational level, 2000 and 2005 (in percent)

	2000	2005

them 50.2 billion Euros for general and vocational education and 18.4 billion Euros for higher education (9.2 billion Euros for higher education research are not included).

Compared to the majority of OECD countries, overall educational expenditure in Germany increased more slowly in recent years than total public expenditure. Therefore, its proportion decreased from 9.9% to 9.7% between 2000 and 2005, whereas the OECD average increased from 12.8% to 13.2%.

In 2005, Germany spent 5.1% of GDP at all levels of the education system (OECD average: 6.1% of GDP). Looking at the expenditure per student at different educational levels, Germany remained below the OECD average in primary education, but above the OECD average in higher education and, due to the dual system, also in secondary education. The OECD clearly postulates that additional investments in education will be important. However, efficiency and productivity in education must also be improved.

General Background

Ghana is situated in West Africa on the Gulf of Guinea. It achieved independence from Britain in 1957 and has been a self-governing republic since then.

Between independence and 2000, Ghana has seen almost 20 years of military rule, about 12 years of restricted emerging democratic practice, and some 10 years of democracy. The election of the New Patriotic Party (NPP) in December 2000 ushered in a new political context for Ghana: for the first time, a sitting government was ousted from office by means of the ballot box. Ghana has a parliamentary form of government with the president serving 4-year terms. The elections in December 2004 saw the NPP peacefully retain power. The last elections were in December 2008. Ghana is now considered an island of peace and stability in the West Africa Sub-region.

Early formal schooling in the Gold Coast (Ghana) became, for a time, a subsidiary function of the large merchant companies who operated schools usually attached to castle chaplaincies which preceded the main mission activity in the Gold Coast by nearly a 100 years. It was the Portuguese who established the first school at Elmina Castle (in the mid-sixteenth century). In 1821, provision was

made from the British Crown funds to set up a series of government schools, though these were later absorbed by missions.

It was not until the late-nineteenth century, with the rise of European missionary societies, that the development of formal educational facilities really took off. Two of the most important missions were the Wesleyan Methodist Missionary Society and the Basel Mission Society. Outside of these early formal schools, skills formation and replication among the early occupational specialists – for example, the goldsmiths, weavers, and wood-carvers – took place through traditional apprenticeship learning. While the literature makes little mention of this type of training during the colonial period, it probably remained the largest provider of skills training in the Gold Coast – as it did in Ghana in 2009.

While World War I increased the opportunities for Africans in the labor market, the expansion of primary schooling during this period soon led to concerns about unemployed school leavers. Technical and vocational education and training (TVET) as a solution to this problem of rising unemployment became popular among policy-makers. In the 1920s, Governor Guggisberg vehemently promoted school-based TVET as a means of re-orientating youth toward manual work thereby reducing unemployment. However, the unpopularity of school-based TVET led to school curricula becoming increasingly more academic during the 1930s until the period of self-governance in 1951. The development of Achimota secondary school during the 1920s is an interesting case in point. The initial intention was to create a secondary school with a strong agricultural core as part of the curriculum but, as a result of pressure from youth, parents, educated Africans, and the press, by 1951, Achimota had become a very academically orientated institution.

By 1951 there were only 23 technical institutions with some 3300 pupils – less than 1% of pupils in all types of school. Unemployment has remained a major problem in the post-1951 period. During the 1950s–1970s the government of Ghana attempted to tackle this with work-creation schemes like the Brigades and by setting up technical institutes and national vocational training institutes (NVTIs). Since the 1960s, there have been repeated attempts to reform the education system to make it more orientated toward work. The 1987 attempt to vocationalize the junior secondary level has been officially acknowledged as a failure. In September 2007, a new education reform came into effect (see **Case study 1**).

Case study 1 Ghana's 2007 Education Reform

In 2004, the Government of Ghana (GoG) came out with a *White Paper on Educational Reforms* which outlined the reforms for the education and training system which commenced in September 2007. This reform came about due to the persistent high levels of youth un- and underemployment and the belief that something must have gone wrong with the education and training system to have caused, or at least not solved, the youth employment problem. The previous education reforms of 1987 – which were intended to equip the youth with directly employable skills for the world of work through a vocationalized junior secondary school system – have been deemed a failure by many in the GoG. Moreover, the new reforms are meant to put in place a second-cycle system that caters in a better manner for the majority of youth (c.60%) who complete basic education and do not continue to formal senior-secondary education. The major elements in the reform include:

1. Universal and compulsory basic education extended to include 2 years of preschool teaching and extending basic education from 9 to 11 years.
2. At the primary level, fewer subjects are to be taught so that grounding in the basic skills (literacy, numeracy, problem-solving skills, and creative arts) would be improved.
3. The junior secondary school (JSS) system, that includes – in theory, but frequently not in practice – an element of pre-vocational and pre-technical skills training, has been discontinued. In place of the JSS will be the renamed Junior High School (JHS), with a more general, comprehensive curriculum. The government intends that the JHS should not be like the present JSS “which served as a terminal programme for most pupils. . . [but] should become the entry stage” (p. 5) to further postbasic education and training in the new diversified system of senior high schools or in a new system of structured apprenticeship.
4. Senior secondary schools will be renamed Senior High Schools, extended from 3 to 4 years, and diversified into four streams: vocational, technical, agricultural, and general education. It is the decision of the government “that the Senior High School system should be organised both as terminal education for entry into the world of work, and as a preparatory stage for entry into tertiary education” (p. 8).
5. The government intends to partner with the private sector to promote more formalized apprenticeship training programs, with government assuming full responsibility (p. 9) for the first year of the program. Related to the new education reform is the new TVET policy which is meant to complement the White Paper and to reform skills training in Ghana and to dramatically expand the formal TVET sector.
6. By 2015, all levels of education are to be staffed by professionally trained teachers.

Factors critical to the successful achievement of the proposed education reforms include: training sufficient teachers to staff all levels of education and effective decentralization of responsibility for provision and management of primary and second cycle schools to the districts. District assemblies would be responsible for providing equipment and infrastructure to all basic schools.

From GoG (Government of Ghana) (2007). *Preliminary Education Sector Performance Report June 2007*. Accra: Ministry of Education, Science and Sports; Palmer, R. (2005). *Beyond the basics: Post-basic education and training and poverty reduction in Ghana. Post-Basic Education and Training Working Paper Series No. 4*, Centre of African Studies, University of Edinburgh; and page references refer to GoG (2004b). *White Paper on the Report of the Education Reform Review Committee*. Accra: GoG.

Ghana is a predominantly rural, low-income country with a population of about 22.1 million (in 2005) which is expected to grow on an average of 2.1% a year between 2000 and 2015. Ghana had a gross national income (GNI) per capita of US\$450. The structure of Ghana's economy, with an overreliance on primary products (e.g., agriculture, timber, and gold) and a large informal economy, has changed little since independence in 1957. Less than a third of Ghanaians live below the national poverty line (poverty has fallen from 52% in 1991/92 to 28% in 2005/6 – Ghana Living Standards Survey 2005/6). However, income poverty remains widespread, particularly in the three northern regions, among nonexport food-crop farmers and those in the informal economy.

According to the Ghana Statistical Service (GSS, 2000), unemployment in Ghana stood at 6.7% in 2000 though it was more acute in urban than rural areas (11.9% vs. 4.3%). However unemployment figures in Ghana should be treated with a high degree of caution. Not only do they vary widely according to how unemployment is measured, but the huge number of working poor in low-end informal micro-enterprises means that there is a great deal of disguised unemployment or underemployment (Palmer, 2007). The 1998/99 Ghana Living Standards Survey estimated that total informal employment in Ghana was 86.3% (74.1% in urban areas and 91.9% in rural areas). Most new jobs are created in the informal economy, with formal sector employment growth largely stagnant.

Goals of the Education System

In May 2003, the Ministry of Education (MoESS) published the *Education Strategic Plan (ESP) 2003–2015* (GoG, 2003). The ESP was informed by many documents including the Education For All (EFA) Goals, the millennium development goals (MDGs), the President's Committee on the Review of Education (GoG, 2002), the Ghana Poverty Reduction Strategy (GPRS), and many reports of committees on educational reforms. The ESP is the main policy document for the education sector and sets out the government's mission statement and policy goals. (A revised ESP (2010–2020) now replaces the 2003–2015 version.)

The mission of the Ministry of Education is to provide relevant education to all Ghanaians at all levels to enable them to acquire skills that will assist them to develop their potential, to be productive, to facilitate poverty reduction, and to promote socioeconomic growth and national development.

These policy goals are set out to:

1. increase access to and participation in education and training;
2. improve quality of teaching and learning for enhanced pupil/student achievement;

3. extend and improve technical and vocational education and training;
4. promote good health and environmental sanitation in schools and institutions of higher learning;
5. strengthen and improve educational planning and management;
6. promote and extend the provision of science and technology education and training;
7. improve the quality of academic and research programs;
8. promote and extend preschool education;
9. identify and promote education programs that will assist in the prevention and management of human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS); and
10. provide girls with equal opportunities to access the full cycle of education.

Ghana's *TVET Policy Framework* (GoG, 2004a) lays out the specific policy goals of the TVET sector.

Structure and Operation of the System

Note that in September 2007, a new education reform began to be implemented (see **Case study 1**).

Key statistics on enrolments and resources in the major education sectors are provided in **Table 1**.

Preschool and Early-Childhood Care

In the 2006/7 year, the total number of kindergarten schools was 13 750 representing an increase of 2% when compared to the 2005/6 figures of 11 931 (GoG, 2007). Approximately one-third are private institutions (UNESCO, 2007). Enrolment increased from 687 643 to 1 142 784 between 2003/4 and 2006/7.

Primary Schools

The 1992 constitution reiterated the earlier educational intention, as spelt out in the Education Act of 1961, by

Table 1 Key statistics on enrolments and resources in the major education sectors (2006/7 unless otherwise stated)^a

	No. of institutions	No. of students	GER	GPI(%)	Pupil teacher ratio	% of trained teachers	% of total education spending (allocated 2007)

From GoG (Government of Ghana) (2007). *Preliminary Education Sector Performance Report June 2007*. Accra: Ministry of Education, Science and Sports.

introducing a program of free compulsory universal basic education (FCUBE) (launched in September 1995), making schooling in Ghana compulsory and free for children from the ages of 6 to 15. In practice, however, before the introduction of capitation grants in 2005, FCUBE was not free as students were still charged levies for sports, cultural activities, practicals, and so on. FCUBE is still not universal or compulsory in practice. There are still about 990 000 children of primary age out of school (2005) (UNESCO, 2007), and, while basic education (primary and junior secondary school (JSS)) is technically compulsory, there is no real mechanism in place to enforce the compulsory element of FCUBE.

Primary schooling in Ghana lasts 6 years. In the 2006/7 year, the total number of both public and private primary schools was 16 410, representing an increase of 7% when related to the 2005/6 figures of 15 307 (GoG, 2007). Approximately one-fifth are private institutions (GoG, 2007; UNESCO, 2007). Between 2003/4 and 2006/7 enrolments grew by 17.4% (2 957 491–3 473 229). The year 2006/7 saw large improvements in the net enrolment ratios, indicating that the number of appropriately aged children for primary has increased. The primary completion rate is 86%.

Junior Secondary Schools

The transition rate from primary to lower-secondary school is approximately 80%. Under the new education reform (**Case study 1**), the 3-year junior high schools will have a general curriculum. In 2006/7 there were 9054 schools (7122 public and 1932 private) against the 2005/6 figure of 7696 schools. Between 2003/4 and 2006/7 enrolments grew by 20% (984 111 to 1 170 801) (GoG, 2007). The lower secondary completion rate is 65%. The basic education certificate examination (BECE) is currently the only way of testing learning outcomes.

Senior Secondary Schools

The senior secondary school (SSS) level of education starts to become more exclusive, with about 36% of lower-secondary graduates gaining access to this level. The current course duration of the senior high school (SHS) is 4 years (increased from 3 years under the new education reform – see **Case study 1**).

Ghana's Poverty Reduction Strategy Paper (GoG, 2005) plans to create one good, or model, senior secondary in each district. The ESP further notes the intention of the government to expand and improve postbasic education, by rehabilitating 10% of existing senior secondary schools by 2015 and providing at least 75% of the districts with a model SHS by 2015.

In the 2006/7 year, there were 478 public senior secondary schools and 127 approved private secondary

schools. Between 2005/6 and 2006/7 enrolment increased by 28% from 384 455 to 492 120. The upper secondary completion rate of 34% indicates that there are many dropouts at this level of schooling. On completion, students receive an SSS certificate.

The policy-related issues in the secondary education subsector are: equitable distribution of well-equipped secondary schools; well-trained and motivated teachers; and inability to absorb the majority of pupils who complete the compulsory basic-education program (GoG, 2005).

Technical and Vocational Education and Training

In Ghana, TVET takes place under no less than nine different ministries as well as in the private sector. TVET is delivered in schools, in institution-based, vocational-skill centers, institutes, and colleges and in the informal economy in traditional apprenticeship.

Most formal public TVET is delivered by the MoESS and the Ministry of Manpower, Youth, and Employment (MoMYE). Formal TVET in Ghana occurs at three levels. Polytechnics, the highest-level training institutions beneath universities, are located in regional capitals ($n = 10$) and are followed by the technical training institutes ($n = 23$), both under the MoESS. Public sector vocational training institutes (VTIs) under the MoMYE number about 111 (national vocational training institutes – NVTIs (30), integrated community centers for employable skills – ICCES (59), and other VTIs (22)). Other ministries have vocationally related institutes, for example: the Ministry of Lands, Environment and Forestry has 15 regional technology transfer units; and the Ministry of Local Government and Rural Development has about 22 VTIs (Palmer, 2007).

In addition to public-skills provision, there is a huge range of private for-profit and nonprofit provision. There are over 450 private training institutions, many of them church-based VTIs with some 10 000 trainees. Some of these, for example, the Catholic Don Bosco training institutes in Tema/Ashiaman and Sunyani, are probably unequalled in quality anywhere in Ghana, and they have a history of training children from poorer families. International nongovernmental organization (NGO) provision is usually concerned with meeting the training needs of poorer children, while much private for-profit provision is beyond the means of poorer parents.

Much of Ghana's public (and, to a lesser degree, private) formal TVET system is characterized by low-quality, obsolete equipment, outdated curricula, and a lack of relationship with industry and employment. Moreover, most public and private VTIs are largely out of reach of the poorest individuals. The formal TVET sector in Ghana, as in other developing countries, is largely orientated toward formal rather than informal employment.

The numbers that formal public TVET reach are low. In 2006/7, enrolment targets set for institutions under the MoESS were not achieved due to lack of interest in the selection of technical vocational causes by lower secondary graduates and their parent/guardians; enrolments were only 18 005 (Table 1) for MoESS TVET institutions.

Altogether there are approximately 50 000 students in different formal TVET institutions (public and private) nationwide at all these levels – in all ministries. Entry requirements for most of the institutes in the TVET system is a (BECE) or middle school leaving certificate (MSLC), and the training period is usually 3 years. Some, like the Integrated Community Centre for Employable Skills (ICCES), do not have any specific entry requirements and cater to both school dropouts and JSS leavers.

Another type of skills-delivery mechanism has been the short-duration modality. In the mid-1990s, the government and the World Bank implemented the Vocational Skills and Informal Sector Support Project which focused on skills upgrading for mastercraftsmen and traditional apprentices. More recently (2003/5) the Skills Training and Entrepreneurship Programme (STEP) offered 3–12 months of training to some 27 000 youth with the intention that the STEP graduates would immediately enter self-employment. The STEP was a highly politicized program that largely had disappointing outcomes (Palmer, 2007).

Traditional apprenticeship training remains the largest provider of skills and is responsible for some 80–90% of all basic skills training in Ghana, compared to 5–10% from public training institutions and 10–15% from NGO for-profit and nonprofit providers. The general features of the traditional apprenticeship training modality in Ghana are well known and similar to those described in other countries in West Africa (e.g., see Johanson and Adams, 2004; Palmer, 2007). Ambitious plans are being put in place in 2007/8 to move toward a more regulated, or formalized, informal apprenticeship system (Palmer, 2009).

Formal TVET is mostly undertaken by males. For example, only 19% of all trainees in formal TVET institutions under the MoESS are female. In traditional apprenticeships, training is highly segregated along gender lines.

Higher Education

Both the GPRS and the ESP call for an improvement in existing tertiary education. By 2015, the objective is to have tertiary education available for at least 15% of the postsecondary cohort. Between 2001/2 and 2006/7, Ghana's tertiary education system saw an increase in enrolments of approximately 66%, from about 67 000 to approximately 113 000. This growing demand for

tertiary-level education has led to a growth in private tertiary institutions, predominantly in Accra.

Private institutions charge fees while government provides support to the institutions in other ways such as access to Teaching and Learning Innovation Fund (TALIF) and mass transport. Since the establishment of the Ghana Education Trust Fund in 2002, students pursuing accredited programs are eligible for the same student loans as their colleagues in public institutions.

At the tertiary level, the critical policy issues relate to: inadequate physical infrastructure to absorb the growing number of young adults who seek admission to tertiary institutions; and insufficient numbers of qualified and well-motivated academic staff (GoG, 2005).

Adult and Nonformal Education

The Non-Formal Education Department (NFED) is primarily responsible for the development and delivery of education programs for out-of-school youth and adults. At present, its program focus is on the coordination and implementation of the National Functional Literacy Project (NFLP), which aims to increase the basic literacy skills for adults and youth, nationally, with particular focus on females and the rural poor. The key ESP target for the nonformal education (NFE) sector is to achieve a decrease in the national rate of adult illiteracy and to improve the gender parity of literate adults. By 2004, 696 177 learners had been recruited into the NFLP. In 2005, 300 000 new learners were recruited. Over 700 000 inputs are distributed to learners – including pencils, exercise books, primers, supplementary readers, etc., with incentive packages provided for 7500 facilitators annually. The target for adult literacy was 64.5% by 2007 (GoG, 2007).

Teaching Profession

The teacher-education division has the responsibility for the training of preservice teachers and the provision of ongoing inservice training (INSET) for serving teachers. The preservice teacher-education program is of 3 years duration leading to a diploma in basic education. In October 2004, the upgrading of teacher training college (TTC) programs to diploma status commenced. Institutional upgrading of the TTCs is in process to ensure the attainment of tertiary status by 2010 (GoG, 2007).

Administrative and Supervisory Structures

Public schools and technical institutes operate under the direct responsibility of the MoESS, while other ministries (principally MoMYE) are responsible for VTIs.

The MoESS is embarking on decentralization to institutionalize the district educational directorate as the primary management unit directing and reporting on education-service delivery.

A growing number of private universities have emerged in Ghana, in part due to the inability of public universities to satisfy the growing social demand for higher education, but also as a result of the increasing demand for employment-oriented courses. The Education Act of 1960 empowered the Minister of Education to approve the establishment of private tertiary institutions, close institutions, and make regulations regarding the conduct of the affairs of institutions. Following the 1987 education reform, the National Accreditation Board now performs these functions. The work of the National Accreditation Board among others will ensure quality assurance in the private institutions to meet acceptable standards.

Ghana has recently set up a Council for TVET (COTVET) which will coordinate and oversee all aspects of TVET, across ministries and the broad spectrum of formal, informal, and nonformal education and training. In November 2007, the board of the new COTVET was inaugurated, over a year after the COTVET Bill was passed in Parliament (July 2006). Three committees are to be set up under COTVET which will undertake the functions of the council:

1. National TVET Qualifications Committee – the main regulatory authority for the National Qualifications Framework.
2. Training Quality Assurance Committee – ensures training providers and qualification awarding agencies maintain satisfactory standards in the delivery of training and the award of qualifications.
3. Industry Training Advisory Committee – to develop national occupational standards or knowledge, skills, and work-performance standards for the definition and issuance of qualifications.

While much is expected of COTVET, there are still concerns that it will not differ greatly from its predecessor – the National Coordinating Committee on Technical and Vocational Education and Training (NACVET) (Case study 2).

Under the education reform, several new structures are being put in place to enhance the effective implementation of the reform (e.g., COTVET).

Educational Financing

In 2006, actual expenditure on education was 6% of gross domestic product (GDP) (same as the target suggested by the United Nations Educational Scientific and Cultural organization (UNESCO) and the African Union).

Case study 2 NACVET and COTVET in Ghana: A new era of coordination or new wine in old wineskins?

In 1990, an attempt was made to resolve the interdepartmental rivalries and bureaucratic constraints that affected the management of training; the National Coordinating Committee on Technical and Vocational Education and Training (NACVET) was set up to coordinate a national skills development system (in particular between providers of skills from the ministries of education and employment). However, even a decade after it had been set up, NACVET had failed to develop a national skills-development policy, continued to suffer from capacity problems and ongoing tensions between the two parent Ministries, and remained inhibited by a lack of any legislative backing.

It is hoped that NACVET's successor, the Council for Technical and Vocational Education and Training (COTVET), that does have legal backing, will be more effective. Parliament passed on 27 July 2006 a Bill to establish the COTVET, which has been almost 10 years in the making. Its remit is to formulate national policies for skills development across the broad spectrum of formal, informal, and nonformal education. With the COTVET in place, the expectation is that a comprehensive demand-driven system can be established and financed. However, there remain some serious challenges to the successful functioning and implementation of COTVET; not least those related to cooperation between, and the multiple (often conflicting) agendas, interests, and politics within each Ministry. Alongside the COTVET is a new TVET Policy Framework which aims to reform the system so that it will be demand driven and competency based. However, the financing mechanisms are yet to be resolved.

From Palmer, R. (2007). *Skills Development, the Enabling Environment and Informal Micro-Enterprise in Ghana*. Doctoral Thesis, Edinburgh: Centre of African Studies, University of Edinburgh.

There are serious questions to be asked about how the expanded vision of second-cycle education and training – as envisaged in the ESP and the new education reform – will be funded. There is concern among some of the donors that the rapid expansion of postbasic levels of education in Ghana risk undermining the push for the education MDG of universal primary education (UPE) by 2015 (cf. Palmer, 2005).

Looking at the total resource envelope for education in Ghana (Table 2), we see that resources to primary education, as a percentage of total resources, has decreased from 40% in 2003 to 27.6% in 2006. However, there has been an actual increase in resources to the primary level over the same time frame. The overall percentage of total resources for the JSS level has decreased from 22% in 2003 to 16.8% in 2006. At the SSS level, resource allocation 2003/6 remained similar in 2003 and 2006 at around 15% (in 2004 and 2005 this figure was about 20%). The most significant increases in resources, in both percentage and actual terms, can be seen at the tertiary levels where resource allocation has increased from 14% to 22.5% between 2003 and 2006.

The budget allocation for 2007 is indicative of policy shifts (Table 2); primary education funding is set to

Table 2 Expenditure by level of education as a % of total resource envelope 2003/6

From GoG (Government of Ghana) (2007). *Preliminary Education Sector Performance Report June 2007*. Accra: Ministry of Education, Science and Sports.

increase from 28% to 38% in 2006/7; lower secondary (JSS) expenditure is set to remain constant; upper secondary (SSS) expenditure is set to decline from 16% to 9%; TVET (under MoESS) will increase from 1% to 2.4%; and tertiary budget allocation is set to remain around 20%.

The MoESS receives a substantial amount of funding from sources other than Government of Ghana (GoG). In 2006/7, approximately 34% of the total resource envelope for the MoESS is provided by nonstatutory and external sources (Development Partners, Ghana Education Trust fund, Heavily Indebted Poor Countries Initiative, District Assembly Common Fund). In addition, the monetary contribution made by NGOs, community-based organizations (CBOs), etc. to the education sector (e.g., the building of schools) is not accounted for in the total resource envelope at all.

The proposals set out in the 2004 White Paper on Educational Reforms (GoG, 2004b) including increasing the duration of SSS from 3 to 4 years and diversifying this level have huge cost implications. These proposals worry development partners in Ghana who see them as potentially taking money away from basic, and especially primary, education (Palmer, 2005). Nonetheless the GoG appears to be very keen to push for this home-grown education strategy in spite of donor pressure to shift their thinking. But given financial constraints, it is not clear how the senior secondary level can be expanded significantly and quality ensured at this level, as well as quality improvements at the basic level achieved so that it does not deteriorate further. This leads to the question: What financing mechanisms are most appropriate for funding postbasic education and training expansion?

Performance Monitoring, Evaluation, and Research

The Planning, Budgeting, Monitoring and Evaluation (PBME) department of the MoESS is responsible for performance monitoring and evaluation. The National Education Sector Annual Review (NESAR), instituted with the implementation of the ESP 2003–15, provides the opportunity for all sector stakeholders to participate in the review of sector performance annually. The process, from its inception, has taken place at the national level with representatives from regional and district offices participating. The establishment of the NESAR has led to tremendous improvement in education delivery in the country. This is a collaborative approach to ensure the pooling together of resources and the harmonization of programs and activities for the realization of the goals and objectives of the education sector. Through the involvement of all stakeholders in the review, the NESAR enhances accountability and transparency within the sector; a key to the successful implementation of the

ESP, where all stakeholders in the sector work together under the overall lead of the MoESS. At the NESAR 2006, the recommendation was made for the conduct of Regional Education Sector Annual Reviews (RESAR) as a prelude to the organization of NESAR. The regional reviews in all the ten regions took place in the first week of May 2007 (GoG, 2007).

The majority of all externally funded initiatives in Ghana's education and training system have built in monitoring and evaluation components. However, public formal TVET in Ghana has very weak monitoring and evaluation dimensions; in many cases, evaluation is completely absent.

Much educational research is financed externally. For example, the UK Department for International Development is currently financing three research programs examining education access, quality, and outcomes in Ghana.

Major Changes and Issues since the 1990s

The 1992 constitution reiterated the earlier educational intention, as spelt out in the Education Act of 1961, by introducing the FCUBE.

With regard to the MDGs, Ghana is judged to be on track to achieve MDG 2 (UPE) by 2015 (and expects to achieve this by 2010), and progress toward UPE received a boost in 2005 with the introduction of capitation grants and the associated removal of all fees and levies on basic education (effective since the start of the 2005/6 academic year); this caused, for example, enrolment of 6–11-year-olds in primary schools to jump by 400 000 in 2005/6, an increase of 14% on the previous year. This increase in enrolments could, by 2015 result in a mini-surge of JSS graduates entering the labor market and also in those seeking postbasic education and training. While capitation grants have undoubtedly increased enrolments, questions still remain concerning the extent to which quality can be improved, or even maintained, given the large increase in student numbers. Indeed, a concern for government now is the need to train more teachers and provide more schooling infrastructure in order to maintain quality. Even with the capitation grants, there are still likely to be large numbers of children and youth out of school.

Since 2002, the NPP government has followed a dual-track education policymaking process. In parallel to the ESP, an education strategy document was drawn up, which had a focus on basic education; the government in 2002 commissioned a panel of academics and other educationalists to examine the education system in Ghana. Some of the main recommendations of this commission (GoG, 2002) were adopted by government in the 2004 *White Paper on The Report of The Education Reform Review Committee* (GoG, 2004b). The White Paper, among other things, proposes to expand postbasic education and to

vocationalize the secondary level (see **Case study 1** on the education reforms). This turn of events, toward post-basic education and training, is obviously one met with some concern, particularly among donors who are focused on the MDGs, like Department for International Development (DFID). DFID Ghana is well aware of this apparent move away from basic education toward postbasic education, and has voiced its concerns to the government and to other donors. A 2005 DFID Ghana report on the education sector notes that the new White Paper is strikingly different in its priorities.

Since 2001, there has been a renewed government focus on skills development and its relationship with combating unemployment. This renewed focus, driven by democratic, poverty-reduction, and economic imperatives, has been reflected in a number of government documents; for example, the 2003/5 GPRS I, the 2006/9 GPRS II, and the 2004 Draft TVET Policy Framework for Ghana. TVET, delivered through public and private schools, VTIs, and traditional apprenticeships, continues to be seen as an important link to work. Between 2003 and 2005 the GoG funded short-duration skills training through the STEP – a direct response to government concerns regarding unemployment. The 2004 education White Paper and the 2004 TVET policy framework have set a challenging agenda for skills reform in Ghana.

General Background

Greece is located in the south-eastern edge of Europe and covers an area of 131 957 km². According to the data from the last census in 2001 provided by the National Statistical Service of Greece, its population is now 10 934 080. Today, the majority of the population lives in large cities; more specifically, in Athens, Thessaloniki, or Patras.

An interesting aspect of the demographic composition of Greece during the recent years is the large immigration influx mainly from the Balkan and Eastern European countries, which started in the beginning of the 1990s. According to the 2001 census, immigrants comprise 761 813 of the total number of the country's inhabitants.

Greece is a presidential parliamentary republic. The Greek Constitution was last revised in 2001. According to it, the legislative function is primarily exercised by the Parliament and the President of the Republic, while the executive function is exercised by the President of the Republic and the government which must also enjoy the Parliament's confidence.

In accordance with the Greek Constitution, the prevailing religion in Greece is that of the Eastern Orthodox Church of Christ. The official language of the country is Greek. It is used throughout the Greek territory and taught at all levels of education.

Education policy in the Greek Republic is mainly implemented by the Ministry of National Education and Religious Affairs (YPEPTH), which is assisted in its work by several supervised bodies with specific goals, jurisdictions, and responsibilities.

Goals of the Education System

According to the Greek Constitution, education is one of the basic missions of the state and every Greek citizen is entitled to it free of charge at all levels. It aims at the moral, intellectual, physical, and professional education of the Greeks, the development of national and religious awareness, as well as the development of free and responsible citizens. It should be noted that foreign and repatriated students (migrants/refugees) enjoy the right to free education exactly as natives do. Every child living in Greece is entitled to education regardless of their parents'/guardians' legal status in the country. Therefore, minor aliens who

reside on Greek territory are entitled to a 10-year minimum compulsory education, just like their Greek peers.

With regard to primary and secondary education, it aims at contributing to the complete, harmonious, and balanced development of the intellectual, psychological, and physical potential of the pupils, so that regardless of their gender or origin they may become integral personalities and live in harmony.

The national priorities with regard to educational policies among others include:

- ensuring high-quality education accessible to all;
- combating educational exclusion;
- catering for every child's specific educational needs, while respecting the child's diversity;
- developing the pupil's abilities;
- providing general education;
- making pupils aware of human-rights-related issues;
- fostering the principles of democratic citizenship;
- raising the pupils' environmental awareness;
- preparing them for the use of information and communication technology (ICT);
- connecting education with the labor market;
- strengthening vocational education and training; and
- promoting adult education and lifelong learning (LLL).

Structure and Operation of the Education System

Education is provided at three levels:

1. Primary education, which includes kindergarten (*nipia-gogeo*) and primary school (*demotiko scholeio*);
2. Secondary education, which includes lower-secondary school (*gymnasio*), general upper-secondary school (*geniko lykeio*), upper-secondary vocational school (*epaggelmatiko lykeio*), and upper-secondary vocational training schools (*epaggelmatikes scholes*);
3. Higher education, which includes universities (*panepistimia*, AEs) and technological education institutes (*technologika ekpaideftika idrymata*, TEIs), the school of fine arts as well as the Hellenic Open University (HOU) and the International University of Greece.

According to the Greek legislation, the 10-year pre-school, primary, and lower-secondary education are compulsory. Preschool education lasts for a year and primary education (*demotiko scholeio*) lasts for 6 years. Pupils who have successfully attended primary school can register in lower-secondary school (*gymnasio*), which lasts for 3 years.

Attendance in the upper-secondary schools is not compulsory and the duration of studies in it is from 2 to 3 years, depending on the type of school.

The training provided by the vocational training institutes (*institutouta epaggelmatikis katartisis*, IEK) is formal and falls into the category of post-secondary nontertiary education.

In state primary and secondary schools, attendance is free of charge and textbooks are distributed free of charge by the state. On successful completion of primary and lower or upper-secondary education, students receive a certificate, the so-called *Apolytirio*.

Preschool Education

Preschool education, which is part of primary education, is provided in public or private kindergarten (*nipiagogeio*). Children can attend it from the age of 4 and it lasts for 2 years. The second year is compulsory for young children who have completed their fifth year of age by 31st December of the year of enrolment. Most kindergartens (*nipiagogeia*) are run by the state. Attendance in state kindergartens is provided free of charge. All-day kindergartens (*oloimera nipiagogeia*) operate on an extended timetable engaging children in creative activities for at least 8 h per day.

Primary Education

Primary education is provided in public or private primary schools. Attendance in primary school (*demotiko scholeio*) is compulsory and lasts for 6 years. It includes six grades and children are admitted at the age of 6. Public education and schoolbooks are provided free of charge. All-day schools (*oloimera scholeia*) operate in parallel with the ordinary primary schools and have an extended timetable and an enriched curriculum. A serious effort is being made for all primary schools to become all-day schools.

Public primary education schools branch out into experimental, intercultural, and special education ones, apart from the ordinary and all-day schools mentioned above.

Secondary Education

Secondary education in Greece is provided at two levels: (1) compulsory (lower-secondary education) and (2) non-compulsory (upper-secondary education).

Compulsory secondary education is provided in lower-secondary schools (*gymnasia*). Attendance lasts for 3 years and the age cohort of pupils is 12–15 years. Upper-secondary education involves two types of schools: general upper-secondary school (*geniko lykeio*) and upper-secondary vocational school (*epaggelmatiko lykeio*). Attendance in both types of secondary schools lasts for 3 years. There are also upper-secondary vocational training schools (*epaggelmatikes scholes*) that operate during the day and attendance there lasts for 2 years.

Furthermore, alternative structures of schools provided by the state include experimental, intercultural, minority, ecclesiastic, arts, sports, and musical lower-secondary schools and upper-secondary schools, along with special education ones.

In state secondary education schools, attendance is free of charge and textbooks are distributed free of charge.

Postsecondary Nontertiary Education/ Vocational Training

The Ministry of National Education and Religious Affairs supervises formal vocational education and training through the Organisation for Vocational Education and Training (OEEK, a legal entity under public law). This organization is independent in administrative and financial terms.

Its objectives are:

- the realization of the goals of the National System of Vocational Education and Training (ESEK);
- the organization and operation of public IEK; and
- the supervision and control of private IEK.

The work of the OEEK mainly focuses on:

- providing any type of vocational training, initial or continuing;
- putting forward proposals to the National Ministry of Education and Religious Affairs for policymaking and programming of vocational education and training;
- drawing up the curricula for both public and private IEK;
- determining the vocational rights at all levels of vocational education and training, in cooperation with the competent ministries and other social partners;
- recognizing the certificates or diplomas that are granted by other public bodies for vocational education and training, certifying the equivalence of certificates or diplomas obtained abroad, and providing information concerning the recognition of the professional rights and of the certificates/diplomas, as well as concerning other terms of access to legislatively guaranteed vocations.

The IEK fall under postsecondary nontertiary education. They provide formal initial vocational education and training as well as the possibility of obtaining a certificate or diploma of vocational training equivalent to that of upper-secondary vocational schools, which equips IEK graduates with professional rights, thus enabling them to access the labor market in both the public and private sector. These institutes accept both lower- and upper-secondary school graduates depending on the specializations they offer.

Today, there are 114 public IEK, of which 100 are independent from an administrative point of view, while 14 operate as branches of independent ones. Alongside the public IEK, private IEK were established for the first time in 1993. There are currently 52 private IEK, whose programs of study and specializations are the same as those of the state IEK.

Tertiary Education

According to the Greek Constitution, tertiary education falls exclusively under the jurisdiction of the state and is

provided free of charge at the undergraduate level. Tertiary education institutions are fully self-governed legal entities of public law and are supervised by the Ministry of National Education and Religious Affairs. Admission of students to tertiary education institutions depends on their performance in the pan-Hellenic university entrance exams which are held at the end of the upper-secondary school on the basis of a *numerus clausus* system.

Tertiary education consists of:

1. the university sector which includes universities, technical universities, and the higher school of fine arts; and
2. the technological sector which includes technological education institutions.

The HOU provides distance-learning courses (at undergraduate and postgraduate level).

The International Hellenic University constitutes an independent and fully self-governed higher education institution. It is a legal entity of public law supervised by the state. It runs study programs at undergraduate and postgraduate level taught in English to foreigners interested in studying in Greece.

In terms of funding, tertiary education institutions are mainly funded by the state. According to the Organization for Economic Cooperation and Development (OECD) data, Greece is one of the countries with the highest public funding of tertiary education institutions in Europe, reaching over 98%.

One of the most important recent reforms that has contributed greatly toward the autonomy and the qualitative improvement of tertiary education institutions is the drawing up and submission to the ministerial services of a 4-year academic development program by all tertiary education institutions. In this way, they will be able to define their mid-term and long-term goals and plan their strategy on the basis of their profile, size, particular needs, and special characteristics. Therefore, planning and decision making can become more flexible and effective.

The 4-year academic-development programs are related to issues such as the particular aims of each academic unit; the designation, the programming, and the measures for the development and support of the educational and research activities and other offered services; the infrastructure and equipment development; the optimal investment of higher education institutions' property and other financial sources; and the number of new students that can be admitted every year which will be agreed upon for the first time in collaboration with the Ministry.

Adult Education

The General Secretariat of Life Long Learning, supervised by the Greek Ministry of National Education and Religious Affairs, undertakes the planning, coordination,

and implementation of LLL at a national level. Under its competence fall the:

- prefectural committees of adult education;
- vocational training centers;
- the center of distance lifelong education and training for adults; and
- education in correctional institutions.

The GSAE is assisted by the Institute of Continuing Adult Education (IDEKE) that serves the purpose of providing technological and scientific support to the programs of the General Secretariat and of realizing activities concerning LLL. Some of the most characteristic lifelong education structures running with the support of the IDEKE are:

- adult education centers,
- parent schools, and
- second-chance schools.

Second-chance schools (*scholeia defteris efkerias* (SDE)) were established in 1997 and offer formal education services. They are attended by adults who have not completed compulsory education and who, after successful attendance, are granted a certificate of study equivalent to the certificate of study of primary or lower-secondary school.

Access to formal adult education can also be gained through attendance of evening lower- and upper-secondary schools and evening upper-secondary vocational schools. These schools belong to secondary education both legislatively and administratively. Any working person interested, can take these classes irrespective of their age. By law, there is a special quota allowing graduates of evening schools – of all types – to be admitted to tertiary education.

Recent reforms in LLL enable higher education institutions to establish lifelong learning institutes and offer lifelong learning programs to graduates and employees.

Finally, the HOU contributes considerably in the field of adult education as well through its undergraduate and postgraduate distance-learning courses.

The Teaching Profession

Teachers of both primary and secondary education complete at least 4-year university studies and they follow preservice training upon appointment. All teachers in the public sector are civil servants. In 2006–07 there were 11 846 teachers in kindergartens, 70 827 in primary schools, and 80 250 in secondary schools. As for tertiary education, 15 761 and 13 102 teaching staff were employed in universities and technological institutions respectively.

The training of teachers runs on both a preservice and in-service basis, and usually takes place at the regional training centers (PEK). The training of teachers is implemented by the Organisation of Teacher Training (O.EPEK)

and supervised by the Ministry of National Education and Religious Affairs in cooperation mainly with the Pedagogical Institute (PI) as well as the Ministry.

The PI conducts a significant number of teacher-training programs. In particular, 8000 newly appointed teachers were trained during 2005–07. The training programs usually concern the new school textbooks, the cross-curricular approach, the teaching of second foreign languages in primary education, modern teaching approaches in the use of ICT in education, classroom management, school administration, as well as European integration issues.

Administrative and Supervisory Structure

The general organization and administration of the education system is as follows:

- Ministry of National Education and Religious Affairs;
- Primary and Secondary Education Regional Directorates;
- Primary and Secondary Education Directorates and Offices at Prefectural Regional Level; and
- school units.

The Ministry of Education and Religious Affairs is responsible for the administration of all schools in the country. The administration and supervision is carried out through the central and regional services as well as through advisory and expert councils that have been created and function in the Ministry's central and regional services.

Tertiary education institutions are self-administered legal entities under public law and the Ministry supervises and monitors the legality of their actions and decisions through the Ministry's central services.

Educational Finance

For the years 2007–13, education is financed by:

- national resources through the regular budget of the state as well as the public investments budget. In Greece, public expenditure accounts for 3.9% of the GDP, with the larger share thereof being allocated to tertiary education (approximately 1.26% of the gross domestic product (GDP) for 2004, i.e., higher than the average European rate for the same period);
- the European Social Fund (ESF), which co-finances the operational program for education and LLL; and
- the European Regional Development Fund (ERDF), which finances all regional operational programs for the construction and maintenance of buildings, for equipment at all levels of education, and also the programs for initial vocational training and LLL.

Performance Monitoring, Evaluation, and Research

Law 2986/2002 lays out particular provisions with regard to teacher evaluation. The relevant measures/actions are implemented transversally and horizontally. The aim is to diffuse a climate of continuous and transparent accountability, enhance the quality of education services, and sustain the constructive efforts of all those involved in the educational process, whether teaching practitioners or administrators.

Teacher self-evaluation is supplemented by a process of assessment/evaluation conducted by the school head and the school counselors. The evaluation and training department of the PI is directly involved in the entire process.

At the institutional level, the PI is entrusted with the comprehensive evaluation of school units and teaching practitioners on a grand scale whereas the Centre for Educational Research (KEE) is responsible for the development and implementation of indicators and benchmarks monitoring performance and learning outcomes at both the school unit and the systemic levels. It also collects and processes reports prepared by the regional support and educational planning centers along with the school unit self-evaluation reports.

With regard to tertiary education, during the period 2004–07, new laws came into effect whose main priority was the establishment of the National Quality Assurance Agency (NQAA). Among them, the Law on Quality Assurance established the European Credit Transfer and Accumulation System (ECTS) as well as the obligatory issuing of the diploma supplement automatically and free of charge by universities.

Consequently, the work and research in higher education institutions is subject to continuous evaluation with the objective of assuring and improving the quality of research and studies. The evaluation of higher education institutions is carried out in two stages: the first stage involves the evaluation performed by the academic units of the higher education units themselves in connection with their profile, objectives, and mission (internal evaluation). After completion of the first stage the second stage follows, which consists of the evaluation of the work performed by a committee of independent experts that also takes into consideration the results of the self-evaluation report of the academic unit (external evaluation).

Major Changes and Issues since the 1990s

After the mid-1990s, important reform measures concerning the education system were implemented. Among others they included:

- establishment of all-day schools and second-chance schools;
 - foundation of the regional counseling and orientation centers;
 - changes in the admission procedure for higher education;
 - upgradation of TEIs by incorporating them into the higher education area;
 - systematization of LLL policies and structures; and
 - significant action in the field of intercultural education to address the needs of groups with special social, cultural, or religious characteristics.
- At the beginning of the twenty-first century, in the context of a broader reform effort, the most important changes that have taken place are the following:
- increase in the duration of compulsory education from 9 to 10 years by including preschool education;
 - introduction of the cross-thematic curriculum framework for compulsory education (DEPPS) and corresponding new textbooks in primary education;
 - introduction of the teaching of a second foreign language in primary school;
 - creating a new institutional framework for the operation of higher education institutions securing the combination of autonomy and accountability (Law 3549/2007);
 - setting up of the quality assurance agency and putting in place the internal/external evaluation procedures to align the domestic higher education landscape with European and compatible international patterns (Law 3374/2005); within the same framework, the stipulation of the diploma supplement and the implementation of the academic credit transfer and accumulation system have further contributed to student mobility and aligned the Greek higher education system with European Union (EU) standards;
 - enhancement of higher technological education through, among others, the improvement of the academic components of the TEIs and the consolidation of their graduates' professional rights; setting up of upgraded and more flexible upper-secondary education vocational schools and training schools (Law 3475/2006);
 - transparency and efficiency with regard to the procedures involved in the recognition of academic titles through the setting up of the *Diepistimonikos Organismos Anagnorisis Titlon Akadimaikon kai Pliroforisis* (DOATAP)/Hellenic NARIC (Hellenic National Academic Recognition and Information Centre) (Law 3328/2005);
 - major policy priority in Greece given to modernization and integration of all LLL platforms into a comprehensive institutional and functional system to cut across both education/training and employment policies, which has oriented the national LLL strategy toward not only the qualitative enhancement of the provided education, but also the increase of employability, and the diffusion of flexible re-skilling training setups; also, social inclusion

and the promotion of citizenship competences have been at the core of the new education and employment outlook on LLL; the new law on the systemization of LLL (Law 3369/2005) constitutes the legal backbone of the entire matrix as it establishes a comprehensive and holistic web of agencies, platforms, and sub-networks operating on the basis of supplementarity and synergy;

- the establishment of the International Hellenic University (IHU) (Law 3391/2005) along with the adoption of the ECTS and diploma supplement and the introduction of postgraduate programs and degrees upheld jointly with foreign academic institutions (Law 3404/2005) which have further opened up Greek higher education to the European and international setups;
- upgrading of the relevant institutional framework on research and technology (Law 3653/2008); and
- enforcing a new law for inclusive education to ensure equal opportunities and equitable access for people with disabilities or special educational needs (Law 3699/2008).

Iceland

M Hardardottir and M Gunnlaugsdóttir, Ministry of Education, Science and Culture, Reykjavik, Iceland

© 2010 Elsevier Ltd. All rights reserved.

General Background

Iceland is an island in the North Atlantic Ocean, bordering the Temperate and Arctic Zones. Its extreme northern point touches the Arctic Circle. Iceland's total area is approximately 103 000 km², of which only about 23% is covered by vegetation. As of 1 December 2007, the population of Iceland was 312 872, with a population density of approximately 3.0 inhabitants per square kilometer.

Iceland was settled from Norway and by Norse settlers from the British Isles in the ninth and tenth centuries. From 1262 to 1264, allegiance was sworn to the Norwegian Crown. In 1383, the Danish and Norwegian Crowns were united, and Iceland was thereafter part of the Danish–Norwegian kingdom. In 1918, Iceland was proclaimed a sovereign state in personal union with Denmark.

Since 1944, Iceland has been a republic with a written constitution and a parliamentary form of government. The president is head of state, elected for a term of 4 years by direct vote of the electorate. Parliament is composed of 63 members, elected for 4 years by proportional representation. The government holds executive power and is headed by the prime minister. Iceland is a representative democracy. The current constitution came into effect on 17 June 1944, when Iceland achieved its independence from Denmark. According to the Constitution of Iceland, the Parliament and the President jointly exercise legislative power. Judges exercise judicial power.

Local government is exercised by 79 municipalities.

Iceland was almost exclusively an agricultural society until the late nineteenth century, when fisheries gradually came to replace animal husbandry as the mainstay of the economy. Apart from fish, Iceland's most significant resource is its vast natural-energy potential, comprising hydro- and geothermal power.

Unemployment has been low in recent years. The unemployment rate was 2.3% in 2007. Gross domestic product (GDP) per capita was USD 39 986 (current *purchasing power parities*; PPPs) in 2006. Economic growth in 2006 was 4.2%.

The twentieth century saw great demographic changes in Iceland, as regards both the number of inhabitants and their patterns of residence. Until the twentieth century the population of Iceland was almost entirely rural. Urbanization was slow, and in 1850 the inhabitants of Reykjavík, the largest urban center, constituted only 1.94% of the total population. By 2005, however, approximately 92.8% of the population lived in communities of

over 200 inhabitants (60 localities), with around 62.1% of the country's inhabitants living in the capital area (including Reykjavík proper and the surrounding communities). This development mirrors the economic changes which took place during the last century, as increasing industrialization, especially in the fisheries and the fishing industry, led to the growth of urban communities, with a corresponding decrease in the importance of agriculture.

In 2006, about 23% of the total population was aged 0–15 years, 67% was 16–66 years, and 10% was 67 years and over. It is estimated that by 2030 the population will have reached 342 000.

Iceland has until recent years been a relatively homogeneous society. However, since 1990 and especially after 2000, there has been a considerable increase in the number of immigrants.

The Evangelical Lutheran Church is the official state church, with 82% membership in 2006.

Icelandic is the native tongue of Iceland and is its only official spoken and written language. It belongs, along with Norwegian and Faeroese, to the West Scandinavian branch of the North Germanic family of languages. Morphologically it has remained the most conservative of the Scandinavian languages, retaining, for example, three genders and a full system of case endings for nouns and adjectives.

From the middle of the seventeenth century, the law required that the clergy provide children with religious education, and during the 1790s it became one of their tasks to ensure that parents taught their children to read. In 1880, legislation was enacted on the instruction of children in reading, writing, and arithmetic and the Christian doctrine of the Lutheran Church. Parents were responsible for this instruction, while all supervision was placed in the hands of the ministers of the state church.

During the nineteenth century, there was a general movement toward public education and an interest in educational affairs. The development of a modern school system at the close of the nineteenth and the beginning of the twentieth century can reasonably be seen as one of the fruits of this movement.

In 1907, the first law on formal schooling for children aged 10 to 14 years was passed. This legislation marked the beginning of state involvement in educational affairs in Iceland, and education, free of charge, became the legal right of every child in the country from 10 to 14 years of age.

School levels in Iceland are four: pre-primary, compulsory (single structure – primary and lower-secondary education), upper secondary, and higher education.

Education in Iceland has traditionally been organized within the public sector, and there are relatively few private institutions in the school system. Almost all private schools receive public funding.

Goals of the Education System

A fundamental principle of the Icelandic education system is that everyone should have equal opportunities to acquire an education, irrespective of gender, economic status, residential location, religion, possible handicap, and cultural and social background.

Basic goals of the education system are set out in legislation for each school level and are supplemented in curriculum guidelines for pre-primary, compulsory, and upper-secondary education and in other policy documents.

In pre-primary schools children receive education and support for their all-round development, thus preparing them for compulsory school and life itself. At the pre-primary school level, the nucleus of educational work is play.

The main purpose of compulsory schooling is to prepare pupils for life and work in a continuously developing, democratic society. The organization of the school, as well as its work is thus to be guided by tolerance, Christian values, and democratic cooperation.

The primary aims of upper-secondary education are to prepare pupils for life and work in a democratic society by offering them suitable opportunities to learn and develop individually, and prepare them for employment through specialized studies leading to professional qualifications or further study.

The main purpose of adult education is to encourage equality of opportunity among adults without regard to location, age, gender, occupation, or previous education.

The role of higher education institutions is contributing to the creation and dissemination of knowledge and skills to students, as well as to society in general. The higher education institutions shall aim at strengthening the infrastructure of Icelandic society and its position in an international context.

Structure and Operation of the Education System

Figure 1 outlines the formal education system. Key statistics on number of schools, students, and teaching staff are provided in Table 1

Pre-primary School and Early-Childhood Care

The present Pre-primary School Act was passed in 2008. The Act's first article defines pre-primary schools as the first level of the educational system, and under the Act, pre-primary schools are to provide education for children

who have not reached the age at which compulsory education begins, that is, 1 September of the year in which the child turns six. The current national curriculum guidelines are based on a child-centered ideology, where the individual development and needs of each child is to be the focal point. All handicapped children have the same right as other children to attend pre-primary schools, and in many cases are given priority status with regard to admission. The program for handicapped children is the same as for other children, but adapted to their ability.

Pre-primary school education is to be provided by staff who have professional training in working with children at this level.

Compulsory Education (Primary and Lower Secondary)

Under the Compulsory School Act of 2008, local municipalities are responsible for the operation of schools at that school level.

The local municipalities pay for instruction (general teaching, substitute teaching, special education, and the teaching of children in hospitals), administration, and specialist services, as well as establishing and running schools at the compulsory level. The Act makes it the duty of parents to ensure that their children register for and attend school. The Compulsory School Act also specifies the duty of the state and local municipalities to ensure that mandated instruction be given.

Compulsory schools operate for 9 months a year. The number of school days is 180.

The state monitors compliance with educational law and regulations; it is also responsible for the publication of educational materials. The state is in charge of coordinated school surveys, national coordinated examinations in core subjects in years 4 and 7, and national coordinated examinations in three subjects in year 10. Furthermore, the state is responsible for evaluating individual schools and the educational work that is carried out.

Upper-Secondary Education

A new Upper Secondary School Act came into force in 2008.

Students may enter upper-secondary schools at the end of compulsory schooling in the year they turn 16. Upper-secondary education is not compulsory; anyone who has completed compulsory education has the right to enter a course of studies in an upper-secondary school. Majority of study programs are 4-year programs. In recent years, 93–94% of students who completed compulsory education have entered upper-secondary education directly thereafter; the dropout rate during

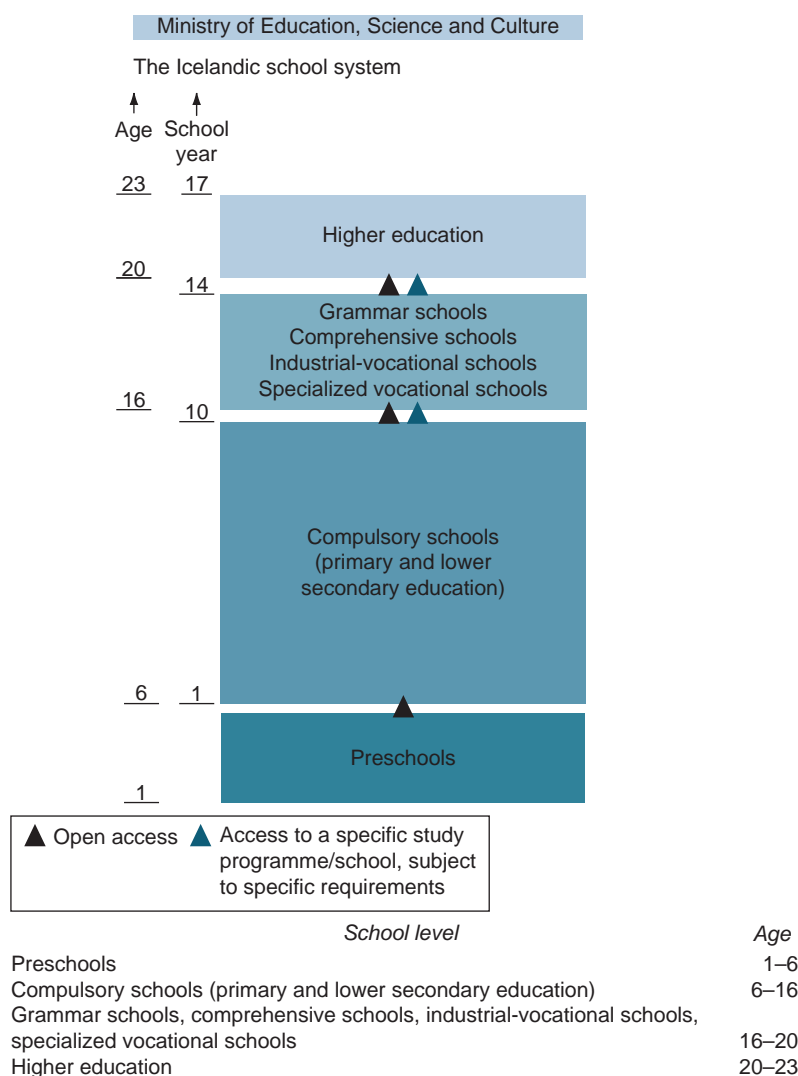

Figure 1 Diagram of the Icelandic school system. From Ministry of Education, Science, and Culture.

Table 1 Educational providers, students, and teaching staff 2007

Provider	Institutions ^a	Students			Teaching staff		
		Total	Male	Female	Total	Male	Female
Pre-primary school	267	17.216	8.778	8.438	4,459 ^b	134	4.325
Compulsory school	173	43.875	22.412	21.463	4.969	1.074	3.895
Upper-secondary school	36	24.459	11.440	13.019	1.880	889	991
Higher education	8	16.738	6.305	10.433	2,039 ^c	1.060	979

^a31 pre-primary schools, 7 compulsory schools, 7 upper-secondary schools, and 3 higher education institutions were private with government support in 2006.

^bTotal number of all involved in teaching. Number of pre-primary school teachers and staff with other educational training: 1792.

^cTotal number of all involved in teaching. Number of permanent teaching staff: 694.

From: Statistics Iceland and Ministry of Education, Science and Culture.

upper-secondary schooling has, however, been considerable. Completion rates are significantly higher for women than for men.

The school year, which lasts for 9 months, is divided into autumn and spring terms. Students generally attend 32–40 lessons per week, with each lesson lasting 40 min.

The main types of upper-secondary schools are as follows:

- Grammar schools (high schools) which offer 4-year academic programs of study which conclude with matriculation examinations.

- Industrial-vocational schools, which offer theoretical and practical programs of study in certified and some noncertified trades.
- Comprehensive schools, which provide academic programs comparable to those of the grammar/high schools and vocational programs similar to those offered by the industrial-vocational schools, as well as other specialized vocational-training programs.

Upper-secondary schools either have a traditional class structure, or operate according to a unit-credit system. The unit-credit system is the most common form of upper-secondary education.

The main types of programs of study are the following: (1) academic programs leading to matriculation, (2) vocational programs, (3) arts programs, and (4) a general program of study.

General academic education is primarily organized as a 3–4-year course leading to a matriculation examination. Vocational education is divided between the school and the workplace or takes place exclusively in the school. A general short program of study is intended for pupils who need further preparation for academic or vocational studies or for those pupils who are undecided as to what to do after compulsory education. In addition there are also fine arts programs of study. The length of vocational courses varies, but most are 3- or 4-year courses. Pupils in vocational programs of study can choose between training for the certified trades or vocational training in other areas, for example, in the field of agriculture, travel industry, fisheries, food production industry, health, or commerce.

Higher Education

The Icelandic higher education system is made up of seven university and nonuniversity institutions of which three are private. The Higher Education Act, enacted in 2006, establishes the general framework for the activities of higher education institutions under the auspices of the Ministry of Education, Science and Culture. The role of each public higher education institution is further defined in a separate act of parliament on its activities. The charters of private institutions define their engagement in research, internal organization, etc.

The Higher Education Act fully implements the Bologna Process into Icelandic higher education. The Act emphasizes quality work and quality assurance in higher education. All institutions that are currently operating are to apply for accreditation in each field of study before July 2008.

Legislation on the Science and Technology Policy Council was enacted in 2003 with the purpose of strengthening science, research education, and technical development in the country. All higher education institutions have in recent years placed increasing emphasis on research activities.

The foundation of the University of Iceland in 1911 marks the beginning of the modern Icelandic system of higher education. This first national university was established by merging three professional schools founded during the previous century – a school of theology, a school of medicine, and a law school – and adding a new faculty of humanities. Before that time Icelandic students had mainly traveled to Denmark for higher education.

In the last three decades the higher education system has grown more diverse. New higher education institutions have been established and some secondary institutions have been upgraded to the higher education level.

In recent years there has been a significant rise in the number of students in higher education, followed by an increase in the availability of higher education programs of various lengths.

Private institutions receive state support and can also charge tuition fees. Public institutions are only authorized to charge registration fees.

Adult and Continuing Education

Adult and continuing education is an extensive sphere in Icelandic society, provided by various parties such as public authorities, private institutions, companies, and organizations. The educational opportunities provided by public authorities are open to all, although with certain restrictions in some cases. They are intended to serve everyone according to their needs, especially young school leavers and adults who want to improve their basic education, general knowledge, or professional capabilities, or who want to cultivate their hobbies.

The Teaching Profession

The training of teachers and specialist educational personnel for the pre-primary, primary, and secondary levels is undertaken by universities. According to a legislation of 2008, training for pre-primary, primary, lower, and upper secondary teachers is to be 5 years.

In 2006, 78% of compulsory school teachers (primary and lower secondary) and 53% of upper-secondary school teachers (general and vocational education) were women. In pre-primary school education 97% of teachers were women. Many people with teaching qualifications are not employed as teachers. As there is a shortage of qualified teachers, especially in some regions outside the capital area and in mathematics and science, some of the teaching staff is unqualified. In 2006, 16% of compulsory school teachers and 24% of upper-secondary school teachers were unqualified. At the higher education level 34% of permanent educational staff in 2006 were women.

A variety of in-service training courses for teachers are offered annually.

Administrative and Supervisory Structure

The Icelandic parliament is legally and politically responsible for the educational system. It determines its basic objectives and administrative framework. All education comes under the jurisdiction of the Ministry of Education, Science and Culture.

The educational system has to a large extent been decentralized, with regard to both responsibilities and decision making. This reflects a general trend in Icelandic society. Local municipalities are responsible for the operation of pre-primary schools and compulsory education (primary and lower-secondary schools). On the other hand, the state runs upper-secondary schools and institutions at the higher education level.

The Ministry of Education, Science and Culture issues national curriculum guidelines for compulsory and upper-secondary education. These national curriculum guidelines are intended both to provide the detailed objectives necessary to implement the law and offer direction as to how they should be carried out in practice. The Ministry furthermore issues national curriculum guidelines for pre-primary schools that specify the aims that pre-schools are to follow and describe the basic means and attitudes that apply in the education of young children.

The National Centre for Educational Materials (under the auspices of the Ministry of Education, Science and Culture) develops and publishes educational materials for compulsory schools and distributes them to schools free of charge.

The Educational Testing Institute is an independent institution funded by the state through the Ministry of Education, Science and Culture. The institution is responsible for organizing, setting, and grading the national coordinated examinations and for undertaking comparative analysis of the educational system through participation in international surveys such as Organization for Economic Cooperation and Development Programme for International Student Assessment (OECD PISA).

Educational Finances

Since the late 1990s, the government has considerably raised expenditure on education. The OECD figures in *Education at a Glance 2007* indicate that Iceland's overall spending on education as a proportion of GDP was 8.0% in 2004; Iceland's expenditure was then the highest of any OECD nation. In that year the average figure for OECD nations was 5.8%.

Spending on education accounted for 19.94 % of total public spending in 2006. Almost half, or 9.54%, went to the compulsory educational level, 3.42% to upper-secondary

education (including vocational training), and 4.05% to higher education.

The Icelandic Student Loan Fund offers loans to students in higher education and some vocational students to cover costs incurred by studies, as well as the cost of living. In order to receive loans, students must complete at least 75% of full-time studies according to the program of the educational institution, approved by the board of the Fund. Repayment of loans begins 2 years after completion of studies.

Performance Monitoring, Evaluation, and Research

The Ministry of Education, Science and Culture is responsible for the evaluation and supervision of educational institutions and of the entire educational system in Iceland. The monitoring of the educational system consists mainly of external evaluations of schools and institutions or special aspects of the school system; national coordinated examinations in years 4, 7, and 10 of compulsory education; and by the use of data collected by Statistics Iceland.

Laws on pre-primary, compulsory, upper-secondary, and higher education levels place strong emphasis on regular internal evaluation by individual schools/institutions. Every compulsory and upper-secondary school is expected to implement methods to evaluate its work, including its teaching and administrative methods, internal communications, and contacts with parties outside the school. The internal-evaluation methods of compulsory and upper-secondary schools are subject to regular external evaluations by the Ministry of Education, Science and Culture.

Schools/institutions at all educational levels may be subjected to an external evaluation organized by the Ministry of Education, Science and Culture. This evaluation is conducted by external evaluators. The purpose of external evaluations of schools/institutions is to obtain an overall picture of each school's or institution's activities or of specific aspects at any given time. Attention is directed toward various features of the school or institution's internal activities, such as administration, teaching, development work, cooperation, and communications within the school/institution, study achievements, and the connection between the school or institution and society.

Every 3 years, the Minister of Education, Science and Culture is to deliver comprehensive reports to parliament on compulsory and upper-secondary education, based on systematically gathered information, national and international research, and evaluation.

Research is mostly carried out by higher education institutions in the country. Iceland has in recent years also participated in international research such as the

OECD PISA and Progress in International Reading Literacy Study (PIRLS). In addition, Iceland participates on a regular basis in OECD work on developing student-achievement indicators. The Icelandic educational system has been regularly reviewed by OECD experts. Iceland also participated in the OECD thematic review of tertiary education. The report: Thematic Review of Tertiary Education, Iceland Country Note, was published by OECD in April 2006.

Major Changes and Issues since the 1990s

Great changes have taken place in education in Iceland since 1990, at the same time as society has undergone considerable change due to the influence of globalization and a free-market economy. Greater demands are made on the educational system in terms of quality and efficiency.

As the economy has become more diversified and internationalized the demand for a highly educated workforce has increased significantly. Rising numbers of students over the period, and increased services, have necessitated an increase in the number of people involved in education; they represented 5.7% of the workforce in 1991, which had risen to 7.5% by 2006.

Participation in international collaboration in education has increased greatly since 1990, not least due to Iceland's membership of the European Economic Area since 1994. Iceland thus became a full member of European Union collaborative programs in the field of education and science. Participation in Nordic collaboration in education and science has also increased, for example, the Nordplus programs.

In the 1990s legislation was enacted for all four educational levels. The Pre-Primary Schools Act was passed in 1994, the Compulsory Schools Act in 1995, the Upper-Secondary Schools Act in 1996, and the Higher Education Act in 1997. A new Higher Education Act was passed in 2006. The legislation entailed *inter alia* increased autonomy and responsibility for educational institutions, and greater emphasis on evaluation and monitoring of educational activities. Under the Compulsory Schools Act of 1995, the operation of the schools was transferred to local government.

Current curricula for the compulsory school level date from 2007, and for the pre-primary and upper-secondary level from 1999. The duration and structure of upper-secondary studies leading to matriculation examinations have been under review by the Ministry of Education, Science and Culture.

Considerable changes have taken place in higher education over the period. The range of study programs has increased greatly, not least at the postgraduate level. The

number of higher education institutions has increased, *inter alia* by educational institutions previously at upper-secondary level being upgraded to higher education level. Seven institutes of higher education now operate in Iceland; three are privately run, but with state funding. Their funding is based upon the same allocation rules as for state-run higher education institutes.

At all educational levels except the compulsory level, proportional enrolment has increased greatly. From 1997 to 2006 the number of students in higher education in Iceland doubled, that is, from 8372 to 16 738. In addition, 2308 Icelandic students were studying abroad in 2006. Women constituted 62% of the student body in Icelandic higher education institutions in 2006 and were 67% of graduates in the academic year 2005–06.

The proportion of 16-year olds enrolled in the first year of upper-secondary education rose over the same period from 83% to 93%. In 2006, about 95% of children aged 3–5 attended pre-primary school.

Research and development expenditure was 3% of GDP in 2006, up from about 1% in 1990.

Indonesia

A C Alwasilah and Furqon, Indonesia University of Education, Bandung, West Java, Indonesia

© 2010 Elsevier Ltd. All rights reserved.

Indonesia has an area of 1.9 million sq km and is inhabited by more than 230 million people; thus making it the world's fourth most populous country and the world's largest archipelago country consisting of more than 17 000 islands. The country consists of urban areas (95 449 616 sq km) and rural areas (123 020 384 2 km). More than 60% of the population (and more than 500 ethnic groups) live in the rural area. The country includes 33 provinces, 440 districts or municipalities, 5641 sub-districts, and 71 555 villages. The country's official religions include Islam (191 303 211), Christian (13 242 316), Catholic (7 846 779), Hindu (4 022 993), and Buddhist (2 789 701). The per capita income (or gross domestic product) is Rp 11 193 855.8 (around US\$1120). **Table 1** summarizes the school age-group population and the target population of students.

Until 2004, the average number of years of schooling of 15-year-olds or above was 7.2 years, while their literacy rate was 90.4%. Early-childhood education programs were very limited and disproportional. Out of 28.2 million 0–6-year-olds, only 7.2 million (25.3%) received education. Out of 8.14 million 5–6-year-olds, only 2.63 million (32.36%) went to kindergarten. School participation of 7–12-year-olds and 13–15-year-olds was 96.8% and 83.5%, respectively. Around 76% of the families suggested that economic factors were the major reasons for this matter, where 67% had no budget and 8.7% of school-age youth had to earn a living. In 2004–05, there were around 330 000 students in 2870 junior secondary schools. They were students who could not afford to continue their studies at regular secondary schools. There were 1.5 million students with special needs, but only 4% of these received an appropriate education. In tertiary education, the college participation of 19–24-year-olds was relatively low at 14.6%. **Figure 1** depicts the ladder of national education.

The National Education System

The national education in Indonesia evolved from its earlier form during the three-and-a-half centuries of Dutch occupation and the 2-year Japanese occupation. The nation formally started its national system in 1945 immediately after independence. Elitist policymaking by the Dutch resulted in resentments leading to independent movements among indigenous people. This was even more noticeable during the Japanese occupation when Indonesian was encouraged to be used as the medium of instruction. As in other parts of the globe, education in

Indonesia developed over the times to meet the challenges of contemporary life. National education is based on *Pancasila* (five pillars of the state's philosophy, i.e., belief in God, humanism, nationalism, democracy, and social justice) and the 1945 Constitution of the Republic of Indonesia.

Referring to Law No. 20/2003 on national education system, the vision and missions of national education are described as follows. National education has a vision of realizing an Indonesian society that observes peace and democracy; possesses expertise and competitiveness; and achieves advancement and prosperity in the unity of the Republic of Indonesia supported by citizens who are healthy, independent, faithful, and pious to God, the Almighty; possess morals and noble character; love the country, observe laws, and conserve the environment; master science and technology; and possess work ethos and discipline. To accomplish the vision, the Ministry of National Education (MONE) has the following missions:

1. to strive for the expansion and even distribution of opportunities for quality education for all Indonesian citizens;
2. to assist and facilitate the development of children's potentials, from early childhood throughout life, in order to bring into being a learning society;
3. to improve quality of educational inputs and processes to optimize the building of moral character;
4. to enhance the professionalism and accountability of educational institutions as centers for acculturation of sciences, skills, experiences, attitudes, and values based on national and global standards; and
5. to empower community participation in the provision of education based on the principles of autonomy in the context of the unity of the Republic of Indonesia.

The current education system is a result of legal reform, beginning with the amendment of the 1945 Constitution. The amendment stipulates that education is not only the right of Indonesian citizens but it is now part of human rights. All Indonesian citizens have to get primary education and the government has to pay for it. The amendment also mandates at least 20% of the state budget at the national as well as regional levels to be allocated for education. The amendment was then elaborated in the following laws, among others: Law No. 20/2003 on educational system, Law No. 14/2005 on teachers and lecturers, and Law No. 43/2007 on library. During the 2005–07 period alone, MONE has accomplished nine major policies which are as follows:

1. *Massive education funding.* The government spent a total amount of Rp 11 532 484 429 000 00 for school-operating grant, special grant for students, and quality management grant.
2. *Improvement of qualification, competencies, as well as certification of teachers and educational personnel.* As mandated by Law No. 14/2005, teachers as professionals should have S1 or D4 qualifications, while university lecturers should have S2 or S3 qualifications. It suggests that there are around 1.75 million teachers yet to achieve S1/D4 qualifications and more than 150 000 university

lecturers yet to achieve S2/S3 degrees; there are around 2.5 million teachers and 300 000 university lecturers to be certified in the next 10 years. In 2007, MONE allocated Rp 579 billion to improve the qualification of 81 800 teachers and 8540 lecturers. Moreover, 147 217 teachers were already certified.

3. *E-learning and E-administration.* Information technology (IT) has been used to support the three pillars of national education, namely (1) better access to education, (2) better quality of education, and (3) improved governance, accountability, and public image. IT is relevant for Indonesia with a population of 230 million, with more than 50 million of formal education participants occupying more than 17 000 islands.
4. *New facilities.* To facilitate the implementation of the Education Act, the government built new schools, state universities, libraries, and laboratories.
5. *Reconstructing educational facilities.* On reconstructing facilities, the central government and regional government shared the funding in a ratio of 50:30:20% of the fund was to be paid by the central government, provincial government, and city or district administration.
6. *Textbook provision.* The textbook policy has changed drastically as follows: (1) there is no more monopoly by MONE on textbook writing, provision, publishing,

and distributing; (2) textbooks are selected by school committees and are to be used for at least three consecutive years; (3) students are recommended to buy the books from the bookstores, while the teachers are not allowed to get involved in the textbook business; (4) education units have to provide libraries with textbooks as many as necessary to help the students who cannot afford to buy any; (5) MONE and Ministry of Religious Affairs (MORA) are encouraged to buy the copyrights of selected textbooks so that they can be mass-produced for students at relatively low costs; and (6) MONE, MORA, and provincial government are encouraged to provide the prospective textbook shop-owner with subsidy and capital.

7. *Improvement of quality, relevance, and competitiveness.* MONE has adopted a comprehensive strategy to improve the quality, relevance, and competitiveness of education through the enactment of Law No.19/2005 on the national standards of education. The law mandates the government to form the National Board of Education Standards, whose function is to set the eight national standards on the following: (1) content, (2) competency, (3) educators and educational personnel, (4) educational facilities, (5) evaluation, (6) educational process, (7) management, and (8) funding. In addition, the government promotes school-based curriculum, where every educational unit has autonomy to develop its own curriculum.
8. *Improving the governance, accountability, and public image.* The government has taken several steps, among others as follows: (1) canceling laws or regulations that contradict other laws and regulations, (2) enacting new laws or regulations to enhance the three pillars of education, and (3) restructuring the MONE organization.
9. *Intensifying nonformal and informal education.* To reach the hitherto unreached sectors of the population, the government has launched some programs among others as follows: (1) nonformal early-childhood education programs, (2) literacy campaign, (3) package A, B, and C, (4) life-skill education, (5) community literacy circle, and (6) gender mainstreaming. In 2007, nonformal early-childhood education programs served 9 542 776 out of 28 426 500 children, while the formal early-childhood education programs served 5 193 298 children. In 2004, the number of illiterates aged 15 years or older was 15 million (10.2%), and in 2007, the number significantly decreased to 11 million (7.2%).

Educational Streaming

Indonesian education consists of formal education, nonformal education, and informal education. Level of education consists of basic education, secondary education,

and higher education, while types of education include general education, vocational education, and special education. The streams, levels, and types of education can take the form of an educational unit organized by the central government, local government, and/or community. All these are managed by MONE through four directorate generals as follows: Directorate General for the Management of Primary and Secondary Education, Directorate General for Higher Education, Directorate General for Nonformal and Informal Education, and Directorate General for Quality Improvement of Teacher and Educational Personnel.

Basic education is the foundation for the secondary education. Basic education takes the form of primary schools, *Sekolah Dasar* (SD) as well as *Madrasah Ibtidaiyah* (MI), or other schools of the same level, and junior secondary school, that is, *Sekolah Menengah Pertama* (SMP) as well as *Madrasah Tsanawiyah* (MTs).

1. Secondary school is the continuation of basic education. Secondary education comprises general secondary education and vocational secondary education. Secondary education takes the form of senior general secondary schools, *Sekolah Menengah Atas* (SMA), *Madrasah Aliyah* (MA), senior vocational school, *Sekolah Menengah Kejuruan* (SMK), and *Madrasah Aliyah Kejuruan* (MAK).
2. Higher education is the level of education after secondary education consisting of diplomas (1–3-year program), bachelor's (*sarjana*), master's, and specialized postgraduate programs, and doctorate programs imparted by a higher education institution. Higher education institutions are provided in a flexible system, and take the form of academies, polytechnic (*sekolah tinggi*) institutes, or universities. Higher education institutions can also run academic, professional, and/or vocational and technical programs.
3. Nonformal education is designed for community members who need education service that functions as a replacement, complement, and/or supplement to formal education within the framework of supporting lifelong education. It is aimed at developing learners' potential emphasis on the acquisition of knowledge and functional skills, and developing personality and professional attitudes. Nonformal education comprises life-skills education, early-childhood education, youth education, women-empowerment education, literacy education, vocational training and internship, equivalency programs, and other kinds of education aimed at developing learner's ability.
4. Informal education can be in the form of self-learning, provided by families and communities. The outcomes of informal education shall be recognized as being equal to the outcomes of formal education and nonformal education after successfully passing an assessment according to national education standards.

5. Early-childhood education is organized prior to basic education. It is provided through formal education, non-formal education, and/or informal education. Early-childhood education provided through formal education can take the form of kindergarten, or *Taman Kanak-kanak* (TK), as well as *Bustanul Athfal*, or *Raudhatul Athfal* (RA). Early-childhood education provided through nonformal education can take the form of playgroups, that is, *Kelompok Bermain* (KB), childcare centers, or *Taman Penitipan Anak* (TPA), or other similar forms of nonformal education. Early-childhood education provided through informal education can take the form of family education or social education.
6. In-service education is professional education provided by government departments or nongovernment institutes. In-service education functions to enhance the ability and skills to carry out the duties for government officials, and is provided through formal education and nonformal education.
7. Religious education is provided by government and/or by any group of people belonging to the same religion in accordance with the law. Religious education functions to prepare learners to become community members who understand and practice religious values and/or acquire expertise in religious studies. Religious education can be conducted through formal education, nonformal education, or informal education. Religious education can take the form of *diniyah* education, *pesantren*, *pasraman*, *pabbaja samanera*, and other similar forms of education.
8. Distance education can be organized in all streams, levels, and types of education. It provides educational services to any group of people in the community who cannot attend face-to-face courses or regular classes. Distance education is organized in various forms, models, and coverage by learning facilities and services, and an assessment system which ensures that the quality of graduates is in accordance with national education standards.
9. Special education is provided for learners who have difficulties in following the learning process because of physical, emotional, mental, or social deficiencies. It is also for those with proven intelligence and those who are especially gifted. Education with special services is provided for learners in the remote and less-developed areas, isolated areas, and/or for learners who are victims of natural disasters who suffer from social deficiencies, and those who are economically disadvantaged.

National Curriculum Guidelines

The national center for curriculum development has the task of developing curriculum with reference to the national standard of education. At all levels of education, the curriculum is developed based on the diversification

principle relevant to education units, local potential, and students. The curriculum is developed within the framework of maintaining the unified state of Indonesia, based on the following principles:

- strengthened faith and obedience to God Almighty;
- improved character;
- increased potential, intellect, and interest of students;
- diversity of local potential and environment;
- local and national development demands;
- employment demands;
- development in science, technology, and arts;
- religion;
- global developments; and
- national unity and national values.

The curriculum of elementary and secondary education must include the following: religious education, civic education, language, mathematics, science, social studies, arts and culture, physical education and sports, vocational skills, and local contents. The curriculum of higher education should include religious education, civic education, and language.

Teacher Education

According to Law No. 20/2003 on national education system, teachers are professionals who are responsible for carrying out the following tasks: planning and implementing the learning process, as well as evaluating its results. Teachers must have the minimum qualification and be certified to teach at relevant levels of educations; be healthy physically and mentally; and be capable of implementing the goal of national education. Teacher promotion is based on educational background, experiences, competencies, and achievements in the field of education. In formal education settings, teaching at the level of early-childhood education, elementary education, and secondary education must be done by graduates of accredited universities. Teacher certification is offered by selected universities that have relevant educational programs. The central and local governments must provide support for training teachers at all levels in their respective jurisdictions. **Table 2** summarizes the number of teachers at all school levels.

Table 2 The number of teachers in 2005/2006

No. of schools private/ public	No. of teachers	No. of students
144 262	1 346 846	25 982 590
23 853	616 364	8 073 389
15 342	469 360	5 729 347
187 457	2 432 570	39 785 326

Source: Indonesia Educational Statistics in Brief 2005/2006.

Since independence, teacher education has been carried out by public or private institutes of teacher training or faculties of education. In the 1990s, those institutes changed into universities with the wider mandate mission of carrying out education as well as noneducation programs. Throughout the country, there are 12 public teacher training universities and a number of private ones. The existing teacher training has been carried out using the concurrent mode rather than consecutive mode of training. Since the first semester, the prospective teachers have to take subject-matter courses as well as pedagogical courses. However, Law No. 14/2005 on teachers and lecturers implicitly states that a graduate with a bachelor's degree from any university can be admitted into the certification program and later become a certified teacher. In other words, any graduate of a noneducation university can apply for certification to be a certified teacher. Many suspect that in the long run, the existing concurrent program could be legally terminated, in favor of consecutive mode of training as is common in other countries.

Higher Education

Up to 2007, there are 82 state universities and 2800 private universities, offering 14 000 study programs at various levels, including diploma, S1 (BA), S2 (master's), and S3 (doctorate). The participation rate at universities under MONE, MORE, and open university has reached 17.25%, which is far from ideal. There are 231 757 lecturers teaching at 2811 universities, excluding those under non-MONE such as MORA, and others. In 2008, there are around 2.6 million students at universities under MONE, so quantitatively the lecturer–student ratio of 1:11 is fairly good. In general, lecturers at public universities are more qualified than their counterparts at private universities. There are 42 069 lecturers with S2/3 qualifications, that is 62.61% of the total of 67 192 lecturers at

MONE. **Table 3** depicts academic qualification of lecturers in MONE. As mandated by Higher Education Long Term Strategy (HELTS) IV 2003–2010 that higher education developments are aimed at the following: (1) creating competitiveness among universities, (2) developing autonomy, and (3) establishing healthy organizations.

The government encourages all public universities to be autonomous. There are already seven public universities that have enjoyed this autonomy, namely UI in Jakarta, ITB in Bandung, IPB in Bogor, UGM in Yogyakarta, USU in Medan, UPI in Bandung, and UNAIR in Surabaya. Among the public universities some are already included among the top 500 universities in the world and they are also among the best 100 universities in Asia. In 2007, according to the *Times Higher Education Supplement*, six universities were short listed, namely UGM (218 study programs), ITB (100 study programs), UI (202 study programs), UNDIP (115 study programs), UNAIR (96 study programs), and IPB (80 study programs), while UT (47 study programs) is accredited by OECD.

Funding

A comparative study on educational funding in the 1990s showed that the budget for education allocated at the central government as well as provincial government is relatively low. In 2007, for example, the budget for education was around US\$4.63 billion. This figure does not include the education budget allocated at the provincial levels for 33 provinces and 440 districts or cities. With this allocation, MONE is the department that has the highest budget. In general, the budget is allocated for social assistance (63.47%), buying goods (16.01%), paying salaries (15.22%), and investment (5.29%).

In response to the call for reform in 1997, the People's Consultative Council has amended the 1945 Constitution. Chapter 31, Article 4 of the Constitution mandates that the government should allocate 20% of the state budget

Table 3 Number of lecturers and their qualifications in MONE

No	Levels of education	Gender		Statistics	
		Male	Female	Total	Percentage (%)
1	S-3	5962	1635	7597	11.72
2	S-2	19 371	9998	29 369	45.30
3	S-1	16 390	9709	26 099	40.26

for education, so that in 2009 the allocation for education will be around US\$22.8 billion. This figure includes the budget for education administered by agencies outside the MONE, yet does not include the education budget at regional levels. To ensure quality education at the school level, Law No. 20/2003 mandates standardization of education budgeting. To realize it, the government has issued Regulation No. 9/2005 on national standards of education, which sets the standards for financing schools and other educational units in terms of investment, operation, and personal budgets.

Major Changes and Issues since the 1990s

One of education milestones in Indonesia is the enactment of a new law on education known as Education Act No. 2 on the national educational system that was officially launched on 27 March 1989. Some of the major issues in the law include the following:

1. Consistent with the centralistic management of administration system as a whole, national education management is the responsibility of the MONE. The school learning activities are based on the national curriculum. Recently, there have been the Curriculum 1975, Curriculum 1984, and Curriculum 1994, all of which were based on ministerial decisions and were implemented at the elementary and secondary education levels nationwide. The law mandates the implementation of 9-year compulsory education, namely 6-year elementary and 3-year secondary education. However, up to now (2008) this has not been fully implemented. Due to economic reasons, many elementary school-agers are not admitted into school or drop out from school.
2. There were four major issues of education in Indonesia, that is, access to education, quality of education, relevance of graduates to the needs of community, and effectiveness and efficiency of educational management. Access to education is made possible through the 9-year compulsory education programs and the establishment of new schools in various remote areas to accommodate all school-agers for elementary and secondary education. The issue of quality education is concerned with attempts to help all students achieve a specified standard of competency. Hence, the society will expect that graduates of education levels have the minimum of a specified set of competencies. The issue of relevance of education is concerned with the relevance of quality and competence of school graduates with the needs of society and industry. The link-and-match policy was once introduced to ensure the relevance of graduates with the community's needs. The issue of effectiveness and efficiency in managing educational resources from the lowest level of educational units up to the national level was facilitated by programs to propose solutions to the three problems mentioned above.
3. Since the 1980s, EBTANAS (National Final Learning Assessment) has been implemented at SD/MI, SMP/MTs., SMA/MA, and SMK. EBTANAS was a solution to the perceived quality of national education which decreased since the school examination replaced the national examination in the early 1970s. Some people proposed to revive the national examination to increase the quality of education, while some others wanted to continue with the school examination. The current EBTANAS was a compromise to combine the scores of the national examination (called EBTANAS) and those of the school examination (called EBTA). When the 9-year compulsory education policy was mandated, EBTANAS was no more relevant for SD/MI.
4. In response to the issue of relevance of education with the community's needs, the Minister of Education launched the link-and-match policy. The school was recommended to collaborate with the industry in designing the curriculum and learning programs to ensure that the school graduates have skills more relevant with the employment demands.
5. There were at least two factors that should be noticed during the implementation of the Education Act No. 2 1989 that significantly affect educational development in Indonesia: national consensus on the implementation of decentralization and democratization, and the introduction of a new curriculum known as competence-based curriculum. Under Law No. 22 Year 1999 on district autonomy, management of education with few exceptions is decentralized to district level. The central government focuses, among others, on the establishment of regulations needed for the implementation of the new law, and the development, monitoring, and evaluation of national standards in education. Meanwhile, MONE through the Center for Curriculum Development developed a new national curriculum for primary and secondary school known to be a competence-based curriculum.
6. With respect to those issues and national political consensus on decentralization and democratization through Law No. 74/2000, education reform was badly needed. In response to the need for education reform, MONE established a commission for education reform or KRP (*Komisi Reformasi Pendidikan*). It is worth noting that education reform is a part of nation reform as a whole. The commission was to review and revise Education Act No. 2 of 1989 with respect to the issues above and district autonomy under coordination of the head of the office of research and development of national education. The commission came up with a new law of education known as that of Education Act No. 20 of 2003.

The Major Issues in Education Law No. 20/2003

The economic crisis that hit the country in 1997 caused total reform movements in education. There have been major changes in education policies ever since, among others, as follows:

1. Consistent with the law on regional autonomy, Law No. 20/2003 mandates decentralization of government. Education management was shared by the district or city and the central government with the focus on (1) developing, monitoring, and evaluating the national standard of education and its implementation, and (2) proposing or drafting regulations for the implementation of Law No. 20/2003.
2. Early-childhood education is specifically mandated in several articles. Also mandated in the law is special education. Earlier managed by a section in the directorate of kindergarten, elementary education, and secondary education, special education is now managed by a directorate. Distance learning, which was formally mandated to *Universitas Terbuka* or open university is now explicitly stated in the law.
3. National standards of education (SNP) are now explicitly stated in the law. Chapter 35 lists eight standards, namely on content process, competency process, graduate's competency, education personnel, facilities, management, funding, and evaluation. The government has formed an independent board of standardization and quality assurance responsible for implementing and monitoring the standards.
4. As realization of Law No. 20/2003 on the national education system, some government regulations have been enacted, such as Regulation No. 19 Year 2005 on national standard of education. The board of national standard of education was formed and mandated to assist the minister to develop and monitor the implementation of the national standards, that is, on content process, competency process, graduate's competencies, educator and educational personnel, facilities, management, funding, and evaluation; and to make recommendations to the government. BSNP is also tasked with administering the national assessment and evaluating the elementary and secondary textbooks in terms of content, presentation, language, and graphics.
5. A new directorate general was formed to manage teachers and educational personnel called directorate

general for quality improvement of teacher and educational personnel improvement. Consistent with government commitment to improvement, supported by PGRI (Indonesian Teachers Union) and Association of LPTK (Teacher Training University), Law No. 14/2005 on teachers and lecturers was enacted. According to the law, any teacher has to be certified. Practically all working teachers have to be certified, and those certified teachers will get extra payment.

6. The government has set a policy on increasing the number of vocational high schools so that by 2015, the ratio of vocational high schools to general high schools will be 60:40. The policy was motivated by demands for middle labor force required to transform Indonesia from an agricultural country to an industrial one.
7. The government reiterates the commitment to education characterized by access to quality education, cheap education, and access to education for all. To implement this, the government has launched inexpensive book programs. The public are encouraged to write elementary and secondary school textbooks. The books are evaluated by the Board of National Standard of Education (BSNP) and quality textbooks will be mass-produced for school children to access manually as well as electronically.

Background

As of late 2006, Israel's population was at 7.1 million – 16.5% Muslim, 2% Christian, 1.6% Druze, and slightly over 80% Jewish. The founding of the State of Israel in 1948 as a Jewish national home – following the destruction, on the European continent, of a third of the Jewish people during World War II – triggered waves of Jewish immigration to Israel from countries around the world – a phenomenon that continues to this day. Israel is a rich and unusual demographic mosaic, in which diverse cultures intermingle and the streets resound with a medley of languages besides the official Hebrew and Arabic. Jews from 79 countries, representing about 39 different languages (CBS, statistical Abstract of Israel, 2009: 237) have made their home here. In addition to the formidable task of building a nation, Israel has had to cope, through the years, with a tense geopolitical situation in the Middle East. These facts elucidate the complex reality with which the Israeli education system is faced.

Complex though it may be, Israeli society is perceived as a creative and vibrant one in all spheres of life. For example, during the 5-year period between 1999 and 2003, Israel ranked third in the number of scientific papers *per capita*, a world leader in applied science, and ranked second worldwide in astrophysics, third in computer science, and fourth in molecular biology (Czapski and Ilan, 2004). All seven of the country's universities were included in the list of the world's 500 leading research institutions in 2005. The local thirst for culture has led to the creation of a wide and growing variety of cultural institutions. Indeed, recent years have witnessed an unprecedented growth of cultural activity, reflected in a threefold increase in cultural consumption on the part of Israeli children and adolescents over the last two decades.

On the economic level, since the 1980s, Israel has undergone the transition from a planned to a liberal economy. As of 2007, Israel's gross domestic product (GDP) is US\$26 500 *per capita*; economic growth rate was 5% in 2007, nearly double that of the Organization for Economic Cooperation and Development (OECD) countries. Annual inflation is about 2%, the labor-force participation rate is 55.2%, and the unemployment rate is 8%. During the 1990s, the information and communication technology (ICT) sector was the main force driving Israel's economic growth. To give some perspective, in 2004, the sector's share of Israel's total exports was 20%, compared with 13% for the same year in the OECD countries.

Despite Israel's achievements in the areas of economic growth, immigrant absorption, reach of cultural life, science, and research, social disparities persist. A quarter of Israel's children live below the poverty line; the disparity in per-pupil spending on education between the highest and lowest decile has held steady for the past decade at 11-fold (Israel Shekel Exchange Rates (NIS) 126 per month for the lowest decile vs. NIS 1355 for the highest decile in 2005).

Against this background, it becomes easier to understand the complex circumstances in which the Israeli education system operates: absorbing new immigrants whose native language is not Hebrew, profound social and economic disparities, and, above all, the drive to meet international standards – as well as a demanding public's expectations – for scholastic performance. The Israeli education system based on the foundations laid during a 50-year prestate period, of all walks of life, was administered by the Vaad Leumi, or Jewish National Council, mainly during the British Mandate in Palestine. This infrastructure was influenced by the numerous initiatives, organizations, and ideological tracks that were active in Palestine from the end of the nineteenth century onward and from which a growing variety of educational enterprises emerged. These enterprises included vocational education networks as well as boarding school systems (youth village) that rescued children via youth *aliyah* frameworks prior to the European catastrophe besides assisting young people in immigrating to Israel after the establishment of the state. At that time, these youth villages served a third of Israel's children. Alongside the youth village system, a joint school system developed, that encompassed over 400 kibbutzim and which in itself absorbed numerous immigrant children.

While the language of instruction for Jewish pupils is Hebrew, the language of instruction for Arab pupils is Arabic. Israel's Arab and Jewish education systems do not operate on an equal footing. Over the years, various infrastructural and service disparities have been identified between the Jewish and Arab, as discussed below. These disparities have been a persistent source of frustration as well as of action.

In this article, we look at the various levels of Israel's education system, from early-childhood education through higher education, with particular attention to the system's internal contradictions, complexities, and weaknesses, as well as to the major challenges faced at each successive level.

Early-Childhood Education

Israel's Compulsory Education Law calls for compulsory schooling from age 5 through 18. However, when the law was passed in 1949, a year after the founding of the state, compulsory education was defined as 8 years of schooling only, from age 5 to 13. Israeli legislators at the time were divided into two camps – those who attached importance to the age at which schooling was to end preferring that it continue until age 15, and who, due to limited resources, proposed that schooling begin at age 7, and those who attached special importance to preprimary education, insisting that compulsory schooling begin at age 5. The State of Israel was founded in May, 1948, while the Compulsory Education Law was enacted in September, 1949. The latter approach viewed early-childhood education as a preparatory stage crucial to ensuring young children's readiness for primary school and, in particular, to narrowing educational disparities. This approach has found practical expression, particularly since the 1980s, in intensified governmental efforts to encourage the enrolment of children in preschools from age 3 – efforts that have taken the form of state subsidies for early-childhood education in Israel's disadvantaged population sectors. As a result of this policy, 37% of Israeli children, aged 2 and above, 75% aged 3 and above, 86% aged 4 and above, and 95% aged 5 and above were enrolled in preschools in 2006, with a total preschool enrolment of 400 000 between ages 2 and 5.

From a pedagogical point of view, the Israeli early-childhood education system has gone through two distinct stages. During the first stage, the focus was on education for positive social habits, arts and crafts, music, holidays and festivals, hygiene, and linguistic usage (Michaelovich, 1999), while until the late 1980s, the preprimary education system came to be perceived as a framework for preparing children in accordance with the requirements of older pupils in the system. This trend led to the development of a more demanding curriculum that taught basic scholastic skills and strove to ensure a smooth continuum between kindergarten and primary school. What occurred was, in essence, a complete overhaul of the kindergarten curriculum, which was now oriented toward teaching arithmetic, science, art, life skills, and the historical-cultural heritage. The transition from a relaxed pedagogy, free of external policy pressure to a policy with more defined standards and prerequisites generated considerable controversy within Israel's education system that has continued to resonate into the twenty-first century. Despite the pedagogical differences of opinion, Israel's early-childhood education system is generally thought to possess many positive features and has earned a high degree of professional and public esteem.

Primary Education

Israel's primary education system, in which some 800 000 pupils currently participate at 2200 educational institutions, developed in three main stages.

The first stage, which spanned the first two decades of Israel's existence, was characterized by a melting-pot policy. Half of the country's pupils came from immigrant families; in some localities, immigrants formed the decisive majority. In order to promote the development of a homogeneous society and to blur differences and disparities between immigrants and veteran Israelis and between Jews of Western and of Middle Eastern ethnic background, a uniform curriculum was adopted for the entire pupil population. The main goal was to do away with the various educational streams that had existed prior to the founding of the state and to absorb and unite the immigrants under a single uniform curriculum – to ensure the development of one unified people within one state, by means of a single curriculum (Tsabar-Ben Yehoshua and Zilberstein, 1999). Schools and teachers were regarded as partners in the ideological mission to forge a cohesive society. This aspiration to uniformity cast the teaching profession in a conservative mold and impaired its ability to address the tremendous differences that actually existed between different pupil groups (Dror, 2004).

The second period began in the late 1960s, when an approach gradually emerged that called for emphasizing differences in pupil needs over uniformity in the provision of educational services. This approach engendered the policy of a child-centered approach. It led Israel's primary education system to stress upon individually tailored instruction, to encourage independent learning, and to foster the acquisition of inquiry-based learning; it promoted active learning, enrichment of the learning environment, the offering of electives, schedule flexibility and a multiyear curricular structure, democratization of the school social framework, involvement in the community, an emphasis on identifying individual pupil needs, and a diminished reliance on standardized assessments (Bentoitz, 1960; Eden, 1971; Tsameret, 1977; Shtall, 1991; Tsabar-Ben Yehoshua, 1990). Additionally, a trend toward differential allocation of learning resources took hold, in which priority was given to disadvantaged populations (Tsabar-Ben Yehoshua, 1988; Zilberstein, 1984; Tsabar-Ben Yehoshua and Zilberstein, 1999). This in turn created the conditions for large-scale adoption of a school autonomy philosophy – to a point where a third of Israel's schools became self-managing (Volansky, 2003; Dror, 2006; Gibton and Goldring, 2002; Gibton *et al.*, 2000).

The third stage in the development of Israel's primary education system is characterized by contradictions in the realm of pedagogical policy. On the one hand, there was a teacher-empowerment policy and a trend toward trans-

ferring authority to the schools – an understanding of the new information age and accessibility to knowledge and its concomitant recasting of the teacher as facilitator guiding the pupil to knowledge sources, rather than serving as the sole source of knowledge in the classroom. This trend harmonized with the growing tendency toward encouraging pupils to actively build their own individual knowledge maps and toward employing the computer for instructional purposes. At the same time, contradictory pedagogical approaches began to garner support, approaches that called for increased standardization of teaching, learning, and testing methodologies. These approaches drew strength from Israel's medium-to-low rankings on international scales of scholastic performance, and from growing criticism of instructional methods that gave pupils excessive degrees of creative and scholastic latitude. This is reflected in the growing use of strictly defined and rigid instruction frameworks for the entire pupil population, as well as in the development of a culture of high-stakes testing.

Israel's primary schools have, thus, undergone three major changes in pedagogical approach – changes that have, necessarily, affected their organizational and administrative structures. Schools have transitioned from a climate of extreme centralization to one of pedagogical autonomy and self-management, while a current trend toward standardization is restricting the freedom of the teacher and the educational institution and transferring significant pedagogical latitude from the schools back to the central planning authorities.

Secondary Education

At the end of primary education, pupils move on to the secondary education system, divided into junior and senior high schools. In 2007, 610 000 pupils were enrolled in 1588 schools comprising grades 7–12.

Nearly half (47%) of these schools are operated by not-for-profit organizations, while the other half are run by local authorities (38%) or the Israeli government (15%) (Facts and Figures, 2004).

Until 1979, when secondary education became open to the majority of Israel's pupils, a selective system was in place. Graduates of the primary education system were divided into three groups: those headed for academically oriented study in grammar schools, those headed for vocational training at technology schools, and those who entered the workforce directly. A series of policy changes opened the gates of secondary education (through grade 12) to a growing percentage of young people. These measures included: the decision at the end of the 1960s to enact an education reform lengthening the period of compulsory education to age 16 and the period of free schooling to age 18; the establishment of junior high

schools with upgraded curricula; the elimination, in 1973, of screening examination for secondary education; the reformed matriculation examination system, instituted in 1979, which provided for a more varied curriculum reflecting pupil needs, multiple intelligence and differences; and the trend toward differential budgetary allocation as a means of strengthening disadvantaged populations. All of these things contributed to a profound change in the structure of secondary education in Israel (Iram and Schmida, 1998). Over the course of the last three decades, this change has been reflected in three main indices: a greater number of pupils from the middle-to-low range of the socioeconomic scale completing the 12th grade; a greater number of pupils finishing high school with a matriculation certificate; and a greater number of pupils gaining admission to institutions of higher education (Drori, 1999).

These measures, taken both individually and together, led to changes in Israel's educational structure, particularly in terms of offering educational opportunity to disadvantaged populations for whom the gates of learning had previously been closed (Shmueli, 1998; Volansky, 2005). These changes may largely be credited to the increased scope given to schools for defining study disciplines with a high degree of relevance to their pupils and communities, without renouncing the duty to teach and test the entire Israeli pupil population in six or seven core subjects. A wide variety of unique and innovative curricula were developed that had never before been on the education system's agenda: animal care, cosmetology and beauty, music and art, sports, and culture – all in addition to the required subjects comprising Hebrew/Arabic, English, mathematics, the sciences, history, Bible, geography, and civics. This was an era of exceptional creativity and innovation in the education system, one that lives on in memory as a golden age.

This age came to an end during the 1990s, when the education system was forced to yield to growing pressure from Israeli society. The first to oppose the aforementioned educational approach were the universities (Volansky, 1999, 2005), which argued the impossibility of ensuring qualitative matriculation standards in a situation where study disciplines were developed by the schools and not by the state. The second group to oppose the innovative educational approach was the Mizrahi Democratic Rainbow Coalition, a movement involved in guaranteeing the rights of Jews of Middle Eastern (*Mizrachi*) origin. One of the movement's claims was that the education system's vaunted flexibility and variety had actually created a situation in which *Mizrachi* pupils were being channeled toward less-prestigious courses of study, mainly in the technology schools, and were, thereby, being barred from acquiring higher education – in contrast to native Israeli pupils and to those of European/American origin. A third, back-to-basics group called, quite simply, for the elimination of noncore disciplines and for a re-embrace of the basics,

that is, of six or seven uniform subjects for the entire Israeli pupil population. By the early years of the twenty-first century, these pressures had gathered momentum in generating change in the education system (Yogev, 2007). The change consisted primarily of a transition to an academically oriented study, consistent with the back-to-basics approach. This approach has been a source of discord since it began to gain currency during mid-1990s. On the one hand, the overall percentage of Israeli pupils eligible for the matriculation certificate has risen to about 50%. This is, indeed, an impressive improvement, considering that in 1990 only 35% of Israeli pupils were eligible for the matriculation certificate. On the other hand, this contraction of the curricular structure has left the other half of the secondary school population behind. These pupils have been deprived of the kind of flexible educational option that they need in order to complete 12 years of compulsory schooling in an environment that engages them, challenges them, brings their talents and abilities to the fore, and secures them a matriculation certificate so that they can go on to tertiary education.

Brand-naming schools as successful or outstanding and using league tables to rank them have intensified pressures with regard to pupil screening. The slashing of education budgets during the past decade has also resulted in the inability of schools to implement special curricula which by their very nature are more expensive. This development has caused schools to limit their study offerings and to focus overwhelmingly on curricula that require little more than a blackboard and chalk. School networks that developed over decades as frameworks offering a broad variety of curricula spanning the range of academic, technological, and practical subjects, have been forced over the last 10 years to confine the bulk of their instructional activity to scientific/engineering subjects geared mainly for the more academically oriented segment of the pupil population. In effect, school principals have been obliged to intensify their pupil-screening activity as a way of boosting the prestige of their schools, and to adopt curricula that are, in practice, suitable for only the upper 50% of the pupil population. The ramifications of this policy may be seen in Table 1.

Table 1 shows both the strengths and weaknesses of Israeli secondary education. The larger the cohort, the greater the number of pupils who complete 12 years of schooling; but in absolute terms, the number of pupils completing grade 12 without a matriculation certificate adequate for tertiary education has also grown, reaching 54 000 in 2006. This illuminates the significant challenge facing the Israeli education system – that of adapting the curricular structure to make it relevant and meaningful for the lower 50% of its enrollees who, despite the system's success in ensuring that they complete grade 12, nevertheless remain bereft of a ladder of opportunity leading to higher education.

Table 1 Percentage of those completing 12 years of schooling and percentage of those eligible for the matriculation certificate, per cohort, since the founding of the state

Year	Size of cohort ^a	% of cohort members enrolled in grade 12	% of cohort members eligible for the matriculation certificate at the end of grade 12
1949 ^b	12 000	6.7	1.6
1960	25 000	27.0	14.2
1970	52 900	39.7	20.0
1980	65 500	53.4	21.3
1990	85 000	72.0	34.7
2000	103 000	86.0	43.6
2006	107 000	92.0	49.2

It may be assumed that the coming decade will bring with it a search for balance between the two trends described above, that of instructional standardization and uniformity, and that of variety in educational offerings – variety that encompasses a broader range of intelligences and talents than that currently addressed by the system.

Higher Education

Legal authority for Israel's system of higher education, which in 2007 comprised a quarter of a million students in 65 educational institutions, lies with the Council for Higher Education. A higher education planning and budgeting committee operates within the Council's framework. These bodies, which are responsible for formulating higher education policy, initiated a reform in 1993, which led, over the course of the subsequent decade, to a substantial restructuring of higher educational opportunity in Israel.

For most of the State of Israel's existence, the higher education system was a monolithic structure founded mainly on seven research universities. Starting in the mid-1990s, the system underwent a profound transformation, expanding to include new colleges and evolving into a pluralistic structure that includes 65 institutions offering a broad range of study options. This increase in the number of institutions was made possible in part by the trend toward legitimizing degree conferral in disciplines not normally associated with the research but on professional studies. Five main reasons may be identified for this large-scale opening of the gates of academia. The first of these is the disparity that existed around 1990 between the percentage of those eligible for the matriculation certificate (35%) and those admitted for first-year studies at Israel's institutions of higher learning (20%). A particularly low

rate of admittance to higher education was found among *Mizrachi* Jews and in the Arab sector. The second factor was the growing pressure exerted by professional postsecondary institutions for accreditation to grant academic degrees. These were institutions offering courses of study in tourism services, communications, insurance, optometry, dental hygiene, laboratory technology, architecture and design, and various technological disciplines – as well as teacher-training colleges, only a minority of which awarded academic degrees prior to the reform.

The third factor was the rigorous screening policies that prevailed in the more desirable and prestigious disciplines, such as law, psychology, medicine, computer science, and economics. As the planning echelon of that period felt that the economy's needs in these fields was limited, the number of student places was likewise limited in conformity with projected needs. The fourth factor that led to the development of academic colleges was the rapid increase in the number of students at the universities – 8% – 4 times higher than the annual growth rate of the population (to ensure their stabilization at current levels through 2000). Growing public expenditures on higher education were the fifth factor that came into play. The national expenditure per full-time student (including tertiary and higher education) in Israel was high at the time (US\$11 100) compared with other countries. All of these factors culminated in the decision to develop academic colleges whose cost of maintenance as teaching facilities would be a third lower than that of expanding the universities. A decision of the Council for Higher Education was supported by the Israeli government decision and by a legal amendment passed by the Knesset.

Thus, starting in the mid-1990s and over the course of a decade, Israel's higher education system doubled in size and absorbed nearly one out of every two (42%) members of the high-school graduate cohort, compared with one out of every five at the beginning of the 1990s, mainly due to the development of the academic colleges. **Table 2** illustrates the change in access to higher education:

The rapid growth of the higher education system also had a swift impact on the quality of teaching and learning within the system. Governmental funding in institutional budgets, particularly those of the universities, was cut by 20%; the senior faculty/student ratio, which in the mid-1990s was 1:16, had reached 1:25 by 2006; branches of foreign institutions in Israel were opened; nine new private institutions were established; and there was an increase in the number of public colleges and an overall rise in the number of institutions to 65 in 2007. The structural changes have produced an effect opposite to that anticipated – intensified competition, which led to lowering academic quality rather than enhancing it. Criticism of academic quality and frequent budgetary crises, particularly in the universities, gained momentum and led to the creation of a governmental commission that, in 2007, formulated

Table 2 Percentage of students admitted for first-year academic study, per age cohort^a (1949–2004)

% enrolled in institutions of higher education, per cohort	% eligible for matriculation certificate, per cohort	Size of cohort	Year

recommendations intended to improve the state of affairs. These recommendations included returning the budget to its 2001 level; raising student tuition by 50%; expanding the support system for students from the lower rungs of the socioeconomic ladder; merging existing colleges; recruiting new faculty staff to enhance instructional and research quality; defining the universities as the exclusive venues of research and the colleges as institutions geared solely toward academic teaching; and having an external quality control system.

The commission's recommendations, which will be coming up for government approval in early 2008, are controversial. While the universities regard the recommendations as a potential lifeline, two other factions oppose them: the students, who are unwilling to pay higher tuition, and the colleges, which are unwilling to see research defined as an area of activity in which their instructional personnel have no part. All of the stakeholders are gearing up for the coming battle.

Special Issues

The *Haredi* (Ultra-Orthodox) Sector

Until the early 1990s, the percentage of Israeli pupils studying in the *Haredi* sector was 6%. This figure began to increase in the early 1990s, and by 2006, about a quarter (25.6%) of Israel's Jewish primary education population was *Haredi*. Main features of education in the *Haredi*-school sector include the nonstate status but a public funding of most of its expenses; a focus on religious studies with minimal attention to secular subjects; a sense of alienation from the state; and a tendency to shirk civic duties. This situation has two main consequences: first, many young people who graduate from

the *Haredi* education system find it difficult to gain admittance to institutions of higher education, due to an inadequate education background in secular subjects; and second, this population has obstacles taking its place in the labor force. In a study that was conducted with unemployed *Haredim*, the latter identified their lack of background in English, mathematics, and computer studies as factors preventing them from finding work (Naon *et al.*, 2006). Their limited potential for labor-force participation partly explains why a high percentage of *Haredim* live below the poverty line, and why a high percentage of Israeli children living in poverty belong to this growing sector.

Despite awareness on the part of the *Haredi* spiritual leadership of the community's severe economic plight, and despite increasing calls from within the population, particularly women, to permit secular studies for the purpose of ensuring family livelihoods, the formula has yet to be found that will enable hundreds of thousands of *Haredi* pupils to study secular subjects at the level and scope needed in order to earn a living. To a great degree, the issue is in the hands of the *Haredi* leadership, but it is not their province exclusively. The state has means available to it for generating a new kind of dialog, one capable of striking a new balance between the *Haredi* sector's curricular structure and the budgetary support that the state provides to *Haredi* educational institutions.

The Arab Sector

The educational disparities that exist between Israel's Jewish and Arab populations date back to the prestate period. Jewish organizations were established during the nineteenth and early twentieth centuries to promote Hebrew education in Palestine (Elboim-Dror, 1986). Differences in strength of leadership and budgeting policies led to disparities as early as the British Mandate period, and their effects were felt during the early years of Israel's existence. For example, in 1935 only "20% of Muslim children aged 5–15, versus 80% of Jewish and Christian children," were enrolled in educational institutions (Elboim-Dror, 1986: 36). During the years of Israel's existence, the gaps have narrowed continually. For instance, in 2006, the percentage of those enrolled in grade 12 in the Jewish sector was 93%, compared with 83% in the Arab sector.

Another issue relevant to Jewish–Arab educational gaps is that of the strength of the local authorities. The Arab local authorities' limited economic capabilities make it difficult to collect local rate and to establish complementary educational services, although the government pays teacher salaries and funds most educational services.

The 1980s witnessed a turning point in governmental policy toward the Arab sector. The government initiated 5-year plans to eliminate the deep disparities between the Jewish and Arab sectors. The plans had an

affirmative-action orientation that called for increased investment in Arab education. Although discrepancies between planning and implementation still exist, there has been a gradual trend toward closing the gaps on all measures of inequality. The percentage of school-aged Arabs enrolled in study frameworks has grown faster than that of school-aged Jews; there has been a significant increase in the percentage of Arab pupils eligible for the matriculation certificate; the percentage of Arabs studying in institutions of higher education has grown, although it is still low relative to the Arab presence in the overall population; during the 1990s, priority was given to school construction in the Arab sector; and, no less importantly, in 2003 a new formula was determined for the allocation of teaching hours, giving precedence to the Arab sector over the Jewish one. These corrective measures reached their height in 2007, when the Education Ministry made a politically charged and publicly contentious decision to allow the events of 1948 and their implications for Palestinian society to be taught in accordance with the Israeli Arab community's traditional narrative. The sensitivity surrounding this authorization is rooted in the fact that, while Israel's achievement of statehood – the establishment of a Jewish national home in Eretz, Israel, constituted a tremendous achievement for the Jewish people, for the region's Arab inhabitants, it occasioned a collective trauma, the *Nakba*, inasmuch as many of them left for neighboring countries in the wake of Israel's declaration of independence.

Another issue is that of the development of an Arab educational leadership. From the time of Israel's founding until 1987, education in the Arab sector was administered by Jewish position holders. This had consequences for the development of a senior Arab leadership in the educational sphere, and for the degree to which the sector's educational needs were actually addressed. The Ministry of Education's administrative dominance and its exertion of pedagogical authority were felt in nearly all areas of the education system. This reality led, unintentionally, to a stifling of any original thought that might have encouraged the development of a professional leadership capable of adapting pedagogical programs to Arab-sector needs. This dependence, though it did in some cases generate educational initiatives, nevertheless compromised the Arab-sector leadership's ability to come up with creative programs.

In contrast to this stifling effect of the centralized educational leadership, recent years have seen the emergence of an intelligentsia that has left its mark at every point of the educational map to which it has traveled: inspectors, school principals, professional online forums, or graduate students in education. These individuals have demonstrated professional awareness and a higher degree of administrative ability than anything seen heretofore in the Arab educational sphere. A critical perspective;

educational innovation; needs-assessment capability; a broad educational background; professional leadership ability – all of these attributes have been increasingly evident since the late 1990s in encounters with the new cadre of Arab educators. The paradox of this leadership lies in the fact that it is still trapped in a dependent relationship, with the ideas coming from the Jewish sector. This sense of dependence is still having a paralytic effect and is rendering largely useless the vision, original thinking, talents, pedagogical initiative, and courage of the new intelligentsia. At present, midway through the first decade of the twenty-first century, Israeli Arabs' potential for social integration at middle-class status depends more on the sector's professional leadership and its determination to drive educational initiatives aimed at eliminating disparities, than it does on the establishment itself. Recent years have, unquestionably, witnessed a turning point: philanthropic initiatives to raise funds for education institutes; the establishment of organizations to improve school performance; initiatives on the part of numerous local authorities to increase the percentage of pupils eligible for the matriculation certificate; and an impressive rise in the percentage of Israeli Arabs studying in institutions of higher education (Volansky, 2005, 2007). More than at any time in the past, the Arab sector seems to be aware that the way to upgrade its status in Israeli society is to focus on quality education. The Arab leadership has a decisive role to play in ensuring the continued development of this trend.

The Teacher Crisis

The key to the current teacher crisis in Israel is the teaching profession's relative undesirability, to which several factors have contributed over the years. First, various occupational alternatives to teaching have emerged that are considerably more attractive to young people. These alternative sectors include finance, insurance, tourism, recreational/leisure services, ICT, complementary medicine, etc. Another factor is the harsh public criticism to which the education system is subjected, and the prevailing negative image of the teacher. Articles by key figures in Israeli society that portray the Israeli teacher as a failure, and crude insults to the profession on the part of public leaders have caused this image to become ingrained in the public mind and have deterred young people from joining the teaching profession. A third factor is the expanded sphere of individual, parental, and pupil rights which, albeit unintentionally, has undermined the teacher's authority. Fourth, teacher salaries have eroded to the point where teachers are relying on national-insurance income supports in order to achieve a mandatory minimum income – or taking on additional jobs beyond their professional teaching positions. A fifth factor is the trend that developed during the first decade of the twenty-first century toward a shorter

school day (14% on average), which indirectly contributed to a heavier teacher burden. The final factor is the intensifying public critiques with Israel's performance on international tests.

All of these factors have caused demand for teaching as an academic study discipline in Israel's teacher-training colleges and universities to decline. In 2006, the discipline-demand breakdown in Israel's 27 academic teacher-training institutions is shown in **Table 3**.

Conclusion

Israel's education system is faced with several challenges. The first and most visible of these challenges is the teaching profession's lack of demand. Cumulative damage to the image of the teacher; changes in the Israeli economy's employment structure, including the rise of higher status and better paid occupational sectors; the growing complexity of the teacher's job; and the higher median age of the teacher population – all of these things have led to a situation in which only profound change will draw young people with cultural/educational capital and personal charisma to the Israeli education system's 45 000 classrooms. A second challenge relates to the clear choice of a pedagogic strategy. Over its years of existence, the Israeli education system's standards have traditionally revolved around the matriculation exams administered at the end of grade 12. However, the permeation of high-stakes testing at all educational levels, including the early-childhood level, has created a situation rife with contradictions. Those who support this approach, view it as a major, if not the sole, tool for improving scholastic performance throughout the country. Critics see it as harmful to knowledge-building processes and cultivation of mind by development of thinking skills, and consider it to be a return to mechanistic and formal teaching methods. Those who oppose the standardization process see in the development of ICT a golden opportunity to create challenging new teaching methods relevant to the pupils' world, and they feel that the education system must under no circumstances waste its chance to incorporate ICTs into the teaching and learning process. Hence, today's great challenge is that of choosing a clear pedagogic strategy capable of resolving the existing contradiction.

A third challenge is also connected to the pedagogical sphere – the need to enable the lower 50% of the pupil population to complete 12 years of schooling, based on curricula that will function as a ladder to advancement and give these pupils the requisite background for tertiary education. In order for this to happen, there has to be choice and variety and flexibility in the curricular structure, as in the ideology of variety that came to prominence in the late 1970s – an ideology at odds with the current trend toward a monolithic, academically oriented system

Table 3 First-year student enrolment in primary education programs at teacher training colleges – 2006–2007

founded on a back-to-basics approach that favors the upper 50% of the population. Unless a different attitude is taken toward curricular structure at the secondary level, it will be difficult to ensure equal opportunity for tertiary education to tens of thousands of high-school graduates.

A fourth challenge lies in the *Haredi* sector. The continual growth of this population, which now accounts for a quarter of all pupils in the Jewish sector and which focuses primarily on religious studies at the expense of secular subjects, is responsible for the plight of the *Haredim* themselves, who are largely unable to integrate into the labor force. This in turn dooms the *Haredim* to economic distress, with most of the population's children living below the poverty line; it also keeps the state from increasing the percentage of its citizens who participate in the labor market (the Israeli figure is 10% lower than that of most developed countries). Any effort in this area will entail new definitions for the relationship between the state and the *Haredi* community, definitions capable of encouraging and supporting secular studies within this sector, if only in certain and minimum core disciplines essential for their integration into the labor market.

A fifth challenge is that of formulating an education budget capable of addressing the system's various other challenges. The budget cuts that Israel's education system has absorbed over the last few years have led to larger class sizes, fewer weekly class hours, a heavier burden on the teacher, a loss of pedagogical flexibility in the schools, a cessation of the trend toward school autonomy

and self-management, and fewer resources for advancing disadvantaged populations, including the Arab sector. These are the challenges faced by the Israeli education system in the middle of the first decade of the twenty-first century.

Jamaican Education System

Jamaica is an island nation in the Caribbean. It is part of the Greater Antilles, with a population of approximately 3 million. It was a colony of Great Britain and became independent in 1962. It is the most popular Anglophone country in the Caribbean/North American region, after the United States and Canada.

The Jamaican education system for the masses was established after the emancipation of the slaves. During the period of slavery, there were few schools to educate the local population as the plantation owners sent their children back to England to pursue education. After emancipation, the Indian Commission granted a sum of money to establish elementary schools. The churches also played an important role in the early beginnings of the public school system.

Presently, education in Jamaica is administered primarily by the Government through the Ministry of Education. The involvement of churches and trusts has, however, continued. Hence, there are two types of provisions – public (Government) and private (churches, trusts, and individuals).

The education system consists of four levels:

- Early childhood
- Primary
- Secondary
- Tertiary

Early Childhood

This level caters to children between the ages of 3 and 5 years. There are both public and private schools at this level. There are two types of private schools, namely, basic schools, which are individual- or community-managed and preparatory schools, which are managed by churches or individuals. There are 136 preparatory schools.

The public schools are called infant schools and are fully funded by the State. There are 29 of these schools.

Primary Schools

These schools cater to children between the ages of 6 and 12 years. Primary schools are funded by the State. There are also privately funded schools (preparatory) at this level. Children who attend primary school are mostly

from the middle and lower SES classes of the society while the majority of those who attend preparatory schools are from the upper middle and upper SES groups.

There are 892 public institutions which offer primary level education (grades 1–6).

Promotion from primary to secondary schools is through the Grade Six Achievement Test (GSAT), which is administered by the Ministry of Education annually. Children in grade 6 of primary and preparatory schools sit the test and are placed in secondary schools based on parents choice, performance, and geographic location. Children with the highest performance are normally placed in what are regarded as the “better schools.”

High Schools (Secondary)

High schools cater to students between ages 12–18 years (grades 7–13). Up till recently, secondary education was provided in two types of secondary institutions, high schools and new secondary schools. The high schools were selective schools, meaning that students entered the schools through a selective examination at the end of the primary level. The new secondary schools were nonselective. Students entered these schools from neighboring primary schools (feeder schools), without having to sit a selective examination.

Currently, all schools offering grades 7–11 education are called high schools. Students enter these schools through the GSAT which, as mentioned before, is taken by children in grade 6 of primary and preparatory schools.

There are 155 public high schools with a total enrolment of 236 410 (2005/6), whereas there are 85 private high schools with an enrolment of 9456. Among the public high schools are two agricultural schools and 14 technical high schools. The majority of students at the end of grade 11 sit the Caribbean Secondary Examinations Certificate (CSEC) Examination administered by the Caribbean Examinations Council (CXC). Students at the end of grades 12 and 13 sit the Caribbean Advance Proficiency Examination (CAPE) which matriculates them into the regional and extra-regional universities.

Tertiary

Tertiary-level education is offered in teacher education colleges, community colleges, and universities. There are

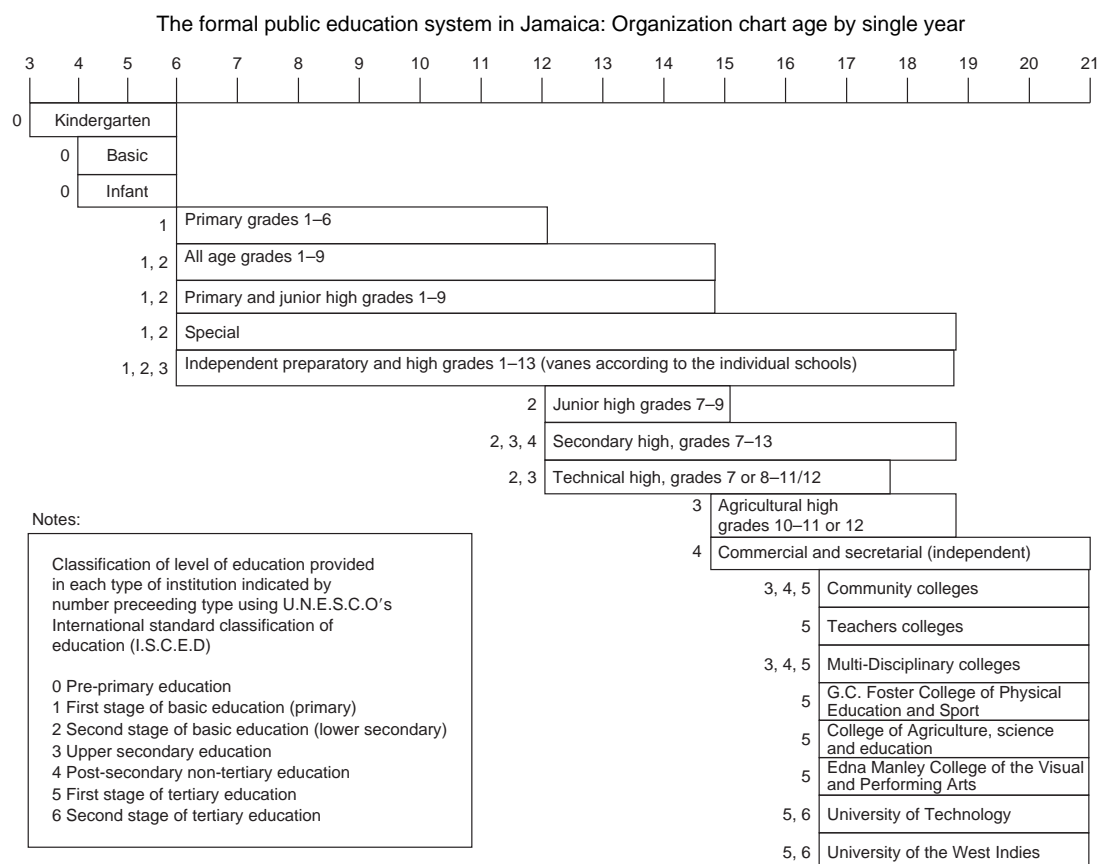

Figure 1 The formal public education system in Jamaica Organization chart age by single year.

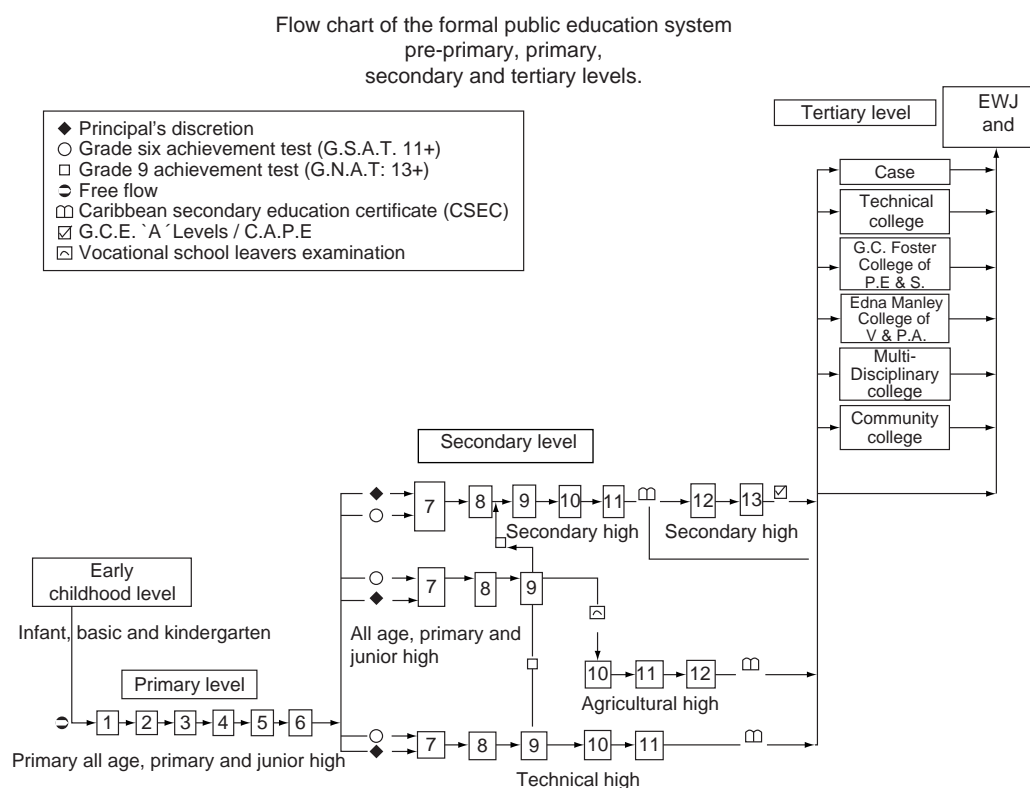

Figure 2 Flow chart of the formal public education system are primary, primary secondary, and tertiary levels.

five teacher education colleges, four community colleges, three multidisciplinary colleges, and two universities. The above mentioned are all public institutions. There are two local private universities. A number of overseas universities offer tertiary-level programs on the island.

There are 59 137 (2005/6) students enrolled in institutions offering tertiary-level education.

General Background

Latvia is a small country in north-eastern Europe, on the coast of the Baltic Sea. The landscape of the country is marked by lowland plains, rolling hills, and thousands of rivers and lakes. Most of the territory of 64 589 km² or 24 937 mi² is less than 100 m above sea level. Latvia has a moderate oceanic climate with average summer temperatures of +20°C and winter temperatures of −5°C, but extremes of +30°C and −25°C or more are not unusual. Latvia is not richly endowed with natural resources, so its future depends in large measure on its intellectual capacity, which is regarded as the nation's greatest resource.

The name Latvia originates from the ancient Latgalians, one of the four eastern Baltic tribes that formed the ethnic core of the Latvian people (c. AD 8th to 12th century). The region subsequently came under the control of Germans, Poles, Swedes, and finally, Russians. Latvia is a relatively new national state, founded on 18 November 1918. Latvia was annexed by the Soviet Union in 1940 and regained its independence only in 1991. Currently, the population of almost 2.3 million inhabitants (in 2006) comprises Latvians, 57.7%; Russians, 29.6%; Byelorussians, 4.1%; Ukrainians, 2.7%; Poles, 2.5%; Lithuanians, 1.4%; and others, 2%. As of 2004, Latvia is a member country of the European Union. It is a parliamentary democracy. The state language is Latvian, which belongs to the Indo-European family of languages.

Since regaining independence, Latvia has made considerable progress in the stabilization and restructuring of its economy from centrally planned to free market. Reforms undertaken in the 1990s have strengthened the private sector. High domestic demand promotes development of services, especially trade and construction. The service sector, which contributed only 32% to the total value added in 1990, had more than doubled to 71% by 2002. In 2007, the total gross domestic product (GDP) for Latvia was slightly under 11.3 million LVL or 4932 LVL per capita (up more than 10% from 2006). Unemployment was at 6.8%.

In 1211, Christian missionaries from Germany founded the first school in the territory of modern-day Latvia. From the thirteenth to the sixteenth century, German was almost exclusively the language of instruction. Schools first started providing Latvian language education in the mid- to late sixteenth century. The purpose was to spread literacy among the Latvian serfs, to promote knowledge of religious literature, including the Bible – translated into Latvian by

Ernst Gluk in 1689. The first textbooks in Latvian were alphabet books, the oldest of which were published in 1683.

From 18 November 1918, with the foundation of an independent Latvian state, the guaranteed right to obtain all forms of education in Latvia was established. From the end of 1919, compulsory free primary education was made compulsory by law for children aged 8–14 (pre-school from age 7). The state also promoted the establishment of schools for ethnic minorities, with teaching imparted in their native language. All types of schools were maintained by municipal or state authorities, and there were private teaching institutions as well. The University of Latvia was established in 1919. Overall, in the inter-war period (1918–40), a modern, unified system of education developed in Latvia, consisting of primary education, secondary education, specialist secondary education, vocational education, and higher education. In general terms, this structure of education is still retained today. Currently, overall instruction is given in Latvian, which is the recognized official language. Latvia also has state-financed ethnic minority schools or classes at the primary through to the upper secondary level where courses are partially presented in Belarussian, Estonian, Hebrew, Lithuanian, Polish, Roma, Russian, and Ukrainian. State-funded higher education programs are taught in Latvian.

Goals of the Education System

According to the Education Law (1998; last amended in January 2007), the National Education Standards provide the strategic goals and main tasks of compulsory curricula, syllabus, basic principles, and procedures for the assessment of education acquired by a pupil.

The long-range conceptual framework document approved by the Parliament in 2005 *The Latvian Growth Model: People Take First Place* proscribes a person-centered model for growth in Latvia. An educated and knowledge-based society becomes the key to internal and external national security. Thus the main goals of the Latvian education and training system are to support the building of a knowledge-based, democratic, and socially integrated society, in order to increase the competitiveness of the Latvian population and economy, and simultaneously preserve and develop the cultural values typical of Latvia.

An analysis of performance in the education sector during the previous planning period (2002–05) indicated a shortage of preschool education providers, unsatisfactory

quality of basic education, low prestige of the teaching profession, poor fit between the education and training profiles offered by vocational and higher education and labor market needs, as well as barriers to access. In order to address these problems, as well as taking into account the new long-term model for national growth and the national development plan, a new basic policy framework for education was approved in September of 2006 wherein particular attention is devoted to the quality of pre- and primary school education, the modernization of vocational training, and the competitiveness of higher education. Emphasis is placed on modernizing the equipment and facilities for acquiring practical skills needed in the labor market. Effective measures for ensuring support to children with special needs and those facing social risk include capacity building for education managers and teachers, as well as increasing cooperation between schools, parents, and society at large.

Structure and Operation of the Education System

Preschool and Early-Childhood Care

While preprimary education was optional until the 2001–02 school year, it became mandatory on 1st of September 2002 for 5- and 6-year-old children. The objective of preschool education is to foster the overall development of children and to prepare them to enter the primary stage of basic general education. It is provided by various preprimary-education institutions, kindergartens (nurseries), or at special preprimary classes in general-education institutions. Preschool education is considered the first stage of general education and all children should complete it by the age of 7. In special cases where the child suffers from certain health or psychological problems, preschool education can be continued, based on either parental request or doctors' recommendations, until the age of 8. The entire teaching process is organized through various targeted games.

Basic (Primary and Lower Secondary) and Upper Secondary Education

Children in Latvia are obliged by law to attend school from the year they turn 7 till the age of 16. In some special cases, the acquisition of basic education may continue till the age of 18. In 2006, there were 974 general education day schools. Around 5.4% of schools were primary (grades 1–4), 48.6% were basic schools (grades 1–9), and the rest were combined basic/upper secondary (grades 1–12) schools. The number of school-age children has remained fairly constant at about 226 000 annually, with around 26 760 teachers. In the next 6 years, the number of school children will decrease significantly (even up to

50% of the current total) due to low birth rates toward the end of the 1990s.

The basic school day comprises of 5 lessons in grades 1–3 and up to 8 lessons in grade 9. The school year is 34 weeks per year in first grade and 37 weeks in ninth grade. The compulsory curriculum includes four subject areas: Introduction to technologies and science; languages; art; and man and society. The curriculum for comprehensive education is defined by 20 subject standards. In 2006, the average number of students per full-time teacher in basic education was ten. After finishing basic education, most young people continue their education at upper secondary level in general upper secondary schools, while about a fourth attend technical and further-education schools.

General upper secondary education normally covers 3 years (grade 10–12). The school year comprises 35 weeks in grades 10 and 11 and 38 weeks in grade 12 with not more than 36 lessons per week and 8 lessons per day. The compulsory curriculum of the 3-year general upper secondary schools is determined by the national standard in the four standardized educational profiles: (1) comprehensive education, without intensive teaching of any particular subject; (2) the humanities and social sciences program; (3) the mathematics, natural science, and technical-science program; and (4) the vocational program, where the general-education curriculum places emphasis on subjects in these particular fields.

Educational standards and regulations regarding assessment of learning achievement for compulsory school and general upper secondary school are drafted by the Centre for Curriculum Development and Examination, which is a national administrative body reporting directly to the Minister of Education and Science, and are approved by the Cabinet of Ministers. Learning achievements of school children are assessed through exams organized both locally at school level and centrally at the national level.

Other Schooling Arrangements

Children may attend vocation-oriented education in arts and music or other areas of personal interest in addition to attending regular school. The so-called little art and music schools are generally founded and maintained by municipal governments.

This type of education is voluntary and provides for a person's individual educational needs and wishes. This education does not lead to a professional qualification.

The number of students enrolled in special-interest education programs has been increasing annually. In the 2001–02 school year, 240 273 students were enrolled, but in 2005–06, 293 527 or 92% of the total number of students had enrolled in general, vocational, and special-education schools.

Special education schools or special education classes within general education schools provide education for children with special needs that corresponds to each individual's physical and mental condition. The structure of special education is very similar to that of the mainstream education, providing opportunities for persons with special needs to attain general knowledge and skills with a strong emphasis on their applicability, thus facilitating social inclusion. There are 64 special education schools in Latvia. Almost all of these schools provide dormitory housing for their pupils.

Vocational and Further Education

In 2006–07, there were 92 nationally accredited vocational-education schools in Latvia with a total enrolment of 40 439 students. The schools employed 4824 teachers, 70% of whom were women. The majority of vocational schools in Latvia provide 2, 3, and 4-year vocational education and training programs at upper secondary level, and only some programs are designed for basic vocational and training purposes.

The national standard of vocational education and the occupational standards determine the curriculum content of vocational education programs. Practical training on the job comprises at least 20–25% of these programs. The theoretical part provides the knowledge needed in modern society: a command of languages, mathematics, natural sciences, and social studies, and good communication skills. In addition, vocational training also underlines the following skills: entrepreneurship, global environmental awareness, internationalization, and citizenship. Sample curricula are drawn up by the Vocational Education Administration, an institution under the authority of the Ministry of Education and Science. Both occupational standards and sample curricula are developed in cooperation with professional associations representing different economic sectors. Based on the relevant standards and sample programs, schools develop their own training programs in accordance with the needs of the local labor market.

Basic vocational and training programs are intended to provide training in simple trades for pupils who have not finished compulsory 9-year basic education by the age of 16. By successfully completing this educational program, the pupil obtains a basic education certificate and may go on to upper secondary education. The number of students enrolled in these programs is not large – only about 2.3% of the total. The aim of this form of education is to prevent marginalization of pupils facing social risk.

Vocational education programs lasting 2 or 3 years provide the theoretical and practical knowledge required by a skilled worker. Even on completion of such a vocational

education program, the student has not obtained a full upper secondary education. For this, an additional year of schooling is required. The proportion of students enrolled in these vocational programs is 18% of the total.

Upper secondary vocational education programs covering 4 years provide much wider theoretical knowledge and practical skills. This is a full secondary education program, so the school leaver is entitled to enter higher education. Approximately 70% of students in vocational education choose upper secondary programs.

In 2006, there were 10 464 graduates of vocational-education programs. Of these, 43% had qualifications in engineering (including processing and technologies), 24.7% in the services, 14% in commerce, 5% in information technologies, 5% in humanities and arts, 4% in healthcare, 1.8% in agriculture, and 2.5% in others.

Higher Education

Latvia has two types of higher education programs – academic and professional. Such a division of higher education allows the student to choose either research or professional activity in the future. Professional higher education is divided into two levels. First-level professional higher education programs cover 2–3 years after upper-secondary education and are provided by colleges. Second-level professional higher education programs cover at least 4 years after upper secondary education or 2 years after acquiring a bachelor's degree (3-year studies). These programs, as well as higher academic education programs are offered at universities or nonuniversity-type higher education institutions.

The right to enter a higher education institution is enjoyed by all those who have completed general upper secondary education or graduated from a 4-year vocational program.

In Latvia, there are both state-financed and private higher education institutions. In 2007, of the 60 accredited higher education institutions, 34 were university/nonuniversity-type institutions (19 of them government-funded and the rest funded by other legal entities or private individuals) and 26 colleges (18, state and eight private) (see **Table 1**).

Of the 43 860 students who enrolled in 2007, 22% enrolled in postgraduate programs, and 1982 were doctoral students. Of the first-year students, 13% had completed upper secondary vocational education, while 87% had completed general upper secondary education. There is no distinct disproportion between city and country dwellers. The total number attending state and private higher education institutions and colleges was 129 497. Almost 63% of students are doing full-time courses. There were 4926 full-time equivalent academic staff members, of whom 23% were professors. In Latvia, there are 568 students per 10 000 inhabitants, which is the second largest student

Table 1 Educational providers, students, and teaching staff, 2006–07 academic year

<i>Provider</i>	<i>Institutions</i>	<i>Students</i>	<i>Pedagogical staff</i>

proportion in the world. Foreign students comprised only 1.1% of the total enrolment in 2007. Programs for foreign students are mainly offered in English or Russian.

Adult and Nonformal Education

Adult education in Latvia is supported by the principle of lifelong education. The Education Law (1998) specifically concerns the development of adult formal and nonformal-education programs. Arrangements for the provision of adult formal education are set by the Education Law, Vocational Education Law, Higher Education institutions Law, and other statutes and regulations.

Different types of further education and training are offered to persons after graduating from general upper secondary or 2–3-year vocational education and training programs. These programs are focused on mastering professional skills and knowledge in line with the requirements of the respective qualification level. The training process and assessment of achievements are organized in a manner similar to that in vocational secondary education and training programs. In 2006–07, 290 279 persons were involved in further education; of these, 24.7% received support from their employers to cover training costs.

Labor market training for the unemployed accounts for the largest number of participants in the adult-education sector. Employment authorities provide a wide range of labor market training mainly targeted at unemployed adults. The courses are free of charge for persons who qualify for official unemployment status.

Adults can also follow a complete program of basic education or upper secondary education at so-called evening schools.

The Teaching Profession

Teachers in Latvia are trained at five higher education institutions. Two training routes can be taken. The most common is a professional bachelor's degree program covering 4 years, which provides a teaching qualification for a specific level of education (preschool, primary, and secondary) and, for secondary school teachers, a specific subject area. Preschool and primary school teachers are qualified to teach all subjects. The second route requires two stages – a bachelor's degree (3 years) in education sciences, plus an additional 2 years of study in a second-level professional program of studies to qualify as a teacher in a specific level of education and/or subject area. Vocational school teachers generally have a professional diploma in a vocational area with an additional qualification in vocational teaching.

Currently, the teaching profession is not attractive due to low social prestige and relatively low salary levels. Of the total number of teachers in the general education sector (grades 1–12) 88% are women (70% in the vocational-education sector). Additionally, 9.09% of teachers currently employed are at pension age. In 2000–01, 19% of teachers were 30 years old or younger; in 2004–05, the proportion is only 15%. However, considering the decreasing numbers of school-age children in the upcoming 6 years, this should not create a drastic shortage of teachers.

Administrative and Supervisory Structure

The educational system is administered on three levels – national, municipal, and institutional. The parliament,

cabinet of ministers, and ministry of education and science are the main decision-making bodies at the national level. The ministry as the leading public administration institution in the field of education and science implements a single national policy and development strategy in education, develops education, science, sport, youth and state-language policies, organizes and coordinates their implementation, in addition to developing draft-regulatory legislation regulating the sector, and draft-policy planning documents.

Every municipality supervises the preschool, basic, and general upper secondary schools located in its administrative territory and participates in funding the maintenance expenses of those educational institutions. A board of education is established by each municipality to perform its education-related functions.

Vocational education and training schools are mainly maintained and supervised by the Ministry of Education and Science in strong cooperation with branch ministries and social partners. Only art and music schools are placed under the authority of the Ministry of Culture. Private and municipal schools must be registered with the National Registrar of Education and comply with government education standards.

In the tertiary sector, decision-making, regulation, funding, and governance are shared between the government and the institutions themselves. Higher education institutions are autonomous bodies established under national legislation, each with its own independent governing body (senate). The primary institution responsible for higher education is the Ministry of Education and Science, which administers government funding, policy, and programs. While higher education institutions are autonomous, they are accountable to the government via accreditation.

Educational Finance

The national education budget in 2007 was slightly over 172 million LVL, up by 27.5% in absolute figures. The proportion of the education budget within the national budget was 4.89 % (4.79% in 2006).

Public primary and secondary general education in Latvia is free and is financed from the municipal budget. At primary and secondary schools, the state pays teachers' wages, while the local authority finances the maintenance of the school building and grounds and covers other expenses connected with teaching. In 2007, the government subsidy to general education schools was almost 5.36 million LVL, or 3.11% of government expenditure on education.

Vocational schools in Latvia usually belong to the state or the local authority, which accordingly finances both teaching and maintenance of the school. Government

spending on vocational education in 2007 amounted to slightly over 56 million LVL, or approximately 32.6% of the education budget.

Private educational establishments at primary–secondary level may set their own tuition fees. Accredited private lower and upper secondary schools receive a subsidy from the national government budget to cover teachers' salaries and related social-security taxes in order to fund the provision of accredited lower and upper secondary education programs. Accredited private vocational education schools receive a national government subsidy based on a training agreement between a government ministry and the training institution for the training of a fixed number of persons in a specific vocational area.

The Latvian state finances all the higher education institutions belonging to the state. In 2007, government expenditure on higher education was slightly over 111 million LVL, or 64.3% of the education budget. The Higher Education Council allocates a certain number of state-financed study places in each field of studies. In 2007, there were 30 172 (23.3%) students funded by the state budget. Those students who pass their entrance examinations at state higher education institutions, but whose marks are not sufficiently high to grant them state-supported education, can take up studies as fee-paying students. Similarly, fees are charged at all private higher education institutions.

Adult education can be financed from the government or local government budget, employers' resources, learners' resources, donations and grants, as well as from other sources. There are different institutions on national and local levels involved in the organization and provision of adult education. The tuition fee regulations for continuing or inservice education and training are established by training providers and covered by individuals or employers. Further training or retraining of persons who are legally classified as unemployed is financed from the state budget.

Performance Monitoring, Evaluation, and Research

The laws on education, general education, vocational education, and higher education prescribe the monitoring and assessment of each respective subsector of the education system by relevant national and local government authorities. Every education institution, regardless of whether it is funded by national or local government or private concerns, must be registered with the National Registrar of Education. In order to begin providing education services, a license must be obtained. The right to deliver nationally recognized diplomas and certificates is only conferred on education institutions accredited by the respective national institutions (the State Agency for Quality Assessment in General Education, the

Vocational Education Administration, and the Higher Education Quality Evaluation Centre).

Statistics collected by the Ministry of Education and Science comprise 182 data tables on general education. This makes it possible to compare performance levels in Latvia with those of other countries in Europe, using the same indicators. The assessment indicators developed by European Centre for the Development of Vocational Training (CEDEFOP) are applied in evaluating vocational education in Latvia. Preparation of annual statistical reports and policy-planning documents on higher education is based on internationally comparable indicators.

The Institute of Education Research at the University of Latvia Faculty of Education and Psychology has participated in 10 major international comparative research projects as a member of the International Association for Educational Assessment since 1992, as well as in the Organization for Economic Cooperation and Development (OECD) Programme for International Student Assessment (PISA) in 2000–2003–2006. A comparison of the PISA results over the three assessment cycles indicates that while there was a significant improvement in reading skills from 2000 to 2003 with a decrease in the percentage of students at or below level 1, from 30.6% to 23.7%, the average score in reading has dropped in 2006 (from 490 points to 470). Math skills, assessed in 2003 and 2006, show a slight improvement – from 482 to 484 points on average. The very small proportion of students performing at top levels (0.3% in science, 1.1% in math, and 4.5% in reading) draws Latvia into a comparative level below OECD and European averages.

Major Changes and Issues Since the 1990s

The break up of the Soviet Union and the restoration of independence in 1990 has generated a considerable transformation in Latvia's system of education. The enrolment ratio in universities has doubled. The Latvian language has been restored to its former prestige and found new utility. The process of modernizing syllabi and teaching standards has begun. Textbook content has been revised. All of these changes have been informed and guided by new legislation and new administrative decrees, and supported by public investment which, in real terms, was 16% higher in the year 2000 than it had been 10 years earlier. Recent national budget endowment in education has also increased.

Local governments have become active in the improvement process of educational institutions through development and implementation of regional, county, and community-level education policy. The facilities and equipment at education institutions have been modernized, information technologies are widely used, and

teaching methods and forms have been enriched. The National Tri-partite Cooperation Council has established a subcommittee on education and employment which approves professional standards and is involved in the accreditation of vocational and higher education programs. The Ministry of Education and Science has established a fund for distributing student loans.

Changes have occurred that will irreversibly impact the development and improvement of the quality of education. Based on these criteria, among others, it can be said generally that education in Latvia has undergone a successful transition from a system effective for a planned economy to a system effective for a market economy and a democratic society.

Glossary

Gross enrolment rate (GER) – Calculated by dividing the total number of students enrolled in a level or stage of education by the wider population of that age group corresponding to that level or stage.

Leadership development program – A professional development program designed for school principals and training-center directors to improve leadership, motivational, and management skills, together with improved understanding of international trends in competency-based contextualized learning.

Medium-term expenditure framework (MTEF) – A multiyear budget that also brings in key performance indicators and an integrated process for monitoring expenditures against budget and performance against targets.

Net enrolment rate (NER) – Estimated by calculating the ratio, dividing the number of pupils attending a certain school cycle (e.g., primary and secondary school, respectively), at normal ages (e.g., 6–11 for primary, 12–18 for secondary) by the number of children belonging to the age group.

Paris III International Conference for Support to Lebanon – The conference held in the French capital on 25 January 2007, in support of Lebanon in which 36 countries and seven regional and international institutions participated and whose pledges amounted to \$7.6 billion.

Performance-based budgeting (PBB) – The budgeting process that focuses on program outcomes and the measure of the program's ability to meet short-term and/or long-term objectives. The PBB systems incorporate three components: planning, budgeting, and performance measurements.

Student–teacher ratios (STRs) – Calculated by dividing the total number of students in a school or type of school by the total number of teachers teaching them.

Subsidized free schools – The private tuition-free schools, which are usually subsidized by the government on a per capita basis. Subsidized free schools cover only the elementary (cycles 1 and 2) level.

Trends in International Mathematics and Science Study (TIMSS) – The study carried out by the International Association for the Evaluation of

Education Achievement (IEA) and used to provide indicators of the degree of learned concepts in math and science for the fourth and eighth grade students.

General Background

The Republic of Lebanon, a parliamentary democratic republic based on respect for public liberties, especially the freedom of opinion and belief, and respect for social justice and equality of rights and duties among all citizens without discrimination, is located in the Middle East. Lebanon became an independent country in 1943 after being occupied by France since 1920. The country's constitution, fashioned after that of the Third Republic in France, was adopted on 23 May 1926. After a 25-year civil war extending from 1975 till 1990, the Ta'if Accord, also called the National Accord Convention, was put in place in October 1989 to restore peace and national reconciliation in Lebanon.

Lebanon is a small country with an area of 10 452 km² and an estimated population of 3 925 502 (the population estimates are as of July 2007, according to the Central Administration for Statistics (CAS) Factbook). The country's population is mainly composed of the 15–64 years age group which constitutes 66.7% of the total population (2 616 889), followed by the 0–14 years age group that accounts for 26.2% of the total population (1 029 439), and finally, the 65 years and over age group that represents the remaining 7.1% of the total population (279 174). Lebanon's population is almost equally divided between females and males as the former constitute 51.4% and the latter account for the remaining 48.6%. Lebanon's per capita income is estimated at \$5700, placing the country in the upper-middle-income economies category along with 40 other countries. (The classification is adopted from the World Bank's country groups classification. The 41 upper-middle-income economies – one among which is Lebanon – are: American Samoa, Argentina, Belize, Botswana, Brazil, Bulgaria, Chile, Costa Rica, Croatia, Dominica, Equatorial Guinea, Gabon, Grenada, Hungary, Kazakhstan, Latvia, Lebanon, Libya, Lithuania, Malaysia, Mauritius, Mayotte, Mexico, Montenegro, Northern Mariana Islands, Oman, Palau, Panama, Poland, Romania, Russian Federation, Serbia, Seychelles, Slovak Republic, South Africa, St. Kitts and Nevis, St. Lucia,

Table 1 Value added by sector 2004

Total GDP	32 357	21.46	100.00%

From *Economic Accounts of Lebanon, 2004*.

St. Vincent and the Grenadines, Turkey, Uruguay, Venezuela, and the Republic of Bolivia (RB)).

The country's economy is free and ensures private initiative and the right to private property. The economy is services oriented as this sector accounted for 32.85% (40.22% when the transportation and communications sector is added to the services sector) of the country's 2004 gross domestic product (GDP; see **Table 1**). The unemployment rate was estimated at around 20% in 2006.

Lebanon is characterized by its cultural openness and its highly qualified human resources. Although Arabic is the official language, the country's constitution derives from that of the Third French Republic. As such, French might be considered the second language in Lebanon. However, English has never been absent. In recent years, the English language popularity as the first foreign language and the second language after Arabic in schools has increased. This can be seen by the fact that the number of students enrolled in schools where English is the first foreign language and the second language after Arabic increased continuously from 33% in the academic year 2000–01 to 36.4% in the academic year 2005–06. In addition, the number of schools that teach English as the first foreign language and as the second language after Arabic has also increased from 19.6% in the academic year 2000–01 to 22.6% in the academic year 2005–06 (see **Tables 2 and 3**).

Goals of the Education Sector

The education sector in Lebanon is governed by

the fundamental principles cherished in the Lebanese Constitution and the National Accord Convention as well as the laws and regulations governing the educational matters which emphasize freedom of and right to education and ensure the accessibility and equality in

opportunities and requirements of education to all. (The National Educational Strategy, 2007: p. 1.)

The education sector goals stress on the availability of education in Lebanon on the basis of equal opportunity as well as on the providing of good quality education that contributes to the building of an information society and that promotes social integration and economic development. The Ministry of Education and Higher Education (MEHE) clearly stated these objectives in the National Educational Strategy, which was sent to the Council of Ministers for endorsement in September 2007.

The National Educational Strategy (The Technical Committee assigned for setting the National Educational Strategy was established under Decree no. 82-3-2004 dated 11 February 2004.) – hereon, the Strategy – is derived from International and Arab educational principles that adopt a humanistic approach to education and that build on the

comprehensive development of the individual; the reinforcement of respect for human beings and their basic freedom; the development of the ability to actively participate in a free society; the development of a sense of responsibility in a spirit of understanding, peace, and friendship; and the commitment of wide social partnership among those concerned with education in order to ensure meeting the human need for education and for building a knowledge society.

The National Educational Strategy states that the mission of MEHE is to:

1. Take a leading role in producing a national educational curriculum which would serve as the reference framework for all its policies, organizational structures, and programs, projects, and activities.
2. Take a leading role in transforming the Lebanese society into an information society and in preparing scientists, experts, and qualified staff in all domains of life.
3. Take a pivotal role in achieving social progress and economic development.
4. Shoulder the responsibility of preparing a thinking, productive citizen and educate her/him in national belongingness and social integration in a society where justice, freedom, democracy, and peace prevail.

Structure and Operation of the Education Sector

Lebanon's educational system is composed of general education (GE), vocational and technical education (VTE), and higher education (HE). The GE system is public, private, or subsidized free (the subsidized free education is only for cycles 1 and 2) with 1399 public, 1025 private, and 364 subsidized free schools, for a total of 2788 schools for the academic year 2005–06. The VTE system, accessible only for students who have completed their cycle-2 elementary education, is either public (83 institutions) or private (362 institutions), while the HE comprises one single public university, the Lebanese University, and

39 private institutions for the academic year 2006–07 which include universities, university institutes, technological institutes, and theological institutes.

General Education

The GE system comprises the pre-elementary kindergarten, the elementary (cycles 1 and 2), the intermediate (cycle 3), and the secondary (cycle 4). With each cycle consisting of 3 years, the total school years (excluding the pre-elementary kindergarten) amount to 12 years (see **Tables 4** and **5**).

Pre-elementary kindergarten

Net enrolment rate (NER) in the pre-elementary kindergarten for children aged 3–5 reached 77.7% for the year 2004. (The NER is calculated for the year 2004, as the latest National Survey of Household Living Conditions, which includes the population distribution by age group, is for the year 2004; see **Table 6**.) When considered for every age, NER is at 26.6%, 72.2%, and 79.6% for children of ages 3, 4, and 5 years, respectively. The drastic percentage drop for the 3-year age group is attributed to the absence of clear policies to incorporate 3-year-old children in the educational ladder and the absence of a nursery class in most public preschools.

There is a huge discrepancy between the student enrolment in private and public pre-elementary kindergarten which is explicit in the fact that for the academic year 2005–06, 63.34% of total number of students were enrolled in the private pre-elementary kindergarten

Table 4 Distribution of students in GE according to cycle and class 2005–06

cycle, while 21.61% and 15.04% were enrolled in the public and the free subsidized pre-elementary kindergarten cycle, respectively (see **Table 7**).

Elementary cycles 1 and 2 and intermediate cycle 3

The NER in the elementary level reached 97% in 2004 (National Educational Strategy, 2007: 6.), while the gross

enrolment rate (GER) for students aged 5–9 and 10–14 reached 98.4% and 95.2%, respectively (The National Survey of Household Living Conditions, p. 149). As for the intermediate level (cycle 3), the average NER drops to 68.5%, clearly indicating that the dropout or the repetition rate at the end of the elementary level is very high. The average NER at the intermediate level concerns the GE enrolment only and excludes a very meager number of students enrolled in the VTE at the intermediate level, a number that would not affect the average NER. At the end of the intermediate level (cycle 3), students sit for official exams; and those who succeed become holders of the Brevet certificate.

In Lebanon, basic education extends from age 6 (grade 1 of the elementary level) to age 15 (grade 9 of the intermediate level); however, Law no. 686 dated 16 March 1998, states that compulsory education stops at the age of 12 (grade 6 of the elementary level).

Secondary (cycle 4)

The secondary cycle-4 level is of 3 years, with the first as general; the second, sciences or humanities; and the third, sociology and economics, general sciences, or life sciences. The percentage of 15–19-year olds enrolled in school is 70.8% (The National Survey of Household Living Conditions, p. 149); however, not all of the students in this age group are enrolled in secondary education, as 31.3% of them are in the intermediate cycle and 16.5% of them are in higher education. As such, only 52.3% of them are enrolled in the secondary level. When one considers the 15–17 age group, the typical age of students in both general

Table 7 Distribution of currently studying residents according to current educational level and age

From *The National Survey of Households Living Conditions 2004*, UNDP, MoSA.

and vocational and technical secondary schools, the NER drops to 50% (The National Educational Strategy, 2007: 8). At the end of the secondary level (cycle 4) students sit for official exams; and those who succeed become holders of a high-school (terminal) diploma, each according to his specialization in one of the three above-mentioned categories.

It is worth noting that the education system in general and the public schools in particular do not cater to integrating students with special needs, whether with disabilities or gifted students. As such, and despite the issuance of Decree no: 11853 dated 11 February 2004 – that states the need for establishing a combined committee between MEHE and local nongovernmental and governmental organizations aimed at setting methodologies that ensure the integration of students with disabilities and gifted students – there has not been issued, to date, any laws that take into consideration the needs of these students and ways to integrate them in schools.

Vocational and Technical Education

The VTE in Lebanon has been reorganized within new curricula under the Council of Ministers Decree dated 16 August 2000, as the importance of VTE has been highlighted to suit the country's construction and development needs. The VTE in Lebanon includes three levels. The first level of vocational preparation consists of two phases culminating in the issuance of a *Certificat d'Aptitude Professionnelle* (CAP) followed by a *Brevet Professionnel* (BP). The second level is a 3-year vocational and technical secondary education for those who have completed their BP or the intermediate cycle; this level branches into two tracks: the Technical Baccalaureate (BT) and Technical Secondary Diploma-Dual System (SD). The third and last level is the vocational and technical higher education divided into the 3-year medium framework which leads to the

Table 8 Number of VTE specializations at every level for the academic year 2005–06

Techniciens Superior (TS) degree, and the 2-year higher framework following the TS which branches into the Licence Technique (LT) and the Licence d'Enseignement Technique (LET; see **Table 8**).

The total enrolment in the 83 public VTE schools and higher education institutes amounted to 35 090 students for the academic year 2005–06, while the enrolment in the 362 private VTE schools and higher education institutes amounted to 41 270 for the same academic year. Similarly, enrolment in the 3-months and 1-year VTE diplomas amounted to 22 435, for a combined total of 98 795 students for the academic year 2005–06, or some 10.84% of the total 911 314 students enrolled in the GE sector (see **Table 9**).

The VTE subsector suffers from high repetition, retardation, and dropout rates. In addition, the VTE as the GE lacks the proper integration systems and procedures for students with special needs. The VTE, in particular,

is characterized by the weak link between the subsector's specializations and the labor needs and the absence of career guidance.

Higher Education

The HE in Lebanon dates back to 1866 when the American University of Beirut (AUB) was established followed by Saint Joseph University (USJ) in 1875. They were the first Anglophone and first Francophone universities to open in Lebanon, respectively. It was not until 1951 that the national public university, Lebanese University (LU), was established. Both the private and the public higher education sectors fall under the jurisdiction of MEHE.

For 2007, the private higher education sector encompassed 39 higher education institutions, including 26 universities, seven university institutions, two technology institutions, and four theological university institutions. The LU, the only public university, is composed of 13 faculties and four institutions comprising 46 branches. Branches of the faculties of LU were established in the different Lebanese regions after the war broke out in 1977. Lately, LU has created three doctoral schools (Decree No. 74, March 2007): Doctoral School of Science and Technology; Doctoral School of Law and Political, Administrative and Economic Sciences; and Doctoral School of Literature and Human and Social Sciences.

The average number of students enrolled in higher education is 4143 per 100 000 habitants, one of the highest in the Arab region. In addition, the average enrolment rate in education for the 20–24 years age group is 29.7%, with about 1/4 of those enrolled in preuniversity education. The number of students enrolled in higher education in 2006–07 was 146 961 students of whom 70 627 (48.1%) were enrolled in the LU, 79 256 (53.9%) were females, and 131 070 (89.2%) were Lebanese.

Academic mobility within HE in Lebanon is highly limited. There is no comprehensive system for HE where definitions of curricula, degrees, and courses are agreed upon in such a way that would allow for academic mobility among institutions of HE. Universities in Lebanon are characterized by cultural diversity where some universities are Francophone while others are either Anglophone or universities whose main language of instruction is Arabic. The LU, with its faculties and branches, is the most diversified and heterogeneous institution with respect to these systems.

In the past few years, the universities that follow the French system started to be influenced by the changes resulting from the European Union Licence Maîtrise Doctorat (LMD) system that was applied in Europe in the beginning of 2004–05. Adoption of this new system might lead to increasing the opportunities for academic mobility within higher education institutions.

Regarding private higher education, there are few universities whose quality has been recognized as a result of meeting international, European, or American standards. Among those, some universities sought accreditation, an external evaluation scheme to assess their quality.

In 2004, the LU conducted a self-evaluation report which pinpointed several quality problems. These problems are attributed to the university's not adopting a reform project, not availing the needed resources, and losing its autonomy in the last decades. The report also presents clear recommendations regarding the needs of the university.

The Teaching Profession

The total teacher workforce in Lebanon in GE reached 87 459 teachers in the academic year 2005–06, of which 40 550 worked in the public sector, 6202 in the subsidized free schools, and 40 707 in private schools (see **Table 10**). The workforce is divided into three categories: within the cadre, contractual, and a very small percentage (2.3% of the total) that are in neither of the categories but rather volunteer teachers (mainly religious clerks). For the academic year 2005–06, the average student–teacher ratio (STR) in GE was 9, 19, and 12 in the public, subsidized free, and private schools, respectively.

The appointment of teachers in Lebanese public GE schools suffers serious problems at all levels, among which is the high percentage of teachers who are above 50 years of age and that account for 30.3% of all public school teachers, compared to 11.4% and 14.8% in the subsidized free and the private schools (see **Table 11**). At the pre-school kindergarten level, the percentage of teachers who have university degrees or special diplomas is less than 30.6% of all preschool teachers (The National Educational Strategy, 2007: 17). Laxity in academic conditions

to appoint teachers at the public elementary education level is evident by the high percentage of teachers whose education has stopped at the baccalaureate level or even before (see **Tables 12** and **13**) and the choosing of teachers with university degrees on a discretionary basis and without having any educational preparation. For the secondary public education, the practice of recruiting

From *ECRD Statistical Bulletin*, 2005–06.

teaching staff also suffers from the contracting of individuals with university degrees to teaching positions without them having educational preparation and the appointment of full-time teachers after offering them only short professional preparation session. As for training, there is a large-scale project which started in 2004–05 to offer continuous training for public elementary and secondary teachers.

The VTE subsector teacher-and-administrative workforce amounts to 16 183 teachers, of which 9141 are in the public VTE schools. Most of the VTE teachers are hired on a contractual basis without consistent hiring guidelines and standards. In addition, there are very limited training programs for VTE teachers in the use of modern technical and educational tools.

As for Lebanon's higher education, the total teacher and administrative workforce in this subsector amounts to 13 770 teachers, among which 4390 teach in the LU, the only public university in the country.

The teaching force at the LU and other private universities and university institutions suffers from the high percentage of hourly contractuels and the rise in the average age of full-time tenured faculty, mainly in the LU.

Administrative and Supervisory Structure

The current organization of MEHE dates back to 1959. Despite the attempts in the 1990s to split MEHE into three ministries (Ministry of Vocational and Technical Education, Ministry of Culture and Higher Education, and Ministry of National Education, Youth and Sports), currently there is only the Ministry of Culture and the

Ministry of Youth and Sports that still operate along with MEHE.

The MEHE is composed of the Common Management Services Directorate, the General Directorate of Education, the General Directorate of Higher Education, and the General Directorate of VTE. The Educational Center for Research and Development (ECRD), an autonomous entity in charge of curriculum development, education reform, preparation of didactic material, data collection, and evaluation, and the Lebanese University are independent institutions attached to MEHE.

Despite the fact that MEHE is expected to carry out its mandate by looking after the public interest in both the public and the private educational sector, its role in the private sector has been limited to

conducting national examinations in general education, vocational and technical education, and higher technical education. It has also included keeping track of the names of students enrolled in private schools, offering financial support for public sector employees to help them send their children to private schools, and offering financial support to subsidized private schools. It is worth mentioning that the Ministry's monitoring of subsidized private schools required by law has been absent during the last few years (The National Educational Strategy, 2007: 52).

Educational Financing

The financing of the education sector in Lebanon is complex given the diversity of the financial resources and the intricacy of the procedures and programs used

to cover the costs of education in the country. Public funds flow to both public and private institutions. A distinction considered very important is that between public funds provided by public education authorities and those provided by agencies whose primary responsibilities lie outside education. The former includes the MEHE and other education departments and municipalities. The latter are of two kinds: (1) ministries or entities with noneducational responsibilities but who provide scholarship allowances to children of civil servants (such as the Civil Servants Cooperatives; ministries of defense, interior, justice; public institutions; mutual funds . . .), and (2) public institutions whose functions cut across educational responsibilities in terms of provision of schools and educational establishments such as the Council for Development and Reconstruction (CDR) and Council of the South (COS).

The MEHE has the highest budget allocation among social ministries (Ministry of Public Health (MPH), Ministry of Culture (MoC), and Ministry of Social Affairs (MoSA). Current expenditures on education within MEHE are mainly concentrated on wages and salaries (see **Tables 14–16**).

As for private spending on education, households spend on tuition fees as well as school supplies, textbooks, and transportation. Public funding from, for example, the Cooperative of Civil Servants, allocated to households for spending on education is simply a transfer from the government and cannot be considered private. However, households also receive funds for education from commercial, industrial, and other sectors (banking, insurance, commerce, and construction).

The mean estimated total expenditure per student in the public and private sector are very similar at the

primary and intermediate levels (1618 thousand LL per student in the public sector and 1680 thousand LL (the current LP/US\$ exchange rate is fixed at LP1507.5/\$) in the private sector). There are greater differences in estimated total expenditure per student between the sectors at the secondary level with an estimated total expenditure per student in the private sector of 2581 thousand LL and 1823 thousand LL per student in the public sector.

Performance Monitoring, Evaluation, and Research

Lebanon participated in the Trends in International Mathematics and Science Study (TIMSS) 2003.

(The TIMSS, carried out by the International Association for the Evaluation of Education Achievement (IEA) is used to provide indicators of the degree of learned concepts in math and science for the fourth and the eighth grade. Lebanon participated only for the eighth grade.) The results showed that Lebanon ranked 31st among 45 countries in mathematics with a score of 433 compared to an international average of 466 and 41st in science with a score of 393 compared to an international average of 473. Compared to the 11 Arab countries that participated in the study, Lebanon came first in mathematics and last in science. This low rank in science achievement may be attributed to the fact that science is taught in Arabic for most of the fourth- and eighth-grade students, while the TIMSS administered the questions in English (see **Table 17**).

Table 17 Mathematics and science achievement of eight grade students in Middle East North Africa – TIMSS 2003

<i>Country</i>	<i>Mathematics average score</i>	<i>Science average score</i>

Yemen	278	250
International average	466	473

From Highlights from The TIMSS 2003, International Association for the Evaluation of Education Achievement (IEA), December 2004.

On another performance-monitoring front, in its 2008 budget circular, Ministry of Finance (MoF) decided to introduce the notion of a medium-term expenditure framework (MTEF) and request line ministries, one among which is MEHE, to prepare forward estimates (FEs) for their financial needs for 2009 through 2011. In addition, MEHE has been chosen as a pilot ministry to prepare performance-based budgeting (PBB) for 2008–09 and present it to MoF by March 2010 as a shadow budget along with the classical budget. As such, MEHE has already set key performance indicators (KPIs) that depict baseline and target levels (see **Table 18** and **Appendix 2**).

Major Changes and Issues Since the 1990s

Pre-Paris III Reforms

The reform efforts starting in the 1990s and culminating in the International Conference for Support to Lebanon, Paris III, held on 25 January 2007 (36 countries and seven regional and international institutions participated in this donor conference and pledges amounted to \$7.6 billion), recognized the importance of education reform, among other social reforms, as a cornerstone for development. Consequently, several steps were and are currently taken to restore education quality in public institutions, the information for which appears in The Needs Assessment Report prepared by the Helsinki Consulting Group for MEHE through the Education Development Project (EDP) in 2005.

In 1993, the government launched an interministerial commission to set general policy guidelines for the sector. In 1994, the ECRD issued a 10-year Plan for Educational

Reform in Lebanon, which aimed at restructuring the education system.

In May 1996, the government convened the First National Conference on Education, setting out its priorities and using this opportunity to familiarize both internal and external stakeholders and development partners. The same year, Parliament passed a law making elementary education free and compulsory until the age of 12. A second law extending compulsory education until the age of 15 is under preparation.

In 1997, a project was launched with assistance from the United Nations Development Project (UNDP) to support basic education development. The project, which is executed by the United Nations Educational, Scientific and Cultural Organization (UNESCO), emphasizes strengthening national capacities in education planning and management (education management information system (EMIS), school mapping, training, monitoring and evaluation, etc.) and aims at ensuring quality basic education accessible for all.

In 1998, the law on compulsory primary education was enacted, following advocacy efforts by the United Nations International Children's Emergency Fund (United Nations Children's Fund, UNICEF) and several organizations involved in child rights, in coordination with the Parliamentary Committee for the Rights of the Child, thus providing the basis for ensuring primary education for all.

Since the year 2000, MEHE has been implementing the EDP, a \$57 million loan project funded by the World Bank. The EDP's project development objective (PDO) is to enhance access, and build the knowledge base, analytical tools, and institutional capacity within the MEHE, necessary to initiate reform of the general and vocational education systems.

Paris III Reforms and Beyond

The MEHE presented a 3-year reform program at the Paris III conference held on 25 January 2007. The Education Sector Reform Action Plan for the years 2007–09 spans 7 reform programs: (1) consolidating policy, planning, and resource allocation; (2) achieving Universal Basic Education (UBE) for ages 6–15; (3) improving the efficiency, effectiveness, and competence level of the teaching workforce; (4) enhancing the quality of education; (5) strategic management of educational facilities; (6) rationalizing VTE; and (7) quality assurance in HE (see **Table 18** and **Appendices 1** and **2**).

The National Education Strategy document was sent to the Council of Ministers in September 2007 for endorsement. The strategy aims at providing: (1) education on the basis of equal opportunity, (2) quality education that contributes to building a knowledge society, (3) education that contributes to social integration,

Table 18 MEHE's reform programs and their key monitoring indicators

<i>Program</i>	<i>Monitoring indicators</i>
Consolidate policy, planning, and resource allocation	<ul style="list-style-type: none"> • Submission of a shadow budget under MTEF for MEHE by March 2008 • Enhancement in the organization capacity of MEHE through decreasing process duration time by 50%
Achieve Universal Basic Education (UBE) for ages 6–15	<ul style="list-style-type: none"> • Increase in NER for grades 1–6 by 1% from 97% to 98%, and for grades 7–9 by 4% from 68.5% to 72.5% • Increase classroom occupancy for grades 1–6 by 1 from 17 to 18, and for grades 7–9 by 2 from 19 to 21 • Increase the percentage of public basic education students with free textbooks in cycle 1 to 100%
Improve efficiency, effectiveness, and competence level of the teaching workforce	<ul style="list-style-type: none"> • Decrease the number of teachers without a baccalaureate degree and above age 58 and/or who are physically and/or psychologically disabled by 2% (from 9.6% to 7.6%) by 2009 • Increase the number of public school principals who have undergone professional development programs to improve competence to 50% of all public school principals (by 300, from 450 to 750) by 2009 • Increase by 10 500 the number of teachers who have undergone professional development
Enhance quality of education	<ul style="list-style-type: none"> • Decrease in repetition rate by 2% (from 21% to 19% for grades 1–6) and 2% (from 23% to 21% for grades 7–9) by 2010 • Increase of the NER for KGII by 3% from 79.6% to 82.6% in 2009 • Enhance efficiency of examination process through 100% automation of official exams
Enhance the utilization of educational facilities	<ul style="list-style-type: none"> • Decrease the number of unviable schools by 69% from 130 to 40 through consolidation and decrease resource centers by 48% from 33 to 17 • Decrease in the percentage of schools with less than 100 students by 10% from 25% to 15%
Rationalize vocational and technical education	<ul style="list-style-type: none"> • Decrease the number of nonviable VTCs through consolidation by 8% from 20% to 12%, close 10 out of the total 17 unviable VTE schools • Consolidation and reduction of specializations based on the labor-market needs and aligned with the investment priorities in VTE • Redefinition of the program framework in compliance with the labor-market needs
Develop quality assurance in higher education	<ul style="list-style-type: none"> • Increase in the accountability within the Lebanese University to assess the performance of teachers and administration • Enhancement in the autonomy of the Lebanese University • Implementation of national structures for quality assurance in higher education

Develop standards for institutional quality assurance	Draft standards compatible with international patterns in quality assurance in higher education and with local requisites	Undertake a national consultation on the drafted standards and approve them	Implement	MEHE Council of Ministers Parliament	2006: No standards for institutional quality assurance 2009: Standards for institutional quality assurance
Establish national structures for quality assurance	Prepare relevant laws and regulatory decrees to create a national council for quality assurance and define its structure and mechanisms	Approval/ratification of relevant law and decrees	Implement	MEHE	2006: No national structures for quality assurance 2009: Structures for quality assurance established

Appendix 2 Initiatives and their respective KPIs in terms of baseline, current value, and target value

<i>Programs</i>	<i>KPI</i>	<i>Baseline (July 2007)</i>	<i>Current value</i>	<i>Target (closest date)</i>
Consolidate policy, planning, and resource allocation	Percentage of educational policies and plans based on EMIS output	0%	0%	100% (Dec 2008)
	Submission of a shadow PBB for MEHE	PBB	PBB	
	Percent decrease in number of days and processes required to complete a sample of 10 tasks	0% decrease in total number of days	0% decrease in total number of days	50% decrease in total number of days (Dec 2008)
Achieve Universal Basic Education (UBE) for ages 6–15	Percent increase in NER for grades 1–6	97%	97%	98% (Dec 2009)
	Percent increase in NER for grades 7–9	68.5%	68.5%	72.5% (Dec 2009)
	Percent increase in class occupancy for grades 1–6 (cycles 1 and 2)	0%	0%	5.88% from 17 to 18 (Dec 2009)
	Percent increase in class occupancy for grades 7–9 (cycle 3)	0%	0%	10.53% from 19 to 21 (Dec 2009)
	Percent increase in public students with free textbooks in cycles 1 and 2	0%	0%	100% (Dec 2007)
Improve efficiency, effectiveness, and competence level of the teaching workforce	Percentage of teachers without a bacc. and above age 58: who are physically/psychologically disabled	9.6%	9.6%	6.9% (Dec 2008)
	Percentage of PS Principals who have undergone professional dev. prog. to improve competence	10%	10%	30% (Dec 2007)
	Number of teachers who have undergone professional development	16 500 teachers	16 500 teachers	20 000 teachers (Dec 2007)
Enhance quality of education	Percent decrease in repetition rate for grades 1–6	21%	21%	19% (Dec 2010)
	Average student repetition rate in grades 7–9	23%	23%	21% (Dec 2010)
	Percent increase in NER for children aged 3–5 enrolled in public KGs	21.61%	21.61%	29.69% (Dec 2010)
	Percentage automation of public examination process and exams	0%	0%	100% (Dec 2008)
Enhance the utilization of educational facilities	Percent decrease in number of nonviable schools or ecoles normales	0% (nonviable schools) and 0% (ecoles normales)	0% (nonviable schools) and 0% (ecoles normales)	23.1% (nonviable schools) (Dec 2007) and 48.5% (ecoles normales) (Dec 2009)

Rationalize VTE	Identification of number of VTE specializations that comply most with labor-market needs	Zero VTE specializations identified	Zero VTE specializations identified	15 VTE specializations identified (Dec 2009)
Develop quality assurance in higher education	Submission of standards compatible with international patterns in quality assurance in higher education and with local requisites	No unified set of standards submitted	No unified set of standards submitted	A unified set of standards submitted (Dec 2009)

(4) education that contributes to economic development, and (5) governance of education.

Throughout the year 2007, a number of initiatives have been launched to complete the review of MEHE's structure, and to propose new restructured organization in line with the requirements to implement the reform strategy; integrate policy, planning, and information management functions at MEHE; nominate staff to fill key functions during the organizational restructuring transition period; develop and support with training, systems, and technology a core financial planning team within MEHE; initiate the development of an EMIS; develop financial scenario software tool and train a planning team on its use; develop a PBB model for MEHE's budget; perform information audit to identify relevant information and information needs; and prepare and issue a new and contemporary law for LU.

Glossary

Compulsory education – Compulsory and state-guaranteed provision of primary and basic education programs available to individuals under 16 years, citizens of the Lithuanian Republic, and foreigners holding the right of permanent or temporary residence in the Republic of Lithuania.

Education monitoring – Continuous analysis, assessment, and forecasting of the conditions and change of education.

Education provider – School, independent teacher, or any other education provider (institution, enterprise, or an organization involved in education as secondary activity) granted the right to provide instruction services in accordance with the order established by the law on education of the Republic of Lithuania.

Formal education – Instruction provided to teach programs approved and registered in the order regulated by legal acts and granting graduates primary, basic, secondary, postsecondary, or higher education and (or) qualification.

Learner of special needs – One whose ability to learn and participate in social life is limited by congenital or acquired disability.

Nonformal education – Diversity of educational courses providing for different educational needs of professional development and additional competences.

Nonstate-funded school – A school founded by a legal entity of the Republic of Lithuania (except Lithuanian Seimas (Parliament), the Government, the Ministry of Education and Science or other ministries, governmental agencies, agencies at the ministries, county administration office, and municipality council) or a natural person; a school founded by a legal entity or natural person jointly with legal entities or natural persons of other states, or a school founded by a legal entity or natural person of another state.

School-maintenance fund – Funds related to the education process indirectly (dedicated for the running of school as economic entity and exploitation

of its economic assets, providing a lift to pupils and other economic needs).

State-run school – School founded by the Lithuanian Seimas, the Government, the Ministry of Education and Science or other ministries, governmental institutions, institutions at the ministries, county administration office, or municipality council and a school jointly funded by a state institution with legal entities or natural persons of the Republic of Lithuania.

Universally available education – State-guaranteed education available to all citizens of the Republic of Lithuania and foreigners holding the right of permanent or temporary residence in the Republic of Lithuania.

Political, Social, and Economic Context

The Lithuanian State is a democratic republic. Seimas (Parliament), the president of the republic, government, and court are bodies of state power. The boundaries of power vested with each of them are established by the constitution. Questions critical in the life of the state and the nation are decided by referendum. The territory of the Lithuanian state is uniform and further indivisible into state units. Lithuanian is the state language.

The total area under the state of Lithuania is 65 300 sq. km with a population of 3 371 000 (estimate of the fourth quarter of 2007) and a population density of 51.6 people per sq. km. The Lithuanian capital is Vilnius, with a population of 553 600.

Short History

The name of Lithuania is first mentioned in the *Annales Quedlinburgenses*. The State of Lithuania emerged in the thirteenth century. On 6 July 1253, Mindaugas, the Grand Duke of Lithuania, was crowned king for the first time to become the only Lithuanian king. In 1323, Lithuanian Grand Duke Gediminas founded Vilnius, the capital of Lithuania. In 1387, Lithuania embraced Christianity.

The first school was opened in 1397 at Vilnius Cathedral. In 1547, Martynas Mažvydas (Martynus Mosvidius) published the first Lithuanian book, *Catechismus*. Vilnius University was founded in 1579. On 3 May 1791, the Commonwealth of Poland and Lithuania accepted the first written constitution, the first one in the history of Europe. In 1793, an educational commission was established in charge of the education system in the Grand Duchy of Lithuania. It was among the first secular education ministries in Europe. The first Lithuanian language newspaper, *Aušra* (*The Dawn*) was printed in 1883. The Independence Act of Lithuania was declared on 16 February 1918. In 1940, Lithuania was occupied by the Soviet Union. In 1988, a Lithuanian rebirth movement emerged leading to the declaration of the reestablishment of the independence of Lithuania. On 25 October 1992, the constitution of the Republic of Lithuania came into power.

From 29 March 2004, Lithuania is a part of the North Atlantic Treaty Organization (NATO). From 1 May 2004, Lithuania is a member of the European Union (EU).

State Governance

Lithuania has a parliamentary republic form of governance. The head of the state is the president of the republic elected by direct suffrage for a term of 5 years. The president oversees foreign and national security policy. Valdas Adamkus was elected president on 12 July 2004.

The Seimas is the highest body of state power. MPs are elected for 4-year terms. All citizens have the right to vote from the age of 18. From the age of 25, citizens are eligible candidates to the Seimas. The sessions of the Seimas are conducted by the chairperson or the deputy chairperson. The functions of the Seimas are established by the constitution, the statute of the Seimas sets down the structure and working procedures of the Lithuanian Parliament.

The Government of the Republic of Lithuania is composed of the prime minister and 13 ministers. The prime minister is appointed and dismissed by the president with the approval of the Seimas. Ministers are appointed and dismissed by the president on the advice of the prime minister. At the national government level, the responsibility for education is vested with the Ministry of Education and Science.

Religion

There is no state religion in Lithuania. Based on the 2007 census, 79% of the Lithuanian population were Roman Catholics.

National Minorities

Based on nationality, Lithuanian population represents the following composition: Lithuanians – 84.6%; Polish – 6.3%;

Russians – 5.1%; Belorussians – 1.1%; Ukrainians – 0.6%; Roma – 0.3%; Latvians, Tatars, German, and Jewish – 0.1%.

In Lithuania, national minorities enjoy the opportunity to be recognized as such, to teach children their native language and history of their nation, to foster their culture, and practice their religion. During the school year 2006–07, 8% of day-shift learners at general-education schools received instruction in a language other than the state language. Schools of Russian, Polish, and Byelorussian national minorities operate in Lithuania, as well as other mixed schools offering instruction in several languages. There are 46 Sunday schools across Lithuania.

Demographic Situation

The current trend in Lithuania is a decrease in the population. The number 3 403 300 in the early 2006 represents a decrease of 22 000 from early 2005.

Since 1990, the rate of birth in Lithuania has been decreasing and has dropped twice over 15 years. Summary birth rate indicator (average number of births given by a female) was 1.27 in 2005.

In 2006, *migration saldo* (negative net migration) was – 8782 or –2.6 per 1000 of the population.

Economic Situation

The economic development in Lithuania during 2006 was extremely rapid as compared with that in 2005. The gross domestic product (GDP) grew by 7.5% compared with 2005. In 2006, the GDP created per individual increased by 15.8% compared with 2005.

The number of unemployed decreased over 2006 as also did the proportion of unemployed among citizens of working age. Over the last 5 years, the level of unemployment dropped from 13.8% (in 2002) to 5.6% (2006).

The income of the Lithuanian population has grown in recent years. Average gross monthly salary paid to individuals employed with the national economy (except individual enterprises) was LT 1826.3 in the second quarter of 2007, an increase of 20.2% from the second quarter of 2006. It was LT 1847.3 in the state sector, increasing by 16.5% over the same time span, and LT 1814.0 in the private sector, showing an increase of 22.7% from the previous year.

The Development of Education Policy

The first document of significance for education strategy, *The Conception of National School* (1988), was created prior to the reestablishment of independence. Its key idea was to create opportunities for the ex-USSR republics to create their independent education systems.

The Law on Education of the Republic of Lithuania introduced in 1991 defined key goals for the education

system. In 1992, the Lithuanian government approved the *General Concept of Education in Lithuania*, a central conceptual document that informs the reform of education in the country. The concept sets out that in order to achieve its education goals a permanent system based on differentiated and integrated education has to be shaped.

In 2003, the Lithuanian Seimas passed a new edition of the Law on Education of the Republic of Lithuania, which created opportunities to further develop and improve the national education system. Rather than regulating institutional makeup of the system, it introduces a flexible and qualitative process of teaching. The law is learner focused.

On 4 July 2003, the Lithuanian Seimas approved a central political document for the development of education in the Republic of Lithuania, *Provisions of the National Education Strategy 2003–12*. This document sets forth key guidelines and indicators for national education.

Strategy and Goals of Education

The 2003 approved *Provisions of the National Education Strategy 2003–12* identifies three priorities for the development of education:

1. to create an efficient and cohesive education system based on responsible management, targeted financing, and rational use of resources;
2. to develop a continuous, universally available, and socially just system of education providing for lifelong learning; and
3. to guarantee quality education capable of meeting needs of individuals functioning in open society and market economy.

The *Provisions of the National Education Strategy 2003–12* formulates goals for the development of the Lithuanian education system and identifies means to achieve these goals. The provisions define the main qualitative and quantitative indicators to judge by and assess the development of Lithuanian education over the period 2003–12.

General Structure of Education and Levels of Education

Compulsory education in Lithuania starts at the age of 7 and lasts until the learner reaches the age of 16. Parents may opt for their child to start schooling at 6, if he or she shows the necessary maturity.

In Lithuania, boys and girls learn together. For scope of education, numbers of schools, learners, and teachers see **Figures 1 and 2** and also **Tables 1–4**.

Preschool Education

Preschool education is provided to children between 1 and 5 (or 6) years of age. Preschool and preprimary education are not compulsory. The child may be educated at home until the age of 7; the child or his/her family is entitled to receive educational support.

Preprimary Education

Preprimary education in Lithuania was first introduced in 2000. Currently, preprimary education is universal, yet not compulsory. Preprimary education is provided to children who turn 6 that particular calendar year. Preprimary education may be deemed compulsory for individual children should children's rights' protection institutions decide so.

Children of ages 5 and 6, not yet receiving education at educational institutions, are given education support in the family.

Primary Education

Children start primary education in form 1, the year when they reach 7 years. Learners spend 4 years in primary school, from the age of 6–7 to 10–11. After completion of the primary-education curriculum, learners acquire primary education. Learning achievements are not assessed in the form of marks during the stage of primary education. In forms 1–4, children are taught by one teacher providing

instruction in all subjects. In forms 1–4, the maximum allowed number of learners in a class is 24.

Primary school year (forms 1–4) lasts 170 school days.

Schools providing primary education are required to comply with the requirements set forth by the state

general-education curricula and standards for education, yet they can also apply alternative ways of organizing provision of primary education. Alternative education schools of Waldorf, M. Montessori, Suzuki, and others operate in Lithuania.

Basic Education

Basic education is provided to learners who have acquired primary education. After completion of the basic-education curriculum, learners acquire basic education.

School year for learners in form 5 is 170 school days; in forms 6–10, it lasts 195 school days.

Learning achievements are assessed according to a ten-point scale. Schools are free to select other scales, but need to establish a procedure to convert their results into the ten-point scale.

The learner graduating from basic education receives basic education certificate.

Secondary Education

Secondary education curricula are taught by day-general-education schools, vocational schools (their day-time sections), adult-education schools (evening sections), and adult education centers.

Secondary education is acquired after completion of the general-education curriculum and passing of maturity examinations. Currently, graduates may select to take school and/or state maturity examinations. School maturity examination features tasks prepared on the basis of the program (requirements) for school maturity examinations. Such examinations are taken at the school or a local center. The assessment is criteria based and recorded on a ten-point scale. State maturity examinations involve tasks based on the state maturity examinations program (requirements) and are taken at the centers of state maturity examinations. The results are assessed in a centralized manner. Normative assessment is used and results are ranked on a 1–100-point scale. Graduates from secondary school pass the following examinations: credit-tests in the Lithuanian language (state language), native language, and one foreign language; they take compulsory examination in the Lithuanian language and no fewer than three selected maturity examinations.

Vocational Education and Training

Vocational education and training may be initial and continued. Initial vocational education is formal and is

designed to acquire the first qualification. It is available to learners who have basic or secondary education. Learners who have only basic education can receive vocational training combined with secondary education. Initial vocational education can be provided even to learners who do not have basic education but are younger than 14 years.

Continued vocational education is provided to individuals of different ages who already have a qualification. It is designed to improve the existing qualification or provide a new one. The continued vocational education comprises both, formal and nonformal vocational training.

Vocational education and training encompasses formal and nonformal vocational education programs. The formal vocational education program has to meet the requirements in the standards describing the given qualification. Such formal vocational education programs can be provided together with general education programs. Providers of formal vocational education are vocational-education institutions and other institutions licensed by the Ministry of Education and Science. Vocational training can also be organized on the job in the form of apprenticeship, in companies or enterprises.

Individuals receive a qualification upon acquiring the competencies required for it as established by the standards describing the given qualification. The assessment of acquired competencies is performed by institutions (social partners or other legal entities) accredited for that purpose by the qualifications service.

Higher Education

Studies of higher education are universal and are provided to individuals who have acquired secondary education and are capable of studying independently.

The curricula of higher education studies are taught by higher education institutions: universities and colleges. Students may study at different higher education institutions with intermissions and complete these programs in separate modules.

Upon completion of higher education study programs, alumni receive higher education and (or) qualification. Scientific research degrees are granted in accordance with the requirements formulated by the Higher Education Law.

Special Education

Special education is provided as part of all-compulsory and universal-education programs. These programs are modified and adjusted, and also separate specialized programs are created to be provided alongside, with additional support in order to meet learners' special needs.

Special education is provided by all schools teaching compulsory and universal education programs, other education providers, and, in separate cases, by specialized schools.

Formal education programs, when modified for the purpose of special education, can be covered in longer than originally established periods. Learners may take such a program with intermissions and in separate modules.

When individuals with special needs take education programs meeting state education standards, they can acquire education and (or) qualification. In separate cases, qualification may be acquired without standard general education.

Nonformal children-education programs are offered by music, art, sports, and other schools, individual teachers, and other education providers. Music, art, sports, and other schools teaching programs of nonformal education or their modules fall under the same category as the schools teaching formal education programs. Individuals seeking higher education in the fields of music, visual and performing arts have to complete, alongside with secondary education, a specified program approved by the Education and Science Minister, if such a requirement is included in the admission requirements of the given higher education institution.

Adult Education

Adult education is provided to all individuals seeking it, but who are not younger than 18.

There are over 60 adult-education centers across the country operating in each municipality, and over 400 private nonformal adult-education providers.

Competencies acquired through informal education may be recognized as part of a formal education program or qualification in accordance with the order established by the Government of the Republic of Lithuania, its authorized institution, or higher education institution.

Nonformal adult education is regulated by the Law on Nonformal Adult Education.

Education Availability and Quality

Each citizen of the Republic of Lithuania, or a foreigner holding the right of permanent or temporary residence, has the right to learn and acquire education and qualification. Instruction of basic, secondary, and vocation

programs provided by state-run and municipality-funded schools is free.

The Right to Select Educational Programs

Learners are given the opportunity to select educational programs, modifications of these or modules, study programs in different subjects, in line with individual abilities.

Employers must create conditions to learn for working individuals. Vocational and higher education schools provide working learners with the opportunities of learning in different ways, including distance education.

Children in social exclusion, those from poor families, deprived of family and care, and refugees' children who do not attend school are given the opportunity of alternative education in youth schools. Individuals under temporary deprivation or restriction of liberty are provided with the opportunity to learn at the place of rehabilitation or penalization and acquire primary, basic, or secondary education qualification; opportunities of informal education are also available. Instruction according to the modules of general-education programs and non-formal-education programs is available to conscripts during their service period; they can also undertake informal education.

Learners with special needs, based on the decision of parents (guardians and caretakers) have options available to take a full- or partial-integration program at the general-education school, to learn at the school teaching special-education programs, or opt for school sanatorium. Education at medical facilities or at home, also arrangements of independent learning and taking of examinations are available to learners unable to attend general-education schools because of illness or disability. Individuals with special needs have the right of special privileges introduced into admission procedure by vocational or higher education schools when entering these institutions.

Assessment of Learners

Learner achievements are assessed by teachers, education providers, school founders, the Ministry of Education and Science, and authorized institutions. Institutions authorized by the Minister of Education and Science organize examinations and order the creation of other tools to assess learner achievements.

The procedure of examinations, tasks, and the forms of assessment can be modified to assess the achievements of learners with special needs.

Individual learning achievements of general education are assessed by the national examination center. The center organizes and conducts examinations and credit tests; performs assessment of education achievements and literacy, tests of knowledge, abilities, interim and final assessments of educational periods; and performs generalization and analysis of examinations, tests, and education.

Education Quality

The education provider is responsible for the quality of education. The state guarantees for the quality of formal education, and partially so, of nonformal education.

The Minister of Education and Science approves preschool and general/nontraditional/vocational/nonuniversity study programs of general education, establishes the criteria for preschool and nonformal children-education programs, approves general-education plans for general-education schools and standards for primary/basic/secondary education and vocational training; the ministry sets regulations for study fields, teacher training, and maturity examinations programs.

Teachers and Pedagogical Staff

Teacher Education and Training

Teacher education and training represent the first-level university or nonuniversity studies (including teaching practice at school), pedagogical placement, and qualification examination.

Individuals with secondary education are eligible candidates to take university and nonuniversity teacher-training programs. There is no age limit for the applicants. Applicants have to take additional tests to study some of the specialties.

Both parallel and consecutive models are applied to train teachers. Parallel model represents a method when all components of teacher-training curriculum content are studied in parallel. According to consecutive model, academic studies are followed by professional studies, for example, disciplines in education science, methodology of teaching different subjects or integrated courses, and school practice. Teacher training model in Lithuania includes common curriculum content components such as: studies of educational sciences, studies of academic subjects and some disciplines related to school educational programs, methodology of individual subjects or integrated study courses, and pedagogical/school practice.

Teachers working at school, yet having no professional qualification or adequate qualification in the subject they teach, can acquire it by full-time studies, evening studies, or studies by correspondence (distance studies). They acquire knowledge provided by specialized professional studies and write a graduation thesis.

Teacher Professional Development and Retraining

Teacher retraining for a different qualification is an integral part of teacher training. Such retraining studies are organized by university and nonuniversity schools and retraining institutions hold a license for that purpose from

the Ministry of Education and Science. The duration and format of retraining depend on the program, the nature of specialty, and the potential of institution offering retraining services; it also depends on the level of the individual learner and its duration is no longer than 3 years.

Teacher Professional Development

There are four teacher qualification categories in Lithuania: teacher, senior teacher, teacher-methodologist, and expert teacher.

These are the following types of institutions undertaking teacher and school leadership professional-development functions: teacher methodological centers, municipality teacher-education centers, county education centers with regional computer-training centers, regional computer-training centers, and professional-development institutions at higher education schools (with regional computer-training centers).

The following institutions are indirectly involved in teacher professional development: school methodological centers, childhood pedagogy centers, centers of supplementary education under the Ministry of Education and Science, and nongovernmental organizations.

The services provided by professional-development institutions are free. Part of the professional-development events' expenses are covered from the state or municipal budget. Financing for professional development is also earmarked from the school budget; its absolute amount depends on the number of learners.

Work Hours and Workload of Teachers and Pedagogical Staff

The government has established that teachers and psychologists of general education, professional, post-secondary schools, higher education schools, and supplementary-education institutions, and teachers of healthcare and social-care institutions are entitled to 56 calendar-day holidays per year. Teachers of higher education institutions are also entitled to holidays of the same duration.

The teachers' contact hours are defined and limited. The maximum allowed workload (contact hours) of a teacher is 34 h per week. The time teacher spends at school is not limited.

Each academic year, higher education institutions establish the required number of contact hours per position. State-run colleges establish teacher monthly payroll salaries based on 700–740 contact hours per academic year.

School Administration and Management

The founder of the school assigns and dismisses the school head (except higher education institutions). Heads of state-run and municipality-funded schools are hired through

public competition. Heads of nonstate schools are assigned, elected, and dismissed as per the order established by the labor laws.

The rector of the state-run university is elected by school's senate for a term no longer than 5 years, not exceeding two tenures in a run. The procedure is public competition and secret ballot held in the order established by the statute of each higher education school. Eligible candidates are established scholars or artists holding the title of professor. Rectors of nonstate universities are elected or appointed in the order established by the statute of the school.

Education Management

The purpose of education management is to guarantee the quality of the implementation of state education policy with managerial tools: monitoring, planning, distribution, and supervision of authority and responsibility.

Education Monitoring

Education monitoring is performed in accordance with the provisions established by the description of the order of state education monitoring and the list of indicators of state education monitoring. Data and information for the purpose of education monitoring are presented by the education management information system (EMIS) research into the state of education, the national learner achievement, and other types of international research.

The priorities of Lithuanian education, long-term goals, directions in the changes of curricula content, and priorities for financing are established by the State Education Strategy 2003–12. Drafted by the Ministry of Education and Science, the state strategic-education plans are approved by the Lithuanian Government. In order to implement these strategic plans, annual education-activity programs are run on the national, country, municipal, and school level.

School Self-Governance

School self-governance depends on school's specific goals of education, concrete programs run by school, and the school's ethos. The diversity of self-governance bodies, their competence, and principles of formation are established by school regulations (statute). School council is the highest self-governance body representing learners, teachers, parents (foster-parents), guardians, or caretakers and local community. Vocation school council also represents social partners. Teacher council (except higher education institutions and nonformal education schools) is a permanently operating school self-governance body dedicated to solving teachers' professional questions and general

issues of education process. It includes school leadership, all teachers on staff, medical personnel, psychologists, social, social pedagogs, librarians, and other individuals directly involved in education process. Schools may also have other types of self-governance bodies (students, parents (foster-parents), guardians, and caretakers).

Financing of Education

Investments into Development of Education

On the state level, investments into the development of education are made based on approved programs. One-year or long-term investment programs in the field of education are drafted by the Ministry of Education and Science in accordance with the State Education Strategy 2003–12 and the Lithuanian Republic Government Program. At the municipality level, investments into development of education are made based on programs and investment projects included into the budget of municipality.

Financing of Education Programs and Schools

Education is financed from the state budget, municipality budget assignments, and other resources. Preschool and formal education programs run by state, municipal, and nonstate-funded schools (except higher education schools) are financed from state and municipal budgets on the principle of expenditure per pupil. Municipal and nonstate-funded schools providing preschool and general education receive financing for education from the special, targeted donations to municipal budgets from the state budget for concrete year. State-run schools receive financing as state budget assignments. Funds for school maintenance are assigned by the founder in the order it has established. Healthcare at school is covered from the budget of compulsory health insurance fund, state and municipal budgets, and other resources.

Nonstate-funded, traditional religious community, or society schools, when they run programs of formal education, can be financed as per the order established by the Lithuanian Government and receive the same education and school-maintenance funds as do state or municipality schools of the same type.

Programs of nonformal children education are financed by the founder of the school, learners (their representatives), and supporters. The founders also finance vocational, non-formal, adult-education schools and institutions providing support to learners, teachers, and schools.

Each state higher education institution receives annual financing from the state budget, assigned by the Seimas. Financing for state higher education schools includes: state budget funds (earmarked for studies, development of scholarly research and artistic creation, administration and maintenance, maintenance of cultural properties,

coverage of students' tuition fees, students' stipends, implementation of state investment and other programs, and the development of international exchange), other state funds, revenues generated from scholarly work, economic activity, and provided services, recourses received from international and other funds and other organizations, tuition fees paid by students receiving just partial state financing, tuition fees by students who study at their own cost, as well as other legally generated recourses. The founder establishes the structure and allocation of assets of nonstate-funded higher education schools.

Payment for Work

Salary paid to state (except higher education schools) and municipal school head, deputy head for education, and section supervisor responsible for the organization of education depends on individual's education, years of pedagogical work, category of qualification, and complexity of work. The procedure of payment for work is established by the Government.

The head of state higher education school is paid based on the effectiveness of performance and workload; teachers and scholarly staff are paid based on responsibility, scholarly qualifications, involvement in the projects of international scientific and technological-development programs or commissions from economic subjects, and performance of urgent, key, or complex tasks.

Salaries of nonstate schools are established in the order set by the law.

Material Support

Learners taking an initial vocational training program can receive a stipend and be provided with material support.

Students at state higher education schools taking basic (bachelor) university-level programs, integrated and second-stage (master) programs, and doctoral or licentiate students can receive academic (based on academic results) or social stipends. Stipends are paid from the state budget assignments. Students of higher education schools can receive state loans to pay tuition fee, accommodation and subsistence loans, and toward partial studies based on international treaties and agreements.

Learners taking nonformal education programs can also receive material support.

Payment for Education

State and municipality schools teach preschool, primary, basic, secondary, and vocational education (initial qualification) programs for free. Payment for education, teaching, or studies is established by the founder of nonstate school.

Payment for nonformal education (except preprimary) provided by school is established by the founder; it can be reduced with regard to learner's ability and social conditions of parents (foster-parents), guardians, or caretakers.

High-achieving students of state higher education schools are guaranteed free higher education: no lesser than 30% of students following each study program (except those who study at their own cost), selected each semester based on the best academic results (entrance results for the first semester) get their tuition fee paid from the state budget. The number of students whose tuition fee is paid from the state budget is established by the government. If full tuition fee for studies at the state higher education school is paid by the students who take the same or lower-level study program that they have already taken at the state higher education school, they need to pay this fee for only half of completed program's credits. It is also paid by individuals, who simultaneously take two or more programs of the same level, and at least one of these study programs is fully or partially paid by the state; this applies to foreigners also, unless international agreements of the Lithuanian Republic establish otherwise. It also applies to individuals who agree to pay the full fee and get enrolled into evening studies or extra-mural studies.

Students taking nonconsecutive studies or repeating separate subjects from the program of nonconsecutive studies provided by the state higher education school also pay tuition fee proportionate to the scope of subject taken.

Evaluation and Research

Currently, evaluation of educational institutions performs the following functions: formative (when evaluation is done for the sake of improvement), summative (for the sake of accounting for work performed), and administrative (for the sake of improving administrative function).

The founder constantly observes the activity of general-education schools and performs its overall evaluation every 7 years. The evaluation is based on the analysis of self-evaluation, observation of lessons (instruction periods), analysis of learners work, and interviews with learners, teachers, leaders, parents (guardians), and other individuals related with the activity of the organization, or a survey of these analyses of documentation, facts, and concrete indicators. Such an evaluation is performed by the National School Assessment Agency.

The coordinating function for the self-evaluation and the assessment of study quality at scientific and study institutions is performed by the Lithuanian Centre for Quality Assessment in Higher Education. Currently, institutional assessment is performed only in colleges. It is going to be performed in universities only in the future; therefore universities currently prepare self-evaluation only for external evaluation of study programs, performed

on a periodical basis. Lithuanian Centre for Quality Assessment in Higher Education has prepared a methodology for the summary of self-evaluation of study programs and methodological recommendations for colleges on summarizing self-evaluation.

Research in Education

Since 2001, the Ministry of Education and Science orders annual researches on the condition of education, including different levels of education, educational processes, problems arising in teacher training, questions of educational support, and other activities of current significance in the field of education. The results of the research are used to perform analysis of the education system in planning the activity of the education system and decision making with the goal of specifying priorities in the development of education and science.

Annually, national research of learners' achievements is conducted and includes achievements of pupils in forms 4, 6, 8, and 10. The research covers the following fields of education: Lithuanian as native language, mathematics, natural sciences, and social sciences.

Lithuania takes part in international research: International Association for the Evaluation of Educational Achievement Trends in International Mathematics and Science Study (IEA TIMSS), Progress in International Reading Literacy Study (IEA PIRLS), International Civic and Citizenship Education Study (IEA ICCS), IEA Second Information Technology in Education Studies (SITES), Organization for Economic Cooperation and Development Programme for International Student Assessment OECD PISA, OECD Teaching and Learning International Survey (TALIS), and European School Survey Project on Alcohol and Other Drugs (ESPAD).

Scholarly research in Lithuania is carried out by higher education institutions, agencies under the auspices of ministries, scholarly institutions, and institutes.

General Background

Malawi is found on the southern part of the East African Rift valley lying between latitude 9 and 17° E and longitude 33 and 36° S of the equator. The country has an area of 118 484 km² of which 94 276 km² is land mass.

Malawi's total population was estimated to be around 13 million in 2007 based on data from the Population and Housing census conducted in 1998. The most recent population and housing census was conducted in June 2008. Based on the 1998 population and housing census projections, Malawi's population density is 105 persons per square kilometer. The population growth rate is 2.2% per annum. The percentage of the population under 18 years is 50.5. Malawi's socioeconomic indicators are poor and among the lowest in the world. Its gross national income (GNI) per capita was averaged less than US\$200 over the past decade. According to a recent household survey, 52% of the population in Malawi are classified as poor while 22% are classified as ultra-poor, that is, living in extreme poverty (National Statistical Office, 2005). The incidence of poverty is severe in rural areas with an estimated 56% of the rural population classified as poor compared to 24% of the urban population. Inequality levels are quite high with 20% of the richest consuming 56% of the wealth and 20% of the poorest consuming only 5% (National Statistical Office, 2005). Infant mortality stands at 76 deaths per 1000 live births, child mortality at 133 deaths per 1000 live births, and maternal mortality at 984 deaths per 1000 live births and are among the highest in the world (NSO and ORC Macro, 2005). Malawi is also one of the countries worst hit by the acquired immune deficiency syndrome (AIDS) epidemic with an estimated 14.1% of the sexually active population (i.e., 15–49 years) infected with human immunodeficiency virus (HIV; NSO and ORC Macro, 2005). As a consequence of the AIDS epidemic, life expectancy for the average Malawian decreased from 45 years in 1995 to 39 years in 2003. However, the recent Human Development report puts Malawi's life expectancy at 44.5 years (UNDP, 2008). This is attributed to the improved nutritional status due to the bumper harvest of the staple food, maize, that Malawi has experienced from 2006 and improved campaign on the fight against HIV and AIDS (UNAIDS, 2008).

Since the implementation of structural adjustment programs from the early 1980s, Malawi's economic performance was erratic averaging 1% between 1980 and 1994. In 1994, Malawi went through a political transition from a

one-party dictatorship to a multiparty government. At that time, Malawi had an inflation rate of 70% and a budget deficit of 28% of gross domestic product (GDP). Good progress was, however, made in the immediate post-1994 years. Fiscal deficits fell from 28% to 8% in 1997. Inflation fell to 9% in 1997. Growth in GDP averaged over 3% in the period 1992–97. However, during the second multiparty term, between 1999 and 2004, of the then ruling party there was a decline in economic performance. Malawi's official currency, the Kwacha, experienced rapid devaluation from MK68 in December 2000 to MK107 to one USD by January 2004. This was attributed to, among others, withdrawal of external budgetary support from donors and high domestic borrowing by government from the banks. Poor rain pattern coupled with poor policy decisions regarding the sale of the strategic grain reserves led to serious shortage of the staple food, maize, triggering high inflation rates.

The country's economy is currently growing at 8.5% which is above the Southern African Development Community (SADC) average rate of 5.5% and the world's average of 5.4%. The inflation rate decreased from 17.1% in February 2006 to 14.9% in July 2006 and to 7.9% in July 2007. The depreciation of the Kwacha has been contained to less than 10% for a period of 2 years. There has been improvement in managing public finances and domestic debt repayment has improved which has seen interest rates being reduced from 30% in May 2004 to the current 15%. The percentage of people that lives below the poverty line has moved down from 60% to 52%.

Education Policies and Reforms

The legal framework of education is based on the 1962 Education Act, which is currently under review to take into account the current sociocultural and economic environment. Malawi's Constitution defines the nation's educational objectives and regulates the sharing of responsibilities for education among the three key players – the state, religious groups, and the private sector. The religious groups control a large proportion of the primary schools, around 60%.

The Constitution of the Republic of Malawi recognizes the right to education for all persons under chapter IV, Section 25.

The broad policy on education is to develop an efficient and high-quality system of education of a type and size appropriate both to the available resources and to the political, social, and economic aspirations of the nation.

Owing to the limited employment market, the emphasis of education is to equip students with the skills and desire for self-employment and entrepreneurship rather than conventional wage employment (MOEST, 2001). The vision of the education sector in Malawi, as outlined in the National Education Sector Plan (MOEST, 2008), is to be a catalyst for socioeconomic development, industrial growth, and an instrument for empowering the poor, the weak, and voiceless. Its mission is to provide quality and relevant education to the Malawian nation, enabling people to acquire relevant knowledge, skills, expertise, and competencies to perform effectively as citizens, work-force, and as leaders of Malawi, thereby reducing poverty. In implementing the vision and mission, Malawi has made the improvement of quality, equity, relevance, access, and efficiency in basic education as the main strategic priority. Complementing this main priority, at secondary level, the focus is to double the enrolment over the 10-year plan period while at the same time focusing on upgrading quality and on retention of girls. Access to technical and vocational education will expand and the colleges will be rehabilitated. At higher education level, enrolment in existing public universities will be doubled with significant increase in efficiency to minimize costs to the budget, complemented by expansion of private tertiary education. HIV and AIDS mitigation is considered a cross-cutting intervention at all levels/subsectors. The prioritization of the sector's interventions and strategies is premised on the fact that although there has been significant progress in terms of enrolment of school-age children (an increase of 60%) since the introduction of the free primary education (FPE) following the government's commitment in 1994 to the Millennium Development Goals (MDGs) for education and the Dakar, 2000 Education For All (EFA) initiative, both of which prioritize primary school-age children, the quality of primary education is acknowledged to be unsatisfactory and completion rates are very low (approximately 25%). The secondary and higher education sub-sectors (including technical and vocational training) also face some challenges related to quality, equitable access and relevance, and problems related to resource management.

Structure and Operation of the Education System

The Ministry of Education, Science and Technology (MOEST) is responsible for the provision of primary, secondary, and tertiary education. The Ministry of Women and Child Development (MOWCD) is responsible for early childhood development which encompasses pre-primary education, and adult literacy and education, while the Ministry of Youth Development and Sports (MOYSD) is responsible for aspects of nonformal education for out-of-school youths. While the government is the main provider of education at all levels, the private sector is currently

active in the provision of pre-primary, primary, secondary, and tertiary education.

The formal education system under MOEST is divided into three main levels – primary, secondary, and tertiary – and follows an 8–4–4 structure: 8 years of primary, 4 years of secondary, and up to 4 years of tertiary education.

Scope of Basic Education

The Malawi EFA Plan of Action and the NESP recognize the scope of basic education to be from preschool through years of primary school to secondary education as adopted by member states of the SADC in the SADC Education Protocol. This includes all those who may have dropped out of primary school and are pursuing vocational or skills training, and those who enter education at an advanced stage.

Early Childhood Care and Education

Currently, there are 4005 Community-Based Child Care (CBCC) centers and 1940 preschool centers in Malawi that provide early childhood development (ECD) services. A total of 6240 early learning centers have been opened and are operating across the country. A total of 615 478 children, orphans, and other vulnerable children of ages 1–6 targeted through either the preschools or the CBCC program have been reached representing a national coverage of 26.76% of children below 6 years – 2006. A total of 14 127 caregivers were registered within communities with 5335 targeted through a 2-week basic training in ECD. The concentration trend is now changing, majority of CBCCs are concentrated in rural and peri-urban areas with the aim of providing psychosocial support and care to orphans and vulnerable children, whereas most preschools are in urban and semi-urban areas, and the majority of caregivers in both situations are not trained.

So far, early learning programs cater for only 26.7% of the targeted population. This implies that almost 70% of children aged 0–5 do not have access to early learning services.

Primary (Elementary) and Secondary Education

Primary school enrolments which had been expanding, albeit gradually since independence, increased extremely rapidly in 1994 following the introduction of FPE when an additional 13 million children enrolled in school (from 1.9 million to 3.2 million), representing an overall increase of 51% and nearly 60% increase in enrolments in the first grade alone. Prior to the introduction of FPE, 50% of the

school-age children in Malawi were not attending school and the majority of these were girls. In 1990, girls comprised less than half the enrolment – 45%. The proportion of girls steadily increased over the years with remarkable progress seen in the period when girls' education became a focus of government's policy from 1991 with the launching of the Girls Attainment in Basic Literacy and Education (GABLE) program funded by United States Agency for International Development (USAID). During this period, the proportion of girls increased to 48% of the primary school enrolments in 1993–94 only to decrease by one percentage point in 1994 when FPE was introduced. The decrease was due to the fact that many more older boys took advantage of the FPE and enrolled in school as opposed to older girls. Girls' enrolments picked up again after FPE. By 2005, nearly 50% of the primary school enrolments were girls and by 2006 there were more girls enrolled in primary schools, which is reflective of the proportion by sex of the school-age population.

Secondary Education

Secondary education begins after the 8-year primary education cycle, and consists of a junior and senior cycle. The junior cycle consists of the first 2 years of secondary education after which students sit for the Junior Certificate of Education (JCE). The senior secondary education also consists of 2 years, after which students sit for the Malawi School Certificate of Education (MSCE). The MSCE opens a variety of opportunities in terms of employment and further education and training for those who pass this examination. The school census survey of 2005 indicated that there are 978 secondary schools, which enrol 183 854 students (about 17% of the age cohort), with girls comprising 43% of the secondary school enrolment. The secondary school education is offered mainly through four types of schools, namely: conventional secondary schools (CSSs), community day secondary schools (CDSSs), grant-aided secondary schools, and private secondary schools. CSSs are government-supported schools and are the most privileged with regard to educational infrastructure and quality of teaching staff. There are 95 CSSs enrolling 41 412 students, 41% of whom are girls. The CSSs enrol 23% of the secondary school population.

CDSSs, previously known as distance education centers (DECs), are also government schools established with community assistance and they are the most disadvantaged. There are 553 CDSSs with an enrolment of 84 351 students, 40% of whom are girls. The CDSS enrol 46% of the students at the secondary level, which is 66% of the students in the government-run schools. The third group of schools is grant-aided schools. These schools are owned

by nonprofit mostly Church organizations but are also supported by the government and are of similar quality as CSSs. There are 55 grant-aided schools enrolling 15 382 students, 49% of whom are girls. The students in the grant-aided schools make about 8% of the secondary school enrolment. The fourth category is that of private schools managed by individual entrepreneurs with no subsidy from government. Majority of these private schools are comparable to CDSSs from the viewpoint of the available teaching/learning resources.

There are 259 registered private secondary schools enrolling about 39 887 students, of whom 47% are girls. Students in the registered private schools make up 22% of secondary school enrolment. No accurate statistics are available on the number of students attending unregistered private secondary schools.

Access and Equity in Secondary Education

Expanding access to primary education has traditionally been a primary concern of the government of Malawi since 1994. This emphasis has resulted, however, in a lower attention to secondary education. However, the increased enrolment and retention at the primary level inevitably increases demand for the next levels. Accordingly, the government policy gives increased importance to raising the enrolment in secondary education from 17% in 2005 with 43% girls to 30% by 2012, with 50% being girls, as stipulated in the PIF. This would include an increased role for the private sector and community involvement in the provision of secondary education.

The government policy also makes provision for the promotion and strengthening of secondary education programs involving CDSSs, which provide secondary education to the neediest segment of the secondary school age group, and continuing education for the unqualified teachers who staff these schools. Furthermore, although the proportion of girls in secondary education has increased in recent years and some policies and actions to promote girl's education in secondary have been put in place, there is a need to examine more deeply the issues related to further expanding access for girls and improving their retention in the schools.

Quality of Secondary Education

In addition to the problem of low access, the quality of secondary education provided is poor, especially in CDSSs. Examination results taken as one of the standard measurements of quality reveal that the overall students' performance is poor. In 2006, only 29.98% of the students who sat for the MSCE passed the examination. This low quality of the secondary education provided is largely attributed to the inadequate levels of qualified teachers, insufficient teaching and learning materials, shortage of

teaching facilities, and deficient school management and supervision.

There are an estimated 8975 teachers (1723 or 19% female) in the secondary school system. About 72% of these teachers are not qualified for secondary school teaching, adversely affecting the quality of education provided. In most CSSs, the curriculum is delivered by qualified teachers, but in the CDSSs, the great majority (86%) of the teachers is academically and professionally underqualified. The conversion of distance education centers to CDSS in 1998 increased the need for secondary teachers as students are taught face to face. Some primary teachers have been reassigned to teach at CDSSs. These teachers are considered untrained or unqualified to teach at secondary schools until they complete a secondary-teacher-training program. The challenge for the Ministry is increasing the number of qualified teachers graduating from secondary teacher programs as well as upgrading the qualifications of the underqualified teachers. In addition, strategies for addressing these challenges need to be reviewed.

The inadequate provision of teaching and learning materials also negatively impacts on the education provided. In line with government policy of supplying schools with an initial stock of books, textbooks for form IV students were provided in 2004 to secondary schools that did not have the books. Textbooks for form III students were supplied in 2002 to some schools. However, most CDSSs are critically short of or lacking textbooks for forms I, II, and III, which make up over 50% of the secondary school enrolment in government-run secondary schools. Once an initial stock of textbooks is provided, availability of textbooks is sustained through the schools Textbook Revolving Fund (TRF). Schools retain MWK 250 of the school fees per student each year toward the TRF, which each school maintains to partially finance their school needs.

Similarly, the lack of sufficient number of classrooms, science-teaching facilities, and libraries, principally at the CDSSs, undermines the quality of teaching. In general, the condition of classrooms and science teaching and learning facilities (if at all they exist) in CDSSs does not provide conducive environment for teaching and learning to take place and most schools lack libraries and facilities for teaching science.

Technical and Vocational Education

In the face of serious unemployment and especially rapidly increasing numbers of unemployed youth, the government of Malawi initiated the reformation in 1994 of its technical education and vocational training policies (MOEST, 1994). Emphasis was to be placed on the preparation of the trainees for employment in the informal sector, especially by incorporating entrepreneurship

development. In 1998, the government launched the Technical Entrepreneurial Vocational Education Policy. The main objective of the new policy was to enhance the level of productivity in both the formal and informal sectors so as to contribute effectively toward poverty reduction. The new training system was to be very broad-based and no longer laying emphasis on formal educational background as a requirement for training.

As part of these changes, the Technical Entrepreneurial, Vocational Education and Training Act (TEVET Act, 1999) was enacted and the Technical, Entrepreneurial and Vocational Education and Entrepreneurship Training Authority (TEVETA) was created. TEVETA is an autonomous body that aims to regulate and coordinate the provision of technical education, vocational and entrepreneurship training in Malawi.

There are four different kinds of training providers for technical and vocational education (TVE): (1) technical colleges which fall under the Directorate of Technical Vocational Education and Training (DTVET), (2) community-based training centers, (3) church-based training centers, and (4) private commercial training providers, and there is the traditional apprenticeship as well.

The DTVET currently operates seven technical colleges offering formal training in some 22 trades in the fields of building/construction, engineering, horticulture, and printing.

Distance and Continuing Education

The Malawi College of Distance Education (MCDE) was instituted in 1965 under the name of Malawi Correspondence College which in 1987 was changed to MCDE. The idea of establishing MCDE was to meet the increasing social demand for secondary education.

Ever since secondary education was introduced in 1940, only a small fraction of primary school leavers has been able to continue with secondary education. With the attainment of independence, there was a great need for education in rural areas where the vast majority of the people lives. The shortage of resources, both in manpower and financial terms, caused the government to find alternative methods of providing education. MCDE was therefore established to increase accessibility to secondary education; that is, distance education. As described under secondary education, the MCDE centers were turned into CDSSs.

MCDE was also introduced to cater to secondary education needs of those who could not fit into conventional secondary education through its night secondary schools, for example, adults who had missed the normal opportunity to complete certain levels of education. Currently, MCDE remains with its night secondary schools,

correspondence students without face-to-face tutorial assistance and teacher-upgrading programs.

Special Education

This represents the specialized educational services delivery offered to children and adults who are unable to cope with the regular school/class organization and methods. The MOEST has developed a draft policy on special needs education and has plans to develop a national institute for special needs education to replace the only dedicated institute to special needs education since independence which has been turned into a private university by its proprietor, the Roman Catholic Church. The aim is to provide adequate education for all categories of children and adults who require special education services as well as to provide a diversified and appropriate curriculum for each category of disability.

Nonformal Education and Adult Literacy

Adult literacy and nonformal education programs in Malawi are implemented by several ministries. The main ministry that implements adult literacy programs is the Ministry of Women and Child Development. Other ministries include the Ministry of Youth Development and Sports (for nonformal education) and the Ministry of Education which is implementing a complementary basic education program targeting children who drop out of school and the overaged. Other ministries that are involved in one way or another in the implementation of adult literacy and nonformal education programs are the Ministry of Agriculture and Food Security, Ministry of Labour and Social Development, and the Ministry of Health. There are a number of nongovernmental organizations (NGOs) that are also actively involved in the implementation of adult Literacy and nonformal education programs.

The country's concerted efforts to fight illiteracy stretches back to the colonial period. However, the major initiative in the country's overall strategy to combat illiteracy was undertaken between 1981 and 1985. During this period, a functional adult literacy program was launched on a pilot basis, and in this program literacy was perceived as a method of providing illiterate adults aged 15 and above learning opportunities which they missed out in their youth. The idea was that this would enable them access information on health, nutrition, and agriculture and thus improve the standard of living. The pilot phase culminated in the launch of the National Adult Literacy Programme (NALP) in 1986, which is coordinated by the National Center for Adult Literacy and Education (NACLAE).

A recent development in the adult literacy education sector in the country was the launch of the Sustainable

Social and Economic Empowerment Programme (SSEEP) in 2003. The overall objective of the SSEEP, piloted in 12 districts across the country, is to promote the Regenerated Freirean Literacy through the Empowering Community Techniques (REFLECT) approach, which has been championed and popularized by several NGOs notably Action Aid. This approach encourages and enables participants to critically assess their lives, take control of their futures, enhance their literacy skills, generate a written vocabulary, which is relevant to their own community or situation, recognize and build upon their knowledge, and mobilize for individual and collective actions.

It is estimated that there are over 8000 adult literacy classes with an average of 25 learners per class operating across the country annually since the turn of the 1990s. This estimate includes literacy programs provided by other service providers besides the NALP such as NGOs, Faith-Based Organizations (FBOs), Community-Based Organizations (CBOs), and even the private sector. Classes run entirely by the NALP are estimated at 4400 countrywide annually. Some notable nonstate actors involved in the provision of adult literacy programs include Action Aid, World Vision, Oxfam, and the Presbyterian Church of Central Africa (CCAP). However, despite the apparent impressive coverage and a series of interventions stretching back to the colonial era, the problem of illiteracy remains intractable in the country.

The overall illiteracy rate is currently estimated at 42%, but when disaggregated in terms of gender more women than men are illiterate. The illiteracy rates for women and men are estimated at 76% and 23%, respectively, representing an illiteracy ratio of 3:1. The paradox, however, in Malawi is that illiteracy has been decreasing over the years but only in percentage terms. It has been steadily worsening in absolute terms. It is estimated that illiteracy stood at about 87.6% in 1966, 77.9% in 1977, 55% in 1987, and at about 40% following the 1998 Population and Housing Census (NSO, 1998). The number of illiterate adults was projected at 1 976 218 in 1977, 3 848 414 in 1987, and at about 4.6 million during the 1998 Population and Housing Census. The statistics for 2005 indicated that illiteracy in the country had dropped from 90% in 1964 to 37.2%.

The goal of the NALP at its launch was to reach out to at least 2 million of the 4.6 million illiterate adults by the year 2000, but by 2005, the program had only reached about 730 000 learners. These statistics clearly underlie the magnitude of failure of the set of interventions and programs that have hitherto been carried out to fight illiteracy in the country.

The Teaching Profession

There has been an improvement in teacher training and recruitment since 2000. According to Education Management Information System (EMIS), 2007, the teacher-pupil

ratio is 1:78, but the qualified teacher–pupil ratio is 1:88. This is an improvement from the teacher–pupil ratio of 1:118 in 2000 and qualified teacher–pupil ratio of 1:138 in the same year. The country is, however, short of 34 203 and 60 203 primary school teachers to achieve teacher–pupil ratio of 1:60 and 1:40, respectively by 2015. Annually, the country needs to recruit 5200 teachers on average and train 5244 teachers. The government has since 2007 introduced a new teacher training program (the 1+1 Teacher Training Programme) replacing the previous Malawi In-service Integrated Teacher Education Programme (MIITEP) in order to address teacher supply and teacher quality. In terms of gender, the country is short of at least 10 000 female primary school teachers now and needs to recruit around 30 000 more teachers by 2015 to close the gender gap between male and female teachers who are currently 26 893 and 16 304, respectively. There is a need to train and recruit between 10 875 and 15 500 specialist teachers to cater to children with special needs and an expanding special needs sector.

Primary school teachers are trained in four public teacher training colleges. Secondary school teachers are trained at public institutions which include University of Malawi (Chancellor College), Mzuzu University, and Domasi College of Education. Some private universities and colleges have recently been opened up which are also training teachers, such as the University of Livingstonia, African Bible College, the Catholic University, and DAPP Teachers Training College. Admission to these institutions is based on individual academic qualifications.

There is generally a critical shortage of teachers' houses, especially in rural areas which has been cited in some studies as a contributing factor to the inadequate numbers of teachers in the rural areas as majority of teachers, especially female teachers, migrate to urban areas.

Higher Education

There are two public universities in Malawi. The first is the University of Malawi (UNIMA) established in October 1964. The University of Malawi operates five constituent colleges: Chancellor College (for general degrees, education, public administration, and law), the Polytechnic (accountancy, engineering, and journalism), Bunda College (agriculture), College of Medicine, and Kamuzu College of Nursing. The second public university, Mzuzu University, opened its doors in 1998. Currently, there are plans for a third national university which will focus on science and technology.

In addition, in recent years, a number of private universities have been established by churches.

It is clear however, that Malawi has under-invested in the education sector overall, and, more particularly, in tertiary education. The university does not have sufficient

capacity to satisfy the needs of a rapidly growing population of students thirsty for a university education. The growth in absolute student enrolment has been quite modest – growing from a student intake of 90 in 1965 to 5000 in 2004–05 academic year.

Administrative and Supervisory Structure

The MOEST is managed through central, divisional (6), and education district (34) structures. Primary schools are further organized through a zonal system (315 zones) with each zone served by a teachers' development center (TDC). A similar cluster system has been developed for the secondary subsector, with approximately 74 clusters.

Community involvement and partnership among stakeholders are becoming accepted practices in many communities in Malawi, but the bulk of the partnership appears largely limited to efforts of parent–teacher associations (PTAs). Other groups and organizations in the communities are yet to identify fully with the school programs.

Educational Finance

The national budget allocation to MOEST has hovered around 20% in recent years. It should, however, be noted that this does not include education programs implemented by other ministries such as early childhood development and adult literacy, and out-of-school youth programs which are under the Ministry of Women and Child Development and the Ministry of Youth, Sports and Culture, respectively.

The major constraints and challenges of financing are:

- *Mobilizing sufficient funding for education subsectors.* The government should devise a means of mobilizing sufficient funds for the education sector at all levels. This means that all the stakeholders in the education industry should live up to their responsibility of making available sufficient funds for the running of the educational sector in Malawi. These stakeholders include the state, local government/assemblies, the private sector, members of the National Assembly, the civil society, and development partners.
- *Reducing hidden costs to parents of the less privileged.* Although primary education is free, there are some hidden costs that poor households encounter which outweigh the opportunity costs of sending children to school. Such hidden costs include school uniforms/clothes, and learning materials, for example pens/pencils, meals/snacks. A reduction in the hidden costs will relieve the heavy burden on parents of low-income groups. The government has a policy on noncompulsory uniform and has also introduced school feeding programs in some schools.
- *Expanding and strengthening partnerships.* Financing education appears to have become a heavy burden on

government and thus requires participation from other stakeholders. Hence, there is need for partnerships among stakeholders in the education sector, not only with international development partners, but also with private sector, nongovernment agencies, as well as other philanthropic organizations and individuals.

- *Prioritizing needs for optimizing scarce resources.* The current challenge in the education sector is the need for prioritization of needs because the available resources appear grossly inadequate. Currently, there are many compelling needs as far as costing and funding of the education subsector in the country is concerned. These include classroom construction, renovation, furniture provision, teachers' salaries, capacity building, special programs such as HIV and AIDS, problem of enrolment, and enhancing the quality of education delivery at all levels. Given these circumstances, efforts should be made to put these needs in order of their importance and treated as such to ensure optimum use of scarce resources. In this regard, it is required that school management determines which area of expenditure should come before the other. Resource allocation in the various subsectors of the education should also be based on simulation modeling, whereby allocation to each subsector is specified. This should be done in such a way that when all the subsectors are put together it would produce the best result in terms of costing and financing of education in Malawi.

Malta is a small island state, the smallest in the European Union (EU). A total landmass of 316 km² and a population of 405 000 render Malta one of the most densely populated countries (1282 km⁻²). The Islands have an aging population currently averaging 38.5 years, a birth rate of 2.6 per mother, while longevity is 80 years for females, 77 for males. The literacy rate is 92.8% with the majority of illiterates falling in the 60+ age group.

The Maltese Islands lie at the crossroads of the Mediterranean: 100 km south of Italy, 280 km off the North African coast, and almost equidistant from Spain and Greece. Their extensive, sheltered, and deep natural harbors have attracted the dominant seafaring powers in the region. Romans and Carthaginians fought over Malta in the Punic Wars. So did the Byzantines and the Arabs in the Middle Ages, the Christian Knights of St. John and the Muslim Turks in the sixteenth century, the British and the French in the nineteenth century, and the Allies versus the Axis during World War II. Malta's best-kept secret is the origin of the numerous Neolithic Temples dating from 5500 BC and acknowledged as the oldest freestanding buildings in the world. The vast majority of Maltese are Roman Catholics, their predecessors having been converted to Christianity by St. Paul in AD 60. The national language is Maltese, the only Semitic language written in Roman script, while English is the second official language. Many Maltese also speak Italian.

Malta is a parliamentary democracy, gaining independence from Britain in 1964 and becoming a republic in 1974. The Islands joined the EU in 2004, but remain an active member of the British Commonwealth. The Nationalist Party (Christian Democrats) has been in power since 1987, except for the period 1996–98 when the Labour Party (Social Democrats) enjoyed a parliamentary majority. In tune with its small-island-state characteristics, social, cultural, financial, environmental, and religious issues in Malta tend to become highly contentious, often divisive, and invariably politicized, even though the two main political parties espouse similar national policies.

Local economists disagree whether Malta prospers most in time of peace or in time of war. Economic data show, however, that the national economy has flourished since independence when the Maltese embarked on an industrialization drive to divert reliance on British military expenditure to locally generated incomes. Up to the 1990s manufacturing enterprises concentrated on textiles and light industries especially the manufacture of electronic components, while shipbuilding and ship repairing became

a financial hemorrhage. Tourism and construction have evolved as the mainstays of the Maltese economy. Currently, financial services, international banking, e-commerce, and information and communication technology (ICT) make strong inroads as new major employers and important foreign currency earners. In mid-2007, Malta's gross domestic product (GDP) stood at €1504.6 million in real terms, gross national income (GNI) at market prices was €1332.3 million, with unemployment at 7.12%.

History of Education

The first mention of a public school emerges *c.* 1460. The school for boys was co-financed by the Cathedral and the Municipality of Mdina, then the capital city. Girls were tutored in private homes.

On arrival in Malta in 1530, the Knights of St. John set up a school for their young recruits. Members of a naval power, they were taught mathematics, navigation, cartography, and architecture; and in line with their primary vocation as knights hospitalers; medicine and surgery. In 1592, the Knights commissioned the Jesuits to open the Collegium Melitense, which became a public university in 1769, the precursor of the present University of Malta.

The education provided at the time, as in the early years of British rule, catered to the elite. The British launched public-funded education for the masses following the 1838 Royal Commission Report, which castigated the colonial administration in Malta for neglecting to educate the common people. The criticism served its purpose and by 1900 every town and most villages had their own primary school administered by the government's Education Department. Concurrently, the University's Lyceum provided secondary education for boys. In the mid-1920s secondary education for some 5% of the age cohort of both sexes became the responsibility of the Education Department. During the same period, private education evolved through church schools and private colleges. Educational policy in Malta followed closely the UK's, a trend that persists today.

Compulsory school attendance became law in 1924, but could not be enforced until the end of World War II. An extensive schools' repair and building program rendered full-day free primary and secondary schooling possible in the mid-1950s. Free University education was introduced in 1971. In 1974, schooling became compulsory from age 5–16.

Today, two-thirds of the Islands' student population attends state schools; the rest go to church or independent schools (see Table 1). The number of students in the nonstate sector shot up in the mid-1970s when a well-intentioned but badly planned and rashly executed switch from grammar- to comprehensive-type education in the state secondary sector, prompted many parents to transfer their children to church schools. State education still suffers from the shockwaves. Several social engineering devices were tried to stem the flow. First, was the forced abolition of church school fees to render them financially nonviable. This measure had the direct opposite of the intended result since it made the enrolment into church schools less costly, even when parents made voluntary donations. Second, was the establishment of state-run Junior Lyceums, identical to the old grammar schools. The second move, together with the demand for entry into church schools, which far exceeded the supply, led to two highly competitive eleven-plus-type secondary-school entrance examinations. Preparation for these examinations, including extensive private tuition, thwarted the aims of primary education.

All state education from kindergarten to university is free; currently the State heavily subsidizes church schools, while independent schools (very much a minority) charge fees with parents receiving tax rebates. Of the

€2 498 463 000 estimates for 2008, the government devoted 10.88% to education.

In 1978, student stipends were introduced to spur youngsters to tertiary education with the argument that human capital is Malta's main natural resource and it behooves the state to nurture and develop it. Local pundits doubt whether Malta's educational budget affords to devote €21 million, or 7.7% to this extraordinary expenditure, and yet no party in government dares remove it.

Structure of the Educational System

The Minister of Education is responsible also for Culture, Youth and Sports. Her remit reflects the government's determination to transform the Islands' into a hi-tech servicing community with education as the foundation for future economic and social development. Figure 1 illustrates the responsibilities of the education directorates.

A major structural reorganization in the delivery and monitoring of the educational services occurred in 2007 when an Amendment to the Education Act transformed the Education Division into two new directorates. The Directorate for Educational Services includes schools as the service providers; it also acts as the resources provider supplying schools with their human and material

requirements. The Directorate for Quality and Standards in Education monitors the delivery of educational services to ensure best practice. Each directorate is headed by a director general answerable to the permanent secretary and the minister. An important provision in the Amendment allows both Directorates much greater freedom of operation than the old Division enjoyed.

Education Paths

Figure 2 represents the educational paths that Maltese students can follow.

Day Care Centers and Nurseries

The state does not offer services at this level; they are provided by church organizations and private entities. The government does ensure that such services, as well as kindergartens, comply with its guidelines.

Kindergartens

Parents send their children to either free-of-charge state kindergartens or fee-paying ones run by church and independent schools. All three sectors provide good services based on structured play and social development, and the parents' choice depends more on convenience, or the belief that what one pays for is bound to be superior to what is free, than on an impartial evaluation of pedagogical worth. The quality should improve further in the near future when early childhood education teachers will have to hold a Bachelor's degree in the area.

Almost 93% of 3- and 4-year olds attend kindergartens. As a result, grandparents play a crucial role in the upbringing of kindergarten- and primary-aged children where both parents work. Primary schools and kindergartens close at 2.30 p.m. with many grandparents minding the children until the parents return home. Problems arise when elderly grandparents babysit two or three children, or conversely when younger, working grandparents cannot provide the service. It is only a matter of time before the state,

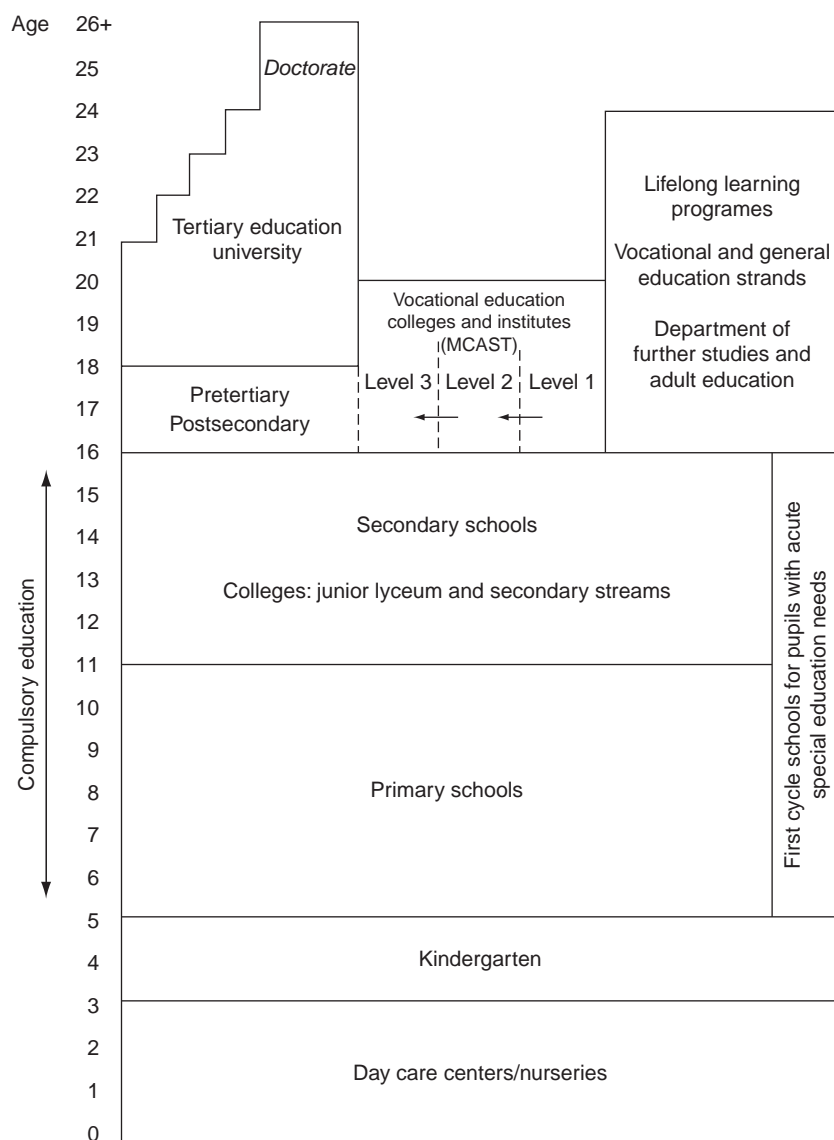

Figure 2 The Maltese mainstream education system. From: Ministry of Education, Culture, Youth and Sports (2008). *Malta: A Guide to Education and Vocational Training*. Floriana, Malta: Government of Malta.

in addition to campaigns to increase the female workforce, will have to offer extended after-school services.

special-needs students in primary and secondary schools, and retains this extremely expensive commitment as an integral part of its inclusive-society policies.

Special Education

The Maltese education system provides robust provisions to integrate the maximum number of students with special needs into the mainstream of the educational process. As a result, only a small fraction of students attend special-education institutions and that too, only when the children are at risk in normal schools. An ambitious support system provides one-to-one facilitators to students needing help to integrate with their intellectually or physically stronger classmates in the mainstream. The state provides the facilitator service free of charge to all

Primary Schools

Children aged 5–11 attend primary schools. The scholastic year starts in mid-September and ends in June, comprising 957 hours of schooling. Primary state and independent schools are coeducational, as are some primary church schools. All state and church secondary schools are single-sex institutions.

All schools in Malta are expected to conform to the National Minimum Curriculum established in 1989, revised

in 1999, renewed into the National Curriculum Framework (NCF) in 2006, periodic revisions since then. The NCF is a far-reaching work in which local experts in the theory and practice of education expound the goals and quality of education Maltese students deserve.

State education officers try to ensure that schools follow the NCF. In the case of primary schools they face a major obstacle. The first 3 years of state primary schooling are generally tranquil for pupils, their parents, and the teachers. The learning is experiential with emphasis on literacy in Maltese and English, numeracy, general knowledge, physical and social development, with prominence given to self-expression through various media. The learning is broad and the pace moderate. Pupils move from one level to the next on the basis of continuous assessment. The situation changes drastically in year 4 when the race toward the secondary school entrance examinations begins. Admission to the state's grammar-type Junior Lyceums and the church's colleges is highly selective, greatly sought after, and consequently exceedingly competitive.

Students wishing to attend independent schools pay for the privilege. Those seeking a place in prestigious state or church secondary schools endure the ordeal of preparing for the 11-plus-type Junior Lyceum Entrance Examination (JLEE) in the case of state schools, or the Common Entrance Examination (CEE) for entry into Church schools. Practically all the children finishing primary school sit for both, although efforts are under way to half the ordeal by amalgamating the two into one national examination. Unfortunately, these examinations condition all pedagogical procedures in the last 3 years of primary school. Pupils are subjected to one continuous swotting exercise toward successful results: the higher the marks, the better the chances of entry into the desired school. In the process the aims of the NCF are seriously undermined.

Pupils attending those church and independent schools that offer both primary and secondary education are more fortunate: they simply proceed from one level to the next without the need to sit for examinations. The demand for places in these church schools is so great that pupils are admitted by a public draw.

Secondary Schools

Successful students in either the JLEE or the CEE proceed to a state Junior Lyceum or a church secondary school as the case may be. The rest either opt for a fee-paying independent school, or attend a tuition-free state area secondary school. Parents and students alike label the latter failure schools. This label is unjustified, because a high number of students will have missed entry into the more sought-after schools by a few percentage points in one of five subjects. With guidance, such students have proceeded to

Matriculation and university studies in tandem with their Junior Lyceum and church schools' counterparts.

Most educators and some parents condemn the transfer of pupils from primary to secondary schools through such a competitive and stress-generating procedure. However, even if parents complain about the enormous tension that the JLEE and the CEE generate, the majority favor this differentiation and selection process. They regard the entrance examinations as the fairest and best chance their children have of attending the better secondary schools. Community pressure has prevented efforts to abolish the examinations.

Another attempt to lessen the impact of the JLEE is currently being tried in state schools, and its potential success is heightened by the fact that the model already exists in several church and independent schools. Students in these schools are admitted at kindergarten or primary levels and proceed to the secondary level of the same or an associated school without having to swot and undergo the trauma of the eleven-plus. This author researched the procedures and their outcome, and proposed the adoption of this system in state schools. The Minister and his advisors saw the potential of the recommendations and expanded them significantly to establish ten state colleges and their networks.

Each college incorporates a Junior Lyceum, an area secondary school, and several feeder primary schools. Students from the Junior Lyceum and the area secondary school merge and are set in classes according to their abilities in the various school subjects. The pupils' progress from the feeder Primary schools is evaluated on a continuous assessment package which, so far, includes a modified form of the JLEE. When the JLEE is sufficiently transformed, primary school pupils will be able to proceed to their college's secondary level without differentiation. The college concept goes beyond the academic sphere since the network's administration, resources, and finances are organized into one management structure regulated by the college principal and the heads of schools within the network. They are allowed a high degree of autonomy, which in the past, only nonstate schools enjoyed.

The college networks are still at their initial stage. Should they succeed in building their ethos and academic reputation sufficiently to defuse the negative impact of the JLEE, or abolish it completely, the sound educational aims of the NCF can come to fruition. Senior state education officials hope that church schools will join the state college networks. This will not occur before church schools feel convinced that they will retain their autonomy, an expectation that in many ways counteracts the principles of networks.

The secondary school program lasts 5 years, at the end of which students sit for the Secondary Education Certificate (SEC) enabling them to proceed to postsecondary education.

Postsecondary/Sixth-Form Colleges

In 2007, five institutions provided a 2-year postsecondary course for 6200 students, 3200 of them attending the University's Junior College. The course leads to the Malta Matriculation Certificate (Matsec) and entry to university. During these 2 years, students replicate their stress-ridden experiences prior to secondary school entry, this time in efforts to join their preferred university course. Although the *numerus clausus*, or restricted entry number, into certain courses no longer applies, most University of Malta courses have entry requirements far more demanding than their counterparts in renowned institutions worldwide.

The government aims to increase the number of students attending postsecondary and tertiary education to the higher percentages prevalent in the EU and provides students with monetary incentives to continue studying beyond secondary education. As a result, all postsecondary and undergraduate education in Malta is tuition free. In addition, students are paid monthly stipends in order not to become a financial burden on their families for the duration of their studies. Furthermore, the state has launched schemes of postgraduate scholarships, mainly in science and technology areas, tenable in Malta and overseas.

Economic commentators claim that such state expenditure is unsustainable. Yet, politicians on both sides of the House of Representatives argue that the expenditure is a justified investment in Malta's human capital. Enrolment figures bear out this argument since the number of university students shot up from 1447 in 1987 to 10 000, 20 years later.

Malta College of Arts, Science and Technology

Malta College of Arts, Science and Technology (MCAST) was revived in 2001 to provide pretertiary vocational education. The institution is an amalgamation of pre-existing vocational schools, renamed institutes, brought together to offer coordinated, harmonized, and improved educational services. Its institutes are: agribusiness, art and design, building and construction engineering, business and commerce, community services, electronic and electronics engineering, information and communication technology, maritime, mechanical engineering, and the MCAST Gozo Centre. The Institute of Tourism Studies, with 900 students is expected to join the MCAST structure in the near future.

The institutes provide tuition to 6000 full-time equivalent students, with ICT and business and commerce

being the most popular. The academic standing of courses varies from sixth-form equivalents to almost first-degree level. The government is investing heavily in the institution and plans that in due course MCAST will become Malta's second university. This should come about through the initiatives of the National Council for Tertiary Education which coordinates the work of MCAST and the University in line with the Islands' social and economic aspirations.

The University of Malta

Malta's university prides itself as the oldest in the British Commonwealth outside the UK. From a Jesuit College in 1592 with the authority to confer degrees, it became a public university in 1769. Arts (including mathematics and science), law, medicine and surgery, and theology formed the foundation faculties; science, dentistry, and architecture and civil engineering were established in the mid-twentieth century; education, engineering, and economics, management, and accountancy were upgraded from polytechnic departments to the University of Malta (UoM) faculties in the late 1970s. The Faculty of Information and Communication Technology is a 2007 creation. In 1999, the University opened its Link Campus in Rome, Italy.

The University also houses 27 institutes and centers, with the Institute of Health Care being the largest. Institutes and centers complement the faculties' work mainly through cross-subject, interfaculty teaching and research. The University's entities, with the Senate's approval, offer certificate, diploma, bachelor, master, and doctoral-level courses, which follow European Education Area directives and the Bologna Agreement of study-units and academic-credits structures. In October 2007, the University had 10 000 full-time equivalent students, of which 750 were foreigners.

A recent phenomenon has been the opening in Malta of numerous branches of EU, mainly British, universities with students enrolling on a fee-paying, part-time basis. Their chief attraction lies in offering subjects which either are unavailable at the UoM or whose entry requirements are not as demanding.

Justifiably proud of its history and traditions, the UoM occasionally finds it hard to shed past practices. Most course content, teaching, and research are at the cutting edge, but administrative and managerial procedures lag behind. In 2006, Council, the University's highest governing body, appointed a new rector with the primary remit to restructure and upgrade the institution's administrative and financial management. Currently, the University strives to enhance quality assurance, minimize bureaucracy, and maximize the efficiency of its human and material resources without sacrificing academic standards.

It endeavors to become less dependent on public funding by generating income through specialized services. The UoM aspires to become administratively and financially autonomous from the government to the same high degree that it enjoys in academic freedom. One augurs that in the process the university will not mutate into a super-efficient bureaucracy driving a soulless institution.

Adult and Continuing Education

The Maltese educational system provides services to encourage and support learning beyond the normal schooling provisions. It offers courses in self-improvement, hobbies and leisure, traditional arts and crafts, as well as in drama and music. Some 600 senior citizens attend the University of the Third Age (U3A) each year. A particularly successful venture is the Employment Training Corporation (ETC) which, besides serving as the national employment agency, runs worker retraining courses, sometimes on its own, more often in collaboration with the University, MCAST, and local industry.

Teacher Education

State-employed teachers began to receive rudimentary forms of teacher training in the nineteenth century. Proper teacher education began in 1946 with the opening of two residential colleges, one for males, the other for females. The initial 1-year full-time course was eventually extended to 2-, 3-, and 4-year durations. Both colleges were closely linked to, and externally examined by, UK colleges associated with the Institute of Education at the University of London. By the mid-1970s, the colleges were reorganized first as an amalgamated Malta College of Education, and later as the Department of Educational Studies at the local polytechnic with sufficient academic clout to offer a bachelor of arts (BA) in Education.

In 1978, the Department evolved into the Faculty of Education at the University of Malta, with this author as its founder Dean. It now offers qualifications ranging from undergraduate diplomas to PhDs with external examiners from European universities forming part of its assessment procedures. The Faculty's contribution to education in Malta has been substantial: the vast majority of teachers hold a bachelor of education (BEd) (Hons) or a Postgraduate Certificate in Education (PGCE) with specializations in either early childhood, or primary or secondary education. Heads of schools must hold the Faculty's Postgraduate Diploma in Education (Administration and Management). The Faculty also offers degree courses in psychology and youth studies. The academic staff has developed a strong research and publications profile

with engagements in national and international projects. Observers argue, with some justification, that in its quest for academic respectability, the Faculty has neglected somewhat the practical pedagogical formation of its student-teachers. The current Dean, the first female Dean at UoM, plans to redress the balance.

The Education Act of 1988 recognized teachers as professionals placing them on the same salary scale as medical doctors and lawyers in public service. In reality, however, they have yet to gain the social status and prestige of traditional professions. The 2006 Amendment to the Education Act established a Teachers' Council with the aim of promoting teachers' work, monitoring their output, and in the process issuing teacher's warrants in lieu of the Ministry. The Malta Union of Teachers (MUT) ardently supports the Council and has a strong representation on it. The MUT, established in 1919 as Malta's first trade union, is powerful and influences government policy in education, mostly with positive results.

Conclusion

The demands made by the extensive education services in Malta constitute a heavy burden on the Islands' limited human and financial resources. In spite of this, the state is committed to provide them, even when the community asks for more. All the indicators show that the state's commitment to and investment in educational development are bearing fruit. One example: the rundown of the British military base in the 1950s and 1960s caused widespread unemployment and hardships with mass emigration being the only solution. In contrast, Malta is managing remarkably well the current transformation from a manufacturing, labor-intensive economy to a striving service and e-commerce one.

Improvements are still necessary. The educational authorities, having overcome the problem of quantity, should now strive to improve the quality, especially in the primary and secondary sectors. At these levels too much attention is devoted to examinations and certification, and not enough to experiential, hands-on, problem-solving, independent learning. Even at the pretertiary and tertiary level, people still need to appreciate the fact that due to globalization the Maltese economy is changing radically. Too many parents, and school career counselors, still push students toward the traditional professions, ignoring the far wider, and more rewarding, career opportunities in such new areas as financial services, special-interest tourism, and ICT. Many Maltese have still to grasp the fact that the right measure of a liberal education combined with new and refined forms of vocational training can improve their quality of life by relying more on their brains, less on their brawn.

General Background

Located between Russia and China, Mongolia is the world's second-largest landlocked and least densely populated country in the world. It spans a territory of 1565000 km², which is larger than the overall combined territory of Great Britain, France, Germany, and Italy. Mongolia's terrain is characterized by vast semidesert, grassy steppe, and mountains. Arable land constitutes less than 1% of the total area. The country is also well known for its extremely cold and dry continental climate.

In 2007, with a population of 2.6 million, the annual growth rate was about 1.4%. As of 2007, the median age is 23.7 years, and life expectancy is 64.52 years; about 33% and 75% of its people are under 14 and 35, respectively. Sixty-three percent of the population lives in cities, the rest live a seminomadic lifestyle.

Mongolia is a homogeneous nation populated mainly by Mongols, who consist of Khalkha and other groups, all distinguished primarily by dialects of the Mongol language. However, a small proportion (up to 5%) is represented by Kazakh and Tuvas. The official language is Mongolian.

The country is divided administratively into 21 *aimags* (provinces), including the capital city, Ulaanbaatar, which has independent administrative status. Further local subdivisions include *soums* (districts), and *bags* ((subdistricts). As of 2007, 1 million people or 38% of its population live in the capital city, which is growing rapidly.

The country uses a unicameral parliamentary system consisting of 76 seats and the president has a symbolic role.

The Human Development Report 2007 ranks Mongolia as 114th out of 177 countries, with its Human Development Index (HDI) at 0.700, and categorizes it as a Medium Human Development Country.

By the time the Mongolian nation came to the dramatic attention of the world in the early thirteenth century, it already had a long and trustworthy history. After declaration of the People's Government in 1921, the country followed Soviet leadership for nearly seven decades. In the period since 1991, Mongolia has been in the midst of transition, from a totalitarian regime with a centralized command economy, to a market-oriented economy. A new constitution was adopted in 1992.

Economic growth reached 8.4% in 2006, bringing Mongolia's gross domestic product (GDP) per capita to \$1037. The animal-husbandry sector continues to be the main source of income for 40% of the labor force, it

produces 21.7% of GDP, and grew by 14.4% in 2006; crop production increased by 63.4% the same year. Mongolia's export is heavily dependent on a few commodities (minerals, cashmere, and textiles) that constitute 80% of total exports and international market prices of which are highly volatile and unpredictable.

The second major contributor to the economy is the mining sector; it continues to benefit from high international gold and copper prices. The tertiary sector is dominated by wholesale and retail trade, as well as transport and communication.

Mongolia's relatively good education system during the socialist period included free and widespread access, good quality, impressive levels of attainment, a policy on nondiscrimination, and measures to deliver education services to the nomadic population through boarding schools. Mongolia claims one of the highest literacy rates (97.8%) in the world (the percentage of male literacy was 98.7% and female literacy was 99.2%). By the mid-twentieth century, literacy rates throughout Mongolia increased drastically with the shift from traditional Mongolian script to Cyrillic.

The national education system consists of a complex set of successive education programs, including formal schooling and a nonformal education (NFE) sector. Mongolia's Education Development Index (EDI) is 0.952 as of 2007. A recent Human Development Report (HDR) revealed that 80% of medical doctors, 70% of lawyers, and 73% of teachers in Mongolia are women.

Goals of the Education System

The Mongolian Constitution (1992) guarantees its people general education free of charge. The fundamental assumptions stated in the Education Law reflect the principle of equality in education: every citizen has equal rights to his or her education regardless of race, ethnicity, nationality, sex, religion, disability, social status, and economic condition. Furthermore, "education shall be humanistic and democratic, universally available and continuing." These provisions state that Mongolia must gear toward a public-education system grounded upon equality in educational opportunities.

The Education Law and sub-sector-specific laws, including the Pre-school Education Law, the Primary and Secondary Education Law, Vocational Education Law, and Higher Education Law, have been enacted. The recent amendments

(2006) to the Education Law of Mongolia provide a legal framework for school structural reform (from 10- to 12-year system); upgrading teachers' social status through the rationalized pay and incentive system and better protection of the rights of children.

The amendments require education settings to be free of discrimination and any kind of emotional, physical punishment and economic pressure on students; education curricula and contents to be gender sensitive. Furthermore, it obliges local governments and education authorities to be responsible for the provision of education for all children in their respective areas, and for state education budget allocations to be sensitive to geographic location and particular specifics of schools, and specific learning needs of children with disabilities. Primary and secondary education delivery through a nonformal, equivalency training program is to receive funding from the state.

As per the Education Sector Master Plan (2006–15), the objectives of the Mongolian education system are: to increase the preschool gross enrolment up to 99%, reduce disparities to provide quality education for students and also provide support to them to enjoy rights to study,

provide continuous educational services in conformity with study needs and the lives of students, and improve accessibility to nonformal and adult educational services.

The goal of these schools is to provide appropriate education for pupils with special abilities in certain fields. The strategic goals of preschool education are directed at improving both accessibility and quality – particularly for poor, rural/remote children, ethnic minority, and children with disabilities, as well as policy regulation and coordination on early childhood care and development (ECCD). Improving efforts of family and community involvement were noted as significant factors in accomplishing these goals, but specific ways to resolve or improve and how to apply family and community involvement, is not yet clear in government policy.

Structure and Operation of the Education System

The Mongolian education system consists of preschool education, primary education, secondary education, technical and vocational education and training, and higher education and a broad range of NFE activities devoted to the various target groups of the population.

The new structural reform of the education system moved from a 4-4-2 system to a 5-4-2 and then to a 6-3-3 in line with international practices. Beginning with the 2004–05 school year, schools began to serve 7-year olds, and from the 2008–09 school year, the school entry age is being reduced to 6.

Preschool and Early Childhood Care

Preschool education is not compulsory in Mongolia. As of 2007–08, there are 768 kindergartens (666 of them are public), with 130758 children nationwide (see **Table 1**). Only 54.1% of preschool-aged children are enrolled in kindergarten (was 30.0% in 2000). Of these, 41.8% are enrolled in formal kindergarten and another 12.3% in nonformal or alternative forms of preschool education delivery (shift classes, *ger* and mobile kindergartens, as well as mobile teachers). Herders' children count for only 15% of the total preschool population. Such disparities cause unequal development opportunities for youngsters and consequent effects on basic educational attainment at later stages. Private-sector participation is invited and the private-service coverage is planned to reach 10% of the total preschool children.

Primary (Elementary) and Secondary Education

General education in Mongolia is 12 years (6 years, primary; 3 years, lower secondary; and 3 years, upper secondary) which has started from the academic year 2008–09. Basic education (6+3) is compulsory and provided by the state free

of charge. Schools for the primary, lower-secondary, and upper-secondary levels, generally do not exist separately and are combined in one school campus. There are only 79 schools offering just primary education in Mongolia (mostly in remote rural areas).

In the 2007–08 scholastic year, in all, 537546 students were studying at 754 schools (public 597, private 152, and international 5) nationwide. The gross enrollment rate of children aged between 7 and 15 years is 95.1%. The dropout rate is claimed at below 2%, which reached its highest point, 8.8%, in 1992–93.

Lower-secondary education is the final stage of compulsory schooling and lasts 3 years (ages 12–15), followed by 3 years of upper-secondary education (ages 16–18). Graduates from grades 9 through 12 are eligible to enter technical and vocational training schools. After graduating, the upper-secondary school (not compulsory) students can enter higher education institutes. In the rural areas, children of nomads are often sent to the *soum* (county) or *aimag* (province) centers to attend boarding schools; they return home only during breaks and summer vacation. The primary school day normally contains about 5 h of tuition, and comprises around 200 school days per year.

Other Schooling Arrangements

Students with special needs: there exist countrywide five schools for students with severe physical or mental disabilities, all located in Ulaanbaatar. Officially, students with special needs are supposed to be integrated into regular schools. According to the National Policy on Inclusive Education approved by the Government in 2006, the goodwill of individual schools is required to systematically integrate students with special needs into schools. The more common forms of schooling for children who have special needs are home schooling by parents and, if private financial resources are available, private tutoring by teachers.

There also exist numerous classes at lower-and/or upper-secondary levels for students who are especially gifted. Majority are classes within a regular school, but in greater agglomerations, there also exist separate schools for gifted students. They provide additional courses in particular subjects for a fee that is retrieved from parents. The most popular subjects are the natural sciences. High-stakes entry exams are used to ensure selective admission.

Technical and Further Education

The vocational education and skills training has been one of the most neglected areas of education in Mongolia. After the initial transition shock in the first half of the 1990s, the number of students in technical and vocational education and training (TVET) sharply declined from 31000 in 1989 to 8000 in 1995. The total number of

students enrolled in technical and vocational schools was 29 906 by year 2008.

The TEVT is provided by professional training and production centers and private-sector participation is increasing. In addition, some branches of colleges and universities also provide TEVT. These schools offer secondary vocational education programs to train skilled workers and technicians.

Higher Education

Higher education in Mongolia is provided by universities, colleges, and institutes. Colleges offer mainly undergraduate programs, while universities focus more on research and graduate study. The higher education sector has expanded rapidly since 1990 mainly due to new private-sector players in the market. As of the 2008–09 academic year, there are 165 higher education institutions, including 48 state- and 117 private-run institutions as well as 6 branches of foreign institutions, and 74% of all higher education institutions are based in the capital city and only 49% are accredited. There are 142 411 students in higher educational institutions, of which 48 552 students study in private institutions. Public institutions of higher education are nonprofit organizations, while private institutions may be either nonprofit or for-profit.

Formerly, higher education institutions used to mainly offer undergraduate programs, leading to the award of a higher education diploma with the title of specialist. In 1992, a more Western model, consisting of BA, MA, and PhD degrees, was introduced. A student must complete a minimum of 120 credit hours to earn a bachelor's degree which requires 3–5 years of full-time study. Professional degrees in dentistry, pharmacy, and veterinary medicine require 5 years, and degrees in medicine are conferred after 6 years. The master's degree requires a total of at least 150 credit hours, which is awarded after 11/2–2 years of study beyond the bachelor's degree. The Doctor of Philosophy requires several years of advanced study beyond the master's degree, in addition to a dissertation and public defense. A total of not less than 210 credit hours is needed for doing a PhD. The doctor of science degree (similar to the German habilitation doctorate) is awarded as an advanced degree, requiring 21/2–3 years of study beyond the PhD.

Some colleges (nonuniversity higher education) offer vocational training, which lasts between 2 and 4 years, and leads to a higher education diploma. Women currently account for more than 63% of university students, with 65% of them earning master's degrees.

Adult and Nonformal Education

The NFE sector caters to two groups. The primary target group consists of those with no or limited formal schooling, that is, school-aged children and youth who are out of

school, as well as adults who never enrolled in or dropped out of schools through the Literacy and Equivalency Programme. The second target group is more broadly defined and includes literate adolescents and adults who take courses in life skills, (e.g., health, market economy, legal education, ecology, and small-business skills), vocational skills, creative skills, postliteracy programs for adults on life skills, income-generating activities, etc. The establishment of the National Non-formal and Distance Education Centre is a major milestone, a nationwide structure to deliver NFE with designated staff. The NFE learning centers – Enlightenment – play a crucial role in providing NFE service. As of 2008, 492 NFE facilitators and teachers worked in 352 NFE learning centers across the country, at least one in each *soum* or district.

The Teaching Profession

The advantage of the education system at all levels is that most of the teachers are professionally prepared in universities, higher schools, and colleges. Professionals who graduate from universities and colleges with a teacher's diploma have the rights to teach. In primary and secondary schools, 98.5% of teachers are professionals with the relevant educational qualification. There are 23897 teachers (7694 for primary, 10873 for lower secondary, and 5330 for upper secondary) working in all schools and 1451 teachers in TEVT. On average, the pupil–teacher ratio (PTR) in primary education in rural areas is 31:1 compared to 34:1 in the capital. However, there are rural schools with PTR as low as 11:1 and urban schools with PTR as high as 77:1 due to the ongoing trends of in-country migration. Woman teachers comprise 99.8% of staff in primary education and 81.3% in secondary education.

Primary school teachers are trained at teacher training colleges. Secondary school teachers are mostly trained at the State University of Education. Graduating students are awarded a Bachelor's degree in education. Also, some private institutions, such as the Gurvan-Erdene Teacher Training Institute, train school teachers.

Administrative and Supervisory Structure

The central education authority in Mongolia is the Ministry of Education, Culture and Science (MECS) which is the central administrative body that formulates the national educational policy and sets the standards for each level of education. The MECS also administers general provisions on education matters, teacher training, curriculum development, and state examination procedures, and is responsible for the accreditation of higher education institutions. The administrative fields of the ministry include not only preschool, primary, secondary,

vocational, higher education, and educational research, but also cultural and scientific affairs, and NFE.

In addition, general provisions on educational matters, such as scheduling of the school year, preparation and publication of textbooks for general secondary education, and state examination procedures, are administered by the ministry. Furthermore, the ministry ensures the smooth implementation of the elaborate contents and standards, and is responsible for providing licenses to establish higher educational institutions, and setting general typical provisions for teaching and research.

Education and culture departments within the local governments at the provincial level serve as the local educational authority. These departments are responsible for the administration and management of education services relating to formal education and NFE, and in-service teacher training. There are some state educational/professional institutions, including the Higher Education Quality Accreditation Centre, Education Assessment Centre, State Treasury Fund for Student Loans and Grants, and Institute of Education, which operate with some degree of autonomy.

Educational Finance

The education sector has always been the priority sector in national development strategy and resource allocation even in the most difficult years of the transition period. The Education Law stipulates that at least 20% of the government budget is to be allocated to education, and since 2000, the actual allocation ranged between 18% and 20%. In 2007, the education budget increased by 29.1% (8.3% of GDP). The Law permits education delivery through both for-profit and not-for-profit institutions. However, more than 70% of the expenditure goes for teachers' salary and heating costs. High spending does not contribute enough to quality.

As of 2007, shares of the subsectors of the education budget were as follows: early childhood care and education (ECCE), 16.8%; primary and general secondary education, 48.3%; VTE, 4.7%; higher education, 14.4%; and other areas, including teacher training, higher education student grants and loans, NFE, and adult education, were at 15.9%.

Schools in Mongolia plan their budget based on a funding formula that distinguishes between variable and fixed costs. Variable spending is proportional to projected student enrollment and covers teacher remuneration items – salaries, supplements, bonuses, insurances, taxes, and pension plans – and other expenses such as stationery, books, periodicals, postage, and communication costs. Fixed costs cover items, such as heating, water, electricity, and sewage, and are estimated from past expenses.

Based on estimations of student numbers and inflation rates, MECS and the Ministry of Finance propose an annual per-student budget every fiscal year, which is called the

normative means that apply to the variable cost component of the education budget. Normative means differ regionally and the government approves them every year. Higher education was fully subsidized by the state until 1993, when fees for students were introduced for the first time. Financing of public higher education institutions comprises three main parts: state budget, tuition fee, and other sources of funding. However, the government continues to provide financial assistance in the form of grants and loans to students from low-income families and to those who demonstrate outstanding achievement.

According to this policy, students from low-income families, disabled families, families of herdsmen with less than 200 heads of livestock, and students from partially orphan families, have access to loans; orphans and disabled students are eligible for tuition-fee grants; and students who have outstanding achievements to show, are exempted from tuition-fee payment.

Performance Monitoring, Evaluation, and Research

Promotion to each educational level is through a system of exams. At the end of primary, lower-secondary, and upper-secondary education, students are required to take state examinations given to pupils who are on the verge of completing each level. Primary education examinations are given in Mongolian language and mathematics. Admission to both university and nonuniversity programs require the Gerchilgee Diploma, awarded at the end of secondary school. Students must also take a competitive entrance examination administered by all institutions of higher education. The examination is held once a year, usually at the end of June and early July.

In 1998, the National Council for Higher Education Accreditation (NCHEA) was established, and since then, all higher education institutions are required to undergo accreditation. Only those institutions that have successfully gone through the accreditation process are eligible to receive government financial support. Likewise, only students enrolled in accredited institutions are eligible for government grants and loans. The private institutions are approved by the MECS, which also sets standards for private higher education. Students enrolled in accredited private higher education institutions are eligible for various aid programs granted by the government.

Major Changes and Issues since the 1990s

With a very strong education system until 1989, Mongolia's educational achievements were seriously undermined following an economic and financial crisis in the 1990s that resulted after the political and economic transition from the

socialist system to a free-market economy. The education system saw a severe erosion in both quality and quantity with falling enrollments.

Innovations in the educational sector, which have been implemented according to a package of laws on education, created a legal basis to adjust the education system and content to those of highly developed countries, enhanced the quality of education at all school levels, upgraded equipment and facilities, and raised social guarantees for students.

The school curricula and contents have been revised and the number of students at all levels of education has also increased. Competence-oriented new Education Standards started from 2004. The Government decided to extend the school system to a 12-year system in 2008, which will align Mongolia's education system with international standards.

Hence, the higher education sector has been transformed from a single, state-run multipurpose university into a decentralized group of specialized universities, all having the freedom to appoint their own instructors, set their admission policies, and confer degrees.

However, there is an imbalance between supply and market demand. Every year, approximately, 14 000 graduates from tertiary institutions join the labor market. Oversupply of specialists, such as medical doctors, economists, business managers, lawyers, accountants, and teachers, appears to be a serious problem, especially when it is combined with inadequate skills of graduates who have demanding specializations.

Many students go abroad to pursue higher education studies, especially to developed countries such as United States, Germany, Japan, and South Korea, instead of the former Soviet Union and Eastern Europe before the 1990s. There has also been a recent shift away from the study of Russian to include more English, Japanese, and Chinese.

Although there were some efforts and progress in promoting student-centered teaching/learning, the practical application is uneven and still limited. The use of information and communication technology (ICT) in education and computerization is increasing.

The key issues in the current Mongolian education system are:

1. poor quality and relevance of the current curriculum for primary and secondary education,
2. inadequate teaching qualifications and skills,
3. lack of consistent education standards,
4. weak learning and teaching environments in schools, and
5. supply-driven irrelevant vocational education for the youth.

To conclude, the Mongolian education sector is at a very important, indeed critical stage of its development with its medium-term development strategy to achieve

the Education for All (EFA) goals and Millennium Development Goal (MDG) education targets of the country. The main challenges ahead include significant improvements in the access, quality, and relevance of education, as well as improving the effectiveness and efficiency of the education system through the successful application of rights-based strategic planning, results-based management, and delivery of education, taking best advantage of the government's genuine commitment to education and the continued support of donors and development partners.

General Background

The political and educational history of Namibia has made education a national preoccupation. Education policy has been intertwined with colonial rule, first by Germany from 1885 to 1915, and then by South Africa, until independence in 1990. Since both colonial powers sought to limit the education of the indigenous black population, striving for education became part of the national liberation struggle, going back to the beginning of the twentieth century when missions were the main providers of education.

African cultures, of course, include traditional forms of education, some of which still exist today, but these are not the subject of this article, for want of space.

Namibia is a vast and arid southern African country of some 825 000 km². Currently, the total population is about 2 million, with settlement being denser in the northern regions because of rainfall patterns. The people are culturally and linguistically diverse, although the Ovambo groups form about 50% of the population, while less than 10% are of European extraction. The education system currently uses 13 languages, and English is the official language, for want of a better choice.

There are perennial rivers only on the southern border with South Africa and the northern borders with Angola, Zambia, and Botswana, the latter lying to the east of Namibia. The westerly Namib Desert, on the Atlantic coast, gave the country its name, partly as this ancient and inhospitable desert kept colonizers at bay until the nineteenth century. With the Namib Desert in the west and the Kalahari Desert in the east, Namibia has been called the land between two deserts.

Although short of water, the country has rich mineral resources, including diamonds, uranium, copper, silver, zinc, gold, and others, which make Namibia a lower-middle-income country, albeit with perhaps the highest inequality in the world. Namibia has significant fisheries, although there was overexploitation under South African rule, also exports red meat, and tourism is of growing economic importance. About 80% of manufactured goods are still imported from South Africa.

The independence constitution of 1990, in Article 20, guarantees the right to education, compulsory and free primary education, and the right to establish private schools at own cost. This has been reinforced through

legislation, notably the Education Act of 2000, and other legislations dealing with open and distance learning, higher education, and vocational education and training (VET). Government expenditure on education has varied between 20% and 25% of the national budget since independence.

Goals of the System

The goals of the Namibian education system were defined in the influential 1993 policy document *Toward Education for All* as access, equity, quality (including lifelong learning), democracy, and using resources well.

Structure and Operation of the System

This section also includes the characteristics and statistics for levels and types of education and training.

Namibia has a ten-level National Qualifications Framework administered by the Namibia Qualifications Authority (NQA) (see diagram).

The national system for schools covers 12 years. Children must be 6 years old to enter grade 1. The school year is from January to December and the three terms provide for 195–200 school days.

The lower primary phase consists of grades 1–4, upper primary grades 5–7, junior secondary grades 8–10, and senior secondary grades 11 and 12. In the first 3 years of schooling, local languages are the medium of instruction. English is a subject from grade 1 and becomes the medium of instruction from grade 4 onwards.

Soon after independence, Namibia decided to jettison the South African curriculum. The University of Cambridge provided the school leaving examination at grade 12. By 2006 this had been localized, with Cambridge still certifying the standard. A national examination is also conducted at junior secondary (grade 10) level.

About 45% of grade-10 learners in the formal school system cannot currently be accommodated in grade-11 classes. However, the Namibian College of Open Learning (NAMCOL) caters to most of those wishing to improve their grade-10 marks in some subjects (and thus gain readmission to the formal stream) or pursue grade-12 subject examinations.

Grade 10 also provides the usual entry point for vocational education, which is now being reorganized with

heavy involvement of the private sector, around occupations and competencies. Access to vocational education without grade 10 is also possible through a system of Community Skills Development Centres (COSDECs). Specialized vocational training has been taken out of schools and replaced by generic subjects such as entrepreneurship and design and technology.

In 2008, the government introduced a 1-year pre-primary year in 100 disadvantaged communities. This will be gradually expanded in future years. The 2001 Census suggested that about one-third of preschool children were attending early childhood centers organized privately or at community level.

Participants in adult literacy programs are able to complete a certificate equivalent to primary education and to continue their studies through COSDECs or NAMCOL. Annually about 25 000 adult learners enrol in the National Literacy Programme, while NAMCOL attracts 28 000 learners, making it the largest educational institution in the country. About 3000 trainees make use of vocational training opportunities.

At tertiary level, Namibia has the University of Namibia (UNAM), the Polytechnic of Namibia, and four colleges of education. Many students also study at a distance, particularly with the University of South Africa (UNISA). Namibia probably has about 30 000 students at tertiary level.

The total number of learners in formal schools was 570 623 in 2007, of whom 50.8% were female. There were 20 333 teachers, of whom 62.1% were female. There were 1661 schools, of which 99 were private. The average class group size was 30.9 learners (30.7 at primary and 32.0 at secondary). The learner–teacher ratio, however, was 28.1 on average (29.9 in primary and 24.6 in secondary). Enrolments in grade 1 were 68 861 learners (33 202 females), grade 5 had an enrolment of 64 552 (31 603 females), grade 8 had 50 575 (26 875 females), and grade 11 had 16 977 (9177 females). The average repetition rate in 2007 was 17.9%, a problem which has slowly been getting worse over the years. The survival rate to grade 5 in 2006 was 94% (95% for females), giving a good indicator of the number entering school who will have acquired stable literacy skills. The survival rate was 81% (82% for females) and 39% (40% for females) for grades 8 and 11, respectively.

In 2007, there were 19 290 classrooms in the system, of which 16 518 (85.6%) were permanent structures, 1171 prefabricated, 1420 traditional, and 181 hired. (There were 16 970 classrooms in 2001.) However, only 76% of schools had adequate toilets, while 80% had their own water supply.

Teaching Profession

One of the main changes in education since independence has been the attention paid to teacher education. In 1993

(3 years after independence), only 12.6% (13.8% for females) of teachers were qualified to teach at primary level, and 40.7% (47% for females) were qualified to teach at secondary level. Overall, the percentage of qualified primary teachers grew to 41.1% in 2001 and to 71.0% in 2007, while at secondary level it grew to 73.2% in 2001 and to 90.3% in 2007.

The current minimum requirement for appointment as a teacher is the Basic Education Teacher's Diploma (BETD), a 3-year qualification taught at the four colleges of education. It has also been provided at a distance by both the National Institute for Educational Development (NIED) and UNAM, although the distance mode is being phased out as demand is declining due to the high level of qualified teachers that has been reached and the limited number of annual vacancies. Equivalent qualifications are also accepted, subject to the assessment of the NQA, and many take this route through South African institutions and their local (private) partners.

Teachers at senior secondary level should have a 4-year degree in education, provided by UNAM, or another degree and a postgraduate diploma in education.

In 2007, 76.6% of teachers had more than 2 years of tertiary education, and most were between 20 and 49 years of age. Of the 13 675 primary teachers, 69.6% had more than 2 years of tertiary education. At secondary level, 91.2% of teachers had more than 2 years of tertiary education; 5.6% of teachers with more than 2 years of tertiary education transferred to another school in 2007. Those without such training were more inclined to stay put. Between 2001 and 2007, the number of teachers has grown on average by 1.9% per year, while the number of teachers with at least 3 years of tertiary education has grown by an annual average of 3.2%.

In 2006, the National Standards for the Teaching Profession were developed under the NQA. They are currently being used to reform preservice and in-service teacher education, and may in future result in the introduction of system of teacher licensing. The Namibia National Teachers Union (NANTU) has accepted the national standards but expresses its opposition to teacher licensing. Namibian teachers are regarded as public servants, but a committee of the Public Service Commission addresses the particular interests of the teaching profession.

One of the big controversies in Namibian education is about why this improvement in teacher education has not resulted in a dramatic improvement in the quality of results achieved by learners. While considerable efforts have been made to inculcate a learner-centered approach to teaching, doubts have been expressed about the subject knowledge of teachers. Preparations are currently being made for programs to ensure that all teachers achieve proficiency in English and mathematics.

Attention is now being given to the development of standards for school managers and the training to go with it.

Although teachers are reportedly not held in high regard as was once the case (when few other professions were accessible to black Namibians), attrition rates do not seem to be alarmingly high, at about 6% per annum. As part of a comprehensive strategy on human immunodeficiency virus (HIV) and acquired immune deficiency syndrome (AIDS), the Ministry of Education is currently implementing a workplace wellness program for all staff to limit the depredations of the pandemic. Members of the public service medical aid scheme have access to antiretroviral (ARV) treatment when needed.

Administrative and Supervisory Structures

At independence, Namibia inherited a number of separate and unequal education departments, for whites, coloreds (or people of mixed race), and various African ethnic groups, each with its own structures and even different curricula. Fortunately, the incoming government had the authority and determination to rapidly establish one integrated system. Drawing on its experience of setting up schools in exile, the South West Africa People's Organization (SWAPO) government changed secondary education first. The National Institute for Educational Development was created to work on curricula.

Initially, seven regional education offices were established, and these were later increased to 13 in accordance with the administrative regions that were determined for the country in the meantime. In 2008, the education system entered a decentralized administration with most functions, staff, and funds being decentralized to the regional councils. The Head Office will (in general terms) remain responsible for policy, curricula, standards, and monitoring and evaluation.

At the subregional level, Namibian schools are organized into inspection circuits and at the next level clusters of five to eight schools.

A national inspectorate administers the National Standards for Schools. These standards (introduced in 2005) have indicators, which have been described in some detail and four levels determined for each. Each school does an internal self-evaluation each year, and the national inspectorate arranges for a limited number of schools (about 30 at present) to be evaluated and rated by a national evaluation team. A school's evaluation in terms of the national standards should result in the drafting of a strategic plan for the development of the whole school.

A subject advisory service provides support for lower primary education and for the various subjects. Its deployment is complicated by the large number of subjects on the curriculum and limited human resources.

In a country as big as Namibia, communication and transport are a constant headache, not to say expense.

Namibia has had several ministerial structures for education since independence. A separate ministry for higher education was instituted in 1995(?) but in 2005(?) the Ministry of Education was again put in place.

Educational Financing

Almost all funds for education come from the central government. In 2008–09, the budget for the Ministry of Education is N\$4.78 billion (about US\$620 million) out of a total budget of N\$22.46 billion (about US\$2.9 billion.) Education thus currently makes up about 21% of total government expenditure. About 60% of all education expenditure is taken up by personnel costs.

Although no fees are charged by government for primary education, learners do pay examination fees at secondary level, and subsidized fees are also charged by NAMCOL and public higher education bodies. The law allows school boards to run a school development fund with voluntary contributions from parents. Although contributions to the school development fund are not compulsory, and are theoretically limited, informal pressures are often brought to bear on parents and learners to ensure payment. At a rough estimate, it seems that private contributions make up about 10% of expenditure on education, and are one of the complicating factors in achieving greater equity.

International aid to the Ministry of Education in 2008–09 is estimated at about N\$100 million.

Performance Monitoring, Evaluation, and Research

The performance of the Namibian education system is currently being measured against targets in terms of the following key performance indicators:

1. number of children from disadvantaged communities who enter primary education having successfully completed 1 year of public pre-primary education;
2. enrolment in grade 11;
3. percentage of learners achieving D or better in mathematics, science, and English in grade 10;
4. percentage of learners achieving D or better in mathematics, science, and English in grade 12;
5. national average Southern and Eastern African Consortium on the Monitoring of Education Quality (SACMEQ) test score (in reading and mathematics);
6. percentage of learners receiving life-skills education;
7. total enrolment in vocational education;
8. average annual completion rates for vocational trainees;
9. employment rates of VET graduates within 1 year of graduation;
10. number of diploma, degree, and postgraduate graduates in key human resource categories; and
11. adult literacy rate.

Particular mention should be made here of the SACMEQ. This regional mechanism for testing primary school learners came as a nasty surprise to Namibia when Namibian learners were found to be at the bottom of the regional league table. Much debate has followed about what should be done. Besides continuing its participation in SACMEQ, Namibia has decided to set up additional national diagnostic tests at grades 5 and 7 within the next few years. It seems that while much attention has been given to secondary education, not enough effort has been put into primary education, where language is the main complicating factor for both learners and teachers.

Research is one of the main functions of NIED. Because of national and international interest in Namibian education, a fair amount of research has been done. It is, however, beyond the scope of this article to deal with this topic.

Major Changes and Issues Since the 1990s

Public concern about the quality of education, reinforced by the finding of SACMEQ and other studies, led to the establishment of the Presidential Commission on Education, Culture and Training in 1999. The Commission consulted widely with the Namibian public and with Namibian educators. They concluded as follows:

The first nine years of education in Namibia have been the years of access. The Commission believes that the next decade should be the decade of equity. . . . This will also be a strong influence on the quality and efficiency of the system. . . . The Commission believe that Namibia should aspire to being "A Learning Nation". . . . Because of globalization Namibia must compete in the knowledge-based production of goods and services, or face increasing marginalization.

Apparently concerned about the slow pace of improvement in education, and doubting that the education system could make its expected contribution to the equitable and knowledge-based society foreseen in Namibia's Vision 2030, the government in 2002 invited the World Bank to undertake a study of the Namibian education system. This was a controversial move as Namibia has no economic need to borrow from the World Bank.

The World Bank study concluded that:

. . . at present, the (education) system is too weak to effectively play its expected role. Key weaknesses pertain to poor quality or ineffectiveness; low efficiency; inequalities; low economic relevance; and low capacity for knowledge creation and innovation.

Further technical assistance from the World Bank, and extensive participation by Namibian educationalists, gave

rise to the Education and Training Sector Improvement Programme (ETSIP), first as a 15-year strategic plan (2005–20) and subsequently as an implementation plan for the first phase (2006–11).

The first phase of ETSIP focuses on strengthening the immediate supply of middle- to high-level skilled labor to meet labor-market demands and support overall national development goals. Second, ETSIP will strengthen the quality, effectiveness, and efficiency of the general education and training system. Third, it will strengthen the knowledge creation and innovation system. Fourth, it will improve the effectiveness, quality, efficiency, and development relevance of the tertiary education and training system. Fifth, it will strengthen the policy, legal, and institutional frameworks to support equitable access to high-quality and responsive adult learning.

ETSIP implementation plans have been developed in greater detail than any previous plans in Namibian education and have attracted widespread support from the government, the Namibian private sector, and international development partners. In fact, ETSIP consists of nine subprograms dealing with all aspects of education from early childhood development to tertiary education, and with cross-cutting programs for information and communication technologies (ICTs), HIV and AIDS, and capacity development. Taking its cue from the Presidential Commission of 1999, ETSIP bears the subtitle, 'Planning for a learning nation'.

Glossary

ERO – Education Review Office, the government department that inspects every early childhood education and school on a 3-yearly cycle.

Kōhanga Reo – Māori-medium early childhood education centers, supporting language and culture as well as early education.

Māori – The indigenous population of New Zealand.

NCEA – The National Certificate of Educational Achievement is the secondary qualification. It has three levels, with the first level usually taken in Year 11.

NZQA – The New Zealand Qualifications Authority is the government department that sets and reviews standards related to qualifications, administers the national secondary school examinations related to the NCEA, and approves courses.

Pacific – Students and people of Pacific Island origin.

Pakeha-European – New Zealander of European ethnic origin.

Te Whāriki – The early childhood education curriculum.

Treaty of Waitangi – The founding document of New Zealand.

Background

New Zealand is a small, mountainous country located in the South Pacific Ocean, 2000 km southeast of Australia. Its total land area of 269 000 m² makes it three-quarters the size of Japan. The population of just over 4 million people live mostly in the coastal cities located on the two main islands. While New Zealand has three official languages, English, Māori, and sign language, English predominates and few people are bilingual.

New Zealand is a democracy with constitutional ties to the United Kingdom. Its founding document is the Treaty of Waitangi, an agreement signed in 1840 by Māori (the indigenous people of New Zealand) and the British Crown. From the British perspective, it was the means by which they gained the right to govern and establish laws and in return the Crown was to guarantee and actively protect Māori tribal authority over their lands,

fisheries, forests, villages, treasures, and culture and extend to them the status and rights of British citizens. The significance of the Treaty of Waitangi has been actively debated in New Zealand over the past 30 years and in recent years the government has sought to address its earlier failure to keep to its treaty commitments.

Once a colony of Britain, by the middle of the twentieth century, New Zealand's agricultural products had made it a relatively wealthy country. However, changes, such as the establishment of the European Union (EU), led New Zealand to look at new ways to generate wealth. More recently, the aim has been to transform the national economy from a basic reliance on primary production to more added value and knowledge-based production. Consequently, a priority for government is investing in educational programs designed to build the kind of skills and knowledge that will be required for a knowledge economy.

Until recently, the country's economic indicators were positive with the labor-force-participation rates rising steadily through the 1990s, matched by a fall in the unemployment rates. There has been strong economic growth in recent years and while the Organization for Economic Cooperation and Development (OECD) economic survey of New Zealand 2007 rates the country as having one of the most flexible and resilient economies in the OECD, it highlights concerns with productivity, the need to maximize improvements in living standards, and to actively manage spending on health and superannuation as the population ages.

The other major change in recent years is New Zealand's ever-increasing ethnic diversity. Of the overall student population in 2004, 59% were identified as European, 21% as Māori, 8% as Pacific, and over 8% as Asian. Statistics New Zealand estimates that by 2021, the population of New Zealanders under the age of 15 will consist of 51% Pakeha-European, 23% Māori, 14% Pacific, and 12% Asian.

Education in New Zealand

The education system is based on several guiding principles including: access to quality early childhood services; legally free publicly provided primary and secondary education; equitable and affordable access to tertiary education; and quality-assured and portable education qualifications. The provision of flexible pathways for study is also an important feature: for example, students are not

streamed or channeled through particular types of school. Māori-medium education also supports the revitalization of the Māori language and culture. There are linked national curricula for early childhood education (ECE) and compulsory schooling which provide frameworks rather than close prescription. Assessment tools that allow comparison with national norms are widely used in schools, and will be used to assess students against national standards in literacy and numeracy from 2010.

The overall aim of education policy is to build a world-leading education system that equips all New Zealanders with the knowledge, skills, and values to be successful citizens in the twenty-first century.

A Devolved System

As part of wide-ranging economic- and public-sector reforms in the 1980s, New Zealand education moved from a relatively centralized structure in relation to resources and staffing, to one in which individual schools and tertiary institutions have considerable responsibility for their own governance and management, working within the framework of guidelines, requirements, and funding arrangements set by central government and administered through its agencies. The Ministry of Education

(MOE), established under the Education Act 1989, carries out functions such as providing policy advice to the Government; allocating funding and resources to schools and ECE providers; and monitoring the effectiveness of the education system as a whole. It does not have a direct supervisory relationship with individual schools, though it provides some support for schools deemed to be at risk. Local authorities have no role in education in New Zealand, nor are there any school districts. New Zealand has the most devolved system of school self-management in the Western world, with each school having its own board of trustees, largely parents elected by parents, in a governance role, and accountable through reporting of annual progress on self-set targets.

Separate education agencies have national responsibilities for quality and qualifications. The Education Review Office (ERO) provides 3-yearly reviews of early childhood centers and schools. The New Zealand Qualifications Authority (NZQA) sets and regularly reviews standards as they relate to qualifications, administers national school-based examinations, and approves courses. The New Zealand Teachers Council registers teachers, renews their practicing certificates, and approves teacher-education programs that lead to registration. All state and private schools and kindergartens employ only teachers with a current practicing certificate, or a limited authority

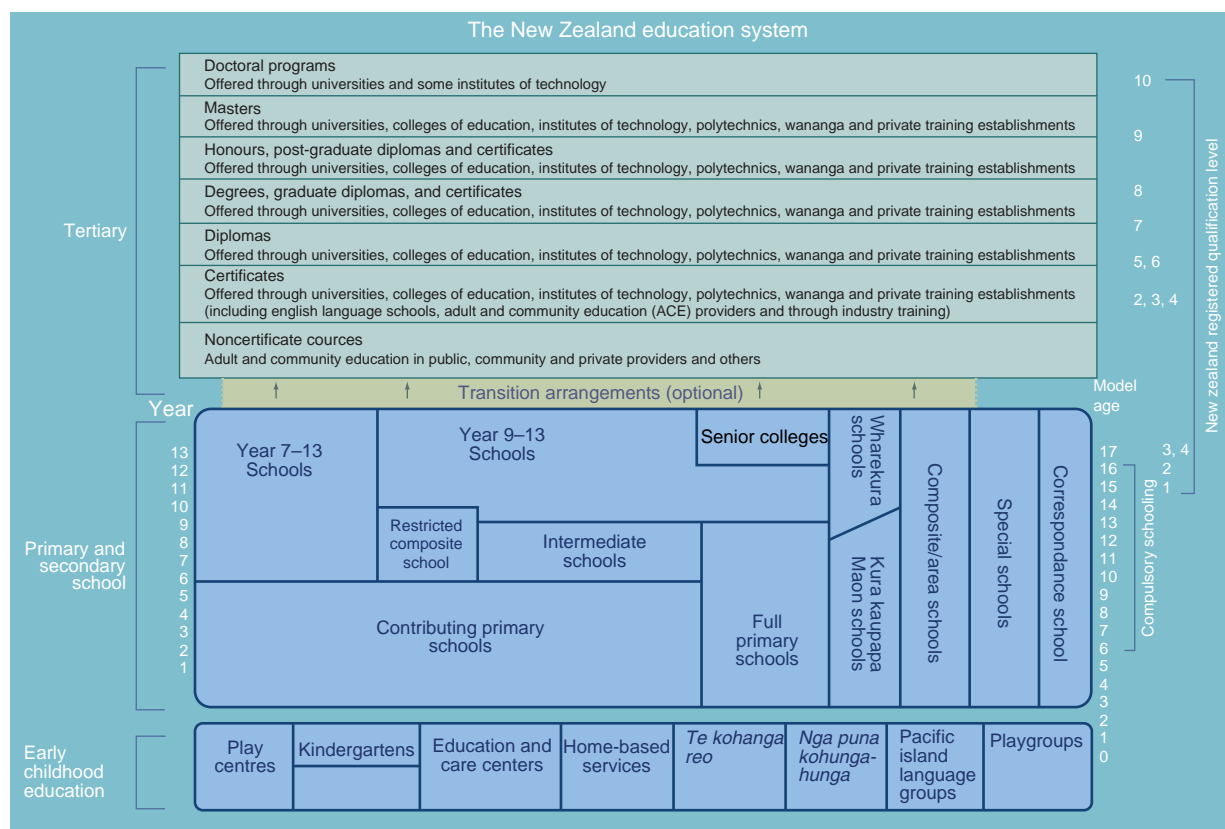

Figure 1 New Zealand education system overview. Courtesy of the International Division, Ministry of Education.

to teach. Registration is optional for teachers in other early childhood centers and in tertiary institutions.

While the Ministry has a strategic leadership role, and monitoring and evaluation roles with respect to the tertiary sector, it is the responsibility of the Tertiary Education Commission (TEC) to oversee implementation of the Tertiary Education Strategy and associated set of priorities. The TEC is responsible for funding all postcompulsory education and training offered by a diverse range of institutions (see **Figure 1**).

Early Childhood Education

New Zealand was the second country in the world after Iceland to reorganize ECE services by integrating responsibility for all of those services within the education system with childcare services moving from the social welfare to the education portfolio in 1986. ECE enrolments rose markedly over the 1990s, and in 2006, 94.5% of new school entrants had had some ECE experience. Since July 2007, 3- and 4-year-olds are entitled to up to 20 h free ECE a week.

ECE services are not state-owned, provided, or managed. They receive per-child government funding, and there are also family-income-related subsidies for some children. They operate within a framework of regulations, 3-yearly review, and an innovative bicultural ECE curriculum, *Te Whāriki*. The Ministry of Education supports ECE services to make the most of this curriculum by providing resources including assessment, planning, and self-review with associated professional development from contracted providers. Most ECE services are teacher-led; some are led by parents, often working alongside a teacher. The latter include playcentres, and *nga kōhanga reo*, providing Māori-medium ECE.

Primary (Elementary) and Secondary Education

As on 1 July 2006 760 761 students were enrolled in primary and secondary school, at which attendance is compulsory between the ages of 6 and 16. Students generally start school on their fifth birthday. Primary schools cater for students from age 5 (Year 1) to Year 8. Secondary schools usually provide for students from Year 9 until the end of Year 13. There are 2584 schools. Approximately 350 are secondary schools, and 46 are schools for students with special educational needs (though most such students attend regular schools). There are 105 private schools. Within the state school system, 10% are integrated schools which represent a range of special characteristics, including religious affiliation. There are also 68 *kura kaupapa Māori* (Māori-medium schools), and a

national correspondence school for students who cannot access a local school due to their remote location or other reasons, or who cannot access a particular subject at their local school. Students and their families can choose any state school, but a quarter of state schools have enrolment schemes, giving first priority to students within a set geographical zone. State schools ask for set donations, and though these are voluntary, they can be sizeable in some schools in high-income communities; and state-integrated schools charge fees to cover property costs that can also be substantial. Private schools receive some government funding.

The average primary school has just 216 students, reflecting the large number of small schools we have in rural communities. There are 49 241 teachers employed in state schools. In the primary schools, the average teacher:student classroom ratio is 1:23.9, and in secondary schools, 1:17.7.

Curriculum and Assessment

New Zealand has an outcome-focused national curriculum that sets the direction for student learning rather than prescribing specific content. In a high-trust/low-stakes accountability climate, schools are charged with developing a curriculum specific to the needs of their students, based on this framework. The curriculum specifies eight broad levels of achievement from Year 1–13. This is intended to bring about a seamless alignment between the school curriculum and *Te Whāriki*, across the years of school, and on into the various tertiary-learning pathways. The key competencies in **Figure 2** (thinking; using language symbols and texts; managing self; relating to others; participating and contributing) are woven into all eight learning areas and form a key curriculum link both to ECE and the tertiary sector.

Assessment up until the final 3 years of school also follows the high-trust/low-stakes policy model. There is an emphasis on formative assessment, and on ensuring all students are making progress relevant to their needs. Schools set their own performance targets and demonstrate their progress toward meeting these. Two main sets of nationally referenced tools are available to help them do this. Both sets of tools focus on literacy and numeracy, as emphasized in the curriculum. A range of other tools are also used at the schools' own discretion and a national monitoring program (NEMP) provides a process for sampling national progress across the wider curriculum, on a 3-year cycle. Internationally, New Zealand participates in the Programme for International Student Assessment (PISA), Progress in International Reading Literacy Study (PIRLS), Trends in International Mathematics and Science Study (TIMSS), and International Adult Literacy Survey (IALS).

The National Certificate of Educational Achievement (NCEA) is the official school-leaving qualification. This is

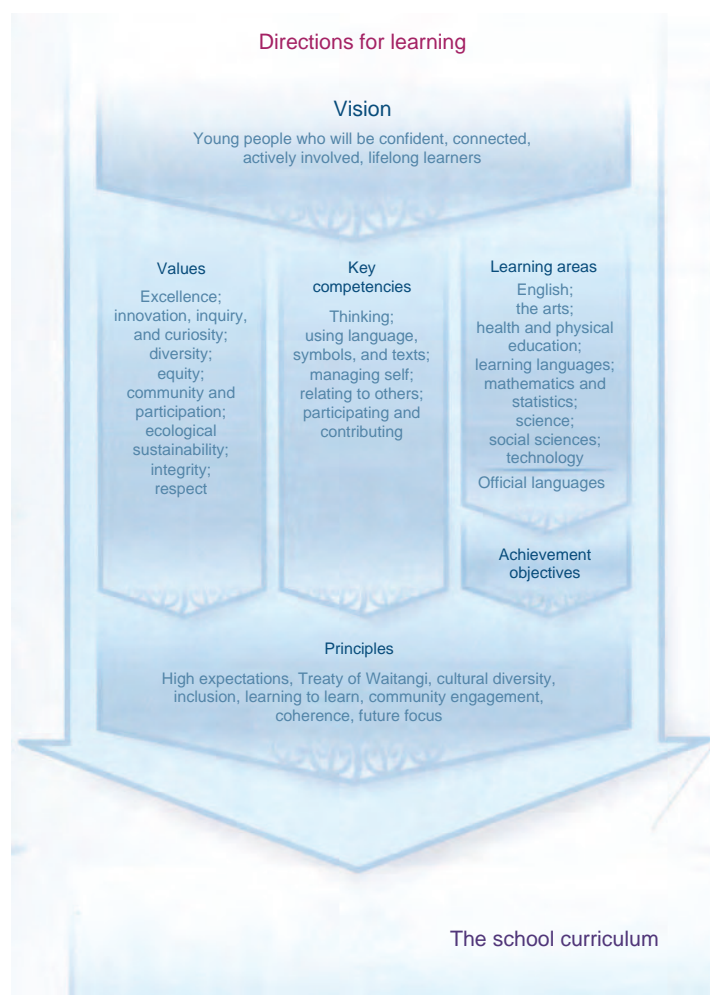

Figure 2 The New Zealand curriculum (2007). Published by Learning Media Ltd. Copyright © Crown 2007. All rights reserved.

awarded at three levels, broadly corresponding to the final 3 years of secondary school (years 11–13) and designed to integrate with other level 1–3 qualifications offered by tertiary providers in a seamless National Qualifications Framework (NQF) administered by NZQA. NCEA awards are earned by aggregating credits from achievement standards (which specify learning directly aligned with the school curriculum) and unit standards which are often more vocational/applied in nature and may also be offered by tertiary providers. In theory, both types of standards have parity of esteem. Credits from them can be combined in any balance to reach the total needed for an award. The modular nature of the standards provides for flexibility in curriculum design. Students wanting to enter university need to ensure their level-3 NCEA credits are aggregated in the correct proportions from an approved subjects list, and that they demonstrate at least a basic level of competence in literacy and numeracy. The most able students may also sit competitive scholarship examinations in individual subjects in their final school year. These provide financial rewards and also

help determine direct entry into elite university courses where limited places are offered. Open entry at the first year of university is more usual, although this is changing.

Tertiary Education

The term tertiary education in New Zealand is used to describe all aspects of postschool education and training. It includes over 900 institutions providing the full range of education from adult literacy and second chance education through to certificates, diplomas, bachelors, masters, and PhDs. It also covers industry training, apprenticeships and adult and community education. The diversity of provision is reflected in the many types of organizations offering tertiary education. The public tertiary education institutions include 8 universities, 20 institutes of technology and polytechnics, and 3 wananga (Māori tertiary education institutions). There are also 46 industry-training organizations, and approximately 895 private training establishments, which include private English-language

schools, registered by the NZQA. In 2006, 448 000 students were enrolled in tertiary education. In 2006, 58% of school-leavers went from school to tertiary education, 30% to certificate-level courses, 23% to degree-level courses, and 5% to diploma-level courses.

While the proportion of those participating in tertiary-level courses has increased markedly in recent years, the growth has been in certificate-level courses, not degree-level courses. There has also been growth in part-time enrolments, with students combining work and study.

Quality within the tertiary system is assured by a requirement that all organizations must be able to demonstrate that they have the policies and procedures relevant for their respective programs. These are then reviewed through processes of registration, approval, accreditation, and monitoring and audit.

Teaching Profession and Teacher Education

Most schools can attract qualified teachers, but in recent years, schools have expressed some concern over the shortage of experienced teachers. There are shortages in low-income and rural areas, and in some subjects in secondary schools. With an increased emphasis on professional development, often occurring during school hours, some schools are also experiencing difficulties finding experienced relief teachers. There are longstanding concerns about the workloads faced by school principals and middle managers, and signs of difficulty in filling these roles in a sizeable minority of schools.

Most primary student teachers undertake a 3-year undergraduate teaching degree, most early childhood teachers undertake a 3-year diploma or degree program, and most secondary teachers undertake a 1-year graduate diploma, following a subject-specific undergraduate degree.

Registration is compulsory for all primary and secondary teachers. Half of all ECE teachers are currently registered, and there are government plans to increase this proportion. Provisional registration requires graduation from an approved preservice program, plus a satisfactory police check, and verification that the graduate meets the teacher's council criteria for being of good character and fit to be a teacher.

All schools employing provisionally registered teachers are required to provide them with a 2-year advice-and-guidance program that enables them to meet the satisfactory teacher dimensions for fully registered teachers. Each school employing a provisionally registered teacher receives a 0.2 salary allowance for the first year and 0.1 for their second year of provisional registration.

Early childhood services employing provisionally registered teachers are entitled to a grant of \$3700 for each of the 2 years to support their induction. The recent

move to increase the registration of early childhood teachers has created issues for the sector in providing appropriate supervision.

Educational Finance

Government spending on all three educational levels has gradually increased, both as a percentage of gross domestic product (GDP) (5.6% in 2006–2007) and a percentage of total government expenses (18.6% in 2006–2007). Our spending is close to the OECD average once the country's relative wealth and demographic structure are taken into account. As New Zealand has a relatively young population, the proportion of government expenses used for education is at the top end of the OECD countries.

Thirteen percent of school funding comes from non-government sources such as parent donations, fundraising, community trusts, and investment. The funding that schools receive for their running costs has risen, but is under pressure with rising costs due to information and communication technology (ICT), the costs of administrative staff due to school self-management, increasing legal compliance costs, and rising expectations of what schools should offer. Teaching-staff capacity is separately calculated in relation to the number of students on the roll, with schools making their own hiring and firing decisions, but with the government meeting the actual costs of the staff appointed. Most resourcing for schools is on a per-student basis, including some additional funding for schools serving low-income populations, in rural areas, or providing Māori-medium education.

The rationale for government funding of tertiary education relies on two principles. The first is that there are both public and private benefits from tertiary education and so costs are shared. Course costs have increased since the 1990s. Student loans to finance tertiary education began in 1991; by 2007, they had been used by 21.7% of the population aged 15 and over. The second funding principle is that there are some areas of more strategic value to society, and these are more heavily subsidized. In practice, institutions are funded through an integrated funding framework. This has three components: funding for domestic students, funding for research, and targeted funding. The latter is designed to promote the overall tertiary education strategy and comprises supplementary grants, for example, to support the participation and achievement of Māori and Pacific students, and funds to support innovation, e-learning, and links with business.

Performance Monitoring, Evaluation and Research

In 2006, the Ministry of Education began an annual report, *State of Education in New Zealand*, which gives

an overview of the overall performance of the education system, providing useful information on trends over time in key indicators and comparisons with other countries. An annual report on the school sector has been made to Parliament every year since 1994. The Ministry of Education also contracts research organizations and universities to undertake evaluations of specific initiatives and policies. The ERO provides a number of evaluative reports each year giving a national picture drawn from analysis of its individual school reports of aspects of particular interest, for example, quality of teaching in a specific curriculum area, quality of school governance. Research into aspects of education is carried out by the New Zealand Council for Educational Research, which receives some annual government funding in order to ensure that there is a sustainable national independent body that can carry out and disseminate educational research, by the universities, and a number of consultant organizations and individuals.

Major Changes and Issues since the 1990s

Compulsory Schooling

During the 1990s, educational institutions were largely left to their own devices, with government agencies taking responsibility for policy, funding, and review, at a distance. This hands-off decade left a legacy of both distrust and sometimes overconfidence in school internal knowledge and skills (in a country that has prided itself on its do-it-yourself approach). But government agencies have taken more of a leadership role to improve the capability and capacity of educators and educational institutions, as it became clearer that there had been no overall improvement in student outcomes over the 1990s. The original school review model, for example, was modified to include advice – if schools ask for it. The ideology of the self-managing school, however, remains, making many aspects of schools sharing information about their operations and progress a sensitive area. Longstanding issues about principal workloads, stress levels, the focus on administration at the cost of leading learning (NZ principals spend more of their time on administration than do principals in most other countries), difficulties in attracting experienced principals to small, rural schools, or those in difficulty, the low level of required preparation for the principalship (a quarter of primary principals have come to their position from being a class teacher with no school management experience) and reports of inequitable or poor appointments made by school boards remain problematic in a system which takes self-managing schools literally, and which does not provide the kinds of connective relationships and processes that exist in the public-school systems of most other countries.

While there was a market element in New Zealand's shift to self-managing schools, it was not accompanied by the kind of performance-management system introduced in England, which made a similar shift at around the same time. Although the media compiles league tables of secondary schools based on their performance in the NCEA, the government does not want league tables for primary schools, when national standards are introduced in 2011. The levers that are being used to improve quality in education, and raise student achievement are centered around developing capability through well-anchored professional development, teaching resources, and assessments. These include national literacy and numeracy programs that have resulted in gains for student achievement, particularly those with initially low achievement. Other levers include funding for schools to work in clusters, for example, on using ICT for learning, and for innovations linked to the new curriculum. Programs for new principals and refresher courses for existing principals have been introduced in recent years, with increasingly high take-up.

The student-achievement issues faced by New Zealand are not new, but there is less acceptance now of the gap between Māori and Pacific student achievement levels and others, of the gap between students from poor homes and others, and the level of students leaving school without a meaningful qualification. While the country is generally in the second-highest set of performers on the international assessments we take part in, with a high proportion scoring at the highest levels, we also have more students performing at low levels than other countries with similar average scores.

Around 90% of students are estimated to stay at school until age 16, but only 71% to age 17. Around 25% leave with no qualification, and 40% leave school without the level-2 NCEA qualification that would provide access to many career pathways. In part, this is because New Zealand has had high employment, and it has been possible for young people without qualifications to find work.

As a consequence, the Ministry of Education has focused on three key areas that research and experience show can make the greatest different to raising student achievement and reducing disparity. These are effective teaching for all students; family and community engagement in education; and developing quality providers. The work program within these three areas includes a major investment in increasing the information and research base so that new policies and the associated development of new practices in teaching, preparation of teachers and principals, and professional development, are well supported by evidence. This work program includes a series of best-evidence syntheses that distil underlying principles and contextual effects from a synthesis of research that analyses the impact of practice on student outcomes. The most recent of these include the teaching of mathematics,

professional development, and school leadership. These best-evidence syntheses are developed through a collaborative knowledge-building approach across policy, research, and practice, with a commitment to knowledge utilization that has led to embedding opportunities for dialog for all key stakeholders within the knowledge-building processes. The national work program also includes research and development focused on researchers working with professional developers, educators, and resource providers on trials of new approaches.

At the same time that the government is implementing policies that support the continuous improvement of the current education system, there is a developing debate about what learning for the knowledge age might actually mean and how schools might better provide such opportunities.

Noncompulsory – ECE and Tertiary

Participation in ECE has increased since the 1990s, largely due to increased government funding. However, concerns remain about uneven quality. Compared to the 1990s, there is less reliance on competition and consumer choice to ensure that children receive good quality ECE, with some movement toward more regulation around gross indicators of quality (e.g., ensuring ECE staff have ECE qualifications), and as with the school sector, providing more resources and professional development to improve teaching capability.

In 2002, *Pathways to the Future – Ngā Huarahi Arataki*, the first long-term strategic plan for any education sector in New Zealand, was published after extensive consultation with the sector. Three goals provide the framework for the plan: increasing participation in quality ECE; improving the quality of ECE services; and promoting collaborative relationships.

During the 1990s, there was a huge expansion in the tertiary sector as it moved from an elite, largely university-based system, to a much more diverse and accessible system. There was an emphasis on market-like competition, student choice, and on the private returns to tertiary education. Associated with this was the requirement for students to pay more for their tertiary education and a student loan system was instigated. Since 2000, while the general direction was maintained, there has been more governmental steering in an attempt to align tertiary education more closely with the social and economic needs of the country.

During 2006, the government embarked on a program of sustainable reforms to the tertiary education system. Under the new funding system, the TEC will fund providers on the basis on investment plans agreed over a 3-year period, against the priorities outlined in the tertiary education strategy. This strategy has six themes: strengthening of the system capability and quality; contributing to achieving the Māori-development aspirations,

raising foundation skills to allow participation in the knowledge society; developing the skills needed for a knowledge society; educating for Pacific people's development and success; and strengthening the research knowledge creation and uptake function.

Niger

A A I Daouda, University Abdou Moumouni de Niamey, Niamey, Republic of Niger

© 2010 Elsevier Ltd. All rights reserved.

Context

Niger is a desert country (three-quarters of its surface), its area being 1 267 000 km². In the area bordering Benin and Nigeria are concentrated three-quarters of the population, but conditions are difficult because of insufficient and irregular precipitation and poor fertility of the soil. Almost 84% of inhabitants live in rural areas. The population of Niger is estimated at 13.475 million (2007), women representing 50.1% of the population. Niger has high birth rates (7.1 children per woman), infant mortality rate (14.8%), and maternal death rate (648 out of 100 000). According to the UN projections, the population will reach 27 million in 2025. The age structure of the population shows a clear predominance of young people; indeed, half the population is less than 15 years, while only 3.2% of the total population is aged over 65 years. The extent to which basic needs are met is set out in **Table 1**.

Niger is a country dominated by the primary sector (namely, agriculture) occupying more than 80% of the population. This sector grew at a rate of 2.2% from 1995 to 2000, and its share of GDP reached 42.8% between 2002 and 2006. Given the climatic risks, the economy is frequently unstable. The share of the secondary industry remains less important, and fell to 13.2% in the period 2002–06. This situation is explained by the prevalence of an unaccounted largely rural sector (70.8% of the GDP in 1990; 74.3% in 2000). Such a structure results in very limited revenues from taxes and affects the capacity of the state to finance its operating costs. According to government's strategy or the development and reduction of poverty (SDRP), "the evolution of the economy of Niger over the decade 1990–2000 was characterized by a weak growth with a real rate annual average of 1.9%. The principal factors related to this poor economic performance are the unfavorable climatic conditions, an inappropriate economic policy characterized by delays in the reforms, an unfavorable external environment, even hostile, and a social and political climate that is often unstable. In terms of structure, the GDP was marked by a preponderance of the tertiary sector coming from trade. The contribution of this component to the formation of the GDP was on average 42.2% during the decade 1990–2000."

The demographic growth rate (3.3%) until 2003 was higher than the annual rate of growth of schooling (3% in 2001, compared to 2% in the preceding years), that is, the supply of education did not match demographic growth. From 2003, with the implementation of the PDDE, access

to schooling made important gains; however, with demographic growth rate reaching 5.1% in 2006, the problems facing education remain enormous. In general, the social deficits with respect to the right of access to basic services (e.g., education, health, information, credit, human rights and protection, land) and other development needs have an extremely harmful effect on the most vulnerable groups, in particular women and children. In the field of education, the indicators place Niger in a very low position globally with a great disparity between boys and girls, and also between urban and rural areas. The education of girls is an essential requirement for development in Niger. Low levels of education and literacy are among a number of the important factors that explain the very low level of the index of human development (IDH) in Niger.

While French is the official language of Niger, in fact, ten languages are spoken, the principal ones being Haoussa (53%), Zarma (21%), and Peulh (10.5%). Niger is a country strongly Islamized (95% of the population, against 4% Christianity, and 1% other religions).

Structure and the Management of Education

At the time of independence, in 1960, Niger was the African country with the lowest provision for education. Educational policy was determined by the need for a rapid expansion of an inherited school system. There were neither better alternatives, nor the time to develop and try out new systems of education. The policy of manpower is certainly called into question during debates on the reform of education: for example, (1974) the meeting of the national commission on the reform of teaching; (1975) the national seminar of reflexion on the reform of teaching; (1979) the seminar general on education; (1982) the national debate on the school native of Niger; (1987) the setting-up of the commission of reflexion on the training of the trainers; (1987) the seminar on the actualization of the programs of the lesson of first and second degree; (1992) states general of education; (1998) law of orientation of the education system; (2001) letter of educational policy; and (2002) decennial program of development of education. However, in practice, the implementation of reforms put forward at national forums met many obstacles, and so the education system evolved in a context characterized by the absence of planning and management according to immediate needs. The first law

Table 1 Basic needs indicators

Access to health services	65% in 2005 vs. 47.6% in 2001
Access to safe drinking water	68.7% in 2005 vs. 43% in 2000
Access to sanitation	78.4% of households have no toilet
Rate of schooling of the children	59% in 2007
Adult literacy rate	28.7% in 2005

for the orientation of the education system was promulgated only in 1998. The present education system of Niger is managed by three government departments:

- the Ministry of National Education (MEN);
- the Ministry for Educations Secondary and Higher of Research and Technology (MESSRT); and
- the Ministry for the Vocational Training and Technical (MFPT).

The formal sector of education comprises of:

- basic education (pre-school, basic cycle 1, and basic cycle 2);
- post-basic education; and
- higher education.

The nonformal education sector comprises of:

- elimination of illiteracy and
- Koranic teaching.

The government departments cover different systems: MEN – preschool education, primary education or basic cycle 1, and elimination of illiteracy; MESSRT – basic education cycle 2, secondary teaching, and higher education; MFPT – the establishments and centers providing vocational training and technical training at secondary level (basis 2). The three departments have an organizational structure similar to that at the regional level, which is under regional and local control:

- in each area, the educational zone is placed under the supervision of a regional director responsible for the coordination of all educational actions and policy;
- each under-area is subdivided into inspectorates according to the type of teaching;
- each inspectorate manages the establishments belonging to its entity at the level of secondary basic education 1, the inspections are organized in teaching sectors directed by education advisers; and
- educational establishments are managed by directors in the administrative and educational plan.

The formal education system in Niger is composed of:

- Preschool education is conducted in the nursery class and kindergarten for children from 3 to 4 years. The duration of this cycle is 3 years.

- Basic cycle 1 (primary education teaching) accommodates 7-year-old children. It includes traditional schools, free-Arabic schools, experimental schools, and specialized schools; it has a cycle of 6 years of studies sanctioned by the CFEPD or the BOLETUS free-Arabic.
- Basic cycle 2 (first cycle of the secondary education) accommodates, by way of an entrance examination in sixth year for 4 years, sanctioned by the BEPC or the BEPC french-Arabic.
- Secondary education (second cycle of the secondary education) that constitutes the second degree of teaching is composed of a general teaching and vocational teaching. The access to average teaching is open to the holders of the patent of studies of the first cycle of secondary education (BEPC). This cycle lasts 3 years and is sanctioned by obtaining the baccalaureat.
- Higher education is the third level of education and includes the whole of the post-school sector.

Educational Policy

The primary goal of the educational policy of Niger is the construction of a system of education able to better develop human resources for a harmonious social, economic, and cultural development of the country. Article 13 of the education law stipulates that “education must be complete. It aims at the development of the intellectual abilities, physical and morals, the improvements in education for a social and professional integration and the full exercise of the citizenship.” The government, in dialog with all the partners of the school and the support of technical and financial partners (PTF), has undertaken the development of the Decennial Programme of Development of Education (PDDE) in Niger over the period 2003–13. This program must henceforth be used as a comprehensive framework of reference to all the interventions in the sector. After the adoption of the law on 1 June 1998, the government confirms by this program, its firm political will and engagement to make education one of its priorities of first order. This decennial approach conforms to the orientations of the Decade of Education of the OAU, with the Special Initiative of the United Nations for Africa, with Tally of action of Dakar on Education for All (EPT) and with recommendations of the summit of the heads of states of the six least-provided-for countries (in terms of education) (Bamako), also translated the national concerns many times affirmed in the world conferences and summits. In fact, it is a question of putting in harmony the ambition of universal schooling and that of the development of a country economically strong, socially structured and stable, and culturally open. The required ultimate goal is the achievement of the fundamental educational needs for all layers of the population in order to enable them to ensure the control of

their destiny by effective development and utilization of human resources.

Strategic Objectives of the PDDE

The primary strategic objectives of PDDE are the following:

- to reinforce and develop the institutional capacities of the MEB1/A;
- to develop a partnership, active and diversified in favor of the system;
- to especially accelerate schooling in rural areas, particularly for girls;
- to promote nonformal education, particularly for young people and women;
- to reform and adapt the provision of education to reduce the disparities between areas, and between boys and girls;
- to improve quality of education by the restoration of the curricula; and
- to reinforce and develop vocational training and technical education.

Operational Objectives of the PDDE

The primary operational objectives of PDDE include:

- to change the rate of pre-schooling from 1% in 2002 to 5% by 2013;
- to raise the primary rate of schooling from 41.7% in 2002 to 91% by 2013;
- to carry the rough rate of schooling of the girls to the basic cycle 1 from 33.3% in 2002 to 91% by 2013;
- to change the primary rate of schooling in rural zones from 38% in 2002 to 90% by 2013;
- to carry the rate of schooling to the basic cycle 2 from 13% in 2001 to 23% by 2013;
- to change the proportion of manpower of the rural CEG from 19% in 2001 to 40% of the total staff complements of the basic cycle 2 by 2013;
- to increase the share of private from 14% in 2001 to 20% of manpower of the colleges by 2013;
- to increase the rate of elimination of illiteracy from 19.9% in 2000 to 38% by 2013;
- to create 50 centers of training under development community (CFDC);
- to carry the rate of survival to the basic cycle 1 from 57% in 2002 to 93% by 2013;
- to reduce the rate of redoubling to CM2 from 36% in 2002 to 10% by 2013 with an intermediate rate of 15% by 2006;
- to reduce the rate of average redoubling of the 6 to 3 from 20% in 2001 to 7% by 2013;

- to reduce the rate of redoubling in 3 from 27% in 2001 to 10% by 2013;
- to carry the rate of survival to the college from 52% in 2002 to 76% by 2013; and
- to carry the rate of success in elimination of illiteracy from 42% in 2000 to 80% by 2013.

Concerning post-primary education, the PDDE, in theory, will implement the reform program as it has with the primary education. Currently, after nearly 5 years of implementation of the PDDE at the level of basic education, significant progress has been made even if much remains to be done. With regard to preschool education, the number of establishments has strongly increased (15.7% on average annually between 2003 and 2005 as a whole and approximately 12% in the rural zones), but the total rate gross of preschool hardly exceeds 1.4% (2005–06). For basic education 1, the gross enrolment rate of primary schooling grew from 41.7% in 2002 to 54% in 2006 (against an objective of 57%). However, disparities according to place of residence remain high. The rate of completion improved from 26% in 2002 to 40% in 2006 (against an initial objective of 46%).

For secondary school education 2 (CEG, first cycle THESE, colleges offering free–Arabic learning), the gross rate of enrolment grew from 13% in 2002 to 17% in 2006. However, there was a high drop-out rate for girls. For secondary education, the gross enrolment rate is 4.1% (girls 2.7%, boys 5.9%). Drop-outs are more frequent among girls, particularly in rural areas. Concerning higher education, the rate of access to the university was only 73 students per 100 000 inhabitants in 2004, lower than the average for sub-Saharan Africa (230 students per 100 000 inhabitants). Technical and vocational training (EFPT) accommodated, in 2005, nearly 2.5% of the pupils in secondary education; of these more than half were in private establishments. Regarding the elimination of illiteracy, remarkable progress was recorded in recent years, even for adults (28.7% in 2005 against 19.9% in 2000). Lastly, teaching in the Koranic schools takes place within ten schools with a total staff complement of 5243, of which 2.948 are female.

Management

With the development and the adoption of the law of June 1998, Niger was equipped, not only with a legal framework for its education system, but also of a new model of decentralized management for its management, the aim of which is to ensure the participation of communities and local actors in financing and managing educational structures. The decentralization policy adopted by the ministry of education follows the law that stipulates that financing and managing publicly owned establishments will be ensured by the state, the communities, the

families, and all the concerned persons or entities. The burden-sharing is as follows:

- State: infrastructure, equipment, handbooks, and school stationery, training the trainers, hired labor charges, logistics, and purses.
- Communities: infrastructure, equipment, supplies, hired labor charges, maintenance, electricity, water, telephone.
- Families: supplies, maintenance of the schools.
- Partners in development: infrastructure, equipment, training the trainers, research, logistics.
- Company: formation, research, and training.
- Other NGOs: gifts and legacy.

Implementation of this law required the creation of several bodies: national, regional, and local. At the national level, the National Council of Education (CNE) is the body that determines the general orientation of education. The Regional Council of Education (CRE) and various Regional Councils of Education (CSRE) follow the same mission as the CNE, and are in charge of the follow-up of the educational policy. At the local level, the Board of Management of the School Establishments (COGES) is the management body that determines the day-to-day running of the school establishments.

Educational Sector Analysis

Tables 4–6 give data charting the progress of education since 2000.

1. Primary education: The access rate TBA (65% in 2007) remains below 100% in spite of a remarkable evolution during the last 5 years. There has been an annual increase of 13% in the number of new pupils entering schooling since 2003 following the implementation of the PDDE. Like the TBA, the gross enrolment ratio shows a marked improvement (37% in 2001 and 57% in 2007).

Taking into account the level of poverty of the populations entirely dependent on the state, the percentage of children from deprived families in private schools remains very low.

2. Secondary: The weakness of the TBS at the secondary level testifies to the weak development of this sub-sector and is explained by a very strong downturn due mainly to the policy of automatic promotion in primary education, and also to other factors such as the early marriage of girls especially in rural areas and the precarious living conditions of pupils obliged to leave their villages and go to urban centers to study. However, the continuing development of primary education as part of the implementation of PDDE involves new challenges with secondary education in Niger.
3. Superior: Like other education sub-sectors, higher education is underdeveloped in Niger. The country has only one national university and one Islamic university managed by the Organization of the Islamic Conference (OCI).

As for the other levels, the rate of access to higher education in Niger is lower than that in other countries of sub-Saharan Africa with similar levels of income. In 2005–06, this rate was estimated at 122 students for 100 000 inhabitants. At the University Abdou Moumouni (UAM), between 2001–02 and 2003–04, the enrolments dropped from 6833 to 6612 students before rising to 8710 in 2005–06. It is estimated that these enrolments are two to three times the capacity for absorption in the labor market of Niger, given its current economic base.

The UAM accommodates most of Niger's higher education student population. Within the UAM, the

TBS	10%	11.2%	13.7%	14.9%	17.1%	17.0%

distribution of students between various faculties is unbalanced. In 2005-06, the arts and social science (FLSH) and economics and legal studies (FSEJ) alone accommodated two-thirds of the registered students accounting for 35% and 32% of enrolments. Since 2001-02, enrolments in these faculties fell by 6%. This unequal distribution reflects an imbalance in admissions to the baccalaureat.

4. Technical and vocational education and training: Technical and vocational training represents the poor relation of the education system of Niger. It accommodates only 2.5% of students. However, the recent adoption of a national policy on technical and vocational training and the PPDE will undoubtedly allow it in future years to develop in ways adapted to national needs.

Disparities

1. Primary education: Regional disparities in term of gross enrolment rates declined over the period 2000-06. Indeed, dispersion around the national rate measured by the standard deviation of the index of disparity moved from 0.62 to 0.34 over this period.
2. Secondary level:

Qualitative Aspects

Success in examinations at the end of the year

1. Primary education level: One of the indicators of the quality of primary education is the rate of success in examinations at the end of the yearly cycle.

The rate of success in the CFEPD shows an improvement since 2001. However, one notes a drastic fall in 2005-06.

2. Secondary level: There is a downward trend in the rate of success in the BEP. This tendency was accentuated in 2006 with the reform in the organization of the BEPC that prohibits any fraud. The fall in the rate of success in the baccalaureat particularly since 2001 was due to the reforms introduced into the organization of the baccalaureat. With the BEPC, as with the VAT, the rate of success was affected by the problems of quality involved in the nearly exclusive recruitment of teachers of the new type (ASCN, EC). In 2006, the fall is explained exclusively by the anti-defraud provisions taken by the government.
3. Higher level: The gender disparities are marked even in higher education: sociocultural and economic obstacles mean a large loss of girls at school, making it rare for them to reach the higher level (source: statistical directory 2005-06, DEP/MESSRT, January 2007).

Factors influencing quality of education: teachers

The improvement of schooling observed in the implementation of the PDDE was achieved, thanks to a massive recruitment of teachers with numbers almost doubling between 2000 (15 668) and 2006 (31 131). However, the recruitment of full-time teaching staff has slowed while that of under-paid contractual teachers has grown from 17% of educational personnel in 2001 to almost 80% of the primary teaching service today, creating problems of professionalization and quality of teaching. In addition,

the small proportion of full-time professional teachers exacerbates the disparities already noted in access to basic education.

1. Secondary level: The weak development of the sub-sector of secondary education is compounded by small number of secondary teachers: 4267 for all cycles for 211 374 pupils. One finds here still the problem of the under-representation of women, and the fact that most secondary teachers are not civil servants (nearly 85%). Quality is problematic, given that teachers who are not civil servants rarely profit from any professional training.
2. Higher level: The number of permanent academic teaching-research staff has also grown only slowly from 245 in 1997–98 to 293 in 2005–06. On the other

hand, more and more recourse to non-permanent personnel was evident: these accounted for 47% of the teaching at the UAM in 2005–06.

Education and Economic and Sociocultural Development: External Effectiveness

There is neither an effective link between education and the labor market, nor is there an employment policy. With the support of the ILO, in May 2004 a study of the employment policy was undertaken, but as yet, the results of the study are not available. Indeed, the National Agency for the Promotion of Employment (ANPE) is the public utility of the modern job created in 1996 in place of the service of the labor. One of the missions of this institution is the follow-up of the labor market; it also provides information on the employment picture. ANPE has set up and carries out programs of promotion in various categories of the labor market. These include a program of insertion of young graduates in small to medium enterprises, a program of reconversion of the unemployed, a program of support of initiatives for independent employment, and a program of support for creation of rural jobs. Moreover, a steering committee was created in May 2003

for the follow-up and evaluation of programs of employment. This committee is composed of the representatives of ANPE, the trade unions of employers, workers and the unemployed. However, it should be noted that the implementation of these programs is always not effective. Under these conditions, prospects for employment will improve only if the effectiveness of implementation improves.

It is noted that distribution in various sectors has not evolved systematically. However, for banks and insurance, transport and communication, and social services, there was a consistent increase in the number of employees from 1999 to 2003.

Education and Sociocultural Development

In Niger, access to education at the primary level is primarily the responsibility of the state. The educational sector reflects the deep disparity that exists between the possibilities provided by the education system and the progression of young people in education and the labor market. With indicators among lowest in the world, the challenges facing schooling in Niger are made more complex with a great disparity between boys and girls. The quality of education is also a concern because the state lacks the capacity to attract, train, and employ qualified teachers; the unsuitability of much of the curriculum to the local context; the lack of textbooks and teaching materials; and deficiencies in infrastructure and school facilities. Enormous disparities exist between the cities and rural areas, provision for girls, and the distribution of educational services. The fundamental problem is poverty: Niger lacks the financial and material resources needed by the sector and it needs workable strategies to remedy the deficiencies. The lingering problems of illiteracy and lack of education for all are among the key factors that explain the very low level of IDH in Niger. However, the national authorities are conscious of the strong correlation that exists between the level of poverty in Niger and the low level of education of the population. Therefore, great efforts are being made by the government with support from partners in the development of programs that aim at increasing levels of schooling, elimination of illiteracy, and the vocational training in general, and in particular for girls and women.

As for the use of national languages in primary education, this has been a 27-year-old experiment undertaken in

42 schools. An evaluation was carried out in 1999 by the Ministry for National Education in collaboration with the GTZ. This evaluation showed that the experimental schools are more effective and better adapted to the socio-cultural context compared to the traditional schools and that, in certain localities, it encourages more of the population to be interested in school life. It showed, moreover, that the use of mother tongue-like languages for teaching facilitated learning by pupils. The training in mother tongue during the first years of the schooling does not act to the detriment of the acquisition of French – in fact, it is just the opposite, a good initiation in reading and writing in mother tongue facilitates the training in French.

Nonformal Teaching

Nonformal education covers the elimination of illiteracy and the training of adults, the community centers of formation under development (CFDC), and the renovated Koranic schools.

Of all these components, only the elimination of illiteracy has permanent structures that facilitate initial and continuous training. Thus, the programs of functional elimination of illiteracy are summarized as:

Table 17 Student and faculty numbers at UAM, 2005–06

Table 20 Evolution of the recurring expenses between 1990 and 2002[illegible]

- learning to read, write, and count in the national languages;
- topics on health, for example, AIDS prevention, hygiene, pregnancy, and nutrition; and
- environment: for example, bush fires, desertification, agriculture.

The program for neo-literates involves support for the village press and libraries. The village press treats topics relating to agricultural and animal production, hygiene and improvement of living conditions of the rural populations, and the organization and management of community activities. As for the village library, it aims at encouraging adults to read, to realize the need to teach reading and writing, and to popularize technical topics. It also takes part in informing the rural population on its rights and duties and in explaining clearly to them the process of holding elections and the outcomes of democracy. All in all, the village library complements the rural press.

Financing of Education

Public expenditure

Since the implementation of the PDDE in 2003, the undersector of basic education has profited from important funds allocated by the financial partners.

In total, the expenditure of education consists of the wages of the personnel, which account for approximately more than 75% of the total expenditure.

Other sources of financing

Apart from public financing (state, parents, communities), education native to Niger receives other sources of financing from donor communities and development banks as technical and financial partners.

Conclusion

The education system is probably one of the least developed ones in the world. However, the difficult context and the deficiencies in the performance of the system have not prevented a few years of relative dynamism of the sector. This dynamism resulted from the engagement of the national authorities, the educational administration, educators, and other partners of the school. Since 2003, the interventions of the PTF through the PDDE also impacted the changes. However, at all levels of education, the development of the education system of Niger is characterized by significant disparities between the zones, the areas, and the sexes. The cover of the education system is higher in urban than in rural zones with regard to basic teaching I as compared to basic teaching II. The gender inequalities are more pronounced in basic teaching II. The improvements in the education system are especially represented by important increases in the number of educational personnel recorded in basic cycle I since the beginnings of the

implementation of the PDDE in 2003. Concerning teachers, one notes that, owing to lack of means, the state is recruiting very few full-time teaching staff and is forced to use contractual and the so-called national civic service staff with secondary education; the latter might not have received any teacher training. With the passing of years, these new types of teachers have become the majority, and the established minority of professionally trained teachers is concentrated in the urban zones. At the secondary level particularly, in spite of the crucial lack of classroom teachers, a great number of teachers easily give up chalk for an administrative office. Lastly, it is necessary to note that even the best education system will be functional only if the pupils remain in good health, and if the combined effects of education and health contribute to economic growth and reduction of poverty – two key objectives for all countries.

Glossary

Sami population – Aboriginal minority population living in the Norway, Sweden, Finland, and Russia.

State education loan fund – Public Financial institution that provides grants and soft loans to students in higher education and upper secondary education and training.

Stortinget – National assembly of Norway.

Tertiary vocational education – Post-secondary vocational courses between 6 months and 2 years, not recognized as higher education.

Training company – Company or public institution that has accepted responsibility and been formally approved for the training of apprentices, as a regular part of national upper secondary vocational training.

Udir – Directorate of Education and Training. Under the Ministry of Education and Research.

General Background

Norway is located in the far north of Europe, with large areas north of the Polar Circle. It consists of the mainland and the islands of Svalbard and Jan Mayen, with a total area of 387 000 km² and a population of 4.7 million. Population density is 15 km⁻² in mainland Norway. Up to 31% of the population are in the age group 0–24 and 20% are 60 years and older. The annual population increase is 0.5–0.6%.

Norway is a unitary state, monarchy, and parliamentary democracy, independent since 1905, after several hundred years under Danish and Swedish rule. Norway is a member of North Atlantic Treaty Organization (NATO) and European Free Trade Association (EFTA). In a referendum in 1994, 52% of the population decided against full European Union (EU) membership. However, through the European Economic Area (EEA) Agreement, Norway is a member of the European Single Market and participates in several EU programs and institutional arrangements, for instance, in the area of education and training.

Norway has three political and administrative levels. Apart from the national level, there are 19 counties (regions) and 431 municipalities. Each of these units has a locally elected decision-making assembly and an executive body appointed by the relevant assembly. The national assembly (Stortinget) decides national political

principles and goals, as well as budgets and legal frameworks for activities under each ministry. Counties and municipalities have specific responsibilities within this framework. Local autonomy is a strong principle. Both counties and municipalities report directly to the national level.

Geographic, topographic, and climatic conditions as well as the availability of major natural resources – oil and gas, fish, forests, and waterfalls – strongly influence the economy and the production and population structure. The topography and climate limit the importance of agriculture. Small- and medium-sized enterprises (SMEs) constitute more than 99% of all companies. As much as 80% of them have less than five employees. SMEs employ nearly 70% of the total labor force. Only about 1 000 enterprises have 100 employees or more.

Despite the dependency on natural resources, Norway is a modern industrial nation. Approximately 21% of employment is in manufacturing and construction, whereas 75% is in tertiary sectors. Mechanization and automation characterize most industries, ensured by a high level of investments. Deliveries of goods and services to the oil sector are substantial. Energy-intensive metals and chemicals production, as well as shipbuilding, are large export-oriented industries. Fish farming has boomed over the last 20 years. The economy is open with an extensive foreign trade and thus vulnerable to fluctuations in international markets. In recent years, inflation has been at 2–3% and the unemployment rate fluctuates between 2% and 4%.

The general education level is high. More than 95% of young people enter upper secondary education and training, and more than 35% attend higher education. Female students are in the majority in upper secondary and higher education. Public spending in education is 6.6% of gross domestic product (GDP) and 16% of total public expenditures. The use of information and communication technology (ICT) is part of everyday family life and work for the vast majority of the population.

The immigrant population comprises nearly 380 000 persons (8% of the total population), of which 75% originate from non-Western countries. Immigrants reside in all 431 municipalities. Up to 48% of non-Western immigrants live in the Oslo area and constitute about 22% of the total population in the capital city. The level of education in the immigrant population varies greatly, according to the background of the country. Among persons born in Norway of two foreign-born parents, enrolment in higher education is higher than the country

average for the age group 25–29. Unemployment is higher than the country average in all immigrant groups.

Education and training are viewed as a central means to achieve national social, economic, and regional policy goals. Hence, the provision of those is considered a national, public responsibility and the education and training policy is shaped in the interface between cultural, economic, and social distribution policies. Vocational education and training (VET) is strongly emphasized in mainstream education, as well as in a broader Lifelong Learning (LLL) perspective.

Principles and Goals of the Education System

Norwegian education is rights based. The overall goal of the Norwegian education system is to give each individual the opportunity and necessary support to identify and develop his/her talents and interests to the end of becoming established as a satisfied, active member of society. Similarly, the education system is expected to provide the various sectors of society with qualified, critical, and constructive individuals who will support and contribute to the maintenance and further development of the welfare society.

Equality and freedom of choice are general political principles, which lie at the heart of Norwegian education and vocational training policy. All residents are to be ensured equal rights of access to quality education, irrespective of gender and social, geographical, and cultural background. Accordingly:

- all education and training in the public domain, including higher education, is supplied free of charge, where costs are covered by public budgets;
- every young person completing compulsory education is entitled by law to 3 years of upper secondary general education or VET;
- the supply of education and training should be of high quality and broad enough to allow for a range of choices, irrespective of geographical location and social factors; and
- state grants and soft loans are available to all students in need of financial support.

Structure and Operation of the Education System

Preschool education is gradually becoming part of the mainstream education system; however, attendance is not compulsory. Kindergartens cater to children aged 0–5 years. In 2006, almost 93% of all children aged 3–5 years had a place in kindergarten.

Mainstream education in Norway is 7 + 3 + 3 years – primary, lower secondary, and upper secondary education (see **Figure 1**). It has a centralized framework with national legislation, curricula, financing, and quality control. However, the delivery of education and training is decentralized to a large number of public and private providers, including more than 35 000 approved training companies (with apprentices). Vast majority of students are enrolled in public education institutions. Both public and private providers of national education and training receive financial support from the government. They are subjected to national quality control and are obliged to organize examination and assessment according to national guidelines, involving external experts.

In 2006, nationally recognized education and training programs were delivered by 3131 primary and lower secondary schools, 453 upper secondary schools, and 70 tertiary education institutions (**Table 1**).

Preschool and Early Childhood Care

Kindergartens cater to children aged 0–5 years. The national Framework Plan for the Content and Tasks of Kindergartens states that they should work in a goal-oriented manner toward children's development and learning, and stimulate children's linguistic and social competences. Besides being quality pedagogical institutions that provide all children a foundation for personal development and regular schooling, they provide care for children while their parents are at work or study. Hence, the kindergartens are also considered a means to promote gender equality in the adult population.

In 2006, about 80% of all children aged 1–5 years had a place in kindergarten. It is the aim of the government to obtain full coverage and introduce a legal right to attendance from 2009. Lack of qualified personnel is a serious obstacle to achieving this goal, as national law states that every kindergarten and each of its department must have staff with a specialized education at the bachelor's level. Approximately 30% of the 70 000 staff in Norwegian kindergartens are trained preschool teachers.

The municipalities are responsible for the establishment and operation of the preschool provision and for ensuring its quality. Nearly 50% of the kindergartens are privately owned and operated with public support, based on formal approval by the municipalities. Financing is shared between the public and the parents; the latter cover 22–30% of the total costs.

Primary and Lower Secondary Education

Compulsory schooling in Norway is for 10 years and children start school at the age of 6. Primary and lower secondary education are founded on the principle of a

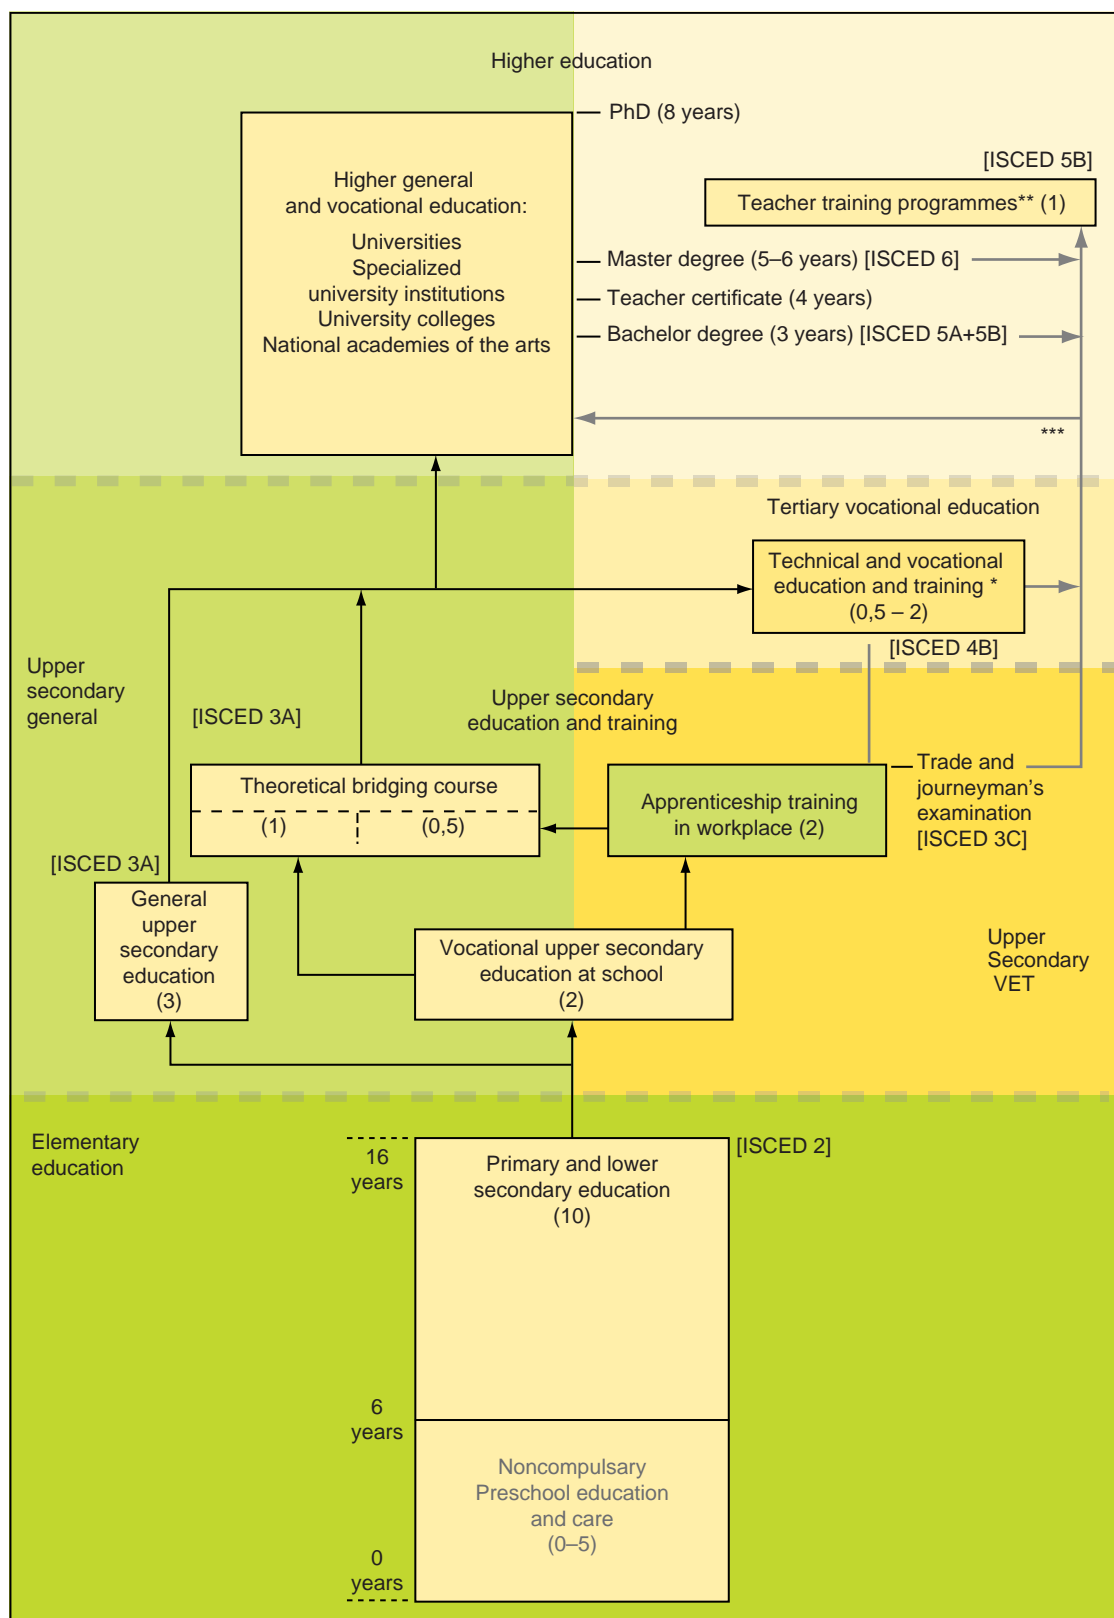

Figure 1 Education and training in Norway – 2008. *Technical school, training of civil servants, health personnel, etc.

Data from Statistics Norway web pages, public web portal for the education sector and Statistics Norway publication: *Utdanning 2007*.

unified school system that provides equal and adapted education for all on the basis of a single national curriculum. An adapted curriculum is being used in the Sami population, and most Sami children have the opportunity to receive instruction in their mother tongue.

The subject curricula lay down a common learning content for all pupils, which increases in scope throughout the school and is greatest at the lower secondary stage. There is, however, room for adaptation to local conditions and to the particular needs of individual pupils. Immigrant students receive mother tongue language training.

Teacher education in Norway is currently 4 years at a university college, but an extension of 1 year is being discussed, thereby turning it into a 5-year master program. Teachers are employed by the municipalities, which own and run the schools at this level. Only those with a teacher diploma can be granted a permanent teacher contract.

Upper Secondary Education and Training

Young people, who have completed compulsory education, are legally entitled to 3 years of upper secondary education leading to admission to higher education, vocational qualifications, or to basic skills. All counties have a follow-up service for dropouts and young persons, who have not applied for, or not accepted, a school or training place despite their statutory right. The purpose and task of the service is to assist the youth in finding appropriate education, work, or to establish a tailor-made combination of education and work for them.

Table 2 Available vocational study programs and number of course alternatives at the various levels in Norwegian upper secondary education and training

From Ministry of Education and Research

From 1976, VET, including apprenticeship, is an integrated part of upper secondary education and, from 1998, is regulated by the same act as general education. Entrants to upper secondary level can choose between 12 alternative study programs. Three of them prepare primarily for further academic studies, whereas the other nine equip the students with specialized vocational knowledge and skills (Table 2).

In general, upper secondary VET includes 2 years of school-based education with practical training in school

workshops and short work placements in industry, followed by 2 years of formalized apprenticeship training and productive work in an enterprise or public institution. National curricula in upper secondary VET cover the school-based as well as the apprenticeship part of the training programs. Students in all VET programs must also follow some classes in general subjects. Those who complete vocational training can add a theoretical bridging course and meet entrance requirements for higher education.

Public-private partnerships (PPPs) constitute the backbone of upper secondary VET. Employers' organizations and trade unions as well as individual companies and public institutions are major contributors to policy formation and operation of the system at national and county levels. The extensive collaboration is firmly institutionalized and takes place within formal frameworks at national and county levels.

Postsecondary VET

Tertiary vocational education is based on completed upper secondary general or vocational education and training, or equivalent knowledge and skills obtained through informal and nonformal learning.

Tertiary vocational education comprises a wide variety of vocational courses lasting from 6 months to 2 years. Around 3000 out of the some 10 000 students (in 2007) attend a 2-year training program for a technician. These students generally have completed upper secondary VET and possess a trade certificate. Technical training is in most cases publicly financed and delivered by the counties. All institutions and study programs under this arrangement must be approved by the government agency, National Agency for Quality Assurance in Education (NOKUT) (see below).

The program of continuing vocational education and training (CVET) provides training as a master craftsman for holders of a trade certificate and several years of relevant work experience for those who wish to set up their own business or hold a managerial position in a craft enterprise.

Higher Education

In 2007, higher education and professional training were delivered by 38 public and 32 private institutions. All the seven universities are public, whereas there are both public and private specialized university institutions and university colleges.

The public universities and colleges are owned and financed directly by the Ministry of Education and Research (MOER), but they have a high degree of professional and budgetary autonomy. In general, the recognized institutions have a degree structure, grading

system, and quality assurance system aligned with other European countries, based on the levels of bachelor, master, and PhD. Only a few university colleges have been approved for the delivery of PhD education, and some education programs still differ from the main degree structure.

About 12.5% of students in higher education attend private institutions. Most of them receive financial support from MOER, provided they meet professional requirements and deliver study programs that comply with national standards. Students in private institutions normally have to pay a tuition fee, but may receive financial support from the Norwegian State Educational Loan Fund that covers most of these expenses.

Higher education normally builds on the successful completion of 3 years of upper secondary general education, but enrolment is also granted on the basis of a combination of work experience and exams in six general subjects from upper secondary general education. Since 2001, access can also be granted for those older than 25 years on the basis of documented informal and nonformal competence.

Adult Education and Continuing Education and Training

All adults have a statutory right to primary (from 2002) and secondary (from 2000) education and training. The municipalities and counties, respectively, are obliged to organize appropriate schooling, free of charge. More than 50 000 persons participate annually in adult education provided by municipal and county authorities.

Second-chance opportunities for dropouts, who wish to come back and complete their education, have been in operation for decades. In general, one does not have to attend organized courses to be allowed to sit for the exam in individual subjects or full study programs. Candidates who meet the intake requirements for a study can register and take the examination as a private candidate. Examinations for private candidates are organized regularly.

Around one-quarter of the adult population participates in work-related updating as well as further education and training, annually. This reflects the need for a highly qualified workforce having gained experience in the industry in the knowledge-based economy. Those with highest education tend to attend CVET more often than those with less formal education, resulting in an increasing educational gap. This is a major challenge to the politicians and to the social partners, who cooperate closely with the government on ensuring that relevant LLL opportunities are available.

Training for the unemployed and for immigrants is organized and financed by public authorities. The volume of training provided varies according to labor market fluctuations and influx of immigrants. A variety of other CVET courses are organized by public, private, and semiprivate

providers. Universities and colleges annually provide further education and training for 80–100 000 individuals in their own program areas, delivered as full-time or part-time studies. Training, according to national curricula, on secondary and tertiary levels, as well as work- and personally-oriented courses are provided by 21 recognized adult education associations, 13 distance education institutions, and 77 folk high schools. In 2007, some 550 000 students attended courses organized by these structures.

Administrative Structure

Whereas legislative power lies with the Norwegian Parliament (Stortinget), the MOER has overall responsibility for national policy development and administration of mainstream education and vocational training at all levels.

Individual municipalities are responsible for the pre-school provisions, and for regular and adult primary and lower secondary education. The counties are responsible for public upper secondary general education and VET for all groups.

The Directorate of Education and Training (Udir) is a national agency responsible for development of curricula, national examinations, and quality control in compulsory school and upper secondary education and training. The National Agency for Quality Assurance in Education (NOKUT) is responsible for approval and quality control of tertiary vocational and higher education institutions and programs.

A county governor represents the government in each county. The county governor's education office controls

delivery and results of compulsory and upper secondary education and VET, including adult education (Figure 2).

In upper secondary VET, social partner organizations and the industry hold the majority of seats in all the most influential bodies at national and county level, listed in Table 3.

At the local level, training offices owned by local enterprises and institutions recruit and supervise training enterprises during apprenticeship on behalf of the county authorities. They often provide training for company instructors and vocational theory classes to apprentices.

Financing of Education

There is no political controversy over the current policy of free education delivery to all pupils and students at all levels in public training institutions. The government finances compulsory and upper secondary education and training through block grants to the municipalities and counties. MOER, in general, covers 80–90% of total budgets of public universities and university colleges, calculated for each institution according to a multi-element formula. The remaining part of their budgets is covered by contracted research and provision of tailor-made training to private enterprises and public institutions.

The municipalities are responsible for providing the establishment and operation of the preschool provision and for ensuring the quality. Nearly 50% of the kindergartens are privately owned and operated with direct financial support from MOER, based on formal approval by

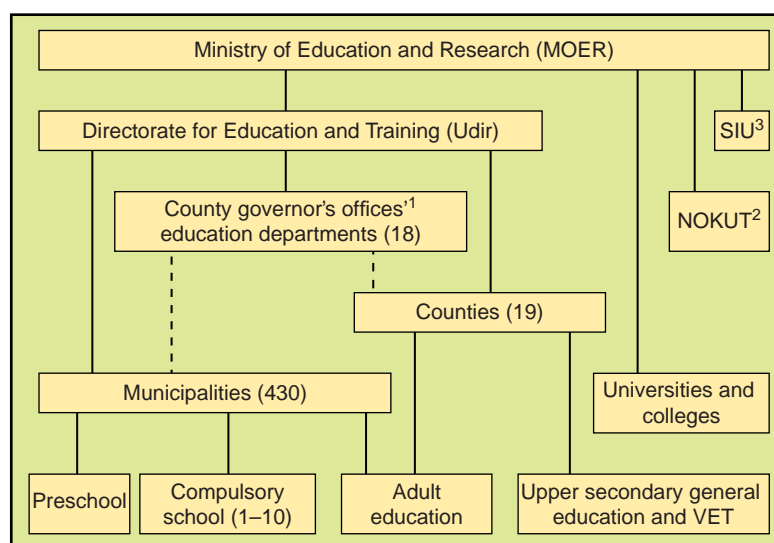

Figure 2 Administration of education in Norway. (1) The county governor is the representative of the national government at county level. (2) The Norwegian Agency for Quality Assurance in Education. (3) The Norwegian Centre for International Cooperation in Higher Education. From *Ministry of Education and Research* (Kunnskapsdepartementet).

Table 3 Overview of bodies in upper secondary VET in which external partners hold the majority of seats and hence execute their influence

<i>Level</i>	<i>Body</i>	<i>Role, responsibilities</i>
National	SRY ^a	Develops national framework for and structure of public VET, including school-based VET, recommends structure of vocational training councils and organizational representation in these, develops national procedures for examination and certification.
	Vocational training councils ^b	Define qualification levels of training in trades under their authority; give input to development of national curricula (VET); and appoint members of SRY and appeals boards.
	Appeals boards	Evaluate and take the final decision when candidates who fail the trade and journeyman's examination appeal the decision of the county-based examination board.
County	Vocational training committees	Recommend regional provision structure and volume of VET. Appoint examination boards, supervise and control apprenticeship training and trade examinations, and issue trade certificates. Main responsibility for development and implementation of quality control system in VET.
	Examination boards	Organize and implement the practical part of the trade and journeyman's examinations and evaluate the results.

^aThe National Council for Vocational Education and Training (Samarbeidsrådet for yrkesopplæring – SRY).

^bThere are nine vocational training councils, one for each of the nine vocational program areas.

the municipalities. Financing is shared between the public and the parents; the latter cover 22–30 % of the total costs.

Approved private education and training institutions that provide public programs receive financial support at the level of 75–90% of costs from the government and cover the remaining part of their budgets by tuition fees paid by the students. Training companies and training offices also receive some financial support from the education authorities, as they accept responsibility for training under public education programs.

A basic principle is that education and training that go beyond mainstream education should be financed by the beneficiaries, that is, the enterprises, the social partners, and the individuals. However, since it is in the interest of the nation to have a well-educated population and a competitive production sector, there is a system of public co-financing by means of targeted subsidies and tax deduction on training investments.

In order to ensure equal access regardless of family economy, students in upper secondary and tertiary education and training, including apprentices, may receive personal grants and subsidized loans from the State Education Loan Fund. This also applies to adult employees who take a leave for further education and training.

Internationalization is a major political objective in upper secondary and tertiary education. All students in tertiary education are encouraged to take half a year or more of their studies in another country. At least 15 000 Norwegians are studying abroad at all times, financially supported by the State Education Loan Fund.

Education and training delivered by formally recognized adult education associations, distance education institutions, and folk high schools is subsidized by the Ministry, but these nonprofit organizations cover most of their budgets by participant fees.

Training for employment under the labor market measures, as well as education of legal immigrants for integration purposes, is fully financed by the government.

Monitoring, Evaluation and Education Research

The legal framework for assessment, validation, and accreditation of learning, as well as for relevant quality-control mechanisms, varies according to the type and level of training and the formal status of training and its appurtenant certificate.

In general, public education authorities are concerned only with training and validation arrangements that are formally recognized under the national education system. Privately organized training that is not aiming for formally recognized certification is not regulated or monitored by the education authorities. However, like any other commercial transaction, privately organized training deliveries are covered by general market regulations.

Individual public and private institutions that have been approved for delivery of recognized training programs are obliged to have a documented system for and to conduct internal quality control of performance and outcomes. Municipalities, counties, and owners of private institutions are responsible for ensuring that such systems are developed and are being used. The national agencies, Udir and NOKUT, conduct random quality control of the training providers.

In every county, there is a system for assessment of prior (nonformal and informal) learning outcomes in relation to upper secondary education and training, whereby immigrants as well as Norwegians may have their vocational qualifications assessed and formally documented with reference to the national program curricula.

Immigrants with documented higher education qualifications from countries and institutions that are not covered by formal agreements on mutual approval of education credits may have their papers assessed by NOKUT.

Education research is conducted by a number of research institutes and higher education and research institutions all over the country, often at their own initiative. MOER and Udir frequently commission studies on selected topics and the ministry employ a number of analysts who are working continuously to identify and further investigate interesting or alarming events and trends in the education sector. Observations are reported back to the decision makers for policy adjustment purposes. Applied and formative research is often implemented in preparation of education reforms and during reform implementation, respectively, in order to establish the situation and reform effects on the ground and guide policy adjustments.

Major Changes and Reforms Since the 1990s

In a rapidly changing world, education reform and policy adjustments are necessarily a continuous exercise. Hence, all parts of the education system have been subjected to adjustments and reforms of varying significance: preschool/kindergarten (2004–2006), compulsory school (1997, 2006), upper secondary education and VET (1994, 2006), tertiary VET (2000, 2003), higher education (1994, 2004), and adult education (1999–2002). (Changes and reforms in terms of legal adjustments with implications for rights and obligations, major changes in content and structure, as well as the introduction of new institutions and re-distribution of responsibilities.)

The reforms have been based on broad political consensus and have targeted both structure and content of training at all levels with the intention to mutually adapt the various parts to each other and create a more streamlined system. A common core curriculum developed in the early 1990s (MOER, 2007a) constitutes the political foundation, providing an overarching framework of principles and goals in education and training, emphasizing both individual rights and needs of society. Major objectives of the reforms have been to:

- further strengthen the general access to the various parts of the education system for all groups, promote equality, and reduce obstacles;
- improve quality and relevance in all parts of the system to meet the needs of the individuals, the labor market, and society in general;
- enhance flexibility in the system in order to allow local adaptations and rapid responses to changing needs relating to developments in technology, markets, and society;

- reduce obstacles to students who wish to move horizontally between academic and VET training paths, to the end of optimal development of human resources;
- ensure the availability of relevant provisions of lifelong and lifewide education and training for adults, as well as various support arrangements to meet the needs of adults choose to educate themselves further.
- increase the efficiency and cost efficiency in all parts of education, at all levels; and
- promote internationalization in education and training.

To these ends, MOER has:

- decentralized responsibilities, but at the same time, strengthened central-level administration and quality control;
- adjusted the administrative and regulatory systems, as well as the financial arrangements for students and providers of education and training according to the strategic intentions of outreach, quality, relevance, control, and flexibility;
- strengthened the emphasis on a broad and general initial education including some core skills in preparation for further specialization and LLL;
- updated the curricula in all types and at all levels of education and training; and
- aligned the Norwegian credit and degree system in higher education with the system of most European countries within the framework of the so-called Bologna Process.

In 2004, the Norwegian government introduced a political strategy with the aim to promote entrepreneurship in education, thereby stimulating innovations and establishment of new production. Three ministries are behind the strategy: MOER, Ministry of Trade and Industry, and Ministry of Local Government and Regional Development. The major social partner organizations and the industry were actively involved in planning the strategy and have formed a separate administrative structure for the implementation, which is based on joint public–private financing (MOER, 2006a).

Major Challenges and Education Policy Issues as of 2008

Enrolment figures show that there are no major structural obstacles to school attainment at compulsory and upper secondary levels in Norway. Inclusive education and follow-up arrangements for groups and individuals with specific needs of pedagogical adaptation and financing are in place. However, performance indicators show that there is still a potential for quality improvements, particularly related to the provision of core skills and the theoretical foundation for further learning:

- Norwegian scores in international tests, for example, PIRLS and Pisa, fall short of the political ambitions; and

- nearly 30% of students who enter upper secondary education drop out or fail to obtain a completed general or vocational certification during a period of 5 years.

Many factors influence these results. The general opinion is, however, that more emphasis must be put on equipping the children with basic literacy and numeracy skills in the early stages of education. More resources should be available for early intervention in cases where children need particular support. Recent research shows that the major explanation for the high dropout rate during the school-based part of VET is insufficient theoretical results in compulsory school and low motivation for further theoretical studies.

In response to the recent findings, MOER is now proposing to give each child a legal right to preschool provision and has increased the financial support to the development of new kindergartens nationwide. School curricula have been changed with the aim to give more attention to basic literacy and numeracy skills at the lowest levels of education, and the training of preschool and ordinary teachers is being strengthened accordingly.

Further improvements in quality and relevance are a permanent issue on the agenda in all parts of the education system. It is a major challenge to further develop appropriate mechanisms to the end of foreseeing short-term and long-term qualification requirements of the labor market. The need to strengthen the services related to counseling and vocational guidance in an increasingly complex world of education and work opportunities, is another issue that receives increasing attention. In the LLL perspective, there is a need for a new and effective strategy on how to motivate and recruit adults with weak educational background to further training, including relevant financial and other support arrangements. Last but not least, an important task is to further align the Norwegian education and training system with systems in other countries in order to further reduce obstacles to international mobility.

General Background

Oman is located on the southeastern edge of the Arabian Peninsula, with a total land area of 309,500 km². It shares its borders with Saudi Arabia, the United Arab Emirates, and Yemen and overlooks the Arabian Gulf, the Gulf of Oman, and the Arabian Sea. As a gateway between the Indian Ocean, East Africa, and the Arabian Gulf, Oman's location has always been strategically important. It covers 309,500 km² with a coastline extending 1700 km. Coastline plains represent about 30% of the total land area, mountain ranges occupy another 15%, and the remainder of the country is mainly sand and gravel desert. Although the mountains only cover about one-sixth of Oman's total area, they have always dominated the country at their feet, and determined the pattern of settlement there. The Sultanate of Oman is divided into eight administrative regions, which are further subdivided into 59 districts or *wilayats*. Each *wilayat* is governed by a mayor, *wali*, who is responsible to the Ministry of Interiors.

Oman's history begins in the early third or late fourth millennium BC, with the rise of a society that had cultural and trade ties to ancient Mesopotamia. Between the fourth and seventh century AD the area was dominated by successive Persian empires. During the first century AD Arab tribes began to migrate into Oman. When the new religion of Islam spread throughout the region in AD 630, Persian rule ended and Oman's Islamic-Arab character was firmly established. In 751, *Ibadhi* Muslims, a moderate branch of the *Kharijites*, established an Imamate in Oman. (The term *Ibadhiyah* applies to a Muslim group, which was considered by most writers as a moderate branch of the *Kharijite* movement. *Al-Ibadhiyah* is one of the earliest Islamic sects, the foundation of which goes back to the first half of the first century H. The adherents of this school still form a number of independent communities holding fast to its teachings. The largest of these today is in the Sultanate of Oman, where *Ibadhis* form the majority and *Al-Ibadhiyah* is the state religion. There are other minorities in Zanzibar on the east coast of Africa, in Jabal Nafusah and Zuwarah in Libya, on Jerba Island in Tunisia, and in Wad Mzab in Algeria.)

Contact with the Western world began when Portugal seized Muscat and other coastal strongholds in the early sixteenth century. Portuguese power waned after 1624, when a strong line of imams asserted itself, and Muscat was recaptured in 1650. The Imamate then flourished again under the *Ya'aribah* dynasty, which extended Omani rule or

influence to both sides of the Arabian Gulf and the East African coast.

Omani society is highly structured, both politically and religiously. Politically, it is a long-standing monarchy; the Sultan is head of state, the highest and final authority, and the supreme commander of the armed forces. There have been some democratizing trends, however, created by Royal Decree in 1997, the basic statute of the state established the state Council. The Council is a bicameral legislature with the *Majlis al Shura* (Consultative Council), whose members are elected by Omani citizens, and the *Majlis al Dawla* (State Council), whose members are appointed by the Sultan. (State Council (*Majlis al Dawla*) is an appointed body of 58 members, picked by the Sultan, established in 1997 and Consultative Council (*Majlis al Shura*) is an elected body of 83 members, established in 1991.)

Islam, the state religion, exerts profound influence over most aspects of Omani society in that the *Quran* prescribes politics, economics, law and justice, and social behavior, as well as theology. Most Omanis are *Ibadhi* with minorities adhering to *Sunni* or *Shia* Islam (Karabenick and Moosa, 2005). Oman's legal system is founded upon the Islamic *Shari'a* traditions of the *Ibadhi* school. Civil, criminal, and commercial cases are handled by the courts of first instance; matters of personal status and family law fall under the jurisdiction of *Shari'a* courts. The White Book which was enacted in 1996 is the most important piece of legislation. Although the Basic Law states that the judiciary is independent, it remains subordinate to the Sultan and the Ministry of Justice. In general, the legal system is based on both English common law and Islamic law. Religious conflicts have not been prominent in Oman since tolerance to both Muslims and non-Muslims is emphasized.

Oman's population was 2,331,391 as of the 2003 Census with a quarter of this number being expatriates: the percentage of females is 49.1% of the total national population. **Table 1** shows the distribution of Omani population by educational status and gender. However, the number has been increasing since that year. It is estimated that the total number extends to 3 million.

Education has expanded dramatically since 1970, when only three primary schools existed and few girls received any schooling. Education is provided free to all Omanis but is still not mandatory. About three-fourths of Oman's adult population is literate; there has been a substantial increase in the number of literate women. Karabenick and Moosa (2005) stated that comparative enrollments of boys

and girls indicate progress in reducing the gender gap with only a slight difference in the gross net enrolment ratios (Table 2). Thus, education is one area in which there is greater equity. Ninety-two percent of all girls who are eligible attend schools (grades 1–12). Girls also represent half of the students attending public schools, approximately half of the students attending Sultan Qaboos University (SQU), and they generally receive half of the government grants to study abroad.

As of 2007 statistics, the number of public schools is 1053, enrolling 563,602 students, employing 39,993 teachers and 4521 administrators. In addition, the number of private schools is 170, enrolling 32,134 students (Ministry of Education, 2007).

The Seventh Five-Year Development Plan (2006–2010), is a continuation of the previous 5-year plans but distinct from the others in that it witnesses the implementation of the development of education beyond basic education representatives in grades 11 and 12 along with the expansion of the application of basic education, in addition to the continuous development and improvement of the quality of educational services in light of the outcome of educational and performance indicators achieved by the Sixth Five-Year Development Plan (2000–2005). One can recognize three stages in the development of education in Oman:

Table 1 Percentage distribution of Omani population by educational status and gender

<i>Educational status</i>	<i>Male %</i>	<i>Female %</i>	<i>Average %</i>
Illiterate	11.81	23.82	17.77
Can read and write	21.17	18.46	19.83
Primary stage of education	23.66	18.10	20.90
Preparatory stage of basic education	19.14	15.78	17.47
Secondary stage	17.36	18.39	17.87
Postsecondary nontertiary	2.77	2.29	2.53
First university degree	3.50	2.73	3.12
Master degree	0.38	0.10	0.24
PhD degree	0.07	0.02	0.04
Not stated	0.14	0.31	0.22

From Sultanate of Oman, Ministry of Information (2007). *Oman 2006–2007*. Oman: Ministry of Information.

- Stage one emphasized the rapid quantitative development of education.
- Stage two started in the early 1980s, when the Ministry of Education (MoE) initiated serious efforts to improve the quality of education.
- Stage three began in 1995, after the Conference on Oman's Economic Future, Vision 2020, when a number of reforms were introduced in order to cope with the educational requirements of the future.

Goals of the Education System

The major aim of education and its philosophy in the Sultanate is to develop the current capabilities of the Omani people. Education is one means through which this aim can be realized. It provides the individual with the basic knowledge that enables her/him to objectively and advantageously employ scientific knowledge and skills that are acquired throughout life. Education also stimulates innovation and helps to develop the linguistic skills necessary for oral and written communication that mirrors the Islamic religion and its high ideals. Furthermore, it seeks to inculcate in Omanis the precepts of Islam to the extent that they are reflected in attitude, word, deed, and lifestyle. It also takes interest in the psychological and mental well-being of the individual, encouraging healthy practices and attitudes to work, health, and hygiene. The general aims of education before 1995 are as follows (Al-Shanfari, 1991: 90–114):

1. To create an Omani generation that is capable of fulfilling its responsibility within the national and patriotic framework.
2. To keep up with the progressive changes of modern life.
3. To develop knowledge in keeping with the noble principles derived from Islam.
4. To develop the physical and emotional aspects of the individual.
5. To acquire an appropriate awareness and skills of the nature of common professions and careers in the individual's environment.
6. To provide Omanis with an awareness of their rights, duties, and the commitment that they should have toward their nation.

Table 2 Enrollment of Omani students by gender in general education 2005–2006

<i>Grade level</i>	<i>Gross enrolment rate</i>			<i>Net enrolment rate</i>		
	<i>Males</i>	<i>Females</i>	<i>Total</i>	<i>Males</i>	<i>Females</i>	<i>Total</i>
Grades 1–6	100.0	99.53	99.83	89.26	90.15	89.69
Grades 7–9	99.85	93.49	96.72	73.98	75.65	74.80
Grades 10–12	85.56	81.99	83.78	62.42	63.60	62.98

From Ministry of Education (2006). Education for all in the Sultanate of Oman 1970–2005. A contribution to the celebration on UNESCO's 60 year anniversary. Muscat: Oman.

7. To develop the students' ability to maximize the use of their leisure time.
8. To provide every member of society with educational opportunities.
9. To inculcate love, pride, and sacrifice for the homeland and the need to protect it and maintain its independence.

The general aims were reviewed in 1995 as a result of changes going on at the national and international levels, and reforms were introduced in the system. The policies and aims were explicit in the National Five-Year Plans (1996–2000), which highlighted the strategies and aims of developing human resources. The plan emphasized the following goals:

- Strengthening and improving science, mathematics, and English-language programs.
- Assessing the quality of the education system and schools' input, processes, and output.
- Introducing computer laboratories at all levels of schooling.
- Using computers in all subjects, especially in English, mathematics, and science.
- Providing learning resource centers (LRCs) in all schools; LRCs would also be designed for use by members of the wider community.
- Developing the inspectorate system and improving processes for the recruitment of staff.
- Application of information technology to the needs of the Ministry.
- Improving the teaching profession through:
 1. Ensuring that all 11,000 existing Omani teachers with 2 years diploma attain a 4-year degree by 2015.
 2. Establishing a pool of substitute teachers in each region to cover longer absences.

Omanization and Manpower Development

The issue of Omanization came into being with the publication of Oman's third National Development Plan (1980–1985). Omanization, according to public agreement, is a process by which jobs are taken up by efficient and competent Omani nationals to fulfill organizational needs at the governmental level.

Al-Lamki and Suleiman (1992) state that in fact all three facets of Omanization – those impacting upon the Omani government, the private sector, and the Omani citizen – resonate with improved education and administration systems. For the individual Omani, Omanization represents new potential for personal economic advancement. Within the government, it has been seen as a countermeasure to the unpopular importation of foreign labor, so necessary to the development of the Sultanate's infrastructure and even

more so, potentially harmful to the delicate fabric of the culture and national security of the Sultanate. Al-Lamki (1992) argues that there have been few instances where the implementation of Omanization in the private sector has been the result of a long-term systematic strategy for the recruitment, retention, and advancement of Omani nationals into the management structure of companies.

While in the private sector, Omanization may result in a slight (and reluctant) increase in Omani employees, the public sector has to abide by certain restrictions regarding the recruitment of expatriate staff. These are embedded in the Civil Service Regulations, which state the following (The Fourth Five-Year Development Plan, 1995):

1. An expatriate official will fill no position in the civil service if a qualified Omani citizen is available for the post.
2. The positions needed by different ministries will be clearly specified once a year.
3. More efforts should be made to achieve self-sufficiency, and at the same time to continue recruiting expatriates when Omanis are not available.
4. Personnel departments should be managed by Omanis in the private sector establishments to ensure that there is an appropriate climate for the placement of the national labor force.
5. Compensation is to be given to the private sector for all expenses incurred in training Omanis to replace expatriate labor and to fill new jobs which require a particular standard of training and skills.

The Ministry of Higher Education contributes toward the promotion of the policy and objectives by increasing the enrolment in colleges and universities, as well as, by ensuring that Omanization remains an important criterion for employment at all levels of educational institutions. Manpower training is an important part of the enhancement process and the government gives top priority to it. The volume of education and training and the resulting number of those who pass through the system depends on the financing of programs. The level of the State's contribution to education affects the number of possible institutions that can be established, the current budget, and therefore the amount of manpower available for employment.

Structure and Operation of the Education System

The educational system in Oman is centralized and controlled by the government, with the exception of prebasic education and private schools. The MoE, in cooperation with other ministries and bodies such as The Sultanate *Diwan*, the Ministry of Social Development, the Ministry of Manpower, the Ministry of Defense and Police, is responsible for education, its expansion, and supervision.

The MoE is the principal executive authority for the general education system which includes preschool education, basic education, and postbasic education. At present there are 11 educational directorates and departments within the Ministry which is distributed throughout all regions of Oman. However, the organizational structure has gone through many changes to meet the expanded educational needs in the growing regions. At present, the Ministry undertakes certain duties. It draws up educational policy within the general policy framework of the State in accordance with its principles and national aims. The Ministry has to keep pace with the needs of production and services. It makes plans and establishes programs and means of implementing policy. It also has to respond to community needs and keep abreast with modern scientific progress. Tertiary education is the portfolio of the Ministry of Higher Education, while vocational training is the charge of the Ministry of Manpower. In addition, there are other government and private institutions that offer specialized education and training in various fields.

Preschool and Early Childhood Care

This education includes kindergartens and nurseries. Most of them come under the jurisdiction of the Department of Private Education within the MoE. The number of children attending these institutions has been increasing since 1970, especially when Omani women began to participate in the labor market. Women's associations, other ministries, and the private sector contribute to develop this kind of education. It is increasingly privatized and parents pay fees to register their children in these institutions which serve about 2.5% of the total age range (3–6 years). The kindergarten curriculum is designed to promote self-learning and enhance emotional, imaginative, and esthetic development through a

range of activities with due consideration being given to the objectives and aims of education as detailed by the MoE. As a result of an increase in the number of kindergartens throughout the Sultanate of Oman, a need arose to expand supervision to include regions outside Muscat. In the academic year 2003–2004, kindergarten supervisors were trained and deployed throughout the various educational regions in the Sultanate of Oman.

Basic Education

In the academic year 1998–1999, MoE introduced basic education. The time span allotted to the process is 10 years. It is divided into two cycles: Cycle One includes grades 1–4 and Cycle Two includes grades 5–10. The MoE pointed out that the distinguishing characteristics of the new system endeavors to encourage students themselves to investigate phenomena and find answers to questions rather than teachers merely giving and explaining the answers to students. The reform plan has adopted the concept of basic education with these aims (Ministry of Education, 2001):

- Integration between theory and application, thought and work, education and life.
- Comprehensive development of the individual's whole personality.
- Acquisition of self-learning skills in the context of a lifelong education.
- Inculcating the values and practices necessary for mastery and excellence in learning.
- Meeting the need of human development in the context of comprehensive social development.

Basic education was phased in gradually in its first year in 1998, starting with 17 schools. By 2004, it had been phased in throughout the country. In general, the basic education program consists of many subjects that aim to

Table 3 Subjects and classes per week for basic education, grades 1–10

Subjects	Grades									
	1	2	3	4	5	6	7	8	9	10

Music	1	1	1	1	1	1	1	1	1	1
Total	40	40	40	40	40	40	40	40	40	40

From Ministry of Education (2006). Education for all in the Sultanate of Oman 1970–2005. A contribution to the celebration on UNESCO's 60 year anniversary. Muscat: Oman. <http://www.moe.gov.om/portal/SiteBuilder/Sites/EPS/English/home.aspx> (accessed July 2009).

satisfy the stated objectives – these subjects are stated in **Table 3**.

Emphasis within the curriculum should be given to the basic social arts of communicating, recording, computing, and measuring, which may be translated as reading, writing, and speaking. The principles of health instruction and inculcation of good health practices are basic phases in the school program. Creative and expressive skills and activities should be part of a child's school experience. A good education should provide for the widening of the space horizon and the boarding of time perspective. Geography and history serve to acquaint learners with the world lying beyond their own immediate experience.

Postbasic Education

Postbasic education system is 2 years of schooling followed by basic education. The new system has been introduced since 2007–2008 with the following goals of education in mind:

1. Promoting loyalty to the homeland and to His Majesty the Sultan.
2. Affirmation of belonging to one's own community and to the Gulf Arab and Islamic world, and to developing awareness of global trends.
3. Reaffirming faith in the principles of the Islamic religion and creed, and the consolidation of spiritual values in the minds of learners – making it a standard of conduct.
4. Having pride in the Arabic language while developing adequate skills in a language of international communication.
5. Developing thinking skills of all kinds and positive trends toward work.
6. Using self-developed skills effectively and continuously learning.
7. Contributing positive trends in the environment.
8. Interacting with others and participating in community activities.

The aim of the school programs is to prepare students for life after school, whether this is for higher education, for further education, or for entry into the labor market. Personal choice is regarded as important in determining individual curricula at grades 11–12. A diverse range of courses relevant to the varying abilities, interests, and aspirations of students are offered. The curricular model emphasizes the learning of essential skills such as communicational skills, mathematical skills, nano skills information, problem-solving skills, and personal and social skills. The program in the postbasic education includes: research methods, life skills, geography and modern techniques, science and technology, environmental science, computer skills, communication skills, and business visual design. The essential skills are delivered by

integrating them into core-subjects-based courses – subjects taken by all students.

Career Guidance

Within the academic plan for grades 11 and 12, where a student has the freedom to choose from a diverse range of subjects, the role of career guidance, and career advisors becomes paramount. They help students to discover their abilities and how to channel them to converge with the goals and ambitions of their future careers. Students as well as their parents receive assistance in identifying and weighing the various employment and/or further education and training opportunities that will be made available to them. The National Center for Career Guidance is also established. It provides the following services: (1) a database of professions and jobs and their academic standards commensurate with the readiness and ability of each student; (2) providing information on the different functions and nature of the work in order to help a student choose his/her future career; (3) adequate information on higher education programs and conditions of enrollment; and (4) organizing of workshops and training programs for career advisors working at schools.

Other Schooling Arrangements

Special education

There are special educational institutions that cater to students with special needs, such as the disabled, deaf, and blind. Most of these schools are located in Muscat. They are coeducational and offer programs for both males and females. They prepare them for any kind of work that may help them and their society and are under the patronage of the MoE and the Oman Women's Association. According to the Ministry's statistic (2006–2007), the institutions are currently serving 770 students.

Private schools

The government has encouraged the growth of private schools and welcomes the contribution made by the private sector to the educational system. In the academic year 2006–2007, there were 170 private schools and kindergartens in the Sultanate providing preschool, general education (grades 1–12) for 17,978 boys and 14,156 girls, as well as about 8452 children between the ages of 3 and 6 years. Private school owners must be of Omani nationality. They follow the same curriculum as government schools and students sit for the same examinations. The Sultan's School at Seeb is an example of an educational institution that operates a demanding bilingual program with specialization in science in higher grades. Emphasis is placed on preparation for citizenship and leadership and the school offers a very wide range of extracurricular activities (Ministry of Information, 2008).

International schools

According to ministerial decree issued on 4 August 2006, international schools are administered by the International Board of Directors elected by the parents of students, and the Council is the body responsible for mediating all administrative matters concerning the school to the MoE. Students are admitted to schools based on admission requirements established in the states of residents (?). With the approval of the Council, schools are allowed to organize cultural celebrations, recreational programs, or other appropriate money-generating activities in order to implement specific projects and/or to provide more educational services to students. The school provides the Ministry with a copy of the annual audited accounts.

Technical and Further Education

The policy of higher education as identified in Vision 2020 is to expand the institutions and specialization of higher education in accordance with skilled labor-market requirements.

In an attempt to implement the policy to further technical education, the State has set out the following measures (Sultanate of Oman, Ministry of Development, 1997):

1. Provide advanced technical education for a period of 2 or 3 years to allow for rapid technological development, as well as to cater to labor-market requirements, that is, technicians in computer, mechanical, and electrical engineering, and building construction.
2. Provide university education and postgraduate studies with emphasis on expansion and diversification, according to market needs.

There are also some private technical and vocational institutes which offer 1-year courses after secondary level or some courses which emphasize focused and specific skills for particular industrial, commercial, and service agencies.

Higher Education

The Ministry of Development (1997) has stated that Vision 2020 for Oman's economy determines the aims of the higher education system as follows:

- To develop a high level of educational system which is flexible and upgradable.
- To increase the enrolment in Higher Education from 9% to 40% in 2020.
- To increase the enrolment of women from the age group 20–40 to 40% in order to provide equal opportunities for males and females in higher education.

- To give special consideration to students from families receiving social welfare benefits and to those from limited income categories.

Oman is attempting to attract more private investment in the country's higher education sector through incentives such as land grants and a matching financial grant for capital investment for private universities and colleges. The government also supports private higher education through the payment of fees for certain qualifying students.

The higher education sector in the Sultanate of Oman consists of a variety of institutions. These can be divided into two basic types: public institutions which are managed and fully funded by the government; and private institutions, which are managed and funded by private companies and individuals and supported by the government through the provision of facilities and the granting of subsidies.

At present, there are 14 privately owned colleges of higher education which operate under license from the Ministry of Higher Education and are at different stages of development. Three of these are designated university colleges: Caledonian College of Engineering, *Majan* College, and *Sur* University College. Most of them are affiliated to universities in the UK, USA, Australia, Jordan, Germany, and India. The existing provision for higher education is still insufficient, which means that a considerable number of Omanis go abroad for their postsecondary education.

Serving a rapidly developing economy and society, Oman's system of higher education has grown very fast over the past two decades since the establishment of Oman's premier government university – SQU in 1986 – with a current enrolment of 13,500 students. The total number of students in higher education in Oman has exceeded 50,000. The system of private higher education grew from one college in 1995 to the present 23 higher education institutions (HEIs), with an approximate number of 17,000 entrants each year.

Some international universities offer degrees through local HEIs (e.g., the University of Hull MBA), but to date, the only international university approved to operate 'independently' in the Sultanate is the Arab Open University, which is affiliated with the British Open University. Over time, the Sultanate may attract a number of prestigious universities to establish 'branch campuses' in Oman, as is already the case in some other Gulf countries. SQU (something, a sentence is missing here) with (Sohar University, University of Dhofar, University of Nizwa, and the Oman-German University of Technology). There are at present six Ministry of Higher Education (MoHE) Colleges of Applied Sciences (CAS) enrolling approximately 7000 students, with a seventh CAS soon to be added. In addition, there are six higher colleges of technology under the jurisdiction of the Ministry of Manpower with an enrolment of 6000 and 16 institutions of health science with an intake of 707 students.

Despite further development of the private higher education sector, there will still be a great need to expand provision so that justifiable expectations for further/higher education can be met. The future development of private universities may absorb more than 2000 school leavers each year. With over 50,000 school leavers seeking further or higher education or jobs, this will impact Oman's development programs.

However, the programs and specializations for these educational establishments tend to reflect a particular vision of the labor-market and market requirements in the next decades. Courses in computer sciences, engineering, commerce, and business are available at most private colleges. Most award diplomas and a few are now able to award degrees.

Adult and Nonformal Education

Literacy has been a key objective of the Government of Oman since the beginning of the Renaissance in 1970. The Government has proceeded to spread adult literacy along with the spread of education among the young. The illiteracy rate is 9.1% in the age group 15–29 years, according to statistics of the census of population and housing conducted in 2003. **Table 4** shows the illiteracy rate of two age groups. Despite the difficulties of reaching people living in desert and mountainous areas, tackling regional disparities remains one of the MoE's major commitments.

Teaching Profession

Teachers represent about 25% of the total labor force in the public sector and 3.8% of the total labor force in the private sector. There are 29 teachers for every 1000 Omanis between the ages of 15 and 64 years. This percentage is higher than that of developed countries where it is estimated that there are 24 teachers for every 1000 people in the same age category (Donn and Issan, 2007).

In light of teacher training, The MoHE was responsible for setting up six teacher training colleges in 1995 to replace the 2-year diploma-awarding intermediate colleges, but in 2005 they were phased out and transformed

to industrial colleges, all except one. At present, College of Education at SQU is the main one that is in charge of qualifying teachers as well as educational administrators.

Various alternatives for retraining have been developed. Currently, Leeds University in England is involved in a 5-year English-language program with the MoE and has been enrolling 46 applicants a year since 2000–2001 on courses at Leeds University at OR5m. The MoE is considering an affiliation with the University of Melbourne to provide information technology, science, and mathematics courses. SQU is involved in a 10-year educational administration program and has commenced enrolling 90 students per year since 2003–2004. Al Rustaq College of Education has also started its programs to upgrade their qualifications in Arabic, Islamic sciences, and social sciences.

That being the case, it has been argued that there is a clear need for continued training of teachers in Oman.

Administrative and Supervisory Structure

Education finance

The government, through the Ministry of Finance, decides on the level of spending for education every year. On behalf of the government, MoE has the responsibility for carrying out a range of functions, including strategic planning, purchasing educational services, managing the education sector assets owned by the government, and providing a range of education related services. MoE General Directorate of Financial Affairs is the body responsible for the allocation of funds both within the ministry and the educational regions. The Ministry receives no income from students since government schooling is offered free of charge for all for the first 12 years. A large share of the annual budget is allocated to education every year and even when the country suffered a significant reduction in the gross domestic product (GDP) in 1999, the government increased the budget for the education sector as seen in **Table 5**.

Performance monitoring, evaluation, and research

As part of the overall reform process, the Ministry encourages a shift in the culture of its schools. The aim is for schools to work toward the continuous improvement of the whole school. Schools should be self-critical: identifying their strengths and areas for development and taking responsibility for their development. With these objectives in mind, the Ministry has introduced the School Performance Evaluation Project in 2002–2003. The aim of the project is to establish national criteria and to introduce a comprehensive system of school self-evaluation which is complemented by an occasional thorough external evaluation. The Ministry is intended to phase in the new arrangements to all schools over a 7-year period.

The aims of assessment and evaluation systems should allow students to seek out assistance to help them address their weaknesses, gain confidence from their strengths,

Table 4 Illiteracy by age group 1993 and 2003

Age Group	1993 Census			2003 Census		
	Male (%)	Female (5)	Total (%)	Male (%)	Female (5)	Total (%)
15–29	4.5	21.0	12.8	1.5	4.2	2.8
30–49	38.8	82.2	60.5	13.5	49.2	31.8

and provide them with opportunities for further challenges and demands. To help achieve these aims, there has also been a move away from the expectation that students should merely rote learn and memorize information. Instead, an increased emphasis has been placed on the testing of higher thinking skills. A wider range of assessment instruments have now been introduced, with continuous classroom assessment being given added prominence in the assessment and evaluation system. Arising out of ordinary classroom activities, teachers are now expected to use a variety of continuous assessment instruments such as short written or oral tests, quizzes, performance assessment tasks, projects, and student self-assessments.

Major Changes and Issues since the 1990s

The vast influx of foreigners into this formerly secluded region emphasized the need to catch up. Oman's government realized that there was a need to provide a well-educated, resourceful local workforce for the future, displacing the continual need for expatriates to undertake even basic maintenance of state utilities. International exposure and cross-cultural interaction is essential if Oman is to attain high standards and remain relevant in today's world. However, Oman witnessed a spectacular educational renaissance in the last three decades of the twentieth century. Spreading education in Oman was an uphill task in view of sparse population over a vast geographical area with difficult terrain. Oman managed to reduce illiteracy ratio from 41% in 1993 to 24.4% in 2000. However, this ratio has been decreasing during the last 8 years of the third millennium. Oman made good progress in merging females in various levels and therefore bridging a sustainable part of the gender gap in the field of education, an indication of good progress in the field of human development. Public spending on education as a percentage of total government expenditure increased from 9.5% in 1991 to 14% in 2005. This put Oman midway in comparison to other Gulf Cooperation Council (GCC)

countries, yet illiteracy and gender issues are challenges to be tackled at all levels and kinds of education.

Glossary

Assistant education officer (AEO) – AEO is responsible for day to day administration of schools in the geographical territory of tehsil (an administrative division under the district).

Dars-e-Nizami – Curriculum based mostly on religious teachings offered by *Deeni Madaris*. This includes subjects on applied and natural sciences.

Darul Aloom – Literal meaning is the abode of knowledge. Offers a 2-year certificate course equivalent to upper-secondary level, after 10 years of education offered by *Deeni Madaris*.

Deeni Madaris – (Singular *madrassah*) Offers 10 years of education (equivalent to secondary level) based mostly on religious teachings.

Directorate of Staff Development (DSD) – A provincial-level institution responsible for continuous professional development of public school teachers.

District education officer (DEO) – Head of the Education Department at the district level. Responsible for planning, budgeting, and coordinating all educational activities in the district.

Executive district officer (EDO) – Head of offices evolved at district level through local government ordinance.

Fiqh – Islamic jurisprudence based on various Islamic schools of thoughts.

Hadees – Sayings/texts compiling the life and traditions of the Holy Prophet (peace be upon Him (PBUH)).

Higher Education Commission (HEC) – Established in 2001 by the Government of Pakistan with a mission to raise the quality of education in the higher educational institutions and further, aimed at capacity building of faculty, developing research culture in the universities, and providing technical and financial assistance.

Iftah – Study of giving legal options (*fatwa*).

Katchi class – Also known as early childhood education. It is equivalent to nursery education.

Local Government Ordinance, 2001 – Also known as Devolution Plan. System of governance decentralizing the government's administrative and financial authority from provinces to the district and

union councils, ensuring maximum participation of the civil society.

National Education Assessment System (NEAS) – The program aimed at developing national capacity for monitoring the learning achievements of elementary-level students in order to improve the equality of services (curriculum, textual material, teachers' delivery, policy formulation, etc.) in the education sector. The basic objective of NEAS is to establish a system of student assessment in the Ministry of Education and to develop national capacity for conducting assessments periodically to monitor student achievement.

National Vocational and Technical Education Commission (NAVTEC) – The Commission is mandated to facilitate, regulate, and provide policy direction for technical education and vocational training to meet national and international demands for skilled manpower. NAVTEC's energies are also dedicated to develop national occupational skills standards, curricula, and trade testing certification systems for all sectors where technical education and vocational training are imparted.

Parent teacher association (PTA) – It is an association established by parents and teachers for resource generation for the uplift of the schools. It is based on equal partnership with the government.

Provincial Institute for Teacher Education (PITE) – A provincial-level institution responsible for imparting pre-service training, development of innovative learning material for in-service training, training of master trainers to work as trainers at local levels, and impart training through distance education for in-service teachers.

Tafseer – In-depth exegesis of the Quran.

Technical Education and Vocational Training Authority (TEVTA) – Aimed at enhancing global competitiveness, through a quality and productive workforce by developing demand-driven, standardized, dynamic, and integrated technical education and vocational-training service.

Village Education Committees/School Management Committees (SMCs) – Representatives from school administration and political leadership that works for the welfare of schools.

General Background

The roots of the Pakistani nation can be traced back both to the great Muslim civilization which flourished between the seventh and tenth centuries in Asia and Africa and to the Indus Valley civilization, which prevailed 5000 years ago. The excavations of Harappa, Mohenjo-Daro, and Soan Valley have provided evidence of the highly organized civilizations which existed around the Indus River. The Indus Valley civilization is one of the oldest civilizations in the world and it achieved a high level of sophistication at an early stage (3000 BC) and flourished for many centuries. The ruins at Mohenjo-Daro (Sindh, Pakistan) revealed that people living there had a well-organized social and economic structure. It was a very well planned city with proper sanitation, general civic facilities, metric system of measurement, and many other aspects indicating that the people of the Indus Valley civilization were well ahead of other civilizations which existed at that time, both in technological crafts and the sociolegal system. The people of that time sailed the Arabian Sea and the Persian Gulf in wooden boats and traded in gems, animal hides, and fabrics. In the fourth century BC, Alexander and his armies passed through this region, and in the sixth century BC, the Persian Empire was extended to the Indus Valley. The Indo-Aryans, who predominate in contemporary Pakistan, arrived between about 1500 and 1200 BC. Later on, Islam was introduced in this region during the seventh century. Art, literature, music, and architecture flourished during this period. This region, therefore, has been a melting pot for diverse races and cultures.

Demographic Characteristics

Pakistan obtained independence in 1947 comprising two regions: West Pakistan in the Indus River Basin and East Pakistan, located more than 1000 miles away in the Ganges River Delta. East Pakistan, now Bangladesh, broke away from West Pakistan in 1971.

Pakistan, constituted on 796 095 km², has four provinces – Balochistan, North Western Frontier Province (NWFP), Punjab, and Sindh. In addition to these provinces, Pakistan also has three areas which include Federal Administered Tribal Areas (FATA), Federal Administered Northern Areas (FANA), and Azad and Jammu Kashmir (AJK). The territory of Pakistan encompasses portions of the Himalayas, Hindu Kush, and Karakoram mountain ranges, and is home to the world's highest mountains. Pakistan shares borders with Afghanistan (2430 km), China (523 km), India (2912 km), and Iran (909 km). Its coastline totals 1064 km along the Arabian Sea.

Pakistan is the world's sixth largest country. Its population is estimated at 160 million; of this, 50% or 77 million is below the age of 18 years. Pakistan in other

words, has one of the youngest populations in the world. The rapid population growth is a heavy burden on the country's limited resources. A majority of the population (65.1%) resides in rural areas largely depending on agriculture. In spite of a significant decline in the level of fertility in recent years, Pakistan's population is still growing at the rate of close to 2% a year. The life expectancy for the year 2006–07 was estimated at 64 years for males and 66 years for females. The crude death rate (CDR) was 7.8 (per 1000) in 1999–2000, declining to 6.5 (per 1000) by the year 2006–07.

Pakistan's economy entered the fourth consecutive year of above 7.0% annual growth rate in 2007, and its poverty headcount fell from one-third to less than one-fourth of the population. In the last fiscal budget (2007–08), a sum of \$8.3 billion was allocated for social-sector development with special emphasis on poverty reduction. The average per capita income was \$680 (US), and the labor-force participation rates were 36.7% for males and 9.3% for females in 2006–07. Pakistan is predominantly an agricultural country with major exports in cotton, yarn, and cotton fabrics.

Despite these developments, however, the economic and social development indicators of Pakistan are still among the lowest not only in the Asia-Pacific region, but also in the world. Pakistan stands at the 136th position in terms of the Human Development Index and is at the 126th position out of 128 countries in the Global Gender Gap Index. Pakistan has scored 42 points and is placed among the ten least equitable countries of the world.

Goals of the Education System

Providing of education is the constitutional responsibility of the state. Based on government policies and target plans, the following are the main goals of education:

- To achieve universal primary and secondary education, following the targets set in Millennium Development Goals (MDGs) and Education for All (EFA). The aim is to eliminate gender disparities in primary and secondary education by 2015, with a focus on ensuring girls have full and equal access to and achievement in basic education of good quality.
- To expand and improve comprehensive early childhood care and education, especially for the most vulnerable disadvantaged children.
- To strengthen technical education at secondary and higher-secondary levels, establish polytechnics at district and vocational institutions at the *tehsil* level, and to introduce more diversified courses in technical and vocational education.
- To follow the gender-based policy in education specially focusing on providing free education to females

up to secondary level (grade 10), improving nutritional status of school-going girls through free school meals and regular health checkup, giving stipends and scholarships to needy students, and providing free uniforms and school bags.

- To translate the dream of a knowledge-based economy into reality by providing (good-quality, merit-oriented, equitable, and efficient higher education) which is the most crucial instruments; to focus on faculty development, developing industrial linkages, and conducting need-based research.

Education Administration

After the introduction of Local Government Ordinance in 2001, the education system has been devaluated. The Federal Ministry of Education is a coordinating body whereas the provincial education departments serve as a bridge between the federal and district governments. The district governments are fully empowered to prepare their own educational development and fiscal plans. However, the formulation of national educational guidelines for curricula, examination, evaluation, standard of education, learning/competency level, and teacher training is the responsibility of the federal government. The provincial education departments, headed by their respective provincial education ministers work in line with the Federal Ministry for the implementation of national policies and plans. In the district, the head of the Education Department is the executive district officer – education (EDO, education). Next in the hierarchy is the district education officer (DEO) followed by the assistant education officers (AEOs). The AEOs at the district level are responsible for providing academic guidance, as well as supervision of the schools. At the grass-roots level, that is, the union council level, village education committees/school management committees (SMCs), and parent teacher associations (PTAs) have been set up to coordinate with schools for their smooth functioning.

Structure and Operation of the Education System

Figure 1 shows the formal structure of education. The statistics on enrolments and resources in the education sector are provided in **Table 1** and **Figure 2**.

Currently, there are 122 349 primary, 38 449 middle, and 25 090 secondary schools in the country. Almost 37% of the total students enrolled are in the primary level, 20% in the middle, while 28% are in the secondary level. The overall teacher–student ratio at the primary level is 1:31, 1:21 at the middle level, and 1:23 at the secondary level in the country but it may vary by urban/rural and

public/private scenarios. At the primary level in rural areas, for example, there are 34 students per teacher while in urban areas the ratio is 1:24.

There are 12 153 *Deeni Madaris* in the country. Around 55% are located in the rural areas and around 97% are privately managed.

Literacy

The literacy levels in Pakistan have improved over time although at a moderate pace. The overall literacy rate (10 years and above) was 45% in 2001, which has increased to 54% in 2006–07, indicating a 9.0 percentage-point increase over a period of only 5 years. Male literacy rate (10 years and above) increased from 58% in 2001 to 65% in 2006–07 while it increased from 32% to 42% for females during the same period. The rate of increase in literacy for females is faster as compared to the males.

Multiple reasons for low literacy include social taboos, poverty, child labor, illiteracy among parents/families, poor infrastructure and educational facilities, constraints on girls' education, high dropout rate, etc.

Early Childhood Education

Until recently, early childhood education had not been formally recognized in public schools in Pakistan. The traditional *katchi* class, to some extent, serves the purpose of early childhood education. In the private sector, however, focus on early childhood education has been there for a long time. There are regular Montessori and kindergarten private schools. The Government of Pakistan, recognizing the importance of early childhood education, has recently included it as a component in Education Sector Reforms and provided funding to the provincial and district governments for the purpose. The gross enrolment rate (GER) for early childhood education rose from 36% in 2001–02 to 91% in 2006–07, for children aged 3–4 years.

Primary Education

Primary education is free and compulsory in Pakistan. The universalization of primary education (grades 1–5) has been recognized by the founding father of Pakistan, Muhammad Ali Jinnah, and Universal Primary Education (UPE) was established as a goal at the first National Education Conference in 1948, soon after independence. Over the years, the goal of UPE has been the of all the educational policies prioritization and plans, but despite this concentration, however, there are still many children between 5 and 9 years of age who are not attending school. Out of the total enrolment of students from primary to post-secondary level, almost 37% are enrolled at only primary level of education. During recent years, there has been considerable progress in the GER which reached

Figure 1 Structure of Education System in Pakistan.

Table 1 Number of institutions, enrolments, and teachers by level of education

Levels of education	Institutions	Enrolment	Teachers
Pre-primary	1081	61 364	3807
Mosque school	14 123	802 904	22 603
Primary	122 349	12 433 240	399 517
Middle	38 449	6 652 870	313 797
Secondary	25 090	9 473 525	418 376
Higher secondary	1882	1 158 589	59 097
Universities and degree-awarding institutions	99	419 189	11 434
Technical/professional	1324	361 534	30 334
Vocational/polytechnics	3059	238 687	15 339
Madrassahs	12 153	1 549 242	58 391
Others	8232	452 752	24 107
Total	227 841	33 603 896	1 356 802

From: Education Census, 2006.

**Figure 2** Gross and net enrolment rates by level of education, Pakistan 2007.

84% in 2006–07 up from 71% in 2001–02. Similarly, the net enrolment rate (NER) also rose from 57% in 2001–02 to 66% in 2006–07. The dropout rate at the primary level has also been controlled through the government's recent education reforms. It fell from 43% in 2001–02 to 28% in 2006–07. Despite progress, however, access rates remain low and Pakistan still faces the risk of defaulting on EFA and MDGs 2015 targets.

Middle-Level Education

The gross and net enrolment rates at the middle level (grades 6–8) have also shown improvement in recent years. The GER for the middle level was 51% in 2006–07 compared to 49% in 2005–06. Female and male GERs have increased slightly over the period, from 42% to 44% and 55% to 57%, respectively, between 2005 and 2007. There are, however, wide urban–rural disparities,

with gross middle enrolment in urban areas at 69%, and 43% in rural areas. The net enrolments are much lower than GERs. The GERs and NERs have been calculated using an age range of 10–12 years and because of large numbers of overage children enrolled at the middle level, the NER stands out as low as 18% in 2006–07.

Secondary and Higher-Secondary Education

Secondary and higher-secondary education is for 2 years each. The statistical figures show improvement in the participation at the secondary-school level in the recent past. The GER and NER had increased to 31% and 24% in 2006–07 in comparison to 31% and 24% in 2001–02, respectively. Enrolment in higher secondary education, which was 2.6% for 2001–02, rose to 3.7% in 2005–06. Secondary education is the first stage where students have to make a choice of subjects according to their interest and capabilities. The diversity offered to students is very limited and the students have to choose one of the two areas of specialization offered at the secondary level, that is, humanities and science. The humanities group consists of general science, civics, and mathematics; while the science-group students study chemistry, physics, mathematics, and biology. The students have to study compulsory subjects in addition to the area of specialization they choose. As a continuation of the area selected in secondary education, in higher-secondary school, the students take premedical, pre-engineering, or specialization in humanities corresponding to their area of specialization in secondary school. The science students are allowed to take any of the above-mentioned areas of specialization while students in humanities group can only study specializations in humanities in higher-secondary school.

Higher Education

Higher education is mainly provided by the universities and postgraduate colleges. There are more than 100 public and private universities in Pakistan. The enrolment in higher education is 0.23 million with males 0.15 million and females 0.08 million, respectively. The gross participation rate is around 4%. Higher education has received a big boost by the allocation of financial resources and improvement in the quality of education in recent years. The universities are being upgraded through a vigorous program of faculty development, scholarships and stipends to needy students, curriculum revision, equipping laboratories and libraries, connectivity to pooled and shared resources, and emphasis on research through the Higher Education Commission. Annual budget allocation has been raised 10 times from \$15 million to \$150 million, while for science and technology it has increased from \$3 million to \$100 million in 2006–07.

Technical and Vocational Education

In recent years, considerable efforts have been made to integrate skill development with the general stream of education. National Vocational and Technical Education Commission (NAVTEC) has been established to manage national policy and planning, curriculum development, standardization of technical education, training of trainees, national accreditation of private polytechnics and vocational-training institutes, and developing strong linkages with the industries. The policy thus formulated is implemented through Technical Education and Vocational Training Authority (TEVTA) in the provinces. At present, there are 1324 technical/professional colleges and 3059 vocational/polytechnic institutes with an enrolment of 361 534 and 238 687 students, respectively, in the country. Around 46 000 teachers are attached to these institutions. Emerging technologies like telecommunication, computer electronics, automation, petroleum, garments, food preservation, printing and graphics, textile, mining, sugar technology, tourism and hotel management, livestock and dairy sector, construction sector, women's participation in economy, etc., are given due importance in courses offered at the technical and vocational institutes.

Adult and Nonformal Education

The nonformal education system includes nonformal basic education (NFBE) schools and adult literacy centers. There are 10 000 NFBE schools with an enrolment of more than 300 000 students. The adult literacy centers cater to the needs of 15+ age-group people. There are 70 000 adult literacy centers having an enrolment of 1.7 million. These centers mainly focus on reading, writing, and numeracy skills.

There are approximately 56 million illiterate adults against the 66 million literate population. Financial allocations in the past for adult literacy have remained severely inadequate. At present, 2 billion Pakistani rupees (approximately \$29 million) per annum are allocated for literacy and nonformal education programs, whereas to meet the EFA targets about 15 billion Pakistani rupees per year are required.

Private Sector in Education

The private sector's role has been expanding in the country. Between 1983 and 2000, the number of private primary and secondary schools increased almost tenfold from 3300 to 32 000, much faster than the population of school-aged children. At present, private educational institutions enrol 3% of students studying basic education (pre-primary through higher secondary). In urban areas, private schools account for more students (51%) than the public sector (49%). However, the situation is reversed in rural areas, where over 80% of students are attending

public schools. Private education has the maximum share at the pre-primary level, where 42% of pre-primary students are enrolled. At the primary stage, 32%; secondary, 30%; higher secondary, 18%; technical/vocational, 52%; vocational/polytechnics, 57%; NFBE, 61%; and *Deeni Madaris*, 97% are enrolled.

A private sector is growing substantially in recent years and the number of private universities has risen up to 57 as compared to 67 in the public sector.

Religious Education

The *madrassab* system has been a part of the education system in Pakistan for long and runs parallel to the general stream of education discussed before. The *madrassab* has remained a popular system of education for the poor masses of the country because it offers free education along with free boarding and lodging facility to students. The age of students in *madaris* typically runs from 5 through 16 years. For study beyond 10 years offered by *madaris*, for grades 11 and 12, one would attend a *darul uloom* (literally, the abode of knowledge). The *darul uloom*, is equivalent to the upper-secondary school in the general stream of education. For study beyond *darul uloom*, one would attend a *jamia*, equivalent to college or university.

Estimates of *madaris'* enrolment range from about half a million to more than 2 million. There are about 4 775 000 enrolled *madrassab* students which is about 4.6% of the total enrolment in the country.

There are five boards (*wiqafhas*) running *madaris* according to their respective schools of Islamic thought: Ahl-i-Hadith, Bareilvi, Deobandi, Jamaat-i-Islami, and Shia. The boards approve the curriculum, conduct examinations, and issue graduation certificates and diplomas. There are around 10 000 *madaris* registered with these five boards. Roughly 70% are Deobandi, 16% are Bareilvi, 5% are Jamaat-i-Islami, 4% Ahl-i-Hadith, and 3% Shia.

Recently the government of Pakistan introduced *madaris* reforms. The Pakistan Madrassah Education Board Ordinance in 2001 established the Pakistan Madrassah Education Board. The Board has the responsibility of establishing new, exemplary *deeni madaris* and *darul ulooms*. The model *Deeni Madarssab* is meant to be semiautonomous, providing an exemplary model to existing *madaris* about how to modernize and train a new generation of liberal-minded *ulema* (religious scholars). In another effort to reform *madaris*, the government has issued an ordinance referred to as Madaris Regulation and Control Ordinance (2002). It demands that all *deeni madaris* and *darul ulooms* get registered with the government and submit regular financial statements. The *deeni madaris* and *darul ulooms* registered with the board would receive scholarships for their students, while the others that do not comply would be closed.

The *madaris* teach either in full or in part a specialized curriculum called *Dars-e-Nizami*. It covers about

20 subjects mainly divided into two categories: *al-uloom an naqliya* (transmitted sciences) and *al-uloom-al aqliya* (rational sciences). Most of the subjects included in the curriculum are religious in nature. Others include medicine, mathematics, astronomy, history, philosophy, poetry, and polemics. Some of the *madaris* also offer postgraduate specialization courses in *tafseer*, *badees*, *iftab*, and *fiqb*. The students can take these courses after completing *Dars-e-Nizami* and it takes at least 2 years to complete. The *madaris* offer degrees/certificates of different durations equivalent to the mainstream education, but the Government of Pakistan accepts only the highest degree (*Shahadatul Alamiya*) (MA in Arabic and Islamic Studies (Institute of Policy Studies, 2002)) offered by *madaris* after 16 years of education.

Almost all the *deeni madaris* (97%) imparting religious/ Islamic education are run by the private sector since the independence of Pakistan in 1947. A *madrassah* generally enrolls students for grades 1 through 10. Most of the *madaris* provide free boarding and lodging facilities to the students.

Curriculum

The Curriculum Wing established at the Federal Ministry of Education works closely with the provisional curriculum bureaus and textbook boards in all provinces for the development of curriculum. A National Curriculum Review Committee, represented by national and provincial experts, gives approval for the textbooks to be published by the provincial textbook boards which develop textbooks up to grade 12. The textbook boards are encouraging use of multiple textbooks as part of the national policy in recent years. The public schools are bound to follow the national curriculum. However, the private schools are free to choose curriculum in line with their aims and objectives. A reasonable number of private schools are affiliated with examination boards/bodies outside Pakistan (mainly British and American) and thus follow their curriculum to prepare students for their examination as external candidates.

Medium of Instruction

The medium of instruction in public schools (grades 1–12) is Urdu. However, at the primary level, medium of instruction could also be the provincial/local language which is different for all four provinces. In contrast to this, majority of the private schools follow English as the medium of instruction.

Teaching Profession

In Pakistan, 270 teacher education/training institutes exist of which 227 are run by the government sector and 53 are operated by the private sector. They offer pre-service and

in-service teachers' training programs. There are two kinds of programs for elementary school teachers (grades 1–8): the Primary Teaching Certificate (PTC), and the Certificate of Teaching (CT). The PTC program is meant for teachers who teach in grades 1–5. The duration of this program is 1 academic year (48 weeks). Admission to the PTC program requires that the applicant should possess Secondary School Certificate (10 years schooling). The CT program prepares teachers to teach all subjects up to grade 8, including English. The duration of this program, too, is 1 academic year. The condition for admission to the CT program is a Fellow of Arts (FA) or Fellow of Science (FSc) certificate, that is, 12 years of schooling.

The institutions preparing secondary-school teachers are known as colleges of education, affiliated with universities and those offering advanced education leading to an MA in Education, MEd, and PhD degrees are either University of Education or institutes of education and research which are part of a general university or departments of education in universities (see Table 2).

At the time of independence, there was only one college of education for men and one for women in the area now called Pakistan. There was no Department of Education or institute offering master's degrees in education. The first such institute, the Institute of Education and Research (IER) was established in 1960 at the University of the Punjab, Lahore, in collaboration with Indiana University (USA), following the recommendation by the National Commission on Education. Other IERs or departments of education were subsequently established. In 2002 the first University of Education was also established in Punjab. At present there is one University of Education, three institutes of education and research, and several colleges of teacher education attached to these universities.

Two types of programs are offered for the preparation of secondary-school teachers, requiring differences in the years of general education and professional training: (1) 1-year Bachelor of Education (BEd) program (14+1 model); and (2) 3-year Bachelor of Science Education (BSEd) program (12+3 model). For the 1-year program,

Table 2 Percentage of teachers (public) with professional qualifications

Professional qualification	Total	Female
PTC	37.3	41.5
CT	12.3	12.8
BEd	17.4	18.0
MEd	5.1	4.0
Other trained	11.1	10.1
Untrained	1.1	1.0
No information	15.6	12.3

PTC – Primary Teaching Certificate; CT – Certificate of Teaching; BEd – Bachelor of Education; MEd – Master of Education.
From: Shami *et al.*, National education 2005.

the minimum qualification required for admission is a BA/ BSc degree. In the 12+3 model, the minimum qualification required for admission is the FSc. The academic and professional qualifications required for the recruitment of teachers at various levels are shown in **Table 3**.

Each province has different departments for the training of in-service teachers. In Punjab, Directorate of Staff Development (DSD), Provincial Institute for Teacher Education (PITE), and Government Colleges for Teacher Education (GCET) are responsible for professional development of teachers. Bureau of Curriculum (BoC) and PITE are given the responsibility of in-service teachers' professional development in Sind and Balochistan while Directorate of Curriculum and Teacher Education (DCTE) and PITE are providing in-service teacher training in NWFP. The number of teachers in each province by type of school is given in **Table 4**.

Accreditation Council for Teacher Education has been established. The council is currently working on developing the national standard for teacher certification and accreditation.

Table 3 Academic and professional qualifications of teachers at different levels

<i>Level of teaching</i>	<i>Type of examination</i>	<i>Academic qualification</i>	<i>Professional preparation</i>
Primary	Grade 5	Matric (secondary)	PTC
Middle	Grade 8	FA/FSc (higher secondary)	CT
Secondary (High)	Matric	BA/BSc (except Punjab) MA/MSc (only Punjab)	BEd/BSEd
Intermediate	FA/FSc	MA/MSc	—
Degree colleges	BA/BSc	MA/MSc	—
University	MA/MSc	MA/MSc/PhD	—

Examination System

A system of automatic promotion up to grade 5 has recently been introduced in public schools. However, at the end of the fifth year of the primary stage, an examination is held by the District Education Department/Examination Commission, which has to be passed to get admission in the next grade (grade 6). Annual examinations are conducted by the respective schools for grades 6 and 7. At the end of middle school (grade 8), external examinations are taken by the respective district education departments/examination commissions. There are 18 boards of intermediate and secondary education (BISEs) in the country including one Federal Board of Intermediate and Secondary Education (FBISE) and one private-sector BISE, that is, Agha Khan University Examination Board (AKU-EB). These boards are responsible for holding examinations for Secondary School Certificate (after 10 years of education) and Higher Secondary School Certificate (at the completion of 12 years of education). Each such board has its defined geographical jurisdiction and all students enrolled in schools/higher-secondary schools in those areas have to appear for examinations conducted by their respective boards except FBISE and AKU-EB. The territorial jurisdiction of FBISE includes schools from all provinces of Pakistan and Pakistani schools in other countries while AKU-EB is allowed to register schools from all areas of Pakistan. The concept of an examination board in private sector is very recent and is meant to create competition among BISEs in government and private sectors for the improvement of the quality of examination in the country. The certificates issued by these boards are considered equivalent for all purposes. Inter Board Committee of Chairmen (IBCC) is responsible for determining the equivalence of certificates offered by these boards. The universities are responsible for conducting examinations at the territory level mainly through semester system.

Table 4 Number of teachers in each province by type of school

<i>Province/district</i>	<i>Teachers</i>				
	<i>Overall</i>	<i>Primary schools</i>	<i>Middle schools</i>	<i>High schools</i>	<i>Higher-secondary schools</i>
Pakistan	629 674	314 712	109 327	162 430	23 849

AJK – Azad and Jammu Kashmir; FANA – Federal Administered Northern Areas; FATA – Federal Administered Tribal Areas; NWFP – North Western Frontier Province.

From: Shami *et al.*, Pakistan education 2005; Kardar (2005).

Pakistan is striving hard to participate in international comparative studies/programs for assessment of student achievement to get information about the comparative performance of Pakistani students. In this connection National Education Assessment System (NEAS) was established as a quality assurance innovative program to develop national capacity for monitoring the learning achievements of elementary-level students in order to improve the quality of services (curriculum, textual material, teachers' delivery, policy formulation, etc.) in the education sector. The NEAS has set up provincial/area educational assessment centers at provincial headquarters – FATA, FANA, and AJK.

Financing of Education

The major share of funding for education comes from the public sector, which spent 2.5% of the gross domestic product (GDP) in 2006–07 on education. Around 0.5% funds are contributed by the private sector, putting the combined resources at around 3% of GDP in 2006–07. The total public-sector budgetary expenditure on education has almost doubled in the last 6 years. It has increased from 1.8% in 2000–01 to 2.5% in 2006–07. However, the public expenditure on education is relatively low as compared to other developing countries in the region. In the allocation of budgetary resources, the primary sector has almost half of the education budget, that is, 44%. The secondary sector has 24% and 13% goes to the tertiary sector, while the rest is distributed among the other sectors. Expenditures on primary and secondary education, therefore, are about five times more than the expenditure on the tertiary sector.

Challenges and Way Forward

Pakistan is facing numerous challenges as many developing countries in the world are also doing. Achieving universalization of primary education, overcoming illiteracy, providing access to quality education, controlling student dropout, bridging the gender gap, addressing urban–rural disparities and active participation of private sector, and improving the quality of teachers are some very basic challenges the government is trying to cope with.

The major challenge facing Pakistan is the mass illiteracy in the country, particularly among females. The government being sensitive to the issue has increased the educational budget and proposes to increase it further in the year 2009–10. An additional 10 000 NFBE schools are planned for the next 4 years to lessen the shadows of darkness. Universalization of primary education and meeting the targets of MDGs and EFA is another top priority of the government. After the reinforcement of Compulsory Primary Education Ordinance all possible facilitation is being provided by the government to achieve

the targets by the year 2015. Pakistan is being supported by international partners like United Nations Educational, Scientific and Cultural Organization (UNESCO), United Nations Children's Fund (UNICEF), World Bank, AusAid, and United States Agency for International Development (USAID) in its effort to achieve the MDG by 2015. The issue of gender parity is also addressed as crosscutting objectives in all such efforts.

Access to education is the basic right provided in the constitution of the country to each individual in the country. Despite being high on the agenda of the government, the goal of universal access has not yet been achieved. The country is making a major effort to expand access to education. The issue is being approached through setting up more primary schools in the public sector and supporting nongovernmental organizations (NGOs)/the private sector to invest in this area. At the same time upgrading of existing primary schools to middle level is also being pursued aggressively.

Gender disparity in education is another major challenge which needs to be addressed, particularly in the rural areas of Pakistan. In urban areas, the public sector has almost closed the gender gap where the proportion of female-to-male enrolment was 1:49. In the private sector, the proportion of female-to-male enrolment was 19:81. This gap in enrolment is expected to close with expansion in private-sector facilities. In the case of enrolment in rural areas, the gender gap in both the public- and private-sector institutions is quite pronounced. In both cases, the proportion of female-to-male enrolment is 62%. With policy emphasis on female enrolment and launching of free textbooks and scholarship schemes, the gender gap should close in the rural areas as well. Both the federal and the provincial governments recognize the need for eliminating gender disparity. Policy reforms are focusing on increasing girls' enrolment and their retention.

As the government alone cannot accomplish the gigantic task of attaining the goal of sustainable quality education, there is greater need to facilitate the private sector by financial, administrative, and management empowerment through public–private partnership. It is expected that efficient private-sector leadership patronized by the public sector will result in better quality education and less dropouts.

Implementation and sustainability of educational goals and allocation of funds is now the responsibility of districts, therefore, increased concentration is being given to improving quality by hiring new teachers, increasing their accountability, improving the learning environment in schools, and cutting nondevelopmental educational expenditures.

Higher Education Commission established in 2002 has been working hard to raise the quality of higher education in accordance with the international standards and developing research culture in universities. There has

been a substantial increase in budgetary allocations to universities and several new disciplines and specializations have been introduced in recent years.

Poland

A Janowski, Academy of Humanities and Economics in Lodz, Poland

© 2010 Elsevier Ltd. All rights reserved.

General Background

The official name of the Poland is Rzeczpospolita Polska, *rzeczpospolita* being the polonized version of the Latin *res publica*. Poland is a parliamentary republic and Warsaw is the country's capital. The beginning of the Polish state is associated with the dynasty of Piast at the end of the tenth century. In 966, Mieszko I, a member of this dynasty, was baptized and brought Christianity to the country. The Piasts united the lands which roughly resembled the present territory of Poland. During the following centuries, the Polish Commonwealth (Poland united with Lithuania) expanded eastward and ruled over vast territories situated between the Baltic and Black Seas. In the seventeenth and eighteenth centuries, neighboring Russia, Prussia, and Austria were increasing their political power. This led to the partitions of Poland during the last decades of the eighteenth century. Efforts to regain independence in the nineteenth century were fruitless. Poland emerged again as an independent state after World War I in 1918. In September 1939, the invasion of Poland by Germany started World War II. In 1945, Poland, occupied by Soviet troops, fell under communist rule. Authoritarian rule led to a growing opposition which culminated in the formation of the Solidarity trade union in 1980. In 1981, martial law was imposed and for many years Solidarity became an underground movement. In 1989, after the so-called round table negotiations, the first free parliamentary elections took place. A dynamic period of political and economic transformation began.

The functioning of the Polish State is defined by the Constitution of 2 April 1997. The legislative power is exercised by the Parliament (Sejm) and the Senate (Senat). The Sejm is the lower chamber of the parliament and consists of 460 members elected according to a proportional representation system for a 4-year term. The Sejm supervises the government. The Senat, the upper chamber, consists of 100 members. The executive power is exercised by the president and the council of ministers. The president, who is the head of the State and protects its sovereignty, is elected by the nation for a 5-year term. These political parties in the first-half of 2008 – since the general election that took place on 21 October 2007 – are the ruling coalition: *Platforma Obywatelska* (Citizens Platform) and *Polskie Stronnictwo Ludowe* (the Polish Peasant Party); and the opposition consists of: *Prawo i Sprawiedliwość* (Law and Justice) and *Sojusz Lewicy Demokratycznej* (the Alliance of Democratic Left).

Poland covers 312 685 square kilometres and has a population of 38.18 million. Sixty-one and a half percent of Poles live in towns and urban areas and 38.5% inhabit rural areas. From the year 2002, we have seen a natural decrease in the population. In the year 2005, there were 9.7 deaths to every 9.6 live births per 1000 inhabitants. In 2006, the birth ratio equalled +0.1%, the number of young people under 29 years of age accounted for 39.9% of the population, and the number of children of compulsory school age accounted for 13.0% of the population. The official language is Polish. Poland is very homogeneous as regards nationality; it is estimated that no more than 1 500 000 people are members of national minorities: German, Byelorussian, Ukrainian, Slovak, Lithuanian, Romany, as well as the ethnic minority of Kashubian. The situation of nationalities is unclear because it is estimated that *c.* 1 000 000 Poles left Poland after 2004 (for an undefined period or for ever?) and moved to Western Europe. Approximately the same number of persons arrived from the countries of the former Soviet Union and Vietnam and they now work in Poland's shadow economy. Poland is predominantly Roman Catholic (about 35.8 million baptized). The Catholic Church also includes the Uniate Church (Greek-Catholic) with a congregation of *c.* 82 000. Other religions and denominations are represented by relatively small communities. Among them the biggest are: Orthodox, 510 000; Protestant and related, 140 000; Jehovah witnesses, 126 000; and Old Catholic, 50 000.

After the collapse of the socialist form of enterprise, Poland is witnessing, in the present decade, the steady growth of gross domestic product (GDP), which in percentage terms was +5.4 in 2004, +3.2 in 2005, and +5.8 in 2006. At the end of 2006, the rate of unemployment was 14.9% and average annual inflation 2.1%. In 1991, Poland became a member of the Council of Europe, in 1996 a member of the Organisation for Economic Co-operation and Development (OECD), and in 1999 of the North Atlantic Treaty Organisation (NATO). On 1 May 2004 Poland became a member of the European Union (EU).

Goals of the Education System

The basic principles of the Polish education system are included in the Education System Act of 7 September 1991. Education is defined as part of the common welfare of the whole of society. It should be guided by the principles

contained in the Constitution. The ideas of unfinished school reform from 1999 create the basis for the future development. Two ideas have become target areas for reform of the system of education:

- creating equal educational opportunities for all children and teenagers and
- improving the quality of education, preparing the graduates both for adult life and for permanent self-development.

Structures and Operation of the Education System

The different levels of the education system in Poland are depicted in Figure 1.

Preschool and Early Childhood Care

Pre-primary education is regarded as the first level of the school system. It concerns children from 3 to 6 years of age.

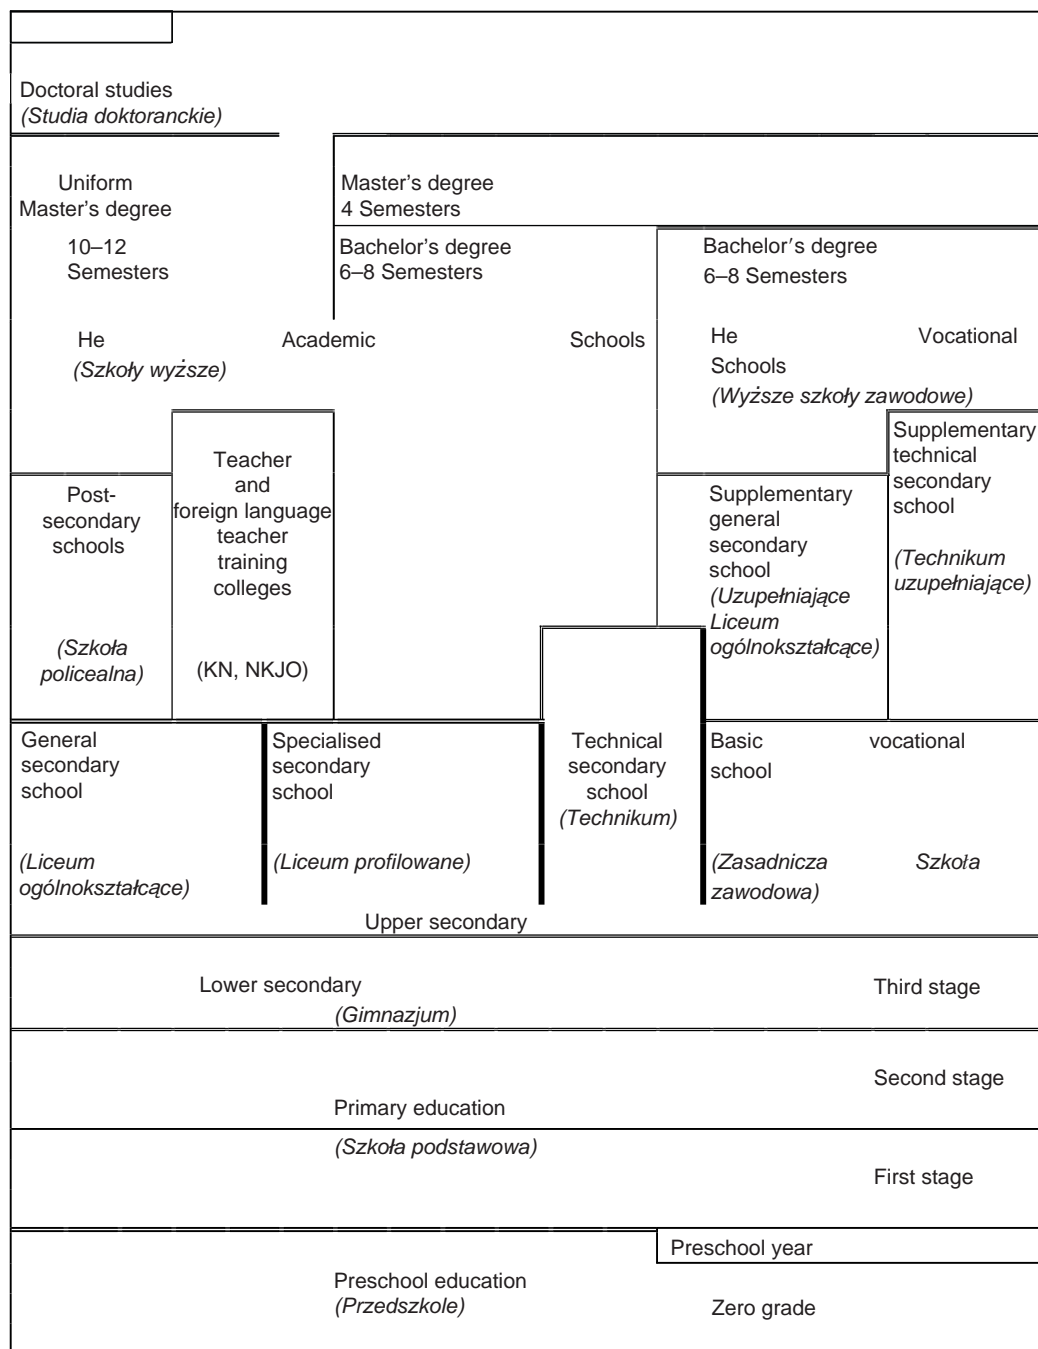

Figure 1 Structure of the education system in Poland.

As of 2004/05, 6-year-old children are obliged to complete a year of preparation for primary education called 0 grade. The classes are attached either to kindergartens or to primary schools.

Primary (Elementary) and Secondary Education

There are three phases of compulsory education: 0 grade, primary school, and lower secondary school.

1. Klasa zerowa (0 grade) is for 6-year-old children.
2. *Szkoła podstawowa* (6 years of primary school) for children 7–13 years of age. This school is divided into two stages:
 - stage 1 – integrated teaching, 7–10 years of age and
 - stage 2 – teaching based on separate subjects, 10–13 years of age.
3. *Gimnazjum* (3 years of lower secondary school) for children 13–16 years of age, and teaching is based on separate subjects.

Post-Compulsory Education (Upper Secondary and Post-Secondary Level)

There are three types of schools in upper secondary and post-secondary general education:

- *Liceum ogólnokształcące* (general upper secondary school) 16–19 years of age;
- *Liceum profilowane* (specialized upper secondary school) 16–19 years of age; and
- *Uzupełniające liceum ogólnokształcące* (supplementary general secondary school) 18/19–20/21 years of age.

Other Schooling Arrangements

Schools can be of two types: public (state) schools, which offer free education within the framework of the core curricula, and nonpublic. The latter can be civic (social), church, or private schools. The schools are called social or civic when they are owned by associations or foundations and they are nonprofit-oriented. All these schools may have their own curricula, which are approved by the minister of education. They are financed by fees received from parents. Most nonpublic schools have small numbers of pupils and small classes. They may be distinguished from the public schools by their personalized teaching programs, by a wider range of curriculum choice, and by a higher standard of foreign language teaching. In 2006/2007 school year, nonpublic school pupils formed 2.0–4.3% of the total number of pupils attending school.

Technical and Further Education

Post-secondary schools (*szkoły policealne*) are included as part of secondary education in the Polish classification and assigned to level 4 in the ISCED. Post-secondary

schools admit first of all graduates of general upper secondary schools. Students in these schools are trained as nurses, accountants, administrative personnel for enterprises and hotels, computer specialists, or librarians. Among upper secondary and post-secondary schools we have:

- *Technikum* (technical secondary school) 16–20 years of age;
- *Zasadnicza szkoła zawodowa* (basic vocational school) 16–18/19 years of age;
- *Technikum uzupełniające* (supplementary technical secondary school) 18/19–21/22 years of age; and
- *Szkoła policealna* (post-secondary school) 19–21 years of age (very rarely 20).

Higher Education

There are state and non-state (private) higher education institutions. The final examination certificate at the end of upper secondary school is required by all institutions for admission to higher education. The first-cycle studies last from 3 to 4 years and finish with the vocational qualification diploma and the title of *licencjat* (equivalent to BA) or *inżynier* (engineer) which gives access to the job market or to extended higher education (the second-cycle studies) to obtain the title of *magister* (MA) or its equivalent. After obtaining an MA diploma, one can apply for doctoral studies – the third cycle of studies.

Adult and Nonformal Education

Adult education aims at the acquisition and extension of general knowledge, upgrading of vocational skills and qualifications needed for a given occupation. Education, training, and in-service training can be provided on daily, evening, extra-mural, distance-learning, out-of-school basis, or in any other system combining the above forms. These tasks are carried out by public and nonpublic adult schools, centers for continuing education, practical training centers, and other institutions run by, among others, associations or foundations. In 2003, external exams were introduced.

All public schools for adults are organized and run by territorial self-government units. The *powiat* (district) authorities are responsible for running of post-gymnasium schools including continuing and practical education centers. The *gmina* authorities are in charge of primary and lower secondary schools for adults (apart from special schools). Nonpublic schools for adults are organized and run by individual persons or by bodies such as associations, social and religious organizations, etc. In the school year 2006/07, in 3666 schools for adults (all types), there were nearly 273.9 thousand students enrolled. Curricula in

schools for adults are usually the same as in youth schools, but adapted by teachers to the needs and requirements of adult education.

The Teaching Profession

The legal act defining the professional status and conditions of service of teachers employed in the school education sector is the Act of 26 January 1982 – The Teachers' Charter (with further amendments). According to the Teachers' Charter, the post of teacher may be taken by a person who has completed either a higher education course with appropriate pedagogical preparation or a course of study in a teacher training college. Any person graduating from these institutions is recognized as a qualified teacher within the specialization he/she has completed. The teacher can obtain the following professional grades: trainee teacher, contract teacher, appointed teacher, and chartered teacher.

The preschool teachers are mostly female – women make up 99.3% of teachers at this level. Teachers with a master's degree constitute 53.6% of preschool teaching staff. In grades 1–3 of primary school, one teacher teaches all subjects (integrated teaching), while in grades 4–6 each subject is taught by a different teacher. To date, teachers have been trained to teach one subject. The newly introduced teacher training standards envisage training teachers as specialists in two subjects. Acquisition of computing skills and a good command of one foreign language is also becoming obligatory.

Teacher training consists of training in subject matter and pedagogical training – teaching methods, psychology, and pedagogy. Teachers working in 6-year primary schools ought to have one of the following qualifications: university education (the title of *magister*), or 3-year teacher training college completed (the title of *licencjat*). Graduates with *licencjat* may complement their education with 2-year university study courses and obtain a master's degree (*magister*). The average salaries for teachers are calculated on the basis of the average salary of the trainee teacher, fixed at a level of 82% of the average state sector salary. This is a fixed mechanism for an annual revaluation and raise in teachers' salaries, identical to that for other parts of the public sector. The average salaries for teachers classified in the remaining categories are calculated as the following percentages of the average salary of the trainee teacher: contract teacher 125%, appointed teacher 175%, and chartered teacher 225%. There is a different division of powers concerning pay regulations. The powers of the minister of national education are limited to fixing the minimum rates of basic pay, whereas the rates for bonuses or allowances and the rules for granting these are determined by the body responsible for the management of a given school.

The working time of the teacher may not exceed 40 h per week. This workload includes the minimum teaching load which for the basic group of teachers (in all types of schools) is 18 h per week (45-min lessons). At the teacher's request, his/her weekly workload may now comprise up to 27 h per week, with any increase in the workload implying a proportionally higher salary. Teachers employed in the 3-year gymnasia ought to have – at a minimum – the qualifications reflected in the title of *licencjat*. Three-year gymnasium teachers are employed according to the same rules as those which apply to 6-year primary school teachers. Upper secondary school teachers ought to have completed a university education (*magister* degree) or equivalent.

Administrative and Supervisory Structure

There are two separate ministries in Poland: Ministry of National Education and Ministry of Science and Higher Education. The main role in initiating and exercising control over policy toward pre-primary, primary, and secondary educational institutions is played by the minister of national education. The Parliament is responsible for the final version of legal acts that determine the orientation of educational policy and the amount of money earmarked for education. Teachers' unions have a considerable role in shaping educational policy. In the last 20 years, we have also witnessed the emergence of a large number of non-government organizations (NGOs) involved in the problems of education, for example, The Centre for Civic Education or the foundation Education for Democracy. They play a very important and stimulating role.

The majority of vocational schools are the responsibility of the Ministry of National Education; only artistic schools, as well as correctional institutions are under the supervision of the Ministry of Culture and the Ministry of Justice, respectively. The national educational policy is developed and carried out centrally, while the administration of education and the running of schools, preschool institutions, and other educational establishments are decentralized. The minister of national education coordinates and carries out the state education policy, and is partly responsible for supervising the work of education superintendents (*kuratoria*). The minister determines the timetables, core curricula, conditions, and procedures for the approval of textbooks. He/she is responsible for the rules for assessing and promoting pupils and for conducting tests and examinations.

The regional level in Poland is the level of voivodship. The number of voivodships is 16. The education superintendent (*kurator*) is the chief educational body at regional level. The education superintendent implements the policy of the minister of education. On behalf of the voivode, the superintendent is responsible for pedagogical supervision

over public and nonpublic schools. At the regional level, self-governing voivodships are responsible for running certain types of educational institutions: teacher training colleges, teacher in-service training centers, pedagogical libraries, schools, and institutions of importance for a given region. The district level in Poland is the level of *powiat* (an intermediate administrative unit between the voivodship and the commune). There are 379 districts. The districts exercise administrative control over upper secondary general and vocational schools, as well as over post-secondary schools and public schools for children with SEN. They are also responsible for the management of art schools, lifelong education centers, psychological and pedagogical guidance centers, and out-of-school education centers.

There are about 500 centers for guidance and counseling in Poland. They are intended mostly for primary and lower secondary school pupils, with the aim of providing psychological assistance.

The local level in Poland is the level of the commune (*gmina*). There are 2478 communes, most of which rural ones. Communes exercise administrative control over preschool institutions, primary schools, and lower secondary schools called a *gimnazjum*.

School heads are recruited on the basis of an open competition and employed by the school governing body for 5 years. The school head decides on the employment of teachers. Some large schools employ a school pedagogical counselor or a psychologist.

Educational Finance

In 2004, public spending on the whole system of education (with higher education included) was estimated at 5.4% of GDP. In 2005, public spending on primary and secondary education (without higher education but with post-secondary schools included) was equal to 4.1% of GDP. All educational tasks carried out by the three levels of local government are financed within the framework of a general subsidy from the State Budget. In the year 2000, a uniform system of allocation of funds, using the algorithmic formula, was adopted. This formula is based on the real number of pupils, adequately increased by the system of weightings (taking into account specific conditions, integration of SEN pupils, sports schools). The local government unit, as a body running the school, is responsible for the designing of a budget program (i.e., a plan of expenditure) for all schools and educational institutions in its respective area.

Performance Monitoring, Evaluation and Research

Pedagogical supervision over the school is exercised by regional education authority (*kurator*-superintendent),

while organizational, administrative, and financial supervision is carried out by the school governing bodies. There are no formal principles for evaluating or monitoring pre-primary school children. The only exception is the so-called balance-sheet of the child aged 6 years which is connected with the recruitment to primary schools. In grades 1–3 of primary school, pupils are promoted automatically if their achievements are assessed positively. Starting with grade 4, pupils are assessed separately in each subject. The evaluation depends on the teacher. Only final marks per semester and at the end of the school year have to be approved by the teachers' council in each school.

An external standardized test upon completion of the primary school (grade 6) was introduced in 2002. These tests are comparable on the national scale. The primary school-leaving certificate is required for admission to lower secondary schools. Internal evaluation at *gimnazjum* level is the same as that in primary education. At the end of the third year of the *gimnazjum*, an external standardized examination is introduced. This examination checks abilities, skills, and knowledge. It is compulsory for all pupils. The results are indicated on the gymnasium-leaving certificate. They are comparable on a national scale. The number of points indicated on the leaving certificate decides about the pupils' admission to an upper secondary school. In the upper secondary general schools, the principles of internal evaluation are the same as those at lower secondary level. On completion of the 3-year general upper secondary school, pupils are awarded a school-leaving certificate. It gives access to the baccalauréat (*matura*) examination. At the end of upper secondary education, pupils may sit for baccalauréat, a national examination, which is compulsory only for those intending to receive the *matura* certificate and to gain access to higher education. At the end of upper secondary technical education (*technikum*), pupils may also sit for (*matura*) examination. In 2004, the new external vocational examination began to replace the old vocational examinations organized by schools.

The measurement of educational achievements and the assessment of school performance are carried out by the Central Examination Commission. This commission is totally responsible for the *matura* examination, as well as for all external evaluation. External support for schools and teachers is mainly provided by the National In-Service Teacher Training Centre, by regional centers, and by educational advisors. Research on educational problems is carried out by the Institute for Educational Research and a number of departments of education within universities.

Major Changes and Issues since 1990

As the first noncommunist government had already taken over the responsibility for education in 1989, it was necessary to:

- introduce new ideas into the teaching of humanities, particularly history;
- draw up and implement a civic education program; and
- increase the scope of foreign language teaching.

The demands for changes were at the beginning of the transformation based on the documents prepared earlier for the round table negotiations by *Zespół Oświaty Niezależnej* (Group for Independent Education) which was secretly active between 1982 and 1989. During those first years (1989–91) it was natural for new educational leaders to define their task in terms of negating whatever the communist authorities had been promoting. For decades, cut off from educational debates going on in the West, it was difficult to imagine what new perspectives for education may emerge. Between 1990 and 1999, there occurred many events which, in modernizing education, prepared the ground for more radical changes. Among them, the following should be considered in more detail:

1. The appearance of educational NGOs.
2. The Parliament's passing of the Act of 12 September 1990 on schools of higher education, which enabled private colleges and universities to be established. Between 1990 and 2005, the number of college and university students increased almost fivefold.
3. Intensive actions aimed at the development of foreign language teaching. According to our estimation, from 1989 there was a need for c. 25 000 teachers of English and the demand for teachers of German and French amounted to about 8000 each. Therefore, in the first half of 1990 a program was prepared for the new type of school – the Foreign Language Teacher Training College. During 1990 and 1991, 55 colleges opened all over Poland, mainly in towns in which there did not exist institutions of tertiary education.
4. The possibility of using other countries' educational experience – consent was given for the creation of Waldorff or Montessori-type schools or schools within the international baccalaureate system.
5. The undertaking of intensive actions aimed at introducing computers and the Internet into schools.
6. A large increase in the number of students applying to secondary schools awarding the baccalaureate (*matura*) diploma and, resulting from this, a decrease in the number of students wanting to study at secondary vocational schools (which did not award the diploma).
7. The abolition of the state's monopoly – that existed before 1989 – in creating the curricula and handbooks. Many institutions and economic entities became empowered to create and publish school books and teaching materials.
8. A gradual handing over to local, district, and regional authorities of the power to run schools and educational institutions and start of the long – and

far-from-finished – process of those authorities learning how to develop and shape local educational policies.

9. The appearance of the possibility for schools to take into account the needs of the region as well as needs connected with the pupils belonging to a specific ethnic group (e.g., teaching the Kashubian language has only been possible since 1990).
10. Until 1998/99, there existed an 8-year primary school, after which students could continue their education in a 4-year general secondary school, technical secondary school, general vocational school, or a 3-year basic vocational school. In 1999, a reform was introduced. Since 1999/2000, the present-day system – described earlier – exists.
11. In 2008, the Minister of Education main assumptions are aimed at finalizing the reform begun 10 years ago. The following activities are foreseen:
 - the dissemination of education of small children, including the compulsory education of all 5-year-olds (gradually, between 2009 and 2011); it will be obligatory for 5-year-olds to undergo 1 year of pre-school preparation;
 - lowering to 6 years, the starting age for children going into the 6-grade elementary school; the above change is connected with the necessity to verify and modify the existing educational programs; and
 - carrying out a curriculum reform of education on the lower and upper secondary schools.
12. Up to now, Poland has no long-term educational policy, that is, a policy which would foresee the state of education in 10–15 years time and point out how this state is to be achieved. In the first-half of 2008, we witness the attempts to create such a strategy.

General Background

Qatar is a peninsula with an area of 11 580 km², which has borders – on the south – with the Saudi Arabia. The head of the State of Qatar is Emir Sheikh Hamad Bin Khalifa Al Thani. The right to rule is passed on within the Al Thani Family. The constitution was ratified in 2003. In 1998, the Emir issued a decree setting an elected municipal council.

The national language is Arabic, and the culture is predominantly Arabic Islamic. The Arabic language is dominant language of instruction in government schools, while English is used in teaching in independent schools, private schools, and in all universities.

In 1997, oil and gas accounted for more than 64.3% of (gross domestic product, GDP). However, oil revenue dropped to 56.2%, in 2003, while the natural gas percentage share to the GDP rose from 10.6% in 1997 to 34%, in 2003. The GDP rose from 29.6 billion QRs in 1995 to 232.4 billion QRs in 2007. The *per capita* income rose from \$14 500, in 1995, to \$47 753, in 2007. The rise in GDP enabled Qatar to increase its expenditure on health and education.

Formal education began in Qatar, in 1952, with the establishment of a primary school – for boys – called Qatar Primary School. In 1956, there were 45 teachers, 1000 students, and 14 schools and kindergartens.

Population and Labor Force

The population in Qatar is composed of Qatari citizens, and the expatriate community which originates mainly from the Asian and other Arab countries. The population increased rapidly in size as a result of both natural growth and expatriate immigration. The population increased from 200 000 in 1975 to 744 029 in 2004, and to an estimated 1.4 million, in 2008 – Qatar citizens representing 14% of the population and noncitizens, 86%. The average annual increase in population between 1997 and 2004 was 5.3%. The economically active population (15+) was 280 122, in 1997, and has increased to 535 807, in 2006, of which 11.5% were Qataris (Table 1).

Responsibility for Education and Training

Formal education in the State of Qatar started in 1952. Since then, comprehensive educational policies have been

developed and supervised by the Ministry of Education (MoE). Such policies have been adherent to the heritage of the Islamic nation and its moderate character and constant endeavors to benefit from modern and technological achievements and new educational experiments.

Until 2002, the MoE was mainly responsible for governmental schools and for the certification of private schools and institutions. Qatar started its reform of educational policy by the creation of Supreme Education Council (SEC), which was established by Emiri decree #37 in November 2002. In 2003, the Qatar leadership released an initiative to reform education – under the slogan “Education for a New Era” – aimed at providing the best education for Qataris to prepare them to meet the needs of economic and social development.

Goals of the Education System

The basic goals of the education in Qatar can be summarized in Qatar Vision, which states, “The state desire to build a modern, world class education system that provides students with a first rate education comparable to that offered anywhere in the world.” The report indicates the characteristics of this system as: “it will encourage critical thinking, creativity and freedom of thought, and will promote social cohesion.”

The goals of the educational system can be summarized as follows:

- Reform the education system to increase the capacity of the student to acquire and use knowledge to benefit the society, to adopt a critical and innovative way of thinking, to increase student understanding for global changes, and build the necessary skills and ethical Islamic values for a productive and rewarding life.
- Vocational education and training (VET) to focus on providing students with the competence and skill to serve the expanding industry sector and to link to the labor market – giving industry a highly skilled workforce to support strong performance in an ever changing economy.
- Higher education sector goals are focused on developing efficient, quality institutions that can provide students with knowledge and enable them to contribute to the economy.

National Goals for Schooling have been set by SEC and its two bodies – the Education Institute and the

Table 1 Economically active population (15+) by occupations and gender

Evaluation Institute. The third body of the SEC – that is, the Higher Education Institute (HEI) – is responsible for supporting high-quality outcomes for postsecondary education, so it provides scholarship to best-performing students and sponsors them to the best and reputable universities, whether these are based in Qatar or otherwise.

As for VET, the State of Qatar recognizes the need to create a system that will certify and accredit VET institutions. In 2005, the Planning Council (at present, called the General Secretary for Development Planning (GSDP)) sponsored the Labor Market Strategy (LMS) that yielded a number of initiatives, which were coordinated by different ministries and agencies. This strategy aims to support the Qatarization process, build human capacity, and serve the fast-growing economic and social development. One of the programs that originated from this strategy is the National Qualification Framework for VET (NQFVET). This project will recommend a NQFVET, set of standards, and quality assurance (QA) system for the VET providers.

Structure and Operation of the Education System

The structure of the education system in Qatar is different from other countries. At present, there is no centralized body responsible for all education providers. The whole educational system is evolving and, possibly, in the near future, it will witness the development of a unified educational strategy:

The main policymaking agencies and their responsibilities are described below:

1. *Ministry of Education*. Founded in the mid-1951 and was called *Wizarat Al Maarif*. The ministry houses four sections: administration and financial affairs, education affairs, cultural affairs, and planning and curricula. It is fully responsible for the governmental schools in terms

of financing, evaluation and staff member recruitment, and educating older people.

2. *Supreme Education Council*. Until 2002, the MoE was mainly responsible for governmental schools and for the certification of private schools and institutes. The SEC was established in November 2002; it directs the nation's educational policy. It plays an integral role in the development and implementation of the education reform effort through its three institutions: The Education Institute – oversees and supports the independent schools; The Evaluation Institute – develops and conducts testing of students, monitors student learning, and evaluates school performance; The Higher Education Institute (HEI) – advises individuals with regard to career options and opportunities for higher education in Qatar and abroad, and administers scholarships and grants.

Population and Education

Population and their percentage distribution by education status in March 2004:

1. The population was 744 029 with the percentage of illiterate standing at 2.6% Qataris and 12.0% non-Qataris.
2. The percentage of population with highest qualification being completion of primary to secondary schooling was 45.4%, percentage of population with a bachelor, diploma, higher diploma, MSc, and PhD degree = 10.2% in 1986, and it increased to 19.8%, by 2004 – with almost all the change of 14.7% being due to the increase in number of university graduates.

Preschool and Early-Childhood Care

In 2006, there were 15 548 children in preschool care in the age range of 4–7 years, of which 6079 were 4 years old,

5935 were 5 years old, 916 were 6 years old, and 92 were aged 7. The total number of children attending kindergarten, in 2004 were 12 877, of whom 6030 were females and 6847 males. There were 93 preschools of which 42 were Arabic.

Primary (Elementary) and Secondary Education

Schooling in Qatar is compulsory for children. In 2006, there were 278 schools in Qatar (Table 2) of which 49.6% are from the MoE, 18.7% independent, and 31.6% are private schools. Over 48.5% of schools were primary, 29.1% preparatory, and 22.3% secondary. There were 112 498 full-time school students and 12 768 full-time teachers. The number of students in private schools is, at present, over 45 446, comprising 40.4% of all students. Teachers in private schools are 26.3%. The number of indigenous students rose from 42 000 in 1986 to over 140 000 in 2006.

According to 2006 statistics, Qatari students represent 59% in the MoE schools, 74% in independent schools, and 49% in private Arabic schools.

Primary education (1–6 years) lasts 6 years. The primary-school day, normally, contains about 5 h of tuition, and comprises two semesters each of 17 weeks. Overall, the average number of students per full-time equivalent (FTE) in primary schooling was 10.7.

Preparatory schools comprise grades 7–9, and last 3 years with 5 days per week. The average number of students per FTE in primary schooling was 10.4.

Secondary education is, normally, for grades 10–12 and is for 3 years with classes 5 days a week and two semesters each lasting 17 weeks. The average number of students per FTE in secondary schools, in 2006, was 8.4.

Other Schooling Arrangements

To decrease the illiteracy rate, the government educates students in night-classes and in all intervals. The number of such students decreased from 2871 in 2002, to 1845 in 2004.

An estimated 0.8% of children, in Qatar, have disabilities requiring special education. There are five institutes and a federation which deal with special needs at all ages. The Shafallah Center deals with special needs arising from disorders such as Down Syndrome and autism. Al Noor Institute deals with the blind. There are other institutes such as the mentally retarded school, Acoustic school, and Qatar Sport Federations, Rumeila and Oshwar.

Other schools which give special education, of all forms, starting from primary and up to secondary schooling are the Qatar Leadership Academy, and Qatar Academy Learning Center.

Technical and Further Education

Some international accredited private institutions offer short courses with certificates in information technology (IT), English as a Second Language (ELS), accounting,

and English. The total number of graduated students is estimated at 5835 per year.

Qatar Aeronautical College (QAC) was established in 1975, and is, at present, the Gulf region's leading provider of training for the aviation industry. It offers full-time, approved courses for pilots, aircraft maintenance engineers, air traffic controllers, meteorologists, and flight dispatchers, as well as short courses in a wide variety of aviation-related disciplines.

College of the North Atlantic, Qatar (QCNA) is a college run and administered by Canadians. Programs include business studies, engineering, and IT. Part-time courses are also available. For the year 2006–07, there were 1859 students registered, of which 623 were female and 1236 male.

Higher Education

Qatar has a number of postsecondary institutions. These include the Qatar University (QU), the Seven United States Universities located at the Education City, the University of Calgary, which is a Canadian University, and Stenden University, which is a Dutch University.

The QU is the only national university to have been established in 1977. It offers six areas of specialization: science, engineering, Sharia and Law, administration and economics, education, and business. The number of graduates in 2000–01 was 1445 (82% Qataris) and decreased to 1332 in 2005–06 (79% Qataris), with graduates from science and engineering representing ~42% of the total.

Since 1995, the Qatar Foundation (QF) established the Education City (EC), which accommodates some of the best world universities. In 1998, Virginia Commonwealth University School for Arts (VCUQ) started offering a bachelor of arts (BA) in design. It accommodates 190 students (2006–07 statistics with 189 being female and one, male). The Weill Cornell Medical College in Qatar (WCMC-Q) educates young people in this region to be physicians, biomedical researchers, and medical educators; it accommodates 148 students (2006–07, 77 female and 71 male). The Texas A&M University at Qatar (TAMUQ) opened in 2003. It offers undergraduate degrees in chemical, electrical, mechanical, and petroleum engineering, and accommodates 178 students (2006–07, 108 males and 70 females). Carnegie Mellon University in Qatar offers undergraduate degrees in two of its most highly ranked programs – business and computer science – and it accommodates 118 students (2007–08, 76 female, 42 male). Georgetown University, established in 2005, offers programs leading to a bachelor's degree in foreign service. The Faculty of Islamic Studies is an international center for Islamic thinking and dialog and is committed to enhancing research into the Islamic culture. The Northwestern University opened in 2008, and offers degree in

journalism and communication and it is the newest institution to open a campus at the EC.

In addition, 151 students study for a year in the Academic Bridge, which prepares students for entrance into the QF universities.

The Stenden University is a Dutch-administered university that offers diploma, bachelor, and master of arts (MA) degrees in hospitality, leisure and tourism, business, retail, and service management. In 2006–07, there were 273 students, of whom 140 were female and 133 male. The Calgary University Faculty of Nursing opened in May 2007 – this Canadian university offers a bachelor of nursing (BN) program. The total student enrolment was 273, of which Qatari students represent 71%.

The total number of students graduating in 2005–06, from all HEIs, was 2239 – among them, 69% were females and 64.8% were Qataris.

Part of the reform policy is the creation of the HEIs. It aims to enhance the quality of higher education, and thus, it has created several scholarship programs, namely:

- *Emiri scholarship.* Awarded to Qatari students with high grades from secondary schools. In 2005–06, there were 114 recipients of this scholarship – only six of them studied abroad and the rest in EC.
- *National scholarship.* Intended for highly qualified students who are accepted in universities selected to be on the national list (250 universities highly ranked, but with lower ranking than the Emiri list, which has 50 universities). A total of 204 students received this scholarship for the year 2005–06.
- *Employee scholarship.* Offered in partnership with the public and private sectors on condition that the students study in HEI-approved universities. The number was 119.
- *Pre-College (Academic Bridge in EC).* The number was 127.
- *VET Diploma.* Usually, students who do not qualify to Emiri or National HEI-approved universities can study in QCNA. The total number of students enrolled was 90.
- *Diploma, Qatar Aeronautical College.* The number was 187.
- *Pre-college grant.* This is for students who are accepted in Emiri and National Scholarship but need a pre-college additional academic preparation. The number of students enrolled in the United States, Canadian, and Australian institutions was 87, in Europe 256, and in the Middle East 261.

Adult and Nonformal Education

Qatar is also home to a very large number (around 90) of nongovernmental providers and others derived from credible overseas institutions. There are many where the quality is, as yet, quite unknown. A recent study identified a large number of organizations that provide training in specific skills highly valued by the labor market, such as

information and communication technologies (ICT) and English. There are no statistics for the number of students engaged in VET and nonformal institutions. Their certificate is only recognized by their employer and not by the MoE.

The Teaching Profession

In 2006–07 (**Table 2**), there were 6747 FTE teaching staff in MoE schools (52%), 2657 in independent schools (20.8%), and 3364 employed in private schools. As a whole, school teaching is a highly feminized profession, for example, in all schools, 69% of the staff are females.

For the higher education sector, there are 1119 full time teachers (FTT) (**Table 2**) 33.8% females.

The training for all primary and secondary schools and specialist educational personnel is undertaken by universities, especially the University of Qatar. In addition, the College North Atlantic provides a teaching diploma which is recognized by the MoE, and it has 492 (FTE).

Administrative and Supervisory Structure

Government schools in Qatar operate under the direct responsibility of the MoE. The independent schools come under the SEC. Private schools have their own administrations but they are established and operated under conditions determined by MoE registration authorities. MoE and SEC recruit and employ teachers for governmental and independent schools, supply buildings, equipment, and materials and provide funding for use by schools.

Private education has always been an important part of the Qatari education system. There are different private schools in Qatar. The first type is Arab schools and the second is the international schools that are administered and run by the foreign embassies in Qatar. The third type is the foreign schools – such as the British, French, Indian, and Iranian schools.

In the higher education sector, decision making, regulation, funding, and governance depend on the statutes of the university. For example, QU is funded by the government and the students. QF universities are governed by the board of the foundation and each university has its own board. Budget is allocated by the QF, together with students' fees. The Stenden University is a private university and it is governed by its own board.

Educational Finance

The total expenditure on education has two components: public and private. For the financial year 2003–04, total

government education and training operating expenses were QR 2 455 342 billion (2.85% of the GDP).

The source of income for government schools is from the government and from students' fees. Income sources for nongovernmental schools are mainly from students' fees and from fees for services. The governmental VET institutes are funded by the government and from fees for services. Private VET institutes are founded by students' fees and fee-for-service fees.

Performance Monitoring, Evaluation, and Research

The general education quality indicators are monitored by governmental agencies, such as the Planning Council (GSDP), MoE, and SEC. At present, all independent schools and their performance and programs are evaluated by the Evaluation Institute. All those evaluation and assessments programs are based on data gathered by different agencies such as SEC, MoE, and Qatar Bureau of Statistics. Educational research is carried out either by the MoE or SEC.

Research programs at QU and QF universities are funded by government grants and private companies. Two years ago, the QF created priority-research initiative and developed an ambitious program. The Emir of Qatar allocated 2.8% of the GDP for research. The QF stated that "Research is an essential component in QF strategy to make EC a world-class center for innovative education. QF Research, Science and Technology Division, with EC branch campuses and Research Centers, is aiming at pursuing cutting-edge research and development." The QF mission is "to organize Research around core platforms of Medicine, Biotechnology, Information and Communication Technologies, Environmental Sciences, Energy, Molecular Sciences and Nanotechnology. Qatar Science & Technology Park QSTP will be an incubator for private companies to partner with government agencies and academic institutions to develop research for commercial applications."

Increasingly, overall system performance is judged using international and national performance indicators. Drop-outs from schools range between 1.3% and 2.1% for females in primary schools compared to 1.3–8.7% for males. For preparatory years, the percentage ranges between 1.9% and 2.6% for females and 4.7–5.5% for males. For secondary schools, the percentage increases for both genders; so, for the females, it ranges from 3.7% to 7.3% and 8.6–13.0% for males. For secondary religious, trade, and industrial schools (only for males), it ranges from 14.3% to 20.8%.

The Evaluation Institute carries out student assessment using four elements: a national test of student's achievement, a process for regular administration, a process for monitoring of these tests, and a process for producing

reports on student's achievement at the national, school, and individual level. Student assessment is done according to a system known as Qatar Student Assessment System (QSAS). The SEC developed new curriculum standards for Qatar in Arabic, English, mathematics, and science. Students in night and illiteracy schools totaled 3271 in 1998, and 3041 in 2004.

All universities at the QF are accredited. In the case of professional schools at the QU, the College of Engineering received the Accreditation Board for Engineering and Technology (ABET), in 2005, for four of its programs; most colleges and departments at QU are, at present, working toward applicable accreditation in their fields. The College of Business and Economics is, at present, nearing completion of its accreditation by the Association to Advance Collegiate Schools of Business AACSB.

Major Changes and Issues Since 2000

Qatar society and government are facing great challenges due to increasing revenues from oil and gas, globalization, and internationalization. Qatar is willing to diversify its economy and education and to build a knowledge-based economy. Qatar is aware of the challenges and it answers them by publishing the document Qatar National Vision which, approved recently, states

The State of Qatar desires to build a modern, world class education system that provides students with a first rate education comparable to that offered anywhere in the world. This system will allow citizens to develop to their full potential and prepare them for international success, while helping them to understand and respect the values, traditions and heritage of Qatari society. It will encourage critical thinking, creativity and freedom of thought, and will promote social cohesion. To further support this pursuit of human development, Qatar aspires to be seen as an active centre in the fields of scientific research and intellectual activity.

Qatar witnessed a number of major changes in education and research. Those changes are outlined below:

1. The SEC was created in 2002, with three bodies. SEC increasing responsibilities are evidenced by the increasing number of independent schools, use of the international approaches to assess the performance of students, administration, and various departments.
2. The creation of QF and its universities, QSTP, the different research centers, the Sidra Hospital, and the Science Research Division. All these changes, combined with increasing expenditure on research, will increase the number of quality graduates, will involve the industry, universities, and research centers in performing research and development activities that will help

serve the society and enable Qatar to tackle a number of issues related to the development of a knowledge-based economy.

3. Qatar has also witnessed great development in many sectors such as construction, services, and hydrocarbon industries that require an increasing number of professionals and knowledge workers. This can only be achieved through providing a quality education, from VET to citizenship education.
4. Qatar is working to link education output to the labor market through programs adopted by the Ministry of Labour and Social Affairs while the GSDP is working with different agencies to create conditions for Qatar to enter the knowledge-based economy.

Russia

V M Filippov and G F Tkach, Peoples' Friendship University of Russia, Moscow, Russian Federation

© 2010 Elsevier Ltd. All rights reserved.

General Information

At 17 075 400 km² (6 592 800 mi²), Russia is, by far, the largest country in the world – covering more than an eighth of the Earth's land area and extending across the whole of northern Asia and 40% of Europe.

With 142 013 000 people (as of 1 November 2007), it is the ninth largest by population with four-fifth of the population living in the European part of Russia. The majority of the population is urban – 73%. The population is multinational – besides Russians (79.83%), there are people from over 180 nationalities. The state language is Russian. The Russian Federation (RF) is a democratic federate state with the republican form of governing; it consists of 86 subjects with equal federal rights-republics, *krais* (territories), *oblasts* (provinces), and federal cities. Local self-government functions within the bounds of given authority.

In 2005, 74 million Russian citizens were economically active; of these, 68.6 million were actually involved in the country's economy. The number of the unemployed totaled 5.6 million people (7% of economically active population). The majority of people were involved in trade and service sector (20.7%), processing industry (17.8%), agriculture (9.5%), and education (9.3%). Russia's economy comprises almost all branches of industry and all forms and types of production and manufacturing. This fact accounts for existing or potential demand for employees of all vocations and levels, which justifies high requirements to the universality and scale of the national education system. On the other hand, fast changes of the vocational and qualification structure of demands for working force in the last 15 years call for high flexibility and adaptation of the educational system, which presents some difficulties considering its scale.

Aims and Tasks of the Educational System

The main strategic task of the development of the Russian education is specified in the Federal Target Program of educational development in 2006–10. The program envisages ensuring conditions for meeting the demands of citizens, society, and labor market in quality education by creating new institutional mechanisms of regulation in the sphere of education, renewing structure and content, developing fundamental and practical character of educational programs, and forming a system of continuing

education. To accomplish this aim, the following strategic tasks should be realized:

- improving content and technologies of education;
- developing the system of ensuring quality of educational services; and
- improving economic mechanisms in the educational sphere.

Talking about concrete indicators of educational activity, the abovementioned tasks envisage the following results by 2010:

- Elaboration and implementation of new standards of general education in 60% of educational disciplines.
- Introduction of third-generation standards in all fields and specialties of higher professional education.
- A 1.5 times increase – in comparison with 2005 – in the number of students trained with the use of information technologies.
- Increase in the number of entrants in institutions of secondary and higher professional education who are enrolled subsequent to the results of the Unified State Examination (USE) from 40% to 90%.
- Increase in the ratio of higher education institutions (HEIs), realizing two-level professional education programs from 15% to 70%.
- A 1.3 times increase in the number of adult population mastering supplementary education programs.

Structure and Functioning of the System of Education

The general scheme of the Russian education system is presented in **Figure 1**. Integral qualitative indicators for main sectors are shown in **Table 1**.

General Characteristics of the System of Education

The system of education of the RF ensures realization of programs of general and professional education of various levels and fields. Key parameters of the educational content and organization of the study process – at all levels of education – are regulated by federal state educational standards, which are elaborated and adopted no less than once every 10 years in the order stipulated by the government.

The standards are a combination of requirements compulsory for all main educational programs in all educational institutions (EIs) with state accreditation. These requirements define: structure, realization terms, and learning outcomes of educational programs. On the basis of these standards, federal bodies of education management elaborate model educational programs for all levels and fields of training – which serve as a basis for study plans and programs realized in various EIs.

Preschool Education

The system of preschool education comprises daycare centers for babies from 12 to 36 months and kindergartens for children from 3 to 7 years. In 2005, 4 630 000 children – that is, 57.3% of all children of the corresponding age

group – attended 46 500 preschool EIs. There is one tutor for approximately ten children. In rural areas, there are 40% of preschool facilities, with 20% of children attending them. Most preschool general education institutions are public (13.6%) or municipal (83.7%) and are funded from corresponding budgets. A recent trend is the appearance of private and semi-private kindergartens (2.2% of the total number). Alongside with educational functions, kindergartens function as social, tutorial, and health-improving facilities. Kindergarten elementary educational program serves as a basis for primary school.

Primary and Secondary General Education

General education comprises three levels corresponding to three levels of educational programs: primary general,

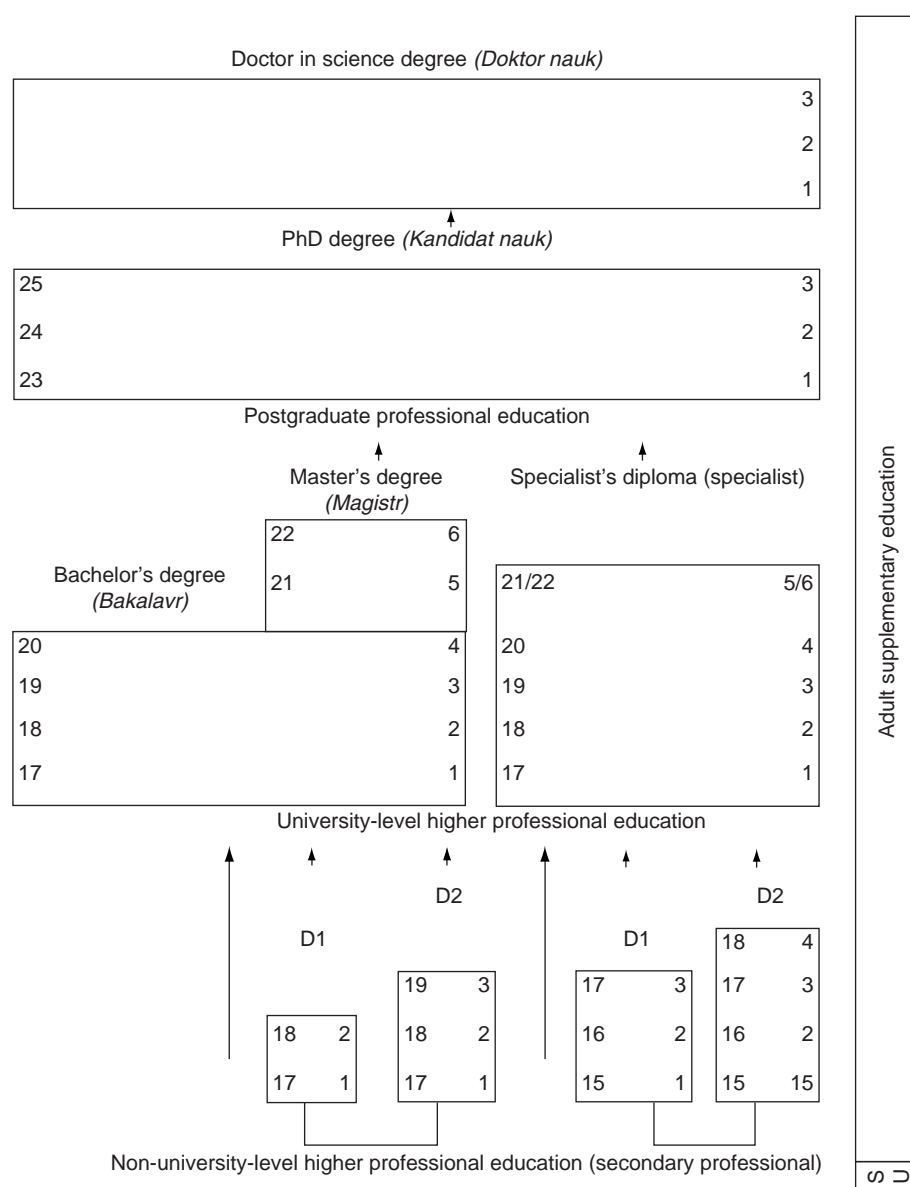

Figure 1 Continued

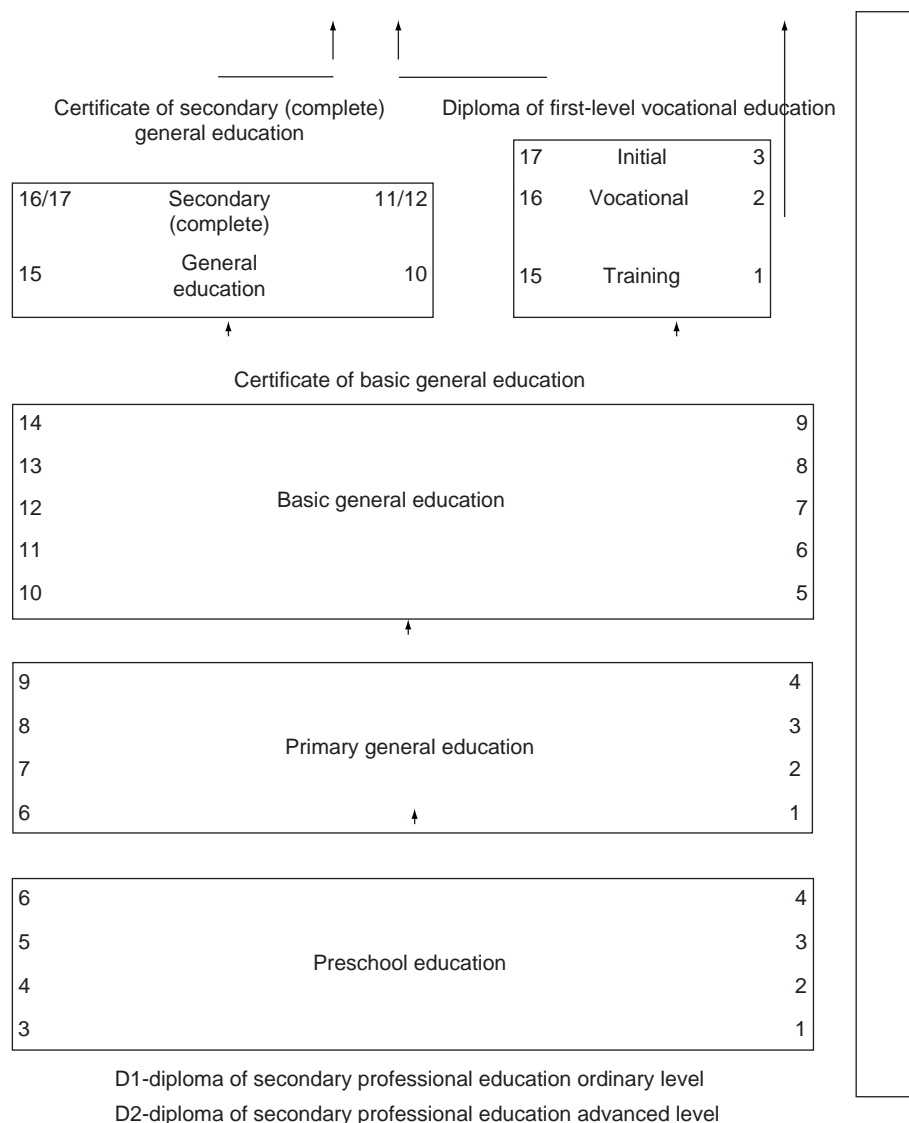

Figure 1 Education system of the Russian Federation.

basic general, and secondary (complete) general – the duration of each is 4, 5, and 2 years, correspondingly. These successive programs lasting, all in all, 11 years (12 in some schools with certain specializations) are usually realized in the same EI, that is, secondary general education schools, lyceums, and gymnasias. Basic general (9 years) education is compulsory. In 2007, a law on transition to compulsory complete (11 years) secondary education – at schools and institutions of initial vocational or secondary professional education – was adopted.

In 2005, 15.6 million pupils studied at 63 200 general education institutions (35% of pupils – primary general, 48% – basic general, and 17% – secondary complete general education). There is one teacher for, approximately, 17 pupils in primary school and 14 pupils in high school. On average, there are 18–19 pupils in one class (23 pupils

in urban areas and 13 in rural areas). Repeater ratio is less than 1%.

Children with disabilities and teenagers with deviant behavior attend specialized corrective EIs (70% of which are boarding schools) and specialized classes at general education schools. In 2005, 236 000 pupils studied at 1946 specialized corrective schools, and 189 000 pupils in specialized corrective classes at regular schools. All correctional schools and classes are either public or municipal.

Children start school at the age of 6. At primary school, they have traditional – for this stage (1st–4th forms) – subjects: the Russian language, mathematics, regional ethnography, the world around us, practical arts, music, arts, and physical training. From the 2nd form, a foreign language (in most schools, English) is introduced. In the 1st form,

Table 1 Education institutions, students, and teaching staff (2006)

<i>Level and type of education</i>	<i>Institutions</i>		<i>Students, thousand</i>		<i>Teaching staff, thousand</i>	
	<i>State</i>	<i>Nonstate</i>	<i>State</i>	<i>Nonstate</i>	<i>State</i>	<i>Nonstate</i>
General education	60 771	726	15 113	72	1575	19
Initial vocational	3025	–	1429	–	152	–
Secondary professional (nonuniversity-level higher professional)	2688	217	2473	118	140	10.4
University-level higher professional	655	413	5985	1079	322	65.2

the workload is 20 compulsory academic hours, 30 in the 4th form; children study 5 days a week.

The basic general education commences from the 5th form (10-year-old children). At the first stage of secondary education (5th–9th forms), mainly, attention is paid to fundamentals of natural sciences, humanities, and social disciplines with teachers in each subject. Study plans and programs at this stage are basically standard. Lyceums and gymnasias introduce elements of early specialization. National autonomies introduce additional hours of the national language.

In the final stage of school education (10th–11th forms), pupils complete the compulsory complex of main general education disciplines at the level of secondary (complete) general education. At this stage, education becomes more differentiated. Region wise, it means realization of the region component – which takes into consideration specific characteristics and demands of each region. Differentiation implies that each school can introduce certain disciplines for advanced studying within the alternative part of the study plan; pupils also take up some elective disciplines. The workload increases from 30 to 36 academic hours a week; pupils study 6 days a week. Russia is, at present, shifting to profession-oriented education in the 10th–11th forms, while simultaneously obtaining complete secondary education.

First and second stages of secondary general education culminate in state final attestation examinations. Final examinations are taken in 5–6 disciplines from the state standard list compulsory for all types of schools. After passing examinations in the 9th form, a pupil obtains a certificate of basic general education – which ensures the right to continue studying in the 10th form or to enter initial vocational or secondary professional EIs. The first two options are available without any entrance examinations or contest, while, at secondary professional EIs, there is a contest. After passing examinations in the 11th form, school-leavers of all Russian schools get a certificate of secondary (complete) general education, which entitles them to enter university and non-university level HEIs, irrespective of the chosen field. Starting from 2009, following long experiments, a USE is to be introduced. It combines state final attestation at schools and entrance exams at HEIs. Schools consider exam results as final attestation, while HEIs score these results as entrance.

Initial Vocational Training and Nonuniversity-Level Higher Education

Initial vocational training aims to prepare qualified workers and employees for all the spheres of economy – carried out mostly on the basis of basic general education. In 2005 – at 3392 professional–technical colleges, professional lyceums, and centers for continuing professional education – 1.5 million students mastered 1–3 years' programs of initial vocational training, 95% of them were full-time students. The majority (80%) were enrolled in 3 years' programs providing vocational training as well as secondary (complete) general education.

Nonuniversity-level higher education is aimed at preparing specialists on the basis of basic general, secondary complete general education, and initial vocational training. There are two types of nonuniversity-level HEIs: technical colleges realizing programs of the basic level (3 years for graduates of basic general school and 2 years for graduates of secondary complete general school), and colleges offering advanced programs (4 years for graduates of basic general school and 3 years for graduates of secondary complete general school). In 2005, 2.6 million students studied at 2905 nonuniversity-level HEIs (among them, 1.3 million students at 1250 colleges). Approximately 58% of students study at nonuniversity-level HEIs on the basis of secondary complete general education and 42% on the basis of basic general education.

At present, nearly 43% of nonuniversity-level HEIs come under the jurisdiction of federal bodies of the department of education; 49% of the subjects of the RF, 7.4% are nonstate. 118 000 students (4.5% of total number) study at 217 nonstate nonuniversity-level HEIs (among them 133 colleges).

All programs of nonuniversity-level higher education are compiled so that, in all cases, vocational training is based on secondary (complete) general education which is always realized at the initial or previous stage. Nonuniversity-level HEIs, thus, belong to the category of post-secondary EIs. Final state attestation of graduates envisages a final examination in a certain discipline, or a final interdisciplinary examination, and/or defense of a graduation-qualification paper. Graduates get a secondary

professional education diploma and are conferred a corresponding qualification in a certain specialty.

University-Level Higher and Postgraduate Professional Education

University-level higher professional education is realized on the basis of secondary (complete) general and secondary professional (nonuniversity-level higher) education. Entrants are admitted based on their performance in competitive examinations, which – starting from 2009 – will be USEs. For some lines of study (arts, sports, etc.) additional specialized tests and examinations are envisaged. Certain HEIs may also get the right to carry out such tests and examinations.

The HEIs are of the following types: universities, academies, and institutes. The category depends on a number of criteria – mostly on the range of lines of study and levels of training, as well as fundamentality and scale of research carried out by the HEI.

In 2005, more than 7 million Russian students studied at 1068 HEIs. Among them, nearly 6 million students studied at 655 public and municipal HEIs (among them: 332 universities, 172 academies, and 151 institutes). A total of 587 HEIs enjoy the federal status, 48 are under the jurisdiction of the subjects of the RF, and 13 of municipal authorities. Nearly 1.1 million students (15% of total number) studied at 413 nonstate HEIs (40% of all HEIs).

The modern structure of higher education includes study programs of higher professional education of two cycles – program leading to a master's degree and program leading to a specialist's diploma (engineer, economist, teacher, medical doctor, etc.). The master's program is based on the bachelor's degree, lasts a minimum of 6 years, includes practical training, and presupposes further research and/or teaching activity of the graduate. Holders of the bachelor's degrees are enrolled in the master's program based on performance in competitive examinations. The specialist's program means a 5–6-year program, including a complex of general scientific, general professional, and specialized disciplines, as well as training practice for further corresponding professional activity of the graduate. All programs of higher education culminate in a final state attestation including final examinations chosen by the HEI, and defense of the final attestation paper (project). The first level of higher education leads to the bachelor's diploma and, the second level, to the master's or specialist's diploma. The master's and specialist's diplomas give the same professional and academic rights to their holders, including the right to enrol in postgraduate programs.

The main aim of postgraduate professional education (doctoral studies), which is realized mainly in the framework of postgraduate studies and doctorate, is the training of highly qualified research and teaching staff.

Holders of the master's or specialist's degree can enrol in postgraduate programs based upon their performance

in competitive examinations. Postgraduate studies last a maximum of 3 years (full-time) and 4 years (extramural). Those with the PhD degree can enrol in the doctoral program based on their performance in competitive examinations. Doctoral studies last a maximum of 3 years. Postgraduate and doctoral programs culminate in public defense of the dissertation at the meeting of the Dissertation council, – which is entitled to confer corresponding degrees. Based on the results of the defense, a PhD or a doctorate degree is conferred. In 2005, 123 000 postgraduate and 4282 doctoral students trained in 640 HEIs.

Supplementary Education

Various types of supplementary education are available at all levels of general and professional education as well as outside of formalized education – at different establishments and institutions. Supposedly, every third pupil and student and every tenth job holder is engaged in supplementary education. Among various types of supplementary education, the best structured is supplementary professional education – including further training, traineeship, and professional re-training. EIs of supplementary professional education include academies, further training institutes, courses (schools, centers, etc.) of further training, and employment service-training centers. Every year, over 1.5 million people undergo supplementary professional training. Of these, nearly 75 000 are employees of professional EIs (17% – teachers of initial vocational training institutions; 26% – teachers of nonuniversity-level HEIs; 47% – university-level-HEIs teaching staff; and 10% – teaching staff of supplementary professional education institutions).

Teaching Staff

EIs are staffed according to their charters – with different types of EIs having different structure and composition. In preschool EIs, the main categories of teaching staff are – head of the kindergarten, tutors, and teachers. In initial vocational training institutions – directors and their deputies, foremen, tutors, counselors, and psychologists, as well as teachers of general educational and specialized disciplines. In nonuniversity-level HEIs – directors and deputies, teachers, and foremen. Main categories of university-level HEIs teaching staff are rectors, deans of schools, heads of departments, professors, associate professors, lecturers, and assistant lecturers.

In 2005, the total number of the teaching staff of EIs of all levels was 5.8 million people. Among them, in preschool and primary general education – 30%, secondary general (basic and complete) – 54%, higher professional – 15%, and adult learning – 1%. Nearly 80% of the teaching staff are women (86% in general education institutions). In initial vocational training, there are 66% women, nonuniversity-level higher professional – 76%,

university-level higher professional – 53%. University-level HEIs have the following structure of the teaching staff: managerial staff (rectors, vice-rectors, deans, and heads of departments) – 11.3%, professors at departments – 9.5%, associate professors – 37.5%, and senior lecturers, lecturers, and assistant lecturers – 41.7%.

Educational qualification and work experience of the teaching staff, on the whole, meet the requirements. Thus, 60% of primary school teachers have higher and 36% have secondary teacher-training education. At the nonuniversity-level higher education level, these figures are, respectively, 93% and 4%. At university-level HEIs, 48% of all the teaching staff possess PhD degrees and 12% have doctorate degrees.

Education Authorities

Authority in education between federal (central), regional, and local bodies of power are allocated according to the RF law, dated 10 July 1992, #3266-1 “On education” and the Federal law dated, 22 August 1996, #125-FZ “On higher and postgraduate professional education.” The legislative body adopts federal laws on education, approves the federal budget, stipulates education levels, and approves federal programs of education development.

The RF government stipulates the procedure of elaboration and approval of federal state-education standards, approves model regulations on state and municipal EIs, establishes the licensing, attestation, and state accreditation procedure for EIs, and acts as a founder of federal state HEIs.

Federal (central) managerial bodies in education are, at present, the Ministry of Education and Science, Federal Education and Science Supervision Service, and Federal Education Agency (both under the jurisdiction of the Ministry of Education and Science). The main function of the Ministry is working out state policy and adopting normative legal acts in the sphere of education. The Federal service and the Federal agency control and provide organizational, financial, material, and technical support to the educational system at the federal level.

Regions (subjects of the Federation) are responsible for: pursuing federal education policy in the region; elaboration and realization of regional programs of education development with due consideration of regional peculiarities; forming and managing state bodies of education management; setting up EIs of general, initial vocational, and secondary professional education; forming regional budgets with regard to educational expenses and adopting regional normative acts on education funding; organizing training, and re-training and refresher courses for teaching staff.

Local self-government bodies are responsible for realization of the right of citizens to compulsory basic general education. Their competence extends to: planning, organization, and control of activity of local bodies of education

management and EIs with regard to implementation of state educational policy; forming local educational budgets and adopting local normative acts with regard to education funding; setting up and reorganizing municipal EIs; appointing heads of municipal EIs; and constructing municipal EIs buildings and developing neighboring territories.

Each EI is independent in implementing the educational process, in choosing and appointing staff – in research, financial, and economic activity within the competence given to them by the RF legislation standard provisions on corresponding EIs and the charter. Nonstate EIs may be set up in the organization and legal forms stipulated by the RF Civil Code for noncommercial organizations. In their activity, such organizations shall be regulated by the education legislation and the charter elaborated independently and approved by the founder.

Education Funding

General education of all levels and initial vocational training are free of charge. State and municipal EIs provide programs of nonuniversity-level higher professional, university-level higher professional, and postgraduate professional education free of charge upon performance in competitive examinations – if the citizen obtains education of this level for the first time.

Funding of EIs is done on the basis of state and local standard norms established per student in each type and category of EI and level of educational program. The funding scheme is determined by standard regulations on EIs of corresponding types and kinds. Norms of funding of nonstate EIs cannot be lower than the ones for state and municipal EIs on the same territory. Nonstate EIs develop the right to state and/or municipal funding the moment they are granted state accreditation, provided they implement main educational programs. Irrespective of their organization and legal form, EIs have the right to attract additional funds rendering additional paid educational and other services stipulated by the charter in accordance with the RF legislation.

Educational expenses from the consolidated budget of the RF in 2005 totaled 801.8 billion rubles, which is 11.8% of total expenses from the RF consolidated budget, or 3.7% of gross national product (GNP). The federal budget accounted for 20% expenses; consolidated budgets of the subjects of the RF accounted for 80% of expenses. The distribution of expenses was as follows: preschool education – 16%, general (primary and secondary) – 51%, initial vocational – 6.4%, nonuniversity-level higher professional – 6.4%, university-level higher professional – 19.2%, and re-training and refresher – 1%.

Education Control and Quality Assessment, Scientific Research

Federal education and science supervision service is the main body authorized to control and assess the activity of EIs with a view to their congruence with educational legislation, federal state educational standards, and federal state requirements. Control is implemented through mechanisms of licensing, attestation, and accreditation.

Every EI is subject to licensing. It determines compliance of the educational process in the EI with state and local requirements with a view to observing material and technical, sanitary, construction and other rules and norms, adequacy of classroom equipment, education qualifications of the teaching staff, and staffing level.

State accreditation confirms the right of the EI to confer to its graduates a state-standard document of the corresponding educational level. State accreditation is granted following a favorable attestation report. Attestation is carried out no less than once every 5 years and is aimed at determining compliance of the content, level, and quality of preparation with federal state educational standards. The state accreditation certificate confirms the status of the EI for another term and determines a list of lines of study and specialties in which the EI can confer corresponding qualifications and state-standard diplomas. EIs can obtain public accreditation at various Russian, foreign, and international educational, scientific, and industrial associations and organizations.

One of the most important attestation parameters of complex assessment of HEIs is evaluation of scale and results of scientific-research activity and its contingency with the educational process. This parameter is crucial for obtaining university status. Participation in research and achieving results is one of the grounds for teachers' re-election and further career growth. Research is funded independently from funding educational activity.

In the overall structure of institutions and organizations doing research in the sector of higher education, 75% are universities and 20% are scientific research institutes and centers. Over 30 000 employees participate in research and elaborations; half of them enjoy the researcher status. Among them, approximately 40% and 30% work in the field of natural and engineering sciences. Social sciences account for 10%, medical and humanitarian – 5% each of the total number of this category of employees.

Principal Changes and Results Since the 1990s

In the first-half of the 1990s, the Russian educational system faced a crisis due to the break up of the Union of Soviet Socialist Republics (USSR) and consequent change of the socioeconomic system. Qualified teaching staff started leaving their jobs, certain sectors of educational activity saw stagnation and reorganization.

As a result, nearly all quantitative and qualitative indicators characterizing education development declined dramatically. However, there were some positive changes during this period – adoption of the 1992 and 1996 framework laws regulating functioning of education in new conditions and partial introduction of multilevel structure of higher education in 1992–93.

In the second-half of the 1990s, the state started taking decisive actions to improve the situation. First of all, it concerned funding education and increasing teachers' salaries. EIs and the educational community gradually started to adjust to new conditions. In the following years, the consolidation process gained momentum. This allowed elaborating and adopting the RF National education doctrine (2000), and the Concept of Modernization of Russian Education till 2010 (2001). The documents were approved correspondingly by the State Council and the government. The modernization concept served as a basis for short-term and mid-term programs of educational development, which formulated concrete tasks and indicated mechanisms of their realization as applied to different educational sectors and types of educational activity.

These programs envisage projects of modernizing structure and content of general and professional education, education quality-assessment system, EIs' material and technical base development, improving mechanisms of funding education, and ubiquitous introduction of information technologies. Further modernization of the Russian education is considered a key factor of socioeconomic development of the country, and envisages concentration of effort in the following directions:

- bringing education content, teaching technologies, and education quality-assessment methods in balance with demands of the modern society;
- elaborating managerial mechanisms adequate to educational system-development tasks;
- creating economic mechanisms ensuring investment attractiveness of the educational system; and
- ensuring effective participation in education internationalization processes.

The education policy of Russia – reflecting nationwide interests in the sphere of education and presenting them to the world community – also takes into consideration general tendencies of world development, which cause the necessity of significant changes in the educational system. There is sufficient evidence that notwithstanding remaining acute problems, the Russian education has, on the whole, overcome negative consequences of the 1990s' crisis and entered the phase of intense growth. In recent years, the attention of the society and government to education has grown considerably. Since 2005, educational development has become one of five priority national projects, which envisages, in particular, considerable

additional funding targeted, first of all, to the most needy sectors of education activity, and second, to intensive formation of education innovation potential.

General Background

The Republic of Rwanda is a relatively small, landlocked country in the Great Lakes region of eastern and central Africa, bordered by Uganda, Brundi, the Democratic Republic of Congo, and Tanzania. With an area of 26 338 square kilometers and a population of 8.1 million (2002 census), it is one of the most densely populated countries in Africa. A green and hilly country, Rwanda whose capital is Kigali enjoys a relatively mild climate, with the mean daily temperature being 24 °C and most of the country being located on the fertile eastern plateau. Rwanda is essentially an agricultural country, 83% of the people living in rural areas and over 88% of the working population engaged in agriculture, 3.3% in services, 3% unskilled workers, 2.6% in business, 1.6% professionals, and 0.8% in manufacturing. With a per capita income of \$ 290, Rwanda is ranked 161st on the human development index (HDI).

The population growth rate in 1998 was estimated to be 2.8%, birth rate at 3.9%, and the infant mortality rate was 107 deaths/1000 live births. Life expectancy at birth for the total population was 41.9 years.

In 1899, Rwanda became a German colony under the Germany East Africa. The Germans ruled indirectly through the King (*Mwami*) and his chiefs. After World War I, in 1919, Rwanda became a mandated territory of the League of Nations under the administration of Belgium. In 1946, after the World War II, the country became a Belgium Trustee on behalf of the United Nations. Rwanda became independent in 1962. The post-independence period has been characterized by political conflicts that affected social and economic growth.

In 1994, within a period of less than 3 months at least a million people were brutally massacred; thousands of women and young girls were raped, maimed – both physically and psychologically.

Education System

Rwanda's education system consists of 6 years of primary education, 3 years of junior secondary, and 3 years of senior secondary. After upper secondary, one can proceed to the university or go in for other tertiary education. University education takes 4–6 years depending on the course of study. Primary education is free and compulsory. A landmark development in the country is the introduction

of 9 years of free basic education. This includes 6 years of primary and 3 years of junior secondary. In implementing this, the Government of Rwanda seeks to ensure that all children leaving school will have acquired reasonable academic knowledge, technical and life skills to survive. Higher education is mainly provided by universities and specialized institutes.

A number of institutions provide formal education, ranging from preschools to universities. The civil service reforms within the ministry of education (MINEDUC) have led to organizational changes which are currently being implemented. The departments and units have been reorganized for increased efficiency and effectiveness. In terms of education delivery, MINEDUC leads policy formulation and is responsible for the setting of norms and standards, and for planning, monitoring, and evaluation at national level; districts administer the personnel and monitor performance.

The Government of Rwanda is also implementing major reforms in the areas of decentralization and public service. With decentralization and public service reform currently being implemented, responsibilities for program and plan implementation and monitoring at the district levels lie with the district education offices. It is anticipated that as school management is strengthened, schools themselves will make more decisions. MINEDUC also works with civil and faith-based partners and the private sector to ensure education provision for all.

National Goals and Policies

Rwanda's Vision 2020 aims at the development of a knowledge-based and technology-led economy. It seeks to eradicate poverty and to move Rwanda to the list of middle income countries (MICs) by the year 2020. The people of Rwanda are its greatest asset as it has extremely limited natural resources. Education is therefore at the heart of the Vision's strategy. In today's globally competitive environment, an educated population is a prerequisite for a country to take on technological challenges and development.

Mission statement for education

The global goal of the Government of Rwanda is to reduce poverty and in turn improve the well-being of its population. Within this context, the aim of education is to

combat ignorance and illiteracy and to provide human resources useful for the socioeconomic development of Rwanda through the education system.

Goals for the education sector

Goals for the education sector seek to build on the strengths of Rwanda while acknowledging the challenges to realize the mission statement for the education sector:

1. to educate a free citizen who is liberated from all kinds of discrimination, including gender-based discrimination, exclusion, and favoritism;
2. to contribute to the promotion of a culture of peace and to emphasize Rwandese and universal values of justice, peace, tolerance, respect for human rights, gender equality, solidarity, and democracy;
3. to dispense a holistic moral, intellectual, social, physical, and professional education through the promotion of individual competencies and aptitudes in the service of national reconstruction and the sustainable development of the country;
4. to promote science and technology with special attention to information communication and technology (ICT);
5. to develop in the Rwandese citizen an autonomy of thought, patriotic spirit, a sense of civic pride, a love of work well done, and global awareness;
6. to transform the Rwandese population into human capital for development through acquisition of development skills;
7. to eliminate all the causes and obstacles which can lead to disparity in education be it by gender, disability, geographical, or social group;
8. to educate a free citizen who is liberated from all kinds of discrimination, including gender-based discrimination, exclusion, and favoritism;
9. to contribute to the promotion of peace of a culture emphasise Rwandese and Universal values of justice, peace, tolerance, respect for human rights, gender equality, solidarity and democracy.
10. to dispense a holistic moral, intellectual, social, physical, and professional education through the promotion of individual competencies and aptitudes in the service of national reconstruction and the sustainable development of the country;
11. to promote science and technology with special attention to ICT;
12. to develop in the Rwandese citizen an autonomy of thought, patriotic spirit, a sense of civic pride, a love of work well done, and global awareness;
13. to transform the Rwandese population into human capital for development through acquisition of development skills; and
14. to eliminate all the causes and obstacles which can lead to disparity in education be it by gender, disability, geographical, or social group.

Specific objectives for the education sector

Specific objectives for the education sector are:

1. to ensure that education is available and accessible to all Rwandese people;
2. to improve the quality and relevance of education;
3. to promote the teaching of science and technology with a special focus on ICT;
4. to promote trilingualism in the country;
5. to promote an integral, comprehensive education orientated toward the respect of human rights and adapted to the present situation of the country;
6. to inculcate in children and sensitize them to the importance of environment, hygiene, and health and protection against HIV/AIDS;
7. to improve the capacity for planning, management, and administration of education; and
8. to promote research as a mobilizing factor for national development and harmonize the research agenda.

Challenges

The Government of Rwanda recognizes the challenges faced in the country which can be summed up as:

1. developing approaches to deal effectively with the legacy of the genocide, notably the education of orphans and child-heads-of-family and the provision of feeding and boarding programs for such children;
2. addressing the shortage of teachers, both qualitative and quantitative, at all levels and insufficiency of qualified personnel at central and provincial administration levels;
3. improving the status of the teacher and providing incentives for the job, given the salary and conditions of service which do not motivate;
4. rehabilitating destroyed or defective infrastructure in some parts of the country (including the replacement of furniture, equipment, and educational materials destroyed during the war and genocide);
5. increasing the recurrent budget for education of which the majority is absorbed by paying salaries, and managing changing donor support as Rwanda moves out of emergency into development;
6. monitoring the system with an inspection service that is still in the early stages of development and building its capacity to meet the norms of planning;
7. completing modernization process for educational legislation;
8. providing adequate supplies of textbooks and relevant educational material in schools;
9. improving internal efficiency (rate of failure, repetition, drop out, and insufficiently developed systems to recoup those who are excluded);
10. improving external efficiency (poor performance of leavers);

11. rehabilitation and strengthening of education in science and technology;
12. increasing the number and quality of researchers in all domains and increasing the very limited allocation of funding to research;
13. identifying appropriate educational strategies and measures to assist in addressing the HIV/AIDS pandemic; and
14. halving the rate of illiteracy.

Guiding principles

The education sector strategic plan (ESSP) is guided by the following six principles that derive from Vision 2020, the poverty reduction strategic paper (PRSP), and the education sector policy:

1. Education will be considered holistically as a sector and so a whole sector, or Sector Wide Approach (SWAp), will be developed to be used to assist the planning and management of the system.
2. A medium-term expenditure framework (MTEF) will be used as a tool to ensure that educational proposals are set within the national fiscal planning and management process in the short and medium term, with close monitoring and regular evaluation.
3. The government affirms the importance of partnerships between government, parents, communities, donors, the private sector, NGOs, faith-based organizations (FBOs), and civil society. There will be regular participative consultations, negotiations, and meetings coordinated by the government. A horizontal coordination between different actors will be established, and, through decentralization processes, there will be effective vertical links between central government, local government, and grass roots groups.
4. There is a need to balance access, quality, and relevance with a special emphasis on a curriculum that is outcome oriented and offers the skills and values necessary for development.
5. There shall be gender consideration especially in learning achievement for girls and access to education for women, especially in rural areas.
6. ICT in education shall be considered as the heart of the education system.

International Compliance

Education sector policies comply with important international goals and aspirations. The ESSP therefore builds upon the government's clear commitment in its PRSP to the key role that education can play to improve social and economic well-being and reduce poverty. This is consistent with the United Nation's 2000 Millennium Declaration and the millennium development goals (MDGs), particularly

those that underline the importance of universal primary education (UPE) and the removal of gender disparities.

In terms of poverty reduction and human resource development, education, particularly basic education, is of central importance. Rwanda subscribes to the education-for-all (EFA) principles and process. MINEDUC has developed an EFA plan of action that puts into effect the six goals arising from the World Education Forum in Dakar, April 2000.

Structure and Operation of the Education System

Preschool and early childhood care

Preschool education is financed by parents while the ministry of education provides policy and coordination services. The government offers technical support and plans to give incentives to the private sector to provide such services. Less than 10% of the eligible children are enrolled in pre-schools. In 2001, there were 257 nursery schools of which only two were government owned. These preschools cater to 18 399 children out of about 2 million preschool-aged children. This is just under 1%. These schools are managed by 327 teachers, the majority of whom have received only in-service training.

In the future, the government will play an active part in the financing of this subsector. In addition, the feasibility of using existing primary and other structures to provide such services will be examined, and further data will be obtained to determine the type of service desired by the public and the potential public benefits.

Primary education

The MINEDUC Planning Directorate has conducted school censuses annually since 1997 and substantial data are now available (**Table 1**) as a basis for planning future provision of primary education.

Eleven teacher training colleges (TTCs) offer both initial and in-service teacher training and help to improve the quality of teaching staff by upgrading existing under-qualified teachers and giving new recruits an intensive basic training. These TTCs have the capacity for approximately 2500 students in total each year. There are also several private or government-subsidized schools with special sections to train primary school teachers.

Secondary education

Currently, transition from primary to secondary schools is approximately 37% including all public and private schools, but only 25% for the public schools. There is a higher proportion of boys (almost 60%) (**Table 2**) accessing public and government-assisted secondary schools, and a higher proportion of girls (again, almost 60%)

Table 1 Primary education indicators (1998–2005)

1998	2005	
		1.0. Students
1 270 733	1 857 841	Number of students
635 765	912 207	Number of boys

-	137.3%	Gross enrolment rate
-	93.5%	Net enrolment rate
21.0%		Transition rate to secondary
56.2%		Promotion rate
32.1%		Repetition rate
11.7%		Drop-out rate
		2.0. Teachers
22 435	29 033	Number of head teachers and teachers
	26 944	Number of head teachers
10 002	12 330	Number of males
12 433	14 614	Number of females
10 463	25 255	Number of qualified teachers
		3.0. Teacher/student
57	69.0	Teacher student ratio
121	73.6	Qualified teacher student ratio
		4.0. Schools
1940	2295	Schools
	29 748	Classroom
	36 175	Number of streams

Table 2 Secondary education indicators (1998–2005)

1998	2005	
		1.0. Students
105 292	218 517	Students public and private
51 811	115 350	Number of boys
53 481	103 167	Number of girls
.	642 990	Boys of school age
.	670 200	Girls of school age
.	16.6	Gross enrolment rate (%)
.	9.0	Net enrolment rate (%)
.	8.7	Repetition rate (%)
		2.0. Teachers
4679	7610	Number of teachers public and private
73.6	78.7	% of male
23.3	21.3	% of female
1544	3940	Number of qualified teachers
33.0	52.2	% of qualified teachers
		3.0. Teacher/Student
21.1	29.6	Teacher student ratio (public)
24.8	27.6	Teacher student ratio (private)
		4.0. Schools
322	553	Schools(public and private)
167	337	Public schools
155	216	Private schools

attending private secondary schools. This is partly due to girls' underperformance at the end of primary school and not achieving the necessary level to enter public secondary schools, and partly due to a preference among many

families for girls to be attending boarding schools, most of which are private. Girls' performance at secondary level is also inferior to that of boys. Consequently, the education gap between girls and boys widens with implications for inequality in career opportunities.

Technical and vocational education

Vocational training

Vocational training is offered in youth training centers (YTCs). These centers cater to about 2000 young people out of a total target population of approximately 1 million. There are 22 public and 16 private vocational centers.

The curriculum in YTCs is tailored to the needs of young people with adequate basic education, so those who have dropped out of primary school very early are unlikely to be able to access these YTCs. The proportion of girls is very low and is concentrated in the traditional domains such as tailoring and catering. Only 5.8% of women benefit from the apprenticeship as against 9.1% of men, and only 2.6% of women benefit from short training. There is an acute shortage of equipment and qualified teachers in most YTCs. Fees are also payable, making access difficult for the poor.

Technical and professional/vocational education

Technical and professional/vocational education are provided at the second cycle of secondary education by the MINEDUC. Historically, Rwanda has had a shortage of technicians, and where technical education has existed, it has often been of poor quality. This situation was exacerbated by the events of 1994, where some of the few technicians that existed were killed in the genocide or fled the country.

At present, there are technical schools (ETOs). Most technical schools lack adequate equipment and teachers are not fully qualified. Technical education in agricultural fields is neglected and the participation of girls is still very limited due to the legacy of colonial education policies and gender stereotypes. Professional/vocational education focuses mainly on traditional skills such as secretarial skills, agro-veterinary, nursing, and teaching, and caters mainly to girls. This reinforces gender stereotypes in careers and professional opportunities.

The ministry of education is in the process of developing a policy for formal vocational training subsector and also revising the curriculum for vocational training centers. It also intends to improve the existing vocational training centers. Each district is encouraged to establish at least one vocational training center.

There exists a technical education policy and strategy. The intention of the ministry is to strengthen the existing ETOs and to upgrade some ETOs to providing advanced diplomas at the level of A1.

Higher Education

Higher education is offered at University of Rwanda and at public and private higher education institutions. However, higher education enrolments are still lower than average south of the Sahara (about 1%). There is a relatively low participation of girls in tertiary education (Table 3), particularly in science, technology, and related fields and in public institutions. Private sector participation is picking up, with women's participation encouraging at 49%, while in public institutions it remains at 26%. The issue of equal access and performance for women in higher education institutions, whether public or private, is being addressed through higher education subsector policy.

Currently, these higher education Institutes are relying on expatriate lecturers. The Government of Rwanda is committed to a staff development program by sending a number of recent young graduates overseas so that they can complete their training in masters or PhD level and replace foreign lecturers/professors when they return to Rwanda, and it also intends to initiate postgraduate programs at masters and PhD level so as to produce its own university professors and highly qualified executive personnel.

A cost-sharing scheme has recently been adopted for higher education, with students receiving loans from the government for their studies, and then having to pay this money back when they start employment after graduation. Thus, enrolment in higher education can be expanded, as students now bear more of the costs. This will reduce the burden on the already constrained government resources when loans begin to be repaid.

The Government of Rwanda (GoR) policy is to establish a coherent and comprehensive strategic framework

that sets out the governance, function, role, form, and shape of the higher education system. This framework is detailed in the higher education law, the higher education policy, and the higher education subsector plan.

A key component of the framework is the 2005 Higher Education Law. This law defines the operating environment for all higher education institutions (HEIs), both public and private. It specifies the roles, responsibilities, and duties of all HEIs. The law mandates the establishment of two semi-autonomous organizations. Together, these new organizations will oversee the development of higher education according to the government's stated aims and priorities. These are outlined in the higher education policy and subsector plan. Each institution will have a specific remit and set of responsibilities within the overall framework.

The National Council of Higher Education (NCHE) will support the development of a national strategic planning framework. It will establish a national quality system and a national qualification framework. It will also have the power to accredit and approve the operations of all higher education providers. The student financing agency for Rwanda (SFAR) will manage all students financing, such as loans, grants, bursaries, and scholarships.

The intended outcome of these initiatives and reforms are to allow maximum autonomy to individual institutions for their own micro-management, while at the same time ensuring that the system as a whole is responsive to national priorities and flexible to changing conditions.

An important premise for growth in higher education is the ability to attract private sector investment. A further area for consideration concerns the training of graduates in Rwanda. This will be done by organizing postgraduate studies within the country and also by sending students abroad to obtain training in those professional fields which cannot be accessed in Rwanda. This strategy will increase the number of nationals working in professional and technical areas, reduce the number of expatriate lecturers, and thereby lower the costs of higher education provision.

Adult and nonformal education

The GoR has set a target of having 80% of the population literate by 2010. The recent synthesis of the 2002 census indicates that some 60% of the population aged 15 years and above can read and write in at least any one language, and that men have a higher literacy rate than women. The highest rates of literacy are within the 15–34 year age range.

A draft policy for youth and adult literacy is being developed by MINEDUC. It will seek to be appropriate to Rwanda's context in terms of cultural links and practices (e.g., using the Umuganda tradition, ensuring peace and reconciliation, etc.). The proposed policy distinguishes between learning to read and write (Kinyarwanda,

Table 3 Higher education indicators

1996	2001	2006	
			1.0. Students
3948	12 802	37 159	Total public and private
3948	8723	16 193	Students(public)

1	6	6	Public institutions
0	4	12	Private institutions

French, and English), and reading and writing to learn. The latter is important if people are to access information easily (life skills, healthcare, etc.).

The revised organizational structure at MINEDUC encourages the linkage between formal and nonformal education (NFE) and places the catch up and adult literacy program within the same NFE unit. This allows any literacy program to be not only a major goal for primary education but also for out-of-school education.

The challenge is to go further by having an intersectoral approach with strong partnerships with faith-based and civil society organizations. This would promote diversified strategies within an over-arching national program for vulnerable groups (rural communities, out-of-school youths, orphans, and vulnerable children and women).

The long-term strategy demands that adult literacy centers be upgraded and that there will be increased production and distribution of diversified literacy material available to adolescents, and younger and older adults. Consideration is also being given to financial incentives and forms of recognition for literacy trainers. Alternative ways of reaching nonliterate persons are important, such as through the media (e.g., radio, television for wide public information), and through the use of school facilities as community resources. An expanded nation-wide literacy program demands adequate funding by the government, sufficient trainers, and materials, as well as a rolled-out national plan within the decentralized context.

New Policy Initiatives

Education in Rwanda is in a dynamic and fast transitional state, and new policies and programs are either under consideration or are being introduced. These incoming policies and programs will affect the strategies and activities during the next years and will change the structure of the education system, besides having important implications for the financing of the education system (Table 4).

Nine-year basic education

This is one of the key emerging priorities. Achieving 9-year basic education for all is one of the main goals of the GoR. It will aim to raise the general level of knowledge and skills in the population, which has the potential to reduce poverty.

The implementation of the 9-year basic education program will demand increased numbers of trained teachers, more learning materials, and more classrooms. The challenge will be to develop effective implementation strategies for a large-scale investment in improved quality, expanded capacity, and managed growth. A major challenge will also be to access the required financial resources.

The following considerations and proposals have been put forward to manage the expansion to the 9-year basic education program:

Table 4 Educational finance

<i>Input indicator</i>	<i>2004</i>	<i>2005</i>	<i>2006 baseline</i>
Education spending as % of GDP ^a	5.0%	5.2%	5.2%
Education spending as % GoR budget ^b	14.6%	13.9%	16.5
Government spending on education as % of total public expenditure ^c	23%	24%	25%
Recurrent expenditure on primary education as % of total recurrent expenditure on education	41%	43%	45%
Recurrent expenditure on Tronc Commun education as % of total recurrent expenditure on education			14%
Recurrent expenditure on upper secondary education as % of total recurrent expenditure on education			6%
Recurrent expenditure on secondary education as % of total recurrent expenditure on education	23%	20%	18%
Recurrent expenditure on higher education as % of total recurrent expenditure on education	30%	29%	29%
Recurrent expenditure per primary pupil (RWF) ^d	9472	10 712	13 653
Recurrent expenditure per Tronc Commun pupil (RWF)	73 884	73 467	70 207
Recurrent expenditure per upper secondary pupil (RWF)	63 150	75 584	86 435
Average expenditure per higher education student	795 418	828 040	958 047
Ratio of higher education to primary education unit cost	86	77	70
STR (IRST) expenditure as % of GDP	0.07%	0.07%	0.08%

^aGDP figures are projections on 5% growth. The base 2004 figure is taken from MASABO (2005) report, MINECOFIN.

^bEducation spending is Government spending on primary, secondary, higher, informal, science, research, technology, and institutions support. This includes the recurrent and development budget of MINEDUC and the provinces.

^cThis recurrent education spending as proportion of the Government budget minus interests payments, debt repayments, arrears, and capital expenditure.

^dThe figures on recurrent expenditure per primary, tronc commun (lower secondary) and upper secondary pupil do not include expenditure on science and technology.

RWF, Rwanda Francs; STR, Science Technology and Research; IRST, Institut de Recherche Scientifique et Technologique.

1. Teacher supply and teacher training: The major strategy is to establish four national colleges of education (each eventually enrolling up to 500 trainees) to train the extra Tronc Commun teachers that will be needed. A new teacher training curriculum will have to be developed in line with the training approach chosen and the needs of new teachers at primary and Tronc Commun level.
2. Curriculum, learning materials, and assessment: These will have to be comprehensively revised within a conceptual framework that provides continuity of learning from grades 1 to 9. Priority will be on the development of a new national core curriculum. This will require decisions concerning which core subjects should be prioritized at primary and secondary levels and what the desired learning outcomes should be. A national assessment strategy linked to curriculum outcomes will have to be developed.
3. School infrastructure development: The increased numbers of pupils will demand extra classrooms and schools. The proposed program will assess the level of underutilization in schools and how much growth can be absorbed through better use of existing structures. However, additional classrooms will need to be built which implies a substantial building program and capital investment.
4. School management and efficiency: Expanded access requires reduction in costs per student if the resource envelop is not to be exceeded. The 9-year basic plan promotes reductions in subsidized boarding and aims to have no more than 10% subsidized boarding at Tronc Commun by 2015 and 20% at upper secondary. Increased efficiency will also be achieved through improved teacher deployment, reduced nonteaching administrative staff, and active and purposeful school improvement plans (SIPs). Management training for education personnel will therefore be required. Effective school monitoring and evaluation systems to track progress and identify potential problem areas will also need to be in place.

The GoR is committed to implementing the 9-year basic education program. Institutional and human resource capacity to implement the program will be critical to its successful implementation and to ensure that expanded access does not detract from the quality of the education in the classroom.

Science and technology in education

This is another key policy with emerging priority along with 9-year basic education for all. The science and technology policy within education is now integrated into the financial framework. Promoting science and technological education is an essential strategy to achieve the human development objectives set out in Vision 2020 and the

economic development and poverty reduction strategy (EDPRS). A national science, technology, scientific research, and innovation policy was approved in July 2005. It forms the basis for an operational integration of the science and technology education program. The policy identifies underdeveloped skills in all areas of science and technology and the lack of resources in teaching institutions to support the teaching of quality science and technology education. The policy proposes an enabling legal and policy framework and its strategy envisages strong partnership with the private sector and the ICT sector. The key objectives of capacity building in science and technology are to achieve sufficient number of students, who are trained to a high level so that graduates from vocational schools, technical schools, and higher technical, professional, and technological institutions meet the development needs of Rwanda. MINE-DUC and the national council for science, technology, and innovation will have coordinating roles and will work with the national council for higher education (NCHE). The development of an ICT curriculum for primary and secondary schools is in progress.

Post-basic education and training

An evolving coherent framework for post-basic education and training (PBET) is under consideration, which includes the re-conceptualization of the present structure of the education system as basic education will soon be P1–P6 + TC1–TC3. This will have consequent implications for the rationalization of the upper secondary curriculum and examinations and for the school building programs.

A major area of focus will be on the coverage or inclusiveness of PBET with regard to professional and technical and vocational training, as well as between formal and nonformal technical education. A coherent framework, backed up by adequate data, is to be developed for management and planning purposes to ensure that incoming policies, projects, and programs will be aligned with a coherent approach to the subsector as a whole. The PBET policy/strategy development will contribute to Rwanda's technical and education policy and strategy and to its national skills development.

Open, distance, and e-learning

There is a draft policy for open, distance, and e-learning (Ode-L) which promotes the expanded use of distance learning in all subsectors (primary, secondary, and tertiary). At present, the main distance education program, which has been developed in country, is for under-qualified secondary teachers (at Kigali Institute of Education (KIE)). The Kigali Institute of Science and Technology (KIST) and the National University of Rwanda (NUR) also have a number of programs offered through the African Virtual University (AVU).

The main challenges to be faced in the deployment of distance and e-learning in Rwanda will be that of developing a vision of the way in which blended learning solutions can be used to develop educational provision in Rwanda, and of developing realistic media and technology choices and access to technology. Building up capacity in distance and e-learning methods will thus be important. It will also be necessary to guarantee the quality and consistency of standards, and any open and distance learning strategy will have to design appropriate qualifications and credit structures that will embrace both face-to-face and distance learning.

The challenges and risks are many including the need for a strong change in the management process in existing institutions to re-gear to a distance learning approach – for example, logistical management (i.e., development, production and delivery schedules, and operations). The need for an effective quality assurance system to ensure the development of appropriate, high-quality materials produced in-country and for strong student support systems (tuition, help desks, etc.) will be important. A major program design consideration will be how to ensure that students acquire the necessary practical experience which is required for some courses.

Girls education

An education policy for girls is to be developed; a draft consultancy report is to be discussed at the JSR 2006. Recommendations have been made to establish a national task force for the coordination of girls education in Rwanda and to include girls education into the MTEF. A communication strategy for girls education is also being proposed so that the various partners (students, teachers, administrators, parents, the private sector and partners, and donors) can address particular issues and harmonize their efforts. MINEDUC further intends to coordinate a girls education movement to sensitize students at all levels in the formal and nonformal system, as well as those not in school.

Key areas of proposed intervention will be to ensure that girls have access to adequate sanitation in schools and that girls should be protected so that they can study in an environment free from abuse. There are also plans to scale up the number of Tuseme clubs in secondary schools so as to empower girls by helping them analyze issues affecting their education and come up with relevant solutions.

The quality of girls education is also a major area of focus in terms of improving the retention rate of girls in post primary and tertiary education, and especially for girls from poor households. Increased consideration of gender issues in education through training programs for all teachers is required if increased number of girls are to enter into maths, science, and technology subject areas.

Cross-cutting issues

HIV/AIDS, and hard-to-reach children are interlinked cross-cutting issues and they correlate strongly to poverty alleviation. They are major determinants of strategic choices – not only for education but for all social services.

The Government of Rwanda has been a strong advocate in ensuring that hard-to-reach children access education through flexible pilot complementary or catch-up programs. A major strategy has been to elaborate what should constitute a minimum learning package to achieve gender best practices, and the integration of life skills and HIV/AIDS education.

Special education needs

There is no policy for special education needs (SEN) but a study has been completed and will help produce a policy and long-term strategy, which will require incorporation into the annual operation plans of all subsectors given that some 10% of all students suffer from some form of disability. Most of the current SEN activities are run by NGOs and churches as there are only five educational centers for children with hearing, visual, physical, and mental disabilities and only one is at secondary school level. Inevitably, SEN activities are restricted to a small number of students with disabilities.

Peace and reconciliation

Education at all levels (primary, secondary, and tertiary) is an important means of addressing issues of peace and reconciliation in the context of Rwanda post-1994. National and individual values emphasizing peace, harmony, and reconciliation will infuse the revision of the history and civic education primary curricula for which the national curriculum development center (NCDC) is seeking resources. The guidance and counseling curriculum is also to be undertaken and will explore innovative ways of counseling for trauma healing of children at primary and secondary levels and to ensure resources in schools.

Private sector involvement

Under MINEDUC's sector-wide approach to planning in the new ESSP, it is recognized that the nongovernment sector must play a crucial role if the dual education aims are to be achieved. That is, all children will have access to 9 years of basic education. Management of the nongovernment sector's expansion and the quality of its provision in a fiscally sustainable manner is a critically important policy issue especially when the proposed route is one whereby the GoR intends to mix government finance with private delivery and private

ownership of a considerable proportion of the post-primary education service.

The Teaching Profession

There are 11 primary school TTCs. Initial and in-service training of secondary teachers is concentrated in two centers: one is at the National University of Rwanda (NUR), the other is KIE. NUR's annual output is approximately 60 teachers. KIE produces at least 300 new teachers for the Tronc Commun (general lower secondary) since the end of 2003. In 2001, a distance-training program (DTP) started at KIE to upgrade underqualified secondary teachers. This new program has ten satellite distance training centers around the country. The first 500 unqualified secondary teachers following the distance-training program graduated in 2006. The objective is, in the long term, to have every teacher qualified. According to administrative data for 2001/2, only 52% of the 6368 teachers in the secondary system were qualified. Of these teachers, approximately 1200 are women of whom only about 25% are qualified. Teacher/pupil ratios at secondary level are approximately 1:24.

The objective of the teacher development and management (TD&M) policy, linked to 9-year basic education, is to strengthen accountability for improving teacher quality in all basic education schools in Rwanda. It forms part of MINEDUC's contribution to Vision 2020 and to reducing poverty. It endorses measures to improve teachers' working conditions and status and affirms that teachers at all levels will be trained in sufficient numbers. The TD&M policy aims to promote a range of training approaches and it supports learner-centeredness. An important component will be to provide incentives to teachers veering them toward continuous professional development.

The policy on teacher development envisages teachers progressing through three professional stages – newly qualified, probation of 3 years, and post-probation with emphasis on continuous development. Core teaching values and competence profiles will be structured according to areas of competencies and will lead to the establishment of a coherent teacher education curriculum and the introduction of a range of new qualifications framework. School-based training, at primary and secondary levels, supported by TTCs and colleges of education (CoE) links, and on-the-job mentoring will become increasingly important. Teacher motivation at all levels is an important consideration.

The problem of teacher demand and supply as key policies like the 9-year basic education are implemented is given special attention. Two strategies are planned:

- First is to upgrade some TTCs to diploma-offering (A1) CoE to supplement KIE in training teachers for Tronc Commun.

- Second is all institutions to embark on internal efficiency mechanisms to ensure optimal production of teachers.

Two important strategies are emerging in teacher management and motivation. These are establishment of a task force to lead the process of establishment of the teachers' service commission. The second one is the establishment of the teachers' cooperative.

Monitoring Education Sector Performances

The process of accountability, to which the GoR is committed, dictates that there should be a joint review of the education sector (JRES) on a regular basis (annually for the foreseeable future). The JRES will review the education sector performance which is led by MINEDUC. It is conducted in concert with all internal and external development partners. In terms of the monitoring of education performance, the purpose of the JRES is to ensure that there are effective returns on the investments being made in the education sector and that the intended beneficiaries, that is, students, children, parents, and all other stakeholders, are all indeed benefited.

The first JRES in April–May 2003 signified the start of the review process. The performance of the sector is evaluated against commissioned reports, inspection reports, sector indicators, target completion, and visits to educational establishments. Working in tandem with their development partners, the performance review will inform future policy, future work programs, and the ongoing development of the ESSP itself (Table 5).

The JRES will be arranged to complement the annual progress report and the budgetary cycle so that informed decisions can be taken. Likewise, the review will take place prior to the revision of the annual operation work plans (AOWPs.) The review will cover whole sector performance and will, of necessity, cover all aspects of annual educational development, including projects and sub-programs.

The ESSP will serve to guide the formulation of the AOWPs and to provide a framework for the monitoring and assessment of achievements. Its purpose is to elaborate GoR's vision through policy objectives. These objectives are realized through outlined key activities within broad budget indications. The process is shown in Figure 1. The strategies and key activities must therefore be realistic and the indicators, standardized monitoring and assessment of relief and transition (SMART) if they are to be useful. Evidence of success includes qualitative indicators that require the application of professional judgment to assess the extent to which they have been achieved. The combination of measurable and qualitative indicators will make monitoring and evaluating progress a relatively straightforward task.

Table 5 Some performance indicators for Rwanda

<i>Input indicators</i>	<i>2004</i>	<i>2005</i>	<i>2006 baseline</i>	<i>2007</i>	<i>2008</i>	<i>2009</i>	<i>2010</i>

^aGDP figures are projections on 5% growth. The base 2004 figure is taken from MASABO (2005) report, MINECOFIN.

^bEducation spending is Government spending on primary, secondary, higher, informal, science, research, technology, and institutions support. This includes the recurrent and development budget of MINEDUC and the provinces.

^cThis recurrent education spending as proportion of the Government budget minus interests payments, debt repayments, arrears, and capital expenditure.

^dThe figures on recurrent expenditure per primary, tronc commun (lower secondary) and upper secondary pupil do not include expenditure on science and technology.

^eThe target is that Pupil-Teacher Ratio is to fall, however, it has been rising since 2001. Head teachers are not included in Pupil-Teacher ratio (PTR).

^fClass size is smaller than PTR and Pupil Classroom Ratio because of double shifting.

^gGross enrolment rate (GER), Net enrolment rate (NER) and completion rate vary slightly from previously published statistics because of updated base population projections.

^hincludes transition to private tronc communs schools. Although this is projected to fall, tronc commun enrolment is still rising significantly.

Glossary

CLD – (Community Learning and Development). Diverse sector of postschool learning including community-based nonformal learning opportunities.

Curriculum for Excellence – Reform of 3–18 curriculum.

HEI – Higher education institution.

HMle – Her Majesty's Inspectorate of Education.

HNC/D (Higher National Certificate/Diploma) – Short-cycle higher education qualifications.

National Course – Subject-specific courses available at several levels leading to National Qualifications awarded by the SQA, delivered mainly in schools.

P1–P7 – Six stages (years) of primary school.

S1–S6 – Six stages (years) of secondary school.

SCQF – Scottish Credit and Qualifications Framework.

SQA – Scottish Qualifications Authority.

Standard grade – Subject-specific qualification awarded at end of compulsory schooling, to be phased out from 2014.

General Background

Scotland is a country, of five million inhabitants, which occupies the northern third of Great Britain. It is less densely populated than the rest of Britain but a large proportion of its population lives in the central belt which includes the two largest cities of Glasgow and Edinburgh.

Scotland was an independent country before 1707, when it joined with England and Wales to form Great Britain, under a single parliament. In 1801, it became part of the United Kingdom (UK) of Great Britain and Ireland (now Northern Ireland). The Scottish education system was already comparatively developed in 1707 and it preserved its distinct identity within the Union. Its historical links with the establishment of a national protestant church have stamped it with features which persist to this day, including institutional uniformity, centralized state control, inclusiveness, and an academic ethos.

In 1872, the Scotch Education Department was created to administer Scottish schools, and in 1885 this was

incorporated into the Scottish Office, a territorial department of the UK government responsible for certain domestic policy areas as they related to Scotland. The Scottish Office took responsibility for the vocational higher education institutions (central institutions) and further-education colleges which were established in the following decades. In the 1980s and 1990s it took over further policy responsibilities including universities and training. By 1999, education and training policy in Scotland was almost wholly the responsibility of the Scottish Office which, although part of the UK government, exercised significant autonomy. In 1999, the Scottish Parliament was created with legislative powers over education. The Scottish Office was relabeled the Scottish Executive (and subsequently, in 2007, the Scottish Government), led by Scottish ministers accountable to the parliament. The first two administrations (1999–2007) were formed by coalitions of the Scottish Labour Party and the Scottish Liberal Democrats; after the 2007 election, the Scottish National Party formed a government with a minority of seats in the Parliament.

The main languages are English, Scots (whose status as a separate language is contested), and Gaelic, together with languages spoken by various immigrant communities. Gaelic, once the majority language of Scotland, is now spoken by only 1% of its population. Scotland has traditionally been a country of emigration, with a net outflow of around 40,000 people per year in the mid-1960s, but this pattern has reversed and in the mid-2000s, there was a net inflow of more than 20,000 per year. These include migrants from new member states of the European Union, who have changed the ethnic composition of schools in many areas.

The last decades of the twentieth century saw a huge decline in employment in the coal, shipbuilding, and steel industries. The Scottish economy is now primarily based on services; financial services, tourism, health, and education are important sources of employment. Fishing and oil extraction are important in the regional economy of the north-east. The UK labor market is flexible, with weak regulation and weak occupational markets compared with other European countries. The Scottish unemployment rate stood at 4.9%, slightly below the UK average, in the 3 months to November 2007, but this figure masks significant regional variations, with unemployment black spots in the old industrial areas of the west.

Scotland is a rich, developed country but it includes areas of poverty and social deprivation. An index of multiple deprivation applied to data zones (small areas) in

the 2001 census showed that more than half of the zones in Glasgow belonged to the 15% most deprived zones nationally. Inverclyde, Dundee, West Dunbartonshire, and North Lanarkshire also had disproportionately high numbers of deprived zones.

Goals of the Education System

The general goals of education are not defined in legislation. The Standards in Scotland's Schools, etc. Act (2000) lays down the duty of (local) education authorities to provide education "directed to the development of the personality, talents, and mental and physical ability of the child or young person," but it does not address broader questions of national purpose. The Act empowered governments to define national priorities in education – in 2001, the government identified broad priorities under five headings: achievement and attainment, framework for learning (the skills of teachers, self-discipline of learners, and school environments), inclusion and equality, values and citizenship, and learning for life. Commentators typically describe the Scottish educational tradition as inclusive, meritocratic, academic, collectivist, and conservative; education tends to be more highly valued than elsewhere in the UK. However, the inquiry into the purposes of Scottish education by the Scottish Parliament's education committee noted that questions of philosophy and purpose had been ignored in debate about Scottish educational policy for several decades. It found widespread support for a broad view of educational purposes including the promotion of positive values and active citizenship. There was wide agreement that a merely utilitarian education is insufficient. In 2004, a government-appointed review group defined the purposes of the 3–18 curriculum as to enable all young people to be successful learners, confident individuals, responsible citizens, and effective contributors to society and at work. These four capacities became the guiding purposes of a large curriculum-reform program, A Curriculum for Excellence.

These statements refer primarily to school education. Another Scottish Parliament committee report, on lifelong learning, identified objectives under four headings: economic development, social justice, citizenship, and quality.

Structure and Operation of the Education System

Preschool Education

Since 2002, free, part-time preschool education has been available to all 3- and 4-year-olds whose parents wish it. In 2007, some 95% of 3-year-olds and 99% of 4-year-olds were registered with local authorities for preschool education,

but these figures double-count those who attended two centers. They attend a variety of centers including nursery classes in primary schools, stand-alone public nurseries, and voluntary and private providers, many of which receive public support. Centers aim to provide a variety of experiences affording opportunities for active learning, including purposeful play.

Primary and Secondary School

Schooling is compulsory from ages 5 to 16. Children usually enter primary school at (or soon after) the beginning of the school session in August, and they move up through 7 years of primary school (P1–P7) and up to 6 years of secondary (S1–S6). They remain with the same year group; grade repeating is rare. In 2006, there were 733,000 pupils in Scottish schools; pupil numbers were declining and were projected to fall by a further 12% by 2016.

About 4% of pupils attend private schools. This percentage is higher among secondary than primary pupils, and highest in Edinburgh where more than 20% of secondary pupils attend private schools. The remainder attend public schools run by the 32 elected local authorities. In 2006, there were 2184 primary schools, 381 secondary schools, and 190 special schools within the public sector. Schools serve defined catchment areas. Children are entitled to a place in their local school, but parents may choose another school if places are available. In 2005–2006 some 30,000 placement requests were received, of which 84% were granted. Most requests were for pupils entering primary school (22% of the P1 cohort) or transferring to secondary (14% of the S1 cohort).

Scottish schools are institutionally uniform. All publicly funded schools are comprehensive, coeducational (with one exception), community based, and nonselective. Slightly more than a fifth of pupils attend denominational schools, nearly all Roman Catholic, which have been fully integrated within the public system since 1918. Scottish secondary schools are less socially segregated than most other European systems and school effects vary little from school to school.

There is no statutory curriculum and local authorities have formal responsibility for the school curriculum. However, they all support national guidelines for the 5–14 curriculum, which define outcomes and recommend approximate time allocations across five broad areas: language, mathematics, environmental studies (science, technology, geography, history, and modern studies), expressive arts, and religious and moral education. The guidelines specify six levels of performance (A–F). Each level is expected to be achieved by a majority of pupils by a given school year, but teaching methods allow pupils to work through the levels at different rates. From 2010 the 5–14 framework is being replaced by A Curriculum for

Excellence, which specifies less-detailed outcomes and experiences in eight curriculum areas at five levels from 3 to 15 years.

The secondary curriculum has traditionally followed a 2 + 2 + 2 pattern, with a common curriculum in S1–S2 followed by courses in S3–S4 leading to subject-based standard-grade qualifications and up to two postcompulsory years in S5–S6. A Curriculum for Excellence proposes to replace this with a 3 + 3 pattern, with a new senior phase starting in S4. Standard grades are to be replaced with new qualifications, but the phasing of courses and qualifications across the 3 years of the senior phase is uncertain and may vary across schools. Opportunities for subject choice increase during the secondary years. The school curriculum is predominantly general but a growing number of vocational options are available from S3 onward. Most pupils are eligible to leave school after S4 or the first term of S5. In 2006, 67% of the year group stayed on beyond the first term of S5 and 44% stayed on to S6. S5 students typically take up to five single-subject national courses, available at different levels with entry determined by achievement in the corresponding standard grade; in S6 they may take further national courses in additional subjects or in the same subjects at a higher level.

Education authorities have the responsibility to identify, and provide for, pupils who require additional support to benefit from their education, for example, due to family circumstances, health, disability, or emotional and behavioral factors. In 2006, 36,148 children in publicly funded schools had additional support needs. Current policies favor meeting their needs within mainstream schools, where appropriate, but about one-fifth were in special schools.

Colleges

The 43 colleges of further education are the largest providers of lifelong learning. Much of their provision is vocational, but they also offer general and academic courses and more specialized opportunities such as literacy and numeracy courses and provision for learners with disabilities. The colleges have a tradition of access and responsiveness. Their programs vary widely in level, duration, and mode of study. There were 351,435 students enrolled on college courses in 2004–2005. A majority were aged over 25, but colleges also recruit young people. Nearly one in four school leavers entered a full-time college course in 2006; others entered apprenticeships or training which included part-time college study. Colleges increasingly provide vocational courses for school pupils aged 14–16, and each school is expected to have a partnership with at least one college. Colleges are also important providers of higher education, primarily

through subdegree courses such as higher national certificate and diploma (HNC/D) courses.

Higher Education

At the end of 2007, there were 20 higher education institutions (HEIs): 15 universities (including the Open University in Scotland), four specialist colleges, and the University of the Highlands and Islands (UHI) Millennium Institute, which offers higher education across north-western Scotland through local colleges and other providers. Universities are informally distinguished on the basis of their age: four ancient universities were founded before 1600, four old universities were created before 1992, and six new universities created since 1992 are former government-controlled central institutions. HEIs in these three categories tend to vary with respect to the age and social origins of students, the balance of full- and part-time study, the numbers of postgraduate students, and the emphasis on research.

Higher education expanded massively in the late twentieth century. The proportion of young Scots entering higher education (including subdegree courses) for the first time surpassed 50% in 2000, although it fell back to 47% in 2005. Participation by older students has also grown. In 2005, 21% of first-degree students were aged 25 or over and 32% were aged between 21 and 24; 60% were female. Of the 285,000 higher education students in Scottish institutions in 2005, 72% were from Scotland and another 10% from the rest of the UK. The remainder came from other countries, led by China, the US, India, and Malaysia. The number of students leaving Scotland to study is not known, but within the UK, the inward flows are much larger.

Other Education and Training

The largest publicly funded work-based learning program is modern apprenticeship (MA). In March 2007, there were 28,626 modern apprentices in training, of whom 73% were male and 65% were aged under 20. Other programs include skill seekers (lower level training for 16–18-year-olds, to be absorbed within the MA program), Get Ready for Work (for 16–18-year-olds with additional needs), Training for Work (for the long-term unemployed aged 25-plus), and New Deal (a UK program for specific groups including long-term unemployed 18–24-year-olds).

The term community learning and development (CLD) refers to informal learning and social development work with individuals and groups within their communities. This diverse sector includes youth work, adult learning in the community (including adult classes, literacy and numeracy classes, parenting education, and family learning), and

building community capacity. It is provided by local authorities and partner agencies in the public and voluntary sectors, and coordinated by local partnerships.

Qualifications

The Scottish Qualifications Authority (SQA) is the main awarding body for nonuniversity qualifications. These include National Qualifications awarded in schools and (nonadvanced) college education, HNCs and HNDs, and occupational Scottish Vocational Qualifications (SVQs) mainly gained in work-based training. The SQA also accredits SVQs awarded by other bodies. All SQA qualifications are unitized (except standard grades) and placed in the Scottish Credit and Qualifications Framework (SCQF), a nonregulatory framework for all qualifications in Scotland. Qualifications within the SCQF, and their component units, are rated in terms of level and credit volume. The SCQF aims to promote access and to encourage transparency and understanding of the system. It underpins articulation and credit transfer between sectors; for example, a relevant HND may allow progression to the third year of a 4-year degree course.

The Teaching Profession

In 2006, there were 51,658 full-time equivalent (FTE) teachers in publicly funded schools, and a further 3300 in private schools. Three-quarters were female. The pupil-teacher ratio was 16.3 in public primary schools and 12.0 in public secondary schools. A further 20,000 FTE staff worked in various support roles, including some 5700 classroom assistants mostly in primary schools. All school teachers must hold a teaching qualification and be registered with the general teaching council for Scotland. Full registration is achieved after completing a university course (either a 4-year education or combined degree, or a 1-year postgraduate course) and a period of probation. A new career structure and conditions of service for school teachers were introduced after 2001 following an agreement between the government and teacher unions, *A Teaching Profession for the 21st Century*.

In 2005–2006 there were 13,157 payroll teaching staff in colleges, of whom 4771 were full time. About one-half were female. Most full-time staff hold the teaching qualification (further education), or an equivalent qualification, taken after entry to the profession; under current proposals, all new permanent full-time and part-time lecturers are expected to gain it within 3 years and 5 years, respectively, of taking up post. In 2006–2007, there were 12,645 full time and 3370 part-time academic staff in HEIs, including those funded from external grants and contracts. There are no general qualification requirements for teaching in HEIs.

Administrative and Supervisory Structures

Legislative powers over education and training were devolved to the new Scottish Parliament in 1999. In 2007, the Scottish Government was organized into five main directorates-general; the directorate-general for education comprises three directorates, responsible respectively for schools, for lifelong learning, and for children, young people, and social care. Certain functions are delegated to nondepartmental public bodies, including the SQA, the Scottish Funding Council (SFC) which funds colleges and HEIs, and Learning and Teaching Scotland which is responsible for school-curriculum development and support.

Publicly funded schools are administered by the 32 local authorities, often through a department which also covers children's or community services. Since the 1980s, significant powers have been devolved to schools, but local authorities retain an important role. School parent councils were introduced in 2007 to represent parents, replacing a more formal system of school boards.

Most colleges are self-governing institutions, led by a board which includes community and industry representatives. Universities are private bodies; like colleges, they have charitable status and are governed by a court or board of governors with substantial lay membership. In the four ancient universities, the court is chaired by a rector elected by students and staff.

From 1990 to 2008, Scottish Enterprise and Highlands and Islands Enterprise, nondepartmental public bodies responsible for economic development in their respective areas of operation, were responsible for MAs and other government-supported training. As of 2008, Scottish Enterprise's training role, along with other skills-related responsibilities, was being transferred to a new body, Skills Development Scotland.

Educational Financing

Public preschool and school education is funded by local authorities out of annual grants from the Scottish Government and local property-based taxes. Headteachers have substantial budgetary autonomy over day-to-day spending. In 2006–2007, gross revenue expenditure was £1683 million (£4403 per pupil) on primary education, £1912 million (£6120 per pupil) on secondary education, and £464 million on special education in special and mainstream schools. About £2.9 billion of expenditure was devolved to headteachers. Total capital expenditure not funded from revenue was £385 million. Further capital spending was supported by arrangements which combine private and public financing.

Most public funding for colleges and HEIs is provided through annual grants from the SFC, following guidance from the government. In 2006–2007 grants to colleges and HEIs totaled £660 million and £1116 million, respectively. A large part of colleges' funding is based on a weighted measure of student numbers. Colleges also receive fees from some students and other customers such as employers. HEIs receive separate allocations for teaching and research. In 2005–2006, 41% of HEIs' income was from SFC grants; a further 21% was from tuition fees and education grants and contracts, 19% from research grants and contracts, and 19% from other sources including accommodation and other services.

School education and full-time, nonadvanced college courses are free. Colleges may provide means-tested bursaries to support students' maintenance costs, travel, and study expenses. In 2006–2007, 38,760 young people received an education-maintenance allowance of up to £30 per week, available to 16–18-year-olds from low-income families in full-time education. Older students on low incomes may receive an individual learning account of up to £200 to support part-time study.

Maintenance grants for UK higher education students were replaced by a system of loans during the 1980s and 1990s. In 1998, tuition fees were introduced for the first time, initially set at £1000 per annum (later increased to £3000 elsewhere in the UK). In the early years of the Scottish Parliament, upfront fees in Scotland were replaced by a one-off contribution of £2000 to a fund to support bursaries, collected through the tax system after graduation. In 2007, the new government introduced legislation to abolish this contribution.

Performance Monitoring, Evaluation, and Research

Her Majesty's Inspectorate of Education (HMIe), a Scottish Government agency, is responsible for evaluating quality and supporting improvement in schools, colleges, initial teacher education, and CLD. It also evaluates children's services and the education function of local authorities. There is a strong emphasis on institutional self-evaluation based on a framework published by HMIe, *How Good is our School?* Quality-improvement officers in each local authority challenge and support schools' improvement activities. Standard performance data are prepared for each school.

Performance in selected school subjects is monitored at a national level by the Scottish Survey of Achievement which samples pupils in selected year groups. Scotland participates as an 'adjudicated region' in the Programme for International Student Assessment (PISA) and in other international surveys. It has consistently performed above the OECD average in PISA with a relatively small proportion of 15-year-olds performing at the lowest levels.

Quality assurance in HEIs is carried out by the Quality Assurance Agency for Higher Education, a UK body with a

separate Scottish office. Since 2003, it has been primarily based on a process of enhancement-led institutional review, which focuses on institutions' self-evaluations and their own policies and practices for quality management. Performance indicators for HEIs, collected on a UK-wide basis, include the age and social background of students, retention, and graduate employment. The SFC collects performance data from colleges including volume of study, age, and social background (based on area) of students; retention and achievement; student satisfaction; and staff qualifications.

Most educational research is carried out by universities and private research organizations. Sources of funding include the Scottish Government and agencies, UK research councils, private foundations, and the European Commission. The Scottish Council for Research in Education, one of the world's first national educational research councils founded in 1928, is now a research center within Glasgow University. Other prominent university centers include the Centre for Educational Sociology (Edinburgh) and the Centre for Research in Lifelong Learning (Glasgow Caledonian and Stirling).

Major Changes and Issues Since the 1990s

The most significant recent change is the establishment of the Scottish Parliament in 1999. Its immediate effect was to place an existing tier of government (the former Scottish Office) under a Scottish legislature, but its longer term effects include further institutional and policy divergence from other parts of the UK and changes in the style of policy-making and administration within Scotland. The first years of the new parliament were an occasion for strategic reappraisal, with a national debate in 2002–2003, major parliamentary enquiries including lifelong learning strategy (2002) and the purposes of education (2003), and a range of strategic government policy reviews including the 3–18 curriculum, lifelong learning, higher education, and the college sector.

In 2006, a government-backed strategic audit identified the education system, along with a strong and well-qualified labor market, as national strengths. It also identified challenges including poor economic growth, poverty, and inequality, young people not in learning or employment, an aging population, a poor health record, and high levels of violent crime. In 2007, the new SNP government made sustainable economic growth its main policy goal and identified five strategic priorities, one of which (for a smarter Scotland) was to expand opportunities for Scots to succeed from nurture through to lifelong learning ensuring higher and more widely shared achievements. Its skills strategy, *Skills for Scotland*, emphasized the importance of skills for economic development.

In 2007, an OECD review of Scottish schooling concluded that Scotland is a well-schooled nation by international standards but identified current challenges

including an achievement gap between children from different socioeconomic backgrounds and low participation and attainment in postcompulsory education. While social inequalities are similar to those in many other OECD countries, the proportion of 16–19-year-olds not in education, employment, or training (12.4% in 2006) is comparatively high. A 2006 report, *More Choices More Chances*, outlined a strategy for reducing this figure, with particular emphasis on improving pupil engagement during compulsory schooling.

The OECD review attributed social inequalities to the uniformly academic ethos and culture of Scottish schools which, it argued, failed to engage learners from disadvantaged backgrounds. It endorsed the inclusive vision of *A Curriculum for Excellence*, the 3–18 curriculum reform, and its goal of a more diverse, personalized curriculum delivered through a wider range of teaching and learning approaches. *A Curriculum for Excellence* is probably the most significant school reform of the early twenty-first century, and it complements other initiatives, for example, to promote formative assessment or to foster school improvement.

Successive governments have promoted increased vocational and prevocational opportunities for young people, but the respective roles of schools and colleges in providing these opportunities is a subject of debate. Following a 2007 review, the Scottish Government identified four strategic purposes for colleges: to provide vocational education and training related to employment needs; to provide positive and clear routes into employment or into HEIs; to develop knowledge and skills to support the confidence of learners; and to encourage employers' demand and utilization of skills.

Current issues for higher education include meeting the country's economic development needs, widening access, and addressing the resource implications of the recent expansion. The policy divergence within the UK – with tuition fees removed in Scotland but increased in England – is seen to threaten the capacity of Scottish HEIs to compete within the UK and internationally.

Finally, a significant recent change is the incremental development of unified arrangements for coordinating a diverse learning system. The best expression of this is the SCQF, which builds on a series of qualification reforms since the 1980s. The SCQF has helped to showcase Scottish education internationally; it has influenced qualifications reform in other countries and it has informed the development of the European Qualifications Framework.

General Background

Singapore is a small island country at the southern tip of the Malay Peninsula. With an area of 660 Km² and a current total population of about 4.5 million, of which 3.6 million people are residents (citizens and permanent residents), she is one of the most densely populated countries in the world.

The modern history of Singapore began in 1819 when Englishman Sir Thomas Stamford Raffles established a port on the island and put the island under British colonial rule. Gaining importance through the India–China trade and the entrepot trade in Southeast Asia, Singapore rapidly became a major port city and a trade center. This growth came to a halt during World War II when Singapore was conquered and occupied by the Japanese from 1942 to 1945. After the surrender of the Japanese, Singapore reverted to British control, but with an increased level of self-governance.

From 1955 to 1963, Singapore gained internal self-governance from the British, though the latter still held on to defense and foreign affairs. In 1963, Singapore broke completely away from the British by formally merging with Malaya, Sarawak, and Sabah to form the Federation of Malaysia. However, the merger was far from smooth. There was much social unrest, ethnic tension, and many political disputes between Singapore and Malaysia. This resulted in the separation of Singapore from Malaysia on 9 August 1965. On that day, Singapore became a sovereign independent nation.

Facing severe challenges such as unemployment, housing crisis, and social tensions, Singapore embarked on a modernization program that focused on industrialization, developing public housing, and investing heavily in public education. The efforts paid off and Singapore's economy grew rapidly. Singapore's industrial structure developed from a basic production industry during the 1960s to knowledge-based industries and high-value services in 2000 and beyond. There has also been a strong push for reforms aimed at equipping workers with the competencies seen to be essential to improving productivity and competitiveness in the global knowledge society. By the 1990s, the country has become one of the world's most prosperous nations, with a highly developed free-market economy, strong international trading links, and one of the highest per capita gross domestic products (GDPs) in the world. In 2006, total GDP stood at S\$210 billion, per capital indigenous gross national income (GNI) at

S\$45 billion, and total foreign reserves at S\$209 billion. In the same year, the labor force was 2.6 million people, with 1.9 million residents (73%). The unemployment rate was a low 2.7%.

The residents in Singapore comprised 75% Chinese, 14% Malays, 9% Indians, and 2% of others in 2006. The early residents (prior to 1965) were mostly immigrants. Due to the diversity of ethnic languages and cultures, and the historical roots of Singapore as a British colony, English became the main language in many official and business activities, including education.

Goals of the Education System

The Singapore education system has always been an important vehicle for social and economic development. Since independence, while education policies have changed to reflect the emphasis of the times, two basic goals have not changed: education develops the individual and educates the citizen.

In terms of developing the individual, education in Singapore aims to develop the child intellectually, physically, morally, socially, and esthetically. There are compulsory components in the school curriculum to address each of these facets. In terms of educating the citizen, education in Singapore aims to teach the child to identify Singapore as home – the place to live in, improve, and defend. A good citizen fulfills his obligations and responsibilities to the nation.

One critical education policy to support the achievement of these two goals is bilingualism. The government adopted English and three local languages (Chinese, Malay, and Tamil) as official languages in 1956 and started compulsory bilingual education at primary level in 1966 and at secondary level in 1969. The bilingual policy requires students to learn two languages: English and a mother tongue, which may be Chinese, Malay, or Tamil. English is the working language in Singapore and the medium of instruction in schools. The policy is based on the premise that English is the language of international business, science, and technology, and a good command of the language will facilitate global business. Moreover, it is a vehicle of communication among the different races in the country and helps to maintain social harmony. But it is also important for students to learn their mother tongue to give them access to their cultural heritage and help them retain their cultural identity and roots.

In 1998, the Ministry of Education (MOE) developed The Desired Outcomes of Education, a statement which summarized the characteristics that the education system was supposed to develop in a student at different levels of their education (primary, secondary, postsecondary, and tertiary, and potential leaders). Briefly, the students who have gone through the education system have to be creative, entrepreneurial, and have a lifelong habit of learning, be able to think global and yet remain rooted to Singapore. They have to be morally upright, culturally rooted, and yet understand and respect differences. They have to be responsible to the family, community, and country. They have to believe in the principles of multiculturalism and meritocracy, appreciate the national constraints, and yet be able to see the opportunities.

Structure and Operation of the Education System

In 2006, there were 1200 preschools, 354 schools (primary, secondary, and preuniversity), five polytechnics, three colleges of the Institute of Technical Education (ITE) and three local government-funded universities. Out of the 354 schools, there were 172 primary schools, 155 secondary schools, 13 mixed-level schools, and 14 preuniversities. The total enrolment in the education institutions (primary, secondary, postsecondary, and tertiary levels) was 689 000 in 2006. The main educational pathways available to a Singapore student are shown in Figure 1.

Preschool Education

Many Singaporean children (age 3–6) attend a kindergarten or a child-care center prior to formal education in the

primary school. At this stage, the focus is generally on structured play and social development.

Kindergartens in Singapore are private schools run by organizations such as community foundations, religious bodies, social enterprises, and business companies. However, kindergartens have to be registered with the MOE. Child-care centers also offer similar preschool programs to children of the same age group but they are licensed by the Ministry of Community Development, Youth and Sports (MCYS).

In 2006, there were about 1200 kindergartens and childcare centers offering preschool education. Of these, 40% were kindergartens and 60% were child-care centers. An estimated 95% of children in Singapore received preschool education.

Primary Education

In Singapore, the Compulsory Education Act, implemented in 2003, ensures that children (except certain categories of children, e.g., those with special needs) receive a minimum period of education up to Primary 6. According to the act, a child of compulsory school age is one who is above the age of 6 years and who has not yet attained the age of 15 years. Parents have the responsibility for sending children to school and ensuring that they attend school.

In 2006, there were 172 primary schools (47% of all schools in Singapore from primary to preuniversity level) and a total of 285 000 primary students (54% of all students from primary to preuniversity level). Primary education consists of a 4-year foundation stage (Primary 1–4) and a 2-year orientation stage (Primary 5–6). At this stage, education aims to give students a good grasp of the English language, mother tongue, and mathematics. Students are also taught science, art and craft, music, health education,

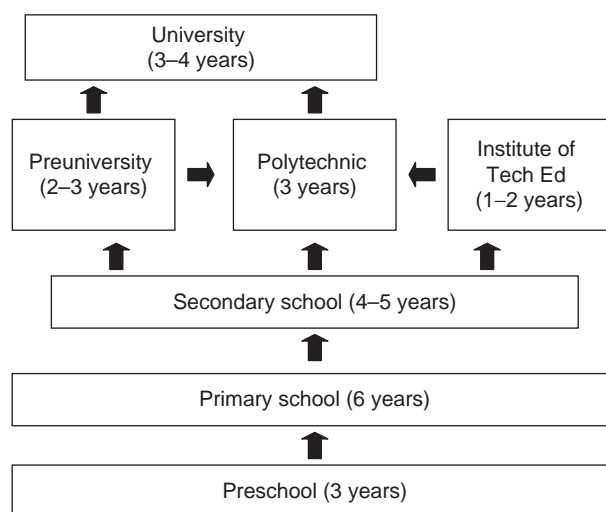

Figure 1 The main education pathways available to a student in Singapore.

physical education, social studies, and civics and moral education. They are also involved in co-curricula activities (CCAs) and Community Involvement Programme (CIP). The student to teacher ratio was 23.5 in 2005, an improvement compared to 25.1 in 2001.

At the end of Primary 6, students sit for the Primary School Leaving Examination (PSLE), except for those admitted to secondary schools under the direct school admission (DSA) scheme. Under the DSA scheme, some secondary schools in Singapore are allowed to admit a certain percentage of their students based on their own selection criteria. This percentage ranges from 5% to 50%, depending on school type and program. After the release of the PSLE results, students make six choices of secondary schools in rank order and the MOE posts them to schools based on merit (PSLE results) and choice.

Secondary Education

During the Secondary-1 posting exercise, the MOE places students in the special, express, normal (academic), or normal (technical) course according to their PSLE results. Each course has a different curricular emphasis designed to match the students' learning abilities. Special and express courses are 4-year programs leading to the General Certificate of Education (GCE) O-level examination. Special course students offer mother tongue at a higher level. Normal (academic) and normal (technical) courses are 4-year programs leading to the GCE N-level examination, in which a fifth year leading to the GCE O-level examination is available to normal (academic) students who perform well in their GCE N levels. Students are allowed to move from one course to another based on their performance and the assessment of their principal and teachers. Other than academic subjects, the students are also involved in CCA and CIP. The student to teacher ratio was 18.5 in 2005, an improvement compared to 19.6 in 2001.

In 2006, there were 168 secondary schools (include mixed-level schools offering secondary education; 47% of all schools in Singapore from primary to preuniversity level) and a total of 213 000 secondary students (41% of all students from primary to preuniversity level).

At the end of their secondary education, students may progress further in their education along a few pathways. For students who are academically inclined and have the necessary GCE O-level qualifications, they may choose to go to a preuniversity leading to the GCE A-level examination (2–3-year program). For students who wish to pursue a more practice-oriented curriculum and have the necessary GCE O-level qualifications, they may choose to go to a polytechnic (3-year program). Polytechnic graduates with good results may pursue tertiary education at the universities. For students with GCE O or N-level certificates and who wish to pursue a more vocationally oriented training, they may choose to go to a college of the ITE, which offers

1–2-year vocational courses. ITE students with good results may proceed to the polytechnics for diploma programs and subsequently progress to the universities, again upon good results.

Preuniversity

Preuniversity education prepares students for the GCE A-level examination at the end of the 2-year junior college or 3-year centralized institute course. The A-level curriculum equips students with life skills, knowledge skills, and knowledge in content-based subject disciplines, and is a preparation for university education. In 2006, there were 14 preuniversity institutions and a total of 31 000 preuniversity students (25% of all students receiving postsecondary education in preuniversity, ITE, and polytechnics).

Institute of Technical Education

Established in 1992, the ITE (formally the Vocational and Industrial Training Board), has established itself as a postsecondary technical institution of excellence. The primary role of the ITE is to ensure that its graduates have the technical knowledge and skills that are relevant to industry. It is also the national authority for standard setting and certification of skills. In 2006, there were three ITE colleges and a total of 24 000 ITE students (19% of all students receiving postsecondary education in preuniversity, ITE, and polytechnics).

Polytechnic

The mission of the polytechnics is to develop middle-level professionals to support the technological and economic development of Singapore. Polytechnic graduates are much sought after by industry because they are perceived as practice-oriented and knowledgeable professionals. The polytechnics are also a significant provider of continuing education and post-employment professional-development programs. In 2006, there were five polytechnics and a total of 68 000 polytechnic students (55% of all students receiving postsecondary education in preuniversity, ITE, and polytechnics).

University

In Singapore, the government aims to provide a diversity of university education for local and international students through local government-funded autonomous universities and private universities, including world-class universities (WCUs).

There are currently three local government-funded autonomous universities, namely the National University of Singapore (NUS), established formally in 1980; the

Nanyang Technological University (NTU), formally granted university status in 1991; and the Singapore Management University (SMU), established in 2000. Each university has its different strengths and emphases.

Private universities can be foreign or local in origin. They operate according to market forces and are at liberty to establish their own international to local student ratio and school fees. One such local private university is the Singapore Institute of Management (SIM) University (UniSIM) established in 2005 with an aim to provide university education and satisfy skills-upgrading needs of the working professional and adult learners. Other private universities include WCUs, which refer to top universities in the world that set up centers of excellence in Singapore to spearhead world-class research and development, transfer knowledge to the industry, and position Singapore as a premier educational hub. Examples of such WCUs that have set up centers in Singapore include *Institut Européen d'Administration des Affaires* (INSEAD), University of Chicago Graduate School of Business, University of Pennsylvania's Wharton School, Massachusetts Institute of Technology, and Johns Hopkins University.

In 2006, there was a total enrolment of 63 000 full-time and part-time undergraduate and postgraduate students in the three autonomous universities. Fifty-five percent of the enrolment was male. The ratio of full-time to part-time students was 3:1. The biggest portion of students enrolled in engineering sciences (37.3%), followed by business and administration (13.6%). About 25% of the enrolment was in a postgraduate program.

Other Schooling Arrangements

Children with disabilities are educated at special-education schools, which cater to distinct disability groups of children who are unable to benefit from mainstream schooling. In 2006, there were 21 such schools run by voluntary welfare organizations (VWOs) receiving funding from the MOE and the National Council of Social Service (NCSS).

There are also a few specialized independent schools such as the Singapore Sports School, the School of the Arts, Singapore, and the NUS High School of Mathematics and Science and private schools such as LaSalle College of the Arts and the Nanyang Academy of Fine Arts.

Adult Continuing Education

Increasingly, adult workers in Singapore continued with their academic education while they are on the job. In 2006, under the continuing academic education programs, some 25 000 places were taken up and 17 000 workers (67%) completed their program.

The Teaching Profession

In 2006, there were 27 000 teaching staff members in the Singapore education service (approximately 46% primary, 47% secondary, and 7% preuniversity). Generally, the education profession (primary to preuniversity) is highly feminized with a female to male ratio of about 3 to 1 in 2006. It is also a quality profession with a graduate to nongraduate ratio of about 5 to 2 in the same year.

The training of teachers and school leaders is undertaken by the National Institute of Education (NIE), an autonomous institute of the Nanyang Technological University. Teacher training at the NIE is normally 4 years for a bachelor degree cum postgraduate diploma in education, and 1 year for the postgraduate diploma in education for degree holders in other disciplines. The NIE also conducts in-service courses for teachers, leadership courses for school leaders, and courses at the master and doctoral levels. The MOE also provides round-the-year training courses for the teachers through its training and development division.

In 2006, there were approximately 1500 ITE, 3700 polytechnic, and 3900 university teachers. These institutions have their own recruitment and internal-development mechanisms for their staff.

Administrative and Supervisory Structure

The government is the principal provider of education at primary, secondary, and tertiary levels. However, there are two general ways in which the government relates with the education institutions: direct supervisory mode and autonomous mode.

The MOE exercises direct supervision over the primary schools, secondary schools, and preuniversities (except a few independent schools which are autonomous entities). That means that the principals of the schools report directly to the MOE. The local government-funded universities, NIE, polytechnics, ITE colleges, and a few independent schools operate in the autonomous mode.

The three local government-funded universities are autonomous entities, based on the recommendations by the University Autonomy, Governance and Funding (UAGF) Steering Committee in 2005. The universities exercise control over their internal governance, fees structure, admission requirements, staff remuneration, and fund utilization out of a block budget for recurrent expenditure within a broad strategic framework set by the government. The university councils are empowered to ensure that strategic plans are aligned to the university's goals, and oversee the internal quality-assurance systems. The NIE, polytechnics, ITE colleges, and a few independent schools are similarly autonomous institutions.

For nonformal education, the private sector plays the complementary role of conducting supplementary

education classes in areas such as business, computers, foreign languages, fine arts, and extra tuition. All private schools have to be registered with the MOE. But the government does not oversee their governance or operations. They are expected to operate within the general business laws of the land.

Educational Finance

Total government expenditure on education was S\$7.0 billion in 2006 (about 4% of GDP). Ninety-one percent of this expenditure went to recurrent expenses while the rest was spent on development. In terms of recurrent expenditure, the approximate cost in 2006 was:

- \$4270 for a primary school student;
- \$6186 for a secondary school student;
- \$10 001 for a preuniversity student;
- \$10 237 for an institute of education student;
- \$11 578 for a polytechnic student; and
- \$18 281 for a university student.

The breakdown of the recurrent government expenditure by the various types of education institutions as a percentage of the total recurrent expenditure in 2006 was as follows:

- primary 20%;
- secondary and preuniversity 28%;
- ITE 4%;
- polytechnic 11%;
- university 26%; and
- others 11%.

The Singapore government is proactive in its approach to education funding. For example, in 1993, the Edusave Endowment Fund was established to give every child between 6 and 16 years old, through the school, a grant to meet specified educational expenses. The money could be used for additional classes in schools, extra courses such as music and information and technology (IT) education, educational tours, and textbooks. The government contributed an initial capital sum of S\$1 billion to the fund, which reached the target of S\$5 billion in August 1997. In 1996, the Edusave scheme was widened to provide needy students with merit bursaries. The Edusave scheme helped to provide every child with resources for education because it was given to every child regardless of academic ability and every school regardless of academic standing.

Quality Assurance and Research

For the school sector (primary, secondary, and preuniversity), the main quality-assurance mechanism is the school

excellence model (SEM), implemented in 2000. Adapted from the various quality models used by business organizations, the SEM, which is a self-appraisal model, stresses the importance of self-assessment and school initiatives as a primary mechanism to drive school improvement. An external team from the MOE validates the self-appraisal results using the same criteria approximately once in 5 years. Linked to the SEM is the master plan of awards for schools, which recognizes schools for their achievement in the various SEM categories.

For the university sector, quality assurance is achieved through an accountability framework, comprising the quality-assurance framework for universities (QAFU) and the policy and performance agreements between the MOE and each university. The other autonomous institutions (such as polytechnics and ITE colleges) have their own quality-assurance frameworks agreed with the government.

Most educational research is undertaken by the MOE and the NIE. In particular, the Centre for Research in Pedagogy and Practice (CRPP), established in 2002 as part of the NIE, is the largest educational research center in the Asia Pacific. The center, which brings together researchers, educators, and administrators to research and develops innovative ways of teaching and learning, as well as informs policymaking, is funded by the MOE.

Performance of the education system is also measured by international performance indicators. Internationally, Singapore measures well in terms of achievement and resource input. For example, Singapore consistently ranks among the highest-performing countries in the Trends in International Mathematics and Science Study (TIMSS). Singapore was first in mathematics and science for grade 4 (Primary 4) and grade 8 (Secondary 2) in TIMSS 2003. In TIMSS 1999, Singapore was ranked first in mathematics and second in science at grade 8 (Secondary 2). In TIMSS 1995, Singapore ranked first at grades 7 and 8 (Secondary 1 and 2) in both mathematics and science. At grades 3 and 4 (Primary 3 and 4), she ranked second and first respectively for mathematics, and ranked seventh in science. In terms of resource input, according to the index of high availability of school resources for mathematics/science instruction by TIMSS, Singapore's 88% and 92% for grade-8 mathematics and science instruction compare very favorably with the international average of 26% and 26%, respectively.

Major Changes and Issues since the 1990s

From independence to the 1980s, Singapore has developed a robust education system through centrally driven policies. But such a centralized approach has also achieved a level of conformity to standards and reliance on external appraisal that in the 1990s, there was a need to

improve the innovation capacity of the schools to provide more quality educational pathways. The success formula that was good for the 1980s was obsolete in the twenty-first-century globalized knowledge economy.

A key milestone in this effort was the launch of the Thinking Schools, Learning Nation (TSLN) vision in 1997, after a strategic review of education, motivated by a preoccupation with the future. It guided subsequent initiatives in the education system until today. Thinking Schools is a vision of a school system that can develop creative thinking skills, lifelong learning passion, and nationalistic commitment in the young. Learning Nation is a vision of learning as a national culture, where creativity and innovation flourish at every level of society. TSLN prepares the nation to face a globalized knowledge economy by responding to the twin challenges of equipping its people for innovation and rooting its people in the country while encouraging them to go global.

Several major educational initiatives followed in the footsteps of TSLN. In particular, the education system adopted an ability-driven education paradigm (ADE) to replace the old efficiency paradigm in an attempt to tailor education to the ability and potential of the child. Creativity and entrepreneurship were emphasized. Syllabi, examinations, and university-admission criteria were changed to encourage thinking out of the box and risk taking. The MOE implemented a comprehensive strategy for developing an ICT-based teaching and learning environment in every school. National Education (NE), launched in 1997, was a significant initiative to develop national cohesion, the instinct for survival, and confidence in the future by fostering a sense of identity, pride, and self-respect as Singaporeans. So, while Singaporeans were encouraged to think global in their business, they were also encouraged to stay local in their commitment and loyalty.

Going into the 2000s and beyond, the government looks set to continue the process of emphasizing innovation and loosening the educational structure to encourage diversity. One sure sign of this phase of innovation and diversity was the shifting of the focus of TSLN to Innovation and Enterprise (I&E) in 2004, which aimed to develop an innovative and enterprising spirit in the young. The latest MOE initiative was innovation and diversity in the curricula and pedagogical aspects of education. Launched in 2005, Teach Less Learn More (TLLM) aimed to enhance the quality of teaching and learning through diverse and innovative methods tailored to the students' needs.

One of the current and major challenges for the Singapore education system is to find the breakthrough from quantity to quality. This is a great balancing act. Singapore has a robust, coherent, and systematic education system from primary to tertiary education, a system that is equally criticized and admired by many Western educators and policymakers. But she needs to address the problems of her students' lack of creativity, focus on memorization over application, and a disconnection between school learning and real-life situations. The challenge is to find the right balance so that the baby will not be thrown out with the bath water.

To encourage diversity and innovation, the government has progressively decentralized its power to the education institutions. However, the government still carries a great responsibility for achieving national outcomes and providing high value for public money. The functioning of the education institutions must be aligned to the goals of social and economic development in Singapore. Thus, there is a need to maintain strategic control so as to ensure accountability and standards. This is again a balancing act – giving power and yet maintaining control.

Whether Singapore can maintain its success and transform its education system from quantity to quality remains to be seen. But the Singapore government has proven itself to be a no-nonsense school master and a master of the balancing act. If history can be a guide to telling the future, there is reason for optimism.

Slovenia

T Plevnik and A B Lakota, Ministry of Education and Sport, Ljubljana, Slovenia

© 2010 Elsevier Ltd. All rights reserved.

General Background

Slovenia is a small country with a population of 2 million, geographically positioned in the heart of Central Europe among neighboring states Austria, Italy, Hungary, and Croatia. Slovenia has a mixture of sub-Mediterranean climate on the coast, continental climate with mild to hot summers and cold winters on the plateaus and in the valleys to the east.

More than half of the territory of 20 273 square kilometers is forested, with hilly plains spreading across the central and eastern regions, the Alpine mountains, valleys, and numerous rivers. The future of Slovenia is conceived as the balance between the economic development and social well-being of its people while conserving the environment, protecting and preserving natural habitats of wild animals and plant species.

Currently, the population of over 2 million inhabitants (in 2007) comprises 81% Slovenians, 0.5% members of the official minorities (Italian and Hungarian), and 18.5 % of other nationalities, mainly of the former Yugoslavia. Slovenian is the state-wide official language and within designated ethnically mixed areas, Hungarian or Italian is used as the second official language. In the last census of 2002, 57.8% of the population declared themselves as Roman Catholics, 2.4% as Muslims, and 3.3% as believers of other religions.

The ancestors of the present-day Slovenians settled in the area in the sixth century BD. In the seventh century, Western Slavic tribes formed an alliance with the Slavic Duchy of Carantania (the center of today's Austrian Carinthia), which fell under the rule of the Frankish Empire in the middle of the eighth century. In the fourteenth century, most of Slovenia came under the power of the Habsburg dynasty and later became part of the Austro-Hungarian-Empire. In 1918, after the collapse of the Austro-Hungarian Empire, Slovenia joined the Kingdom of Serbs, Croats, and Slovenes, renamed the Kingdom of Yugoslavia in 1929. After World War II, Slovenia became a republic in the Socialist Federal Republic of Yugoslavia, and 50 years later, on 25 June 1991, it declared independence. Slovenia joined NATO on 29 March 2004 and the European Union (EU) on 1 May 2004.

Since independence in 1991, Slovenia's economic development has been very successful, making it one of the most prosperous countries in transition. Economic growth has been stable, reaching an average of about 4% per year, enhanced by internalization and the rapid

growth of private consumption and investments. The country is increasingly becoming a service economy; the service sector makes up 63.4% of the economy, the industrial sector 28.2%, and agriculture 2.5%. The services on the rise include telecommunications and business and tourism, with these potentially becoming the leading sectors of the Slovenian economy in the next few years. In 2006, Slovenia reached 88% of the average GDP of the EU per capita. The rate of employment has exceeded the European average (in 2007, 69%, women 62%). The average monthly gross wage in March 2008 was EUR 1352.87.

The history of education in Slovenia reflects the swift and profound changes that occurred in response to numerous political shifts and rapid economic development, affecting education to change from one extreme to another. Some disputable questions arise with each reform and are deeply rooted in Slovenian history. Such questions are: sensitivity to the national language and the fear of being overpowered by a foreign language, private schools and the processes of globalization, and harmonization of the national education system within the rules of the transnational community.

Goals of the Education System

After independence in 1991, Slovenia was faced with fundamental changes in all areas: political, economic, and social. The major education reform (1993–96) took place in the area of total ownership transformation, with the introduction of a market economy, parliamentary democracy, human rights, and increasing globalization. The transition from a centrally administrated system to an open market economy challenged previous systems of education and training. Following studies of developed Western education systems, the new Slovenian model was based on a broadly accepted concept presented in the White Paper on Education (1996) and an entirely new national legislation. For Slovenia, this was of utmost importance since in its history there was little opportunity to develop its own education system.

Independent Slovenia has thus devised and created its own national education system from preschool to university. At the same time, Slovenia has also been involved in the process of joining the EU and, as such, has been obliged to adopt the guiding principles, values, and global goals of the EU as well as those of the wider international community. Slovenia has strived to find certain practical

solutions for these global goals in a way that would be more compatible with its national traditions so that:

- Some management aspects in the autonomy of pre-schools, schools, and tertiary institutions as carried over from the rights given to self-managed communities by the former socialist regime have been maintained and new responsibilities have been added relating to the planning, performance, and evaluation of teachers' work and the professional development of teaching staff.
- An ideological neutrality of public schools has been established preventing the prevalence of any one single ideology; this also means that the constitutional principle of the state being separated from church is enforced in practice.
- An egalitarian understanding of a just school system has been promoted, postponing differentiation among children until they reach the age of 15 years, yet recognizing and respecting the differences among them and providing them with choices and assistance in learning.
- Besides the objectives set out by curricula focused on competence-oriented knowledge, there is also a strong emphasis on the acquisition of systemic theoretical knowledge; development of creativity and individual talents; arts; languages, and literature. History and geography are the backbone of general education in humanities and hold a special place in the general part of all curricula; the goal-oriented curricula are accompanied by catalogs of contents that must be taught.
- To facilitate the needs of rapid economic development, there is a highly flexible system of vocational education and training (VET) in place which is expected to adjust to the current and future needs of the labor market; to allow for a permanent dialog with social partners providing them with an opportunity for their input in the development of goals, course content, and types of qualifications and to establish multiple paths and options for initial vocational preparation.
- Until recently, a relatively isolated higher education system has officially joined the European higher education system; special attention is now given to the recommendation that education is key to the welfare of the individual in the knowledge society, as well as to the economic growth and competitiveness in the world. In this respect, entrepreneurship and privatization in higher education are encouraged.

The current government perceives education as the link between economic development and social welfare. In its strategic documents, lifelong learning is closely related to the economic advancements and employability of the individual thus also ensuring social inclusion. For the time being, the government remains almost entirely responsible for the education and social welfare of its people, although it promotes the possibility of privatizing

educational services. The wider community still recognizes education as a public benefit and in general opposes the spreading of privatization into areas which are, by definition, attributes of a social state, education being one of them. Students and traditional public universities oppose the subordination of higher education to the entrepreneurial interests of capital.

Structure and Operation of the Education System

Figure 1 outlines the formal education system. Key statistics are provided in **Table 1** about educational providers, students and teaching staff, 2007/08.

Preschool Education

After independence in 1991, preschool education became an integral part of the educational system and was transferred from the sector of family and social affairs to the jurisdiction of the ministry of education. The extensive systemic changes in 1996 introduced parental choice and better conditions for children and teaching staff. While the former program was based on group and routine activities, the new one strongly emphasizes individuality and the right of the child to use creative expression and play. Much attention is paid to the equal opportunities of children to progress, including children with special needs, children from ethnic minorities, immigrant groups, and low-income families.

In spite of demographic decline, the number of children in kindergartens has been increasing every year. In the academic year of 2007/08, there were 68% of children in the age group 1–5 years enrolled in preschool. A third of all parents of 1-year-olds opt for kindergarten, while at the age of 5 years, as many as 90% of children are enrolled. Private educational enterprises have started to appear only since 1996 and the percentage of children attending private kindergartens is still very low (1.7%). Regardless of public or private preschool provision, parents pay between 10% and 80% of costs dependent on their income. Families are supported additionally by income tax relief, child allowances, and lower payments for the second child.

Basic and Upper Secondary Education

Education is compulsory for pupils between 6 and 15 years of age. It is offered in basic schools and is organized as a single structure (without distinction between primary and lower secondary levels). Pupils receive the same education divided into three cycles lasting 3 years each without

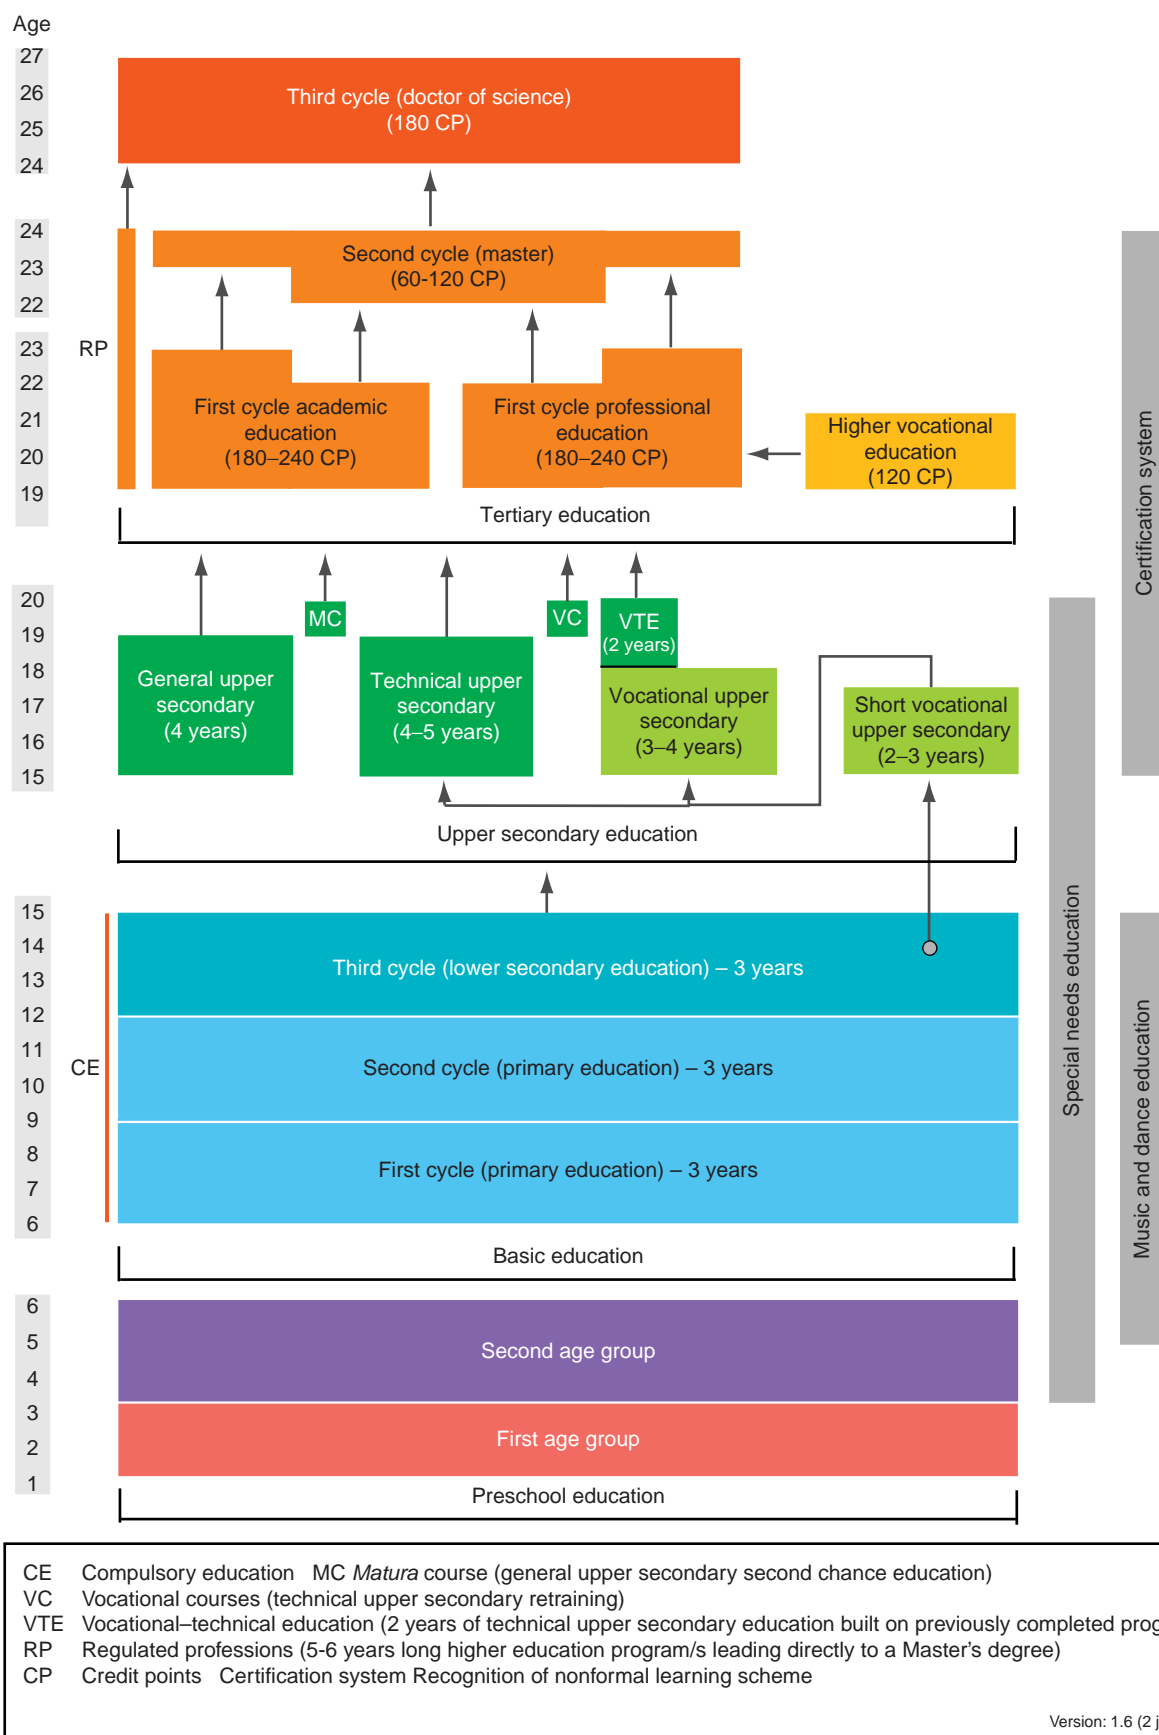

Figure 1 Structure of the education system in Slovenia.

Adapted from Rapid Reports and First Releases, Statistical Office of the Republic of Slovenia; 2007.

^aIn the school year 2006/07, nearly two-thirds of children aged between 1 and 6 years were included in preschool institutions (86% at the age of 5). Children with special needs (759) were included. The figure on professional staff includes assistant educators. Data on the number of preschool institutions include single institutions, branches, and kindergarten units within basic schools.

^bThe figures include basic schools and branches (796) and basic schools or units (59) which provide compulsory school curriculum adapted to the special learning needs of pupils (1624 pupils).

^cMany upper secondary schools do not differ in the type of education program they provide. Of the teaching staff in the second chance courses, only those teachers who work solely in these types of short courses are shown (1 year).

^dIn the academic year 2006/07, 48.2% of the population aged 19–23 were enrolled in higher education (115 944 students).

a change of school. Schools are mainly public and co-educational. Religious education and rituals are not allowed as the Constitution separates state affairs from religious communities. At the end of compulsory education, pupils have the choice to advance to general, technical, or vocational upper secondary education.

Today, almost 100% of 6-year-olds start compulsory education and more than 98% of pupils successfully complete it. Students who drop out are rare, yet they still have the opportunity to continue studies in short vocational courses. A fall in the birth rate since 2003 is reflected in the number of school children, which is 50% lower in 2007 than it was before 1991. A further decline of 17% is expected in the next 10 years. The average number of pupils per full-time equivalent (FTE) teacher is 12. The average number of pupils per class is 19.

Upon completion of compulsory education at the age of 15 years, students normally continue their education at the upper secondary level, split into 4-year general type programs (*gimnazije*) or technical programs and 2–4-year vocational type programs. Traditionally, many upper secondary schools provide all three types of programs. Coursework consists of 45-min lessons, 36 lessons per week (32–36 lessons), organized by subject, together with theory and practical work, compulsory elective components, excursions, seminar work, project work, and individual work. Teaching time is spread over 5 days per week and 38–42 weeks per year. Practical training in vocational or technical education may be provided in schools or in the

form of intensive practical workplace training with an employer.

Statistics show that after completing compulsory schooling, around 40% students enrol in general, 43% in technical, and 17% in vocational education. The state-wide examinations (the *Matura* and technical *Matura*) allow students to enter professionally or academically oriented higher education studies. Drop-out is less than 10% and almost 80% of all upper secondary graduates proceed to higher education, the majority of them being technicians. In 2006, 75% of the population aged between 15 and 29 were studying full-time, that is high above the European average (65%).

Much of the organization, financing, and programming of pre-university education in Slovenia is centralized. The most important decisions (e.g., the content and structure of programs, staffing requirements, and salaries) are taken at the national level. However, schools have a certain level of autonomy in the implementation of the core national curricula, choice of teaching methods, staffing and employment matters, and admission procedures.

Other Schooling Arrangements

Education for children with special needs in Slovenia has traditionally been incorporated into the general education system and integration with their peers has been a planned part of pedagogical treatment for the last 30 years.

A significant proportion of these children, assisted by special mobile pedagogical services, have been integrated in regular schools. There are still 0.9% pupils of compulsory school age who are unable to achieve the same outcome standards as required in mainstream education; they are included in adapted curricula with lower attainment targets. Only a small number of pupils are included in special schools. The education for children with special needs is provided only as a public service and is entirely the government's responsibility.

Music education, which was first introduced in the beginning of nineteenth century, holds a special place in Slovenia. Each education authority has strengthened its position in the public education network by arguing that losing it would impoverish the Slovenian culture and threaten Slovenian national identity. Almost 15% of school-age children attend basic school as well as music or ballet school. Basic schools recognize music education as an elective part of school requirements. Music school programs are public and music schools are almost entirely financed by the government and local councils.

Vocational and Further Education

Initial vocational education in Slovenia has been traditionally school based. Schools providing vocational education usually offer a whole range of educational programs: vocational, technical, and also general. The teaching staff is mostly the same for all three types of education. The responsibilities in this area are rather diffused among ministries, social partners, and councils of experts. In recent years, councils have agreed to broaden their standards, specifying the knowledge and skills that are common to a related set of occupations or functions in industry. The rather limited labor market in Slovenia requires flexible skilled workers with transferable general competences that can quickly adapt to changes in a job structure. One-quarter of the curriculum contents is left to the autonomy of schools and employers. Curricula are being constantly updated and new fields of study have emerged.

To provide a faster and more flexible response to labor-market needs which cannot be satisfied by formal vocational schooling, the so-called certification system for the assessment and award of national vocational qualifications has been developed (2003). It enables individuals to obtain a formal recognition or certification for the skills they have acquired informally. The system is administered jointly by the chambers and their vocational field commissions, trade unions, and the Ministry of Labour.

Continuing education and training also includes preparatory courses for obtaining technical qualification of master craftsman and *Matura* certificate; specialization programs; training and retraining programs; new forms

of project learning; foreign language; and leisure time courses. In 2006, 301 790 students actively participated in 357 registered training organizations. The participation rate in center for employment training (CET) and adult education of 25–64-year-olds has grown enormously: from 7.3% in 2000 to 15.0% in 2006.

Higher Education

Tertiary education in Slovenia is divided into a vocational college sector and a higher education sector with universities. The mission of vocational colleges is to meet the needs of national and local economies, with due regard to specific occupational profiles and middle management teams. Public colleges (25) offer technical subjects, whereas private colleges (34) are more likely to offer commercial and administrative courses. They have to meet the quality standards determined by the national accreditation bodies.

Higher education institutions are autonomous and self-governed institutions accredited by the National Council for Higher Education. This sector is represented by four universities and 19 other private higher education institutions. In 2008, the International Euro-Mediterranean University was founded. In the last two decades, the number of undergraduates has markedly increased and now stands at over 60% enrolments in each year group. In total, there are 89 593 students enrolled in university courses, 71% are full-time students, and more than half of them are female. Of all full-time students, 70% are enrolled in the largest university in the capital city. Foreign students represent less than 1% of all enrolments. The lecturer-per-student ratio is fairly unfavorable (22.2 in 2005). Statistical data show that study efficacy is less than satisfactory. Approximately 57% of students advance from their first year of study to the second one. Students take an average of 7 years to complete a degree even though actual study requirements, on average, do not extend beyond 5 years.

Adult and Nonformal Education

Adult education is a wide ranging and diverse sector that has expanded most rapidly in recent years. It includes all types and stages of formal education as well as nonformal learning opportunities. Private initiative has made significant progress, especially in the area of nonformal education offered by foreign language schools, information and communication technology (ICT) centers, and schools for financial management. In addition, professional associations and societies, municipal resource centers, churches, open universities, the Third Age University, and others also play a considerable role in the education and training

of adults. In 2006, 235 608 adult students participated in non-certified courses, 81% of them wishing to improve their occupational prospects.

The Teaching Profession

In Slovenia, teachers hold the status of public servants. Preschool teachers must have a higher education or university degree (at least 3 years of study). All other teachers and educators must hold a university diploma equivalent to a masters degree and a teaching qualification which can be acquired concurrently or consecutively.

In 2006, there were 26 415 school teachers in Slovenia, or rather 2.9% of the active population. Despite the demographic decline in recent years, the number of teachers in schools has continued to grow slightly. For years there have been no shortages of teachers as each year there are more graduates in education than there are vacancies. The teaching profession in Slovenia is attractive as earnings are solid and employment is relatively safe. There is a prevalence of females with the percentage of women being in inverse proportion to the level of school where they teach: 88% at the basic education level, 65% in upper secondary schools and 33.5% in higher education. Part-time employment is much rarer than in other occupations. There is compulsory training for head teachers provided by the Head Teachers School.

In 2006 there were nearly 9000 teachers and other professional staff employed at higher education institutions (5 786 FTE) and at vocational colleges (532.5 FTE).

Administrative and Supervisory Structure

Public education is managed and supervised by the government, while to some extent, especially in preschool and basic school, local councils also hold some founding responsibilities. Kindergartens and schools have the status of legal entities and, as such, hold many managerial, financial, and educational responsibilities. The government manages work relations and teachers salaries, while staffing and candidate selection is left to schools. However, the government controls the scope, work loads, and teacher qualifications by regulating the salary system and giving its approval to the classification of working positions.

Private education is regulated by the same legislation as in the public sector. Private kindergartens and schools (religious and alternative education schools) can run their own programs or carry out the public program. The government can fund up to 85% of the costs of public schools. Their operation is monitored through a system of program accreditations, funding, and inspection authorities.

Public universities in Slovenia are guaranteed autonomy by the Constitution. This is respected in terms of staff management, research, and pedagogical process, and also to

a great degree in financial matters. The ownership has been transferred from the state to universities. However, limitations set by legislation must be respected, for example, in cases of personnel dismissals, selection of students, and program accreditations. Public institutions are governed by boards with representatives from the state administration and industry. The same legislation and basic rules are applied in the private state-maintained sector, which is co-financed to a large degree by the government. Private institutions are governed by their own bodies; however, they must respect the national legislation in all respects. The independent sector in Slovenia is not significant.

Educational Finance

Funding of education is primarily the government's responsibility, with the exception of some kindergarten and basic school costs where local councils are also an important source of finance.

The percentage of expenditure for formal education in the GDP in Slovenia is relatively high; in 2006 it was 5.83% of GDP, and the total expenditure for educational institutions was 6.17% of GDP. In 2006, the highest percentage of all funds (54%) was budgeted for compulsory and pre-school education, 25% for upper secondary education, and 22% for higher education. The highest percentage of all public expenditure for formal education covered the immediate costs of educational institutions (91%), while 9% went for financial support to students and families.

Within the funding structure allocated for educational institutions, 86% were public funds, whereas 13% came from private sources.

Kindergarten attendance attracts a fee, while full-time education in schools and tertiary institutions is free. Kindergarten fees depend on the parents' socioeconomic situation (0–80% of full cost). Pupils buy or borrow their textbooks and pay for their meals and transport, but with considerable subsidies from local councils or government. The government provides university students with meals and accommodation at subsidized prices.

Performance Monitoring, Evaluation, and Research

Comparable education indicators show that Slovenia is rapidly approaching the standards of a knowledge society. The percentage of population aged between 25 and 64 holding a university degree reached 21.5% in 2006 which is just over 7% more than in 1995. The percentage of people having completed secondary education is also increasing and reached 31% in 2005. The percentage of premature school-leavers is relatively low, except in vocational education. The number of university graduates had been on the increase until 2006. Looking at the

number of years spent in school, Slovenia is close to the OECD (2004) average with 11.9 years.

The government monitors education using data, analyses, projects, and research carried out by the National Statistical Office, institutes, and agencies for development of education, education research institutes, and departments of education at universities. The government has developed a so-called strategic contracted research system, through which researchers are invited to undertake specific research work. Evaluation processes in pre-higher education are coordinated by an authorized expert body, the Council for Evaluation in Education. Evaluation includes self-evaluation, prescribed by law (2007) for all institutions, and other external forms and traditional methods, such as results analysis at the end of each assessment period, school inspections, and external assessment at the end of compulsory schooling and at the end of the 4-year upper secondary school.

Upon completion of the 9-year basic school, as well as completion of general and technical upper secondary school, an external knowledge assessment is compulsory and serves as a measure for the assessment of teaching standards. *Matura* results are used in selection procedures for enrolment in higher education. Slovenia is included in international student assessments, such as PISA, which is another assessment measure of the education system. PISA 2006 results show that Slovenian students' results are above the OECD average.

In higher education, quality assurance of the teaching process is monitored by institutions themselves and discussed by the Quality Assessment Commission (established in 1996). Universities have developed their own systems of quality control since 1999 when they first started addressing the question of quality. The council on higher education (CHE) is responsible for accrediting study programs and institutions and debating the findings from self-evaluation and external evaluation reports. The quality of teaching is annually evaluated by students using commonly accepted questionnaires. The evaluation results are made available for the public online. The results are pivotal when it comes to applications for new projects or for academic promotion.

Self-evaluation reports show high drop-out numbers and excessively long durations of study. Nevertheless, the University of Ljubljana was placed among the top 5% of universities in the world on the 2007 Times ranking table.

Major Changes and Issues since the 1990s

Education in Slovenia has always been very closely related to building and maintaining Slovenian national identity. This was precisely the reason why public education was introduced very early. Up until the 1990s, education was

developed within the guidelines defined by the former Yugoslav republics, one of which was Slovenia. In the beginning of the 1990s, Slovenia became an independent country; hence, one of the key challenges of this period was to develop a new education system in the newly independent country. The development of education system concepts was an extremely demanding task due to the role education had always played in Slovenian history. During this period, Slovenia began joining international associations and networks on a large scale, which became an important influence for the development of its own education policies. In the mid-1990s, Slovenian legislation for the first time defined the position of private and public education and made provisions for different, modern evaluation approaches.

Education policies in recent years have paid special attention to the core questions highlighted by common EU institutions. They include: how to achieve a balance between equity and efficiency, how to provide high quality education for all, how to provide access to education for all, and how to devise evidence-based policies. The Slovenian education policy is facing challenges similar to those faced by other EU member states, and the methods of solving these questions are often subjected to heated debates both in professional circles and in the general public. For decades, education policy was concerned primarily with the acquisition of formal knowledge in educational institutions; however, in recent years it has tried to systemically include and develop all elements of life-long education and has, for this purpose, devised a system of recognition for different types of knowledge and processes of skill acquisition.

Slovenia is one of the countries whose population is quickly aging. At the end of 2006, the average age of the population was 41 and in the same year, for every 100 inhabitants aged under 15, there were 114 inhabitants aged over 65. Projections up to 2050 show that the number of people aged over 65 will have doubled by then and a 33% decrease in active population is also anticipated, which places Slovenia at the top of EU rankings.

An aging population, migration, climate change, and energy restrictions are issues which necessitate a revision of educational concepts in Slovenia. Developmental documents adopted by the government in recent years have already introduced some new aspects and highlights, such as the development of social competences in young generations, development of intergenerational pedagogy, development of methodology to forecast future needs for knowledge and skills, and the development of flexible education forms and methods in adult education.

Solomon Islands

D P Malasa, Ministry of Education and Human Resources Development, Honiara, Solomon Islands

© 2010 Elsevier Ltd. All rights reserved.

General Background

The Solomon Islands form an archipelago in the Southwest Pacific about 1900 kilometers northeast of Australia. With terrain ranging from ruggedly mountainous islands to low-lying coral atolls, the country stretches in a 1450-km chain southeast from Papua New Guinea across the Coral Sea to Vanuatu. It is made up of six large and 992 small islands with a total land area of 27 990 km² and an ocean area within an exclusive economic zone of 1.34 km². The main islands of Choiseul, New Georgia, Santa Isabel, Guadalcanal, Malaita, and Makira have rain-forested mountain ranges of mainly volcanic origin, deep narrow valleys, and coastal belts lined with coconut palms and ringed by reefs. The smaller islands are atolls and raised coral reefs and lagoons. These features impact substantially on logistics and communication and can affect the effective delivery of services such as education throughout the country.

The Solomon Islands comprise diverse cultures, languages, and customs. With a total population of about 496 000, the annual growth rate is estimated to be 2.8%. About 120 vernacular languages are spoken. Despite these many languages, the official language of instruction in schools, administration and commerce is English and the *lingua franca* is Pijin.

Only 57% of 5–14-year-olds attended school, although this percentage has increased in recent years with the change in the government policy to provide free primary education in line with the millennium development goals.

Other key characteristics of the Solomon Islands indicate that approximately 85% of Solomon Islanders live in rural areas, which are still largely subsistence, although they are both increasingly influenced by and also have a desire to join the cash economy. The remainder live in urban centers such as Honiara, Auki, Gizo, and Kirakira, or work in primary industries such as plantations and logging.

The Solomon Islands gained independence from Britain on 7 July 1978 and is a parliamentary democracy within the Commonwealth, with a unicameral parliament and a ministerial system of government. The British monarch is the head of state and is represented by a governor general, chosen by the Parliament for a 5-year term. The national parliament has 50 members, elected for 4-year terms. However, Parliament may be dissolved by majority vote of its members before the completion of its term. Parliamentary representation is based on single-member

constituencies. Suffrage is universal for citizens over age 18. The prime minister, elected by parliament, chooses the other members of the cabinet. Each ministry is headed by a cabinet member, who is assisted by a permanent secretary, who is contracted to direct the staff of the ministry.

For local government, the country is divided into 10 administrative areas, of which nine are provinces administered by elected provincial assemblies, and the tenth is the capital city of Honiara, administered by the Honiara City Council.

Most people reside in small, widely dispersed settlements along the coasts. Sixty percent live in localities with fewer than 200 persons with their distinct sociocultural settings, and only 10% live in urban areas. The capital city of Honiara, situated on Guadalcanal, the largest island, has over 30 000 inhabitants. The other principal towns are Gizo, Auki, and Kirakira.

Most Solomon Islanders are Christian, although about 5% of the population maintain traditional beliefs. The recognition of bonds of kinship, with important obligations extending beyond the immediate family group and local and clan loyalties far outweigh regional or national affiliations. This is considered one of the factors that fueled the recent ethnic tension. The social structure of most communities is generally egalitarian, emphasizing acquired rather than inherited status, and a strong attachment of the people to the land. Most Solomon Islanders maintain this traditional social structure and find their roots in village life. Land generally is still held on a family, clan, or tribal basis and may be handed down from mother or father according to local custom.

Formally organized schooling in the Solomon Islands was introduced by the Christian Missionaries in 1870s and later in 1950s by the British colonial administrators. The early church mission schools were aimed at Christianizing and civilizing the islanders. In contrast, early protectorate government schools were political in nature and were aimed at training elite which would take over the affairs of the country from Britain.

Until 1998, when world prices for tropical timber fell steeply, timber was Solomon Islands main export product, and, in recent years its forests were unsustainably over-exploited. Other important cash crops and exports include copra, cocoa, and palm oil. Since 1998, a gold mine has been developed at Gold Ridge on Guadalcanal, with its first gold export expected in early 2009. Minerals exploration in other provinces continued. Exploitation of Solomon

Islands' rich fisheries offers the best prospect for further export and domestic economic expansion. Tourism, particularly ecotourism and diving, is a potential service industry for Solomon Islands. However, growth in that industry is hampered by lack of infrastructure and transportation limitations.

With its per capita gross domestic product (GDP) of US\$340, Solomon Islands is ranked as a least-developed nation, with more than 75% of its labor force engaged in subsistence farming and fishing.

The recent conflict has devastated the national economy, and traumatized many who were affected by it. The nation and people have thus been urged to look critically at the situation and plan for the future. While the underlying social structures and values may have contributed to the conflict, they have also enabled families and communities to cope with its impact. Many people believe that the values and attitudes promoted through the Westernization of Solomon Islands society, and in particular by the education system, have been a root cause of the conflict. Although this is debatable, there is general acceptance that the current education system has increased tensions within communities, especially between younger people and their more conservative and traditional elders, by its promotion of and focus on economic advancement. The education system is seen by many as being unconnected and antagonistic to the social and cultural values on which Solomon Island communities and society are based. Such views pose great challenges to the government and educational leaders throughout the country.

The current education system in Solomon Islands is administered under the Education Act of 1978. Although in dire need of a review to accommodate the changing needs of the nation and its learners, the Act provides the legal basis on which much administration of the country's education system was decentralized to the education boards of the nine provincial governments and the Honiara City Council. This was necessary because of the geographic isolation and cultural diversity of the country and by the associated issues of communication and transportation. This has enabled most of the administrative problems to be dealt with at local level, and made the schools more responsive to the needs of their immediate communities.

The present education system is responsible for ensuring the operation and development of schools and training institutions across Solomon Islands. It manages over 600 primary schools with a student enrolment of 99 310, 140 secondary schools with a student enrolment of 25 435, and a teaching establishment of over 5609. The vision of the education system is that all Solomon Islanders will develop as individuals and possess knowledge, skills, and attitudes needed to earn a living and to live in harmony with others and their environment. It envisages a united and progressive society in which all can live in peace and harmony with fair and equitable opportunities for a

better life. It envisions an education and training system responsive to its clients and efficiently managed by its stakeholders and clients.

Goals and Strategies of the Education System

The three strategic goals proposed for the National Education Action Plan 2007–09 are:

- to provide equitable access to quality basic education for all children in the Solomon Islands;
- to provide access to community, technical, vocational, and tertiary education that will meet individual, regional, and national needs for a knowledgeable, skilled, competent, and complete people; and
- to manage resources in an efficient, effective, and transparent manner.

The overarching goal is to provide universal access to basic education for all children by 2015, and improved access to technical and vocational education and training. In the Solomon Islands, basic education refers to the first 10 years of formal education from the preparatory year, through standards 1–6 in the primary school, and including forms 1–3 in the junior secondary school. It may also include similar programs offered elsewhere at similar levels for out-of-school youth and adults.

To achieve these, the Solomon Islands Government has undertaken to place priority on refocusing education-sector expenditure on providing services at primary and junior secondary schools to achieve universal basic education by 2015.

Six immediate key strategies have therefore been developed as a focus for the period 2007–09. These include:

- to develop and implement a program of human resource development capacity building;
- to improve the implementation of grants to support school operations;
- to develop an improved school infrastructure;
- to deliver effective teacher training and development;
- to support a program of curriculum development; and
- to improve tertiary education.

Annual work plans and associated budgets have been developed by the Ministry of Education and Human Resources Development for each of 2007, 2008, and 2009 to give effect to these strategies.

Structure and Operation of the Solomon Islands Education System

Figure 1 summarizes the structure and operation of the Solomon Islands education system.

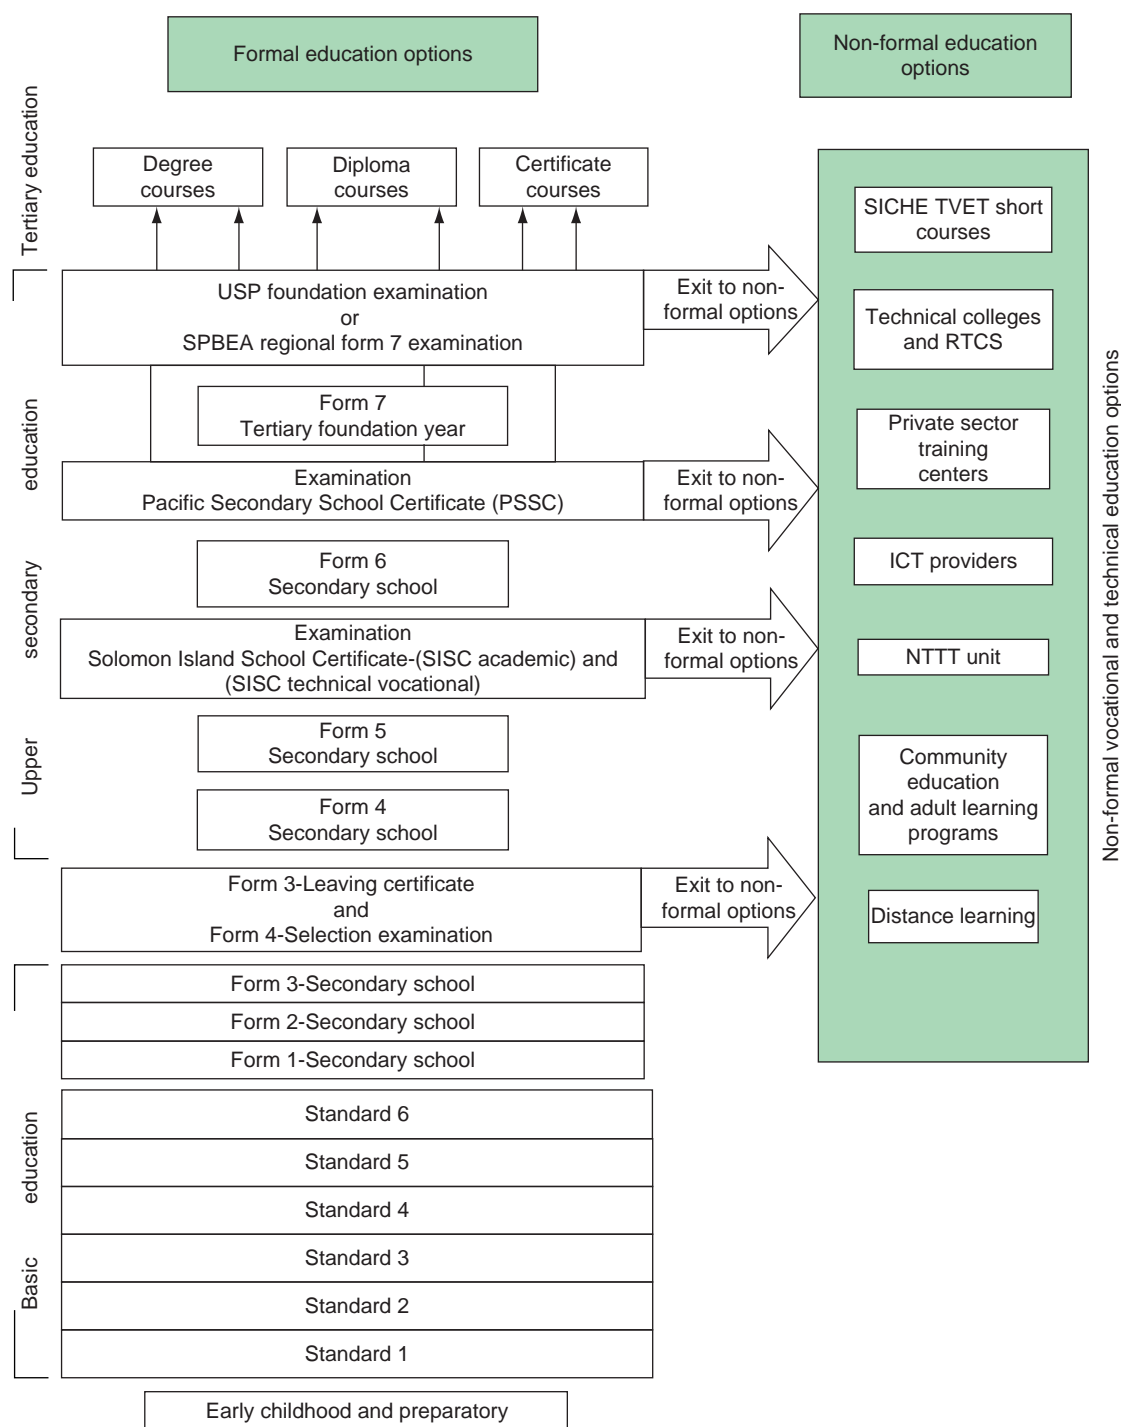

Figure 1 Structure of the Solomon Islands education system.

Early Childhood Education

Until recently, early childhood education (ECE) in the Solomon Islands has not received focused attention from the national or provincial governments. It is viewed as a parental rather than a state responsibility and has remained the domain of the churches and community groups, with little attention or support from the national

or provincial governments. Most ECE programs are therefore supported by the voluntary sector, and are not fully funded by central government. While ECE centers do not receive full financial assistance, they are subsidized to some extent. Salaries of ECE teachers trained at the Solomon Islands College of Higher Education to teacher's certificate level are paid by the government, and the Ministry of

Education and Human Resources Development (MEHRD) employs officers who monitor the provision of ECE.

No formal ECE curriculum has been approved for the Solomon Islands by the government. In general, the ECE curriculum in the Solomon Islands is not structured. Children at this age are encouraged to interact in an environment where they can explore, learn, and discover through play. Communities are encouraged to equip the centers with educational resources and equipment that will enhance children's learning and development. While there are some learning materials available to support ECE programs, supply of these materials is limited.

Thus, learning activities in these early childhood centers are focused on establishing the social values and attitudes and achievement of children in the formal education environment.

In 2006, the total ECE enrolment number was 11 228. This represents 27.5% of the estimated population of the 3–5 age group in the Solomon Islands. ECE therefore is not currently accessible to all children in the Solomon Islands. There is also inequality of access in some constituencies. The difficulty faced by some parents is that access to ECE by very young children is difficult if the ECE center is not close to the home, since young children cannot travel long distances. There is easier access to ECE in the urban centers where enrolment numbers are larger and where it is therefore more efficient to operate a center because the numbers attending make it financially viable. Access is more difficult in remote rural areas.

Primary Education

Primary education covers a formal span of 7 years. The preparatory year prior to standard 1 is regarded as part of primary education. In addition there are 6 years following the preparatory year, starting at standard 1 and ending at standard 6 with a terminal examination. This span makes a total of 7 years primary education in all. These 7 years constitute the basic-education program of the Solomon Islands. A child is expected to commence at the age of 6 or 7 and continue for 7 years.

The overall purpose of primary education is to develop children's literacy and numeracy skills (reading, writing, speaking, listening, and computational skills) and other skills and understandings that prepare young people to take part in society. These other skills and understandings include skills in science, social sciences, community studies, agriculture, art, music, and physical education.

Generally, primary education appears to be available to the majority of children in the Solomon Islands, although 6% of the primary-school-age population do not attend school.

It is worth noting that geographical and settlement patterns in the Solomon Islands greatly affect the question of access. The islands are rugged and divided by huge

stretches of sea and people live in small rural or coastal settlements. Many pupils have to walk or paddle long distances to attend school. Transport systems too are not very good, especially in rural areas. Besides, the weather is intolerable at times. These are unavoidable factors, which hinder access to primary education in Solomon Islands. However, the government and other authorities are doing all they can to minimize these factors, which have caused negative impact on universal access to primary education.

Secondary Education

There are three categories of secondary school in the Solomon Islands. National Secondary Schools (NSS) which were the original secondary schools operated by the government and the churches, and which enrol students from across the country; provincial secondary schools (PSS), which were initiated by the government but are run by the provinces, and whose student enrolment should be restricted to the province only; and community high schools (CHS), which started as primary schools, but which have had a secondary section added on. The CHS are built and managed by communities, and are assisted by church or provincial authorities.

Table 1 sets out the number of secondary schools in the Solomon Islands from 2003 to 2006.

Access to secondary schools is a major issue in the Solomon Islands. The lack of sufficient secondary school places, as a result of a lack of trained teachers and a lack of adequate facilities, is a major barrier to access. The difficulty with transportation also makes access difficult for a number of secondary school students, especially those living in isolated communities.

There is a total enrolment of 25 435 in the Solomon Islands secondary schools. This is an increase of 8.5% from 2005.

Control of the junior secondary curriculum is centralized under the Ministry of Education. Curriculum review of all secondary subjects is currently undertaken by the curriculum development center. Syllabuses, teachers' handbooks, and textbooks for students are developed by curriculum panels.

The current curriculum used by secondary schools is heavily theory based, and thus does not prepare children to go back to their villages to apply the skills they have learnt. The adoption of the policy on technical and vocational education and training (TVET) is intended to

Table 1 Number of secondary schools by type

<i>School type</i>	<i>2003</i>	<i>2004</i>	<i>2005</i>	<i>2006</i>
NSS	9	9	9	9
PSS	17	16	16	16
CHS	104	108	114	117
Total	130	133	139	142

allow junior secondary schools to be able to use TVET-modularized courses relevant to their communities in the near future.

The key questions with respect to the junior secondary curriculum are whether it remains relevant and up-to-date, and whether supporting learning materials and resources (including trained teachers) are adequately supplied to schools. The rapid expansion of CHS is throwing into sharp focus the adequacy of the training and specialist subject knowledge of the teachers who are allocated secondary classes in these junior secondary schools.

Technical and Vocational Education and Training

The development of this alternative pathway in the education system of the Solomon Islands will provide avenues for those young people who do not gain access to a place in the formal secondary school system. There is also a general need to provide adults with a range of vocational skills that are in demand in the workforce, so that they may make a contribution to the economy of the country.

TVET is available in the Solomon Islands through rural training centers (RTCs) controlled by the churches. There are no rural training centers which are administered by national and provincial governments. The TVET policy encourages establishment of more rural training centers and emphasizes the inclusion of practical subjects in the formal education system.

Access to TVET in the Solomon Islands is a significant issue. There are two main target audiences for whom access to TVET is essential: early school leavers, and adults who need return education and training to develop skills needed for participation in the workforce.

At the senior secondary level, it is planned that TVET should be developed as an alternative pathway for school leavers. In the Solomon Islands, there is a need to target those school leavers who leave the formal education system at the end of form 3 and at the end of form 5.

In 2006 the total enrolment in TVET was 2228. There are clearly issues relating to equitable access to TVET on the basis of gender. Currently, enrolments in TVET courses are dominated by males, at the expense of females. An estimated 28% of total enrolments are female, thereby constituting only slightly more than a quarter of total enrolments.

There are few opportunities for the physically disadvantaged to access TVET. In addressing access issues, both gender equity and equity for the disadvantaged will need to be considered.

Tertiary Education

Tertiary (or post-secondary) education in the Solomon Islands is provided by the Solomon Islands College of Higher Education (SICHE), and other overseas universities and

colleges, including the regional University of the South Pacific (USP) in Fiji, and its Solomon Islands campus in Honiara. The focus of SICHE is on middle-level skills and specialized training that leads to a formal qualification such as certificate and diploma, USP and other regional universities and colleges on the other hand offer higher-level tertiary education and training at undergraduate and postgraduate levels.

Most of the Solomon Islanders studying for a degree enrol with the University of the South Pacific, or attend universities and colleges in Papua New Guinea. A significant number also attend universities and colleges in Australia and New Zealand.

In 2006, over 800 students were studying in universities and colleges abroad, supported by the Solomon Islands Government as well as foreign governments (mostly Australia, New Zealand, and the Taiwan-ROC) Scholarship Awards.

Full-time student enrolment at SICHE averages 1800 each year. In addition to these opportunities, programs for part-time students are also offered by some of the schools of the college, on a day release and evening-class basis. The academic year consists of two semesters of 15 weeks each.

Other tertiary-education providers in the Solomon Islands include several church or private-funded education providers that range from theological colleges and rural training centers that focus specifically on religious and TVET. These other providers are effectively delivering tertiary (post-secondary) education, although often at a relatively low level of achievement and accreditation.

Access to tertiary-education opportunities in the Solomon Islands needs to improve significantly. Current participation levels are relatively low. Increasing participation in higher-level tertiary education courses will be necessary to lift the level of productivity and the performance of the workforce.

Adult and Nonformal Education

Many of the adult and working-age population in the Solomon Islands need to develop skills that may lead to employment, or skills that may assist in establishing viable local businesses or self-employment. The scope for developing and increasing access to adult and nonformal education to offer further education and training for the adult population is therefore extensive. Such informal and nonaward training opportunities are provided by existing tertiary (SICHE, USP) and rural training centers, schools, and community-based training centers.

Although enrolments in the nonformal sector are on *ad hoc* basis and are therefore difficult to quantify, such informal training offer opportunities for skills training for most adult and out-of-school population. However, there is still the issue of gender equity that needs to be considered.

The Teaching Profession

The total number of ECE teachers in the Solomon Islands in 2005 was 739 (652 women and 87 men). Over 80% of these teachers were unqualified, although many of these unqualified teachers may have had some field-based training. Teachers who have completed field-based training are technically classified as untrained and need to go on and complete the ECE teacher-training program at SICHE in order to qualify as a trained ECE teacher. The key need is to provide training to upgrade the skills of the ECE teachers who are unqualified. **Table 2** sets out further details.

The teacher pupil ratio for ECE in 2005 was 1:15. This ratio is as per the recommended teacher-pupil guidelines, and suggests that teacher supply is adequate. However, there is certainly an overall shortage of well-trained and qualified ECE teachers throughout the country.

There were 3964 primary school teachers in 2005 in the Solomon Islands education system, although about 33% of these teachers (approximately 1300) are categorized as unqualified. This situation has serious implications for the quality of teaching delivered to some students, and directly affects the standard of student achievement.

On the basis that the teacher:pupil ratio was 1:25.3, there appeared to be sufficient teachers in the system to manage the number of enrolments in 2005. Teacher supply does not appear to be an issue at present, but may become an issue in future as primary school rolls expand.

What does need to be monitored carefully and improved, however, is the quality of the primary school teaching staff. A key issue is the number of unqualified primary school teachers in the Solomon Islands.

Table 3 provides details of primary school teachers in the Solomon Islands in 2005 by province, gender, and sets out the percentage of teachers who are qualified.

Table 3 shows that approximately one-third of primary teachers in the country in 2005 were unqualified, and strategies need to be developed to address how the untrained teachers will be up-skilled. This issue requires

immediate attention if the quality of education in the Solomon Islands primary schools is to be improved.

The current supply of trained secondary teachers is not sufficient to meet the projected requirements of the junior secondary schools. In the junior secondary schools subject specialization is a requirement for teachers, unlike teachers at the primary level who teach all subjects of the curriculum. The curriculum reform being initiated will also require additional specialized teachers, since the introduction of 11 subjects in total (including more practical subjects) into the curriculum. Just over 20% of secondary teachers were estimated to be unqualified in 2005 (see **Table 4**). This percentage is too high.

It is evident from informed professional opinion that there is a shortage of adequately trained and qualified teachers at the junior secondary level. It will be necessary to provide training for the unqualified teachers in the junior secondary schools, and to lift the overall qualifications of teachers in the secondary teaching service.

In TVET, there are 108 trained and 82 untrained teachers. The key teacher-supply issue in this sector is finding an adequate supply of trained and competent

TVET tutors or instructors with high-level skills in the particular specialty in which training is desired.

Increasing the supply of trained TVET tutors is essential in order to increase the number of trainees who can enrol in TVET courses.

Table 5 sets out available 2004 data about the trained and untrained TVET teachers by province.

To summarize, the two key teacher-supply issues that need to be addressed are increasing the supply of qualified TVET instructors (i.e., the number of trained tutors), and providing training to up-skill those tutors who do not have appropriate training or qualifications.

Administration and Supervisory Structure

Schools in the Solomon Islands are operated and administered by their respective education authorities. An education authority is any person or organization the minister of education may approve to establish or maintain a school or schools within Solomon Islands. These include the provincial education boards, churches, and private individuals. There are a total of 24 approved education authorities in the Solomon Islands. A school may only be established or operated by an education authority.

Government schools are under the responsibility of the relevant education boards of their provincial education authority, while the churches and private schools are under the responsibility of their respective education boards.

Church and private-run schools form an important component of the Solomon Islands school system. Although most church-run schools have a religious affiliation, they are required to meet prescribed standards for registration, funding purposes, and to follow the prescribed national school curriculum.

From TVET 2004 Survey Report.

In the tertiary sector, higher education institutions in the country are autonomous bodies established under their respective legislation and independent governing body. However, primary responsibility for funding, policy, and programs remains with the Solomon Islands Ministry of Education and Human Resources Development.

Educational Finance

Although schools in the Solomon Islands are administered by their responsible education authorities, the national government provides over 70% of their operating costs. The rest are funded by parents, communities, and other private sources. In 2005, the total expenditure on education in the Solomon Islands was US\$184 million. It accounts for 7% of the country's GDP and 27% of its total recurrent expenditure.

However, 40% of this is disproportionately used to fund the tertiary sector (mostly on overseas scholarships), which comprise barely 2% of the total student population.

Government funding for early childhood, primary, secondary, and TVET is in the form of an annual grant and teacher salaries.

For tertiary and higher education, most of the government funding is in the form of grant contribution and scholarship fees, especially for students studying in overseas institutions. Most of the students studying at SICHE pay for their own fees.

Performance Monitoring, Evaluation, and Research

The performances of the national education system are monitored using data collected by the Solomon Islands Education Management Information System (SIEMIS).

Table 6 shows the 2006 detailed enrolment data of school-age children.

The above participation rates have shown that quite a number of 13–19-year-olds (30.7%) are neither at school nor engaged in employment activities. This is a threat to the social stability and security of the nation. The last ethnic tension was started by disengaged and disillusioned youths.

There are also some concerns about apparent attrition (particularly among girls) in the later years of primary schooling. There are various factors that may contribute to a significant attrition rate at the primary school level. These include geographical factors such as how children get to schools; the locations of schools far from the catchments areas, with the consequence that travel time is longer; relocation of villages to smaller remote communities; and the frequent movement of families. All these factors sometimes make it difficult for children to be

Table 6 Detail enrolment data by age, 2006

		<i>Official Age Range</i>	<i>Total Enrolment</i>	<i>Enrolment of Official Age Range</i>	<i>Population</i>

	F		10,974	742	39,888
			25,611	1,591	83,386

From Digest of Education Statistics (2006).

placed in the appropriate class. The cultural and social influence of parents and local communities are also sometimes hindrances to access and equity.

Gender equity does not appear to be a major problem, although there is a slight gender imbalance in favor of boys. Of the total enrolments in 2005, 53% were boys and 47% were girls. The reason for this imbalance may be attributable to some slight attrition of girls toward the end of primary schooling. The breakdown of enrolment figures by gender, however, is generally consistent with the distribution by gender in the primary school target-age groups, as reflected in the census estimates for the 2005 primary school-age population (52.2% male and 47.8% female).

Information was not available to determine if there are equity issues with respect to access to primary education for the disabled (e.g., children who are physically disabled, visually impaired, hearing impaired, intellectually disabled, or who have other types of disability).

The National Examination and Standards Unit (NESU) within the Ministry of Education is responsible for management, administration, and monitoring of national examinations, standards, selection procedures, and the progression of students from the exit points in the education system. It also sets national baseline data for literacy and numeracy to monitor educational standards through the administration of the Solomon Islands Standardized Test of Achievement (SISTA) and other support-assessment tools. In addition, NESU also administers three national examinations; Solomon Islands Secondary Entrance (SISE) at year 6, Solomon Islands for Three (SIF3) examinations at year 9 and the Solomon Islands School Certificate (SISC) at year 11, and Pacific Senior School Certificate (PSSC) at year 12 although the PSSC is directly under South Pacific Board for Educational Assessment (SPBEA) qualification framework.

The current national assessments heavily dependent on external examination for selection purposes are at year 6, 9, and 11, and also for selection into form 7 (year 13). The SISTA monitors students' literacy and numeracy levels at the primary. In addition, assessment for learning

tools are being developed to help teachers to address specific problem areas in the teaching and learning based on the key curriculum-learning objectives at the primary level.

The assessment for the TVET is done by individual institution based on the benchmarks set by the national trade and testing scheme. Higher education performance is also assessed by individual institutions using benchmarks and other performance outcomes set out by their respective boards of studies.

Major Changes and Issues since the 1990s

The major changes and issues facing the Solomon Islands education system since the 1990s are to maintain the delivery of education services by providing equitable access to quality education (ECE to tertiary) for all children throughout the country and to manage resources in an efficient and transparent manner.

At the same time, these changes are also linked to the global international goals (millennium development goal 2 and Education for All (EFA) goals) for education and to the broader regional context in the Pacific. In particular, the emphasis on achieving access to universal basic education for all children of Solomon Islands. The target date set by the Solomon Islands education strategic framework (2007–15) is therefore aligned with and is consistent with the target date of 2015 by the millennium development goals and the United Nations Educational Scientific and Cultural Organization (UNESCO)-sponsored Asia and Pacific Regional Framework for Action: EFA.

The national strategic goals are also linked to the regional goals for education adopted by the Pacific Education Forum Basic Education Action Plan and focus on the Pacific Islands Forum, and on the regional initiatives sponsored by the Pacific Regional Initiative for the Development of (basic) Education (PRIDE). The PRIDE initiative, which is consistent with the strategic direction adopted by the Solomon Islands education system, is also

based on the concept of regionalism – that is, countries working together for their joint and individual benefit. Regionalism under the Pacific Plan does not limit national sovereignty. It is not intended to replace national programs, only to support and complement them. This Pacific regional approach is supported because it adds value to the national efforts in the education sector here in the Solomon Islands.

Another initiative since the 1990s was the move to have greater input by the key stakeholders in planning of the education system. This has led to the development of Provincial Education Action Plans (PEAP) for the ten provinces (including Honiara city) that started in 2004. The outcomes, recommendations, and agreements that emerged from the ten PEAPs were synthesized and incorporated into the National Education Action Plan (NEAP) 2007–09, a national planning document that reflects the general needs of all provinces and needs specific to individual provinces.

It has been widely acknowledged that education of our children is a responsibility that can be shared with other education and training providers. Understanding its obligations to ensure that quality education and training is provided to its people, the MEHRD is in the process of establishing policies to guide and regulate other education and training providers to develop and deliver quality education. Other education and training providers include church and private education authorities running schools and tertiary institutions.

One of the key priorities identified by the MEHRD is to incorporate programs and activities that are aimed at achieving gender equity in access to basic education. Of equal priority is the need to identify the needs of students in the 10–19-year-old age groups who have been pushed out or dropped out of formal education, and to design programs to enable them to re-enter the system or to progress along alternate education and training paths.

In addition the MEHRD aims to conduct field studies to identify the scope of problems of people with disabilities and identify the economic constraints to achieving access to education and design programs to overcome these.

There are several issues concerning the current national external examinations, such as too many selection/exit points. While schools appreciate the current selective

examinations to select the bests, many believe that this has influenced and dominated the way teachers are teaching. In addition, critics argue that the current school curriculum and assessment system does not evaluate or report students' progress in achieving desired learning outcomes, and does not promote the adoption of teaching practices that support continued learning through the schooling period. There has been continuous evaluation of the links between the school-curriculum objectives and assessment criteria and procedures and the support for children's learning provided by current system-wide assessment methods. Another emerging issue relates to the relevance of the school curriculum to the Solomon Islands sociocultural context.

Introduction

The current education system in South Africa can only be understood within its historical context and the ongoing transformation efforts since the end of apartheid in 1994. The racial ideology of apartheid recognized four main population groups based on race – African, colored (of mixed descent), Indian, and white – and resulted in differential policies toward those groups, including in the field of education. The post-1994 era has seen major transformation efforts aimed at building a democratic system of education, improving access to education, improving the quality of education for all, and building a nonracial and nonsexist society. The transformation agenda has encompassed the entire education system, including early childhood development (ECD), basic education, further education and training, higher education, and adult education.

Background

In 2007, South Africa had a population of 47.9 million people, of which 51% were female. The population is very diverse, including indigenous peoples as well as substantial minorities of European and Asian origin. The four racial groupings identified by the apartheid system, though no longer a basis for differential treatment by the state, are still generally recognized. Africans constituted 79.3% of the total South African population in 2005, whites 9.3%, colored 8.8%, and Indians 2.5%. Many languages are spoken in the country and the constitution recognizes 11 of them as official languages. English and, to a lesser extent, Afrikaans tend to dominate in government and commercial life. Most of the nine indigenous official languages tend to be regionally based, although in the industrial and commercial heartland of Johannesburg and the rest of Gauteng province, there is a strong presence of all official languages.

Following the country's first nonracial elections in 1994, South Africa became a constitutional democracy. There are nine provinces, which enjoy substantial powers over matters which include, *inter alia*, agriculture, education, the environment, health, language policy, tourism, transport, and welfare. The constitution includes a bill of rights which guarantees the fundamental rights of individuals and groups.

South Africa's economic development owes much to the discovery of diamonds and gold in the latter half of

the nineteenth century. This led to significant infrastructural development and industrialization. The three main branches of the economy – agriculture, mining, and manufacturing – depended strongly on cheap black labor provided by indigenous Africans, whose traditional economy was destroyed as their land was systematically confiscated. For most of the twentieth century, the country enjoyed rapid economic growth. However, growth slowed in the last quarter of the century, partly as a result of labor constraints resulting from apartheid's restrictions on the internal markets for both labor and goods, and partly because of international economic sanctions imposed in protest against apartheid.

When the first democratically elected government took power in 1994, the South African economy was not showing any significant levels of growth. This changed by the late 1990s. From 1996 to 2002, the average real annual growth in the gross domestic product (GDP) was 2.8%. From 2003 to 2007, it rose to an average of over 5% per year.

There are high levels of unemployment in the country, with as much as 26% of the population considered unemployed in March 2007, using the official definition of unemployment which excludes those who are not actively seeking work. Using a broader definition, the unemployment rate is closer to 40%.

Education

Post-Apartheid Reform

Apartheid education was shaped by racial disparities in relation to access, resource allocation, and quality of provision. Education provision for each racial group was undertaken by a separate department, and led to different standards of provision. At the time that the democratic government took office, white education received more than 4 times the amount of money per learner than was allocated for black education. The colored and Indian populations had a level of provision between that of whites and Africans. This situation impacted on the quality of education provided for the various groups. The poor quality of black education is evident in rates of progression and completion of education: only 51% of African children reached grade 8 in 12 years of schooling. In contrast, 96% of white learners reached this grade in 8 years. Enrolments in higher education also reflected

the legacy of apartheid, with fewer blacks enrolling in higher education institutions, especially in fields such as engineering, mathematics, and science.

Through the bill of rights, all South Africans have the right to a basic education, including adult basic education, and the right to receive an education in any of the 11 official languages where it is reasonably practicable. The constitution splits control over schooling between the national and provincial levels of government. The national department of education is responsible for establishing national norms and standards, and nine provincial departments are responsible for administering the school system and establishing provincial policy within nationally set parameters. Higher education is the responsibility of the national government, but the higher education institutions enjoy a high level of autonomy.

When it was formed in 1994, the Government of National Unity tackled the reorganization of the entire education system. Within the schooling system, the first area of education-policy development that it addressed was the organization, governance, and funding of schools. After a lengthy process of consultation and negotiation, the main policies were set out in the South African Schools Act of 1996. The act established two legally recognized categories of schools – public and independent schools – and decentralized many powers to elected school-governing bodies. A new curriculum (known as curriculum 2005) was introduced in 1997. Due to its perceived complexity, it was later reviewed and a revised national curriculum statement (RNCS) was adopted in 2002. The further education and training (FET), higher education, ECD, and adult basic education and training (ABET) sectors also underwent major reforms.

An important component of the government's post-apartheid education-reform strategy was the establishment of the national qualifications framework (NQF). The South African Qualifications Authority (SAQA) is a statutory umbrella body which is responsible for coordinating this framework. The NQF aims to accommodate all recognized qualifications in South Africa – whether they have been obtained through formal education or through workplace training. Its task includes providing equivalence between different types of qualifications, and assuring their quality. The NQF has become understood more broadly as a means to achieve an integrated approach to education and training which recognizes the value of both.

South Africa spends almost 5.5% of GDP on education, one of the highest expenditure rates in the world.

Enrolments across the System

In 2005, there were 13 936 737 students in all sectors of the education system. Of these, 85% were in public schools and 2.3% in independent schools. Public higher education

institutions accounted for 5% of total enrolments, public FET colleges 2.7%, ABET centers 2%, ECD sites 2%, and special schools 0.6%. There were 34 162 educational institutions in South Africa, of which 26 592 were ordinary schools. There were 437 330 educators and lecturers in the education system. Policy is to include children with disabilities as much as possible in mainstream schools.

Early Childhood Development

Under apartheid, there was a rigid distinction between education and care. Child care was provided for in terms of the Child Care Act of 1983, which made provision for the registration of children's homes and places of care. According to the 1996 Interim Policy for Early Childhood, only 9–11% of all South African children from birth to 6 years had access to ECD facilities at the end of the apartheid period. One in three white infants and children received ECD services, compared with one in eight Indian and colored children and one in 16 African children. Twice as many urban children were receiving ECD services compared to their rural counterparts.

Current policy promotes an integrated vision of ECD and views it as the provision of physical, emotional, social, spiritual, and moral development for children between birth and 9 years. Provision is therefore a responsibility of various sectors, including a number of departments within the government (education, social development, and health) and the broader community. In the schooling system, a reception year (grade R) is currently being introduced. It will be part of an integrated 4-year foundation phase program (grades R, 1, 2, and 3) to be located in schools.

The introduction of grade R in schools has improved access to ECD for 5-year-old children. **Table 1** presents data on grade-R enrolment from 1999 to 2005.

In addition to grade-R classes in schools, there are many private providers which offer ECD for children from as young as 2 years, but their enrolments are currently unconfirmed. Although the number of both public and private ECD sites has been increasing, in May 2007

Table 1 Number of children in grade R

	Male	Female	Total
1999	77 718	78 574	156 292
2001	120 449	121 076	241 525
2003	157 532	157 855	315 387
2005	202 590	202 607	405 197

From Department of Education (2005). *Teachers for the Future: Meeting Teacher Shortages to Achieve Education for all*. Pretoria: Department of Education; Department of Education (2006). *Education Statistics in South Africa at a Glance in 2005*. Pretoria: Department of Education; and Department of Education (2006). *The National Policy Framework for Teacher Education and Development in South Africa*. Pretoria: Department of Education.

the Minister of Education identified the sub-sector as “one of our poor performance areas.”

Primary and Secondary Schooling

Compulsory schooling (also known as the general education band) is divided into three phases for curriculum purposes: foundation phase (grades 1–3), intermediate phase (grades 4–6), and senior phase (grades 7–9). The further-education band consists of grades 10–12. Grade 12 culminates in the senior certificate, commonly referred to as matric or matriculation. Most primary schools go from grade 1 to grade 7, while secondary schools normally encompass grade 8 to grade 12. The reason for this division, which breaks the intermediate phase between primary and secondary schools, is historical in that most schools were built before the new curriculum was introduced. There are no plans yet to change this state of affairs.

The South African Schools Act of 1996 made 9 years of education compulsory for all children between the ages of 7 and 15. Since then, enrolment in the schooling system has grown significantly, especially for the African population. Although schooling is still not universal, well over 90% of children of appropriate age are enrolled in the compulsory phase of the system.

Table 2 shows the gross enrolment ratio (GER) in public ordinary and independent schools by province in 1997, 2001, and 2003. The GER measures the number of students as a proportion of the total population of appropriate age. Whereas the table shows a GER of 111 nationally in 1997, this figure had declined to 94% in 2003. The decline is probably a result of new regulations, which have limited the number of times a child may repeat a grade to once in a 3-year phase; they have also prevented schools from enrolling children younger than 6 years of age. This

has resulted in a decrease in the enrolment of overage and underage learners in the system.

From time of the South African Schools Act, schools have been allowed to charge school fees if the majority of parents agree. It soon became clear that even schools in poor communities were charging fees under pressure from school principals and governing bodies who argued that they did not get enough state funding. This caused widespread distress in poor communities, and in 2006 government began to designate schools in poorer communities as no-fee schools. By 2009, 60% of schools will be so designated.

Adult Education and Training

In South Africa, basic education (i.e., up to the equivalent of grade 9) is a constitutional right. This includes adult basic education. In 2007, just over 10% of the population aged 20 and above had had no schooling; a decrease from 18% recorded in the 2001 census and 19% in 1996 census. Adult illiteracy in South Africa has a race and gender bias, as shown in **Table 3**.

There are a number of providers of ABET in South Africa, including various government departments, non-governmental organizations (NGOs), and employers.

In addition, Cabinet approved approximately ZAR6 billion for a mass literacy campaign to be undertaken from 2008. The project seeks to eradicate illiteracy by 2012, by reaching approximately 4.7 million people who are considered functionally illiterate. This is in addition to the various preexisting literacy programs.

Further Education and Training Colleges

FET colleges provide vocational education and training in six broad fields. These are:

Table 2 Gross enrolment ratio (GER) (percentage) in ordinary public and independent primary and secondary schools by province, 1997, 2001, and 2003

Province	1997			2001			2003

FET colleges offer programs at levels equivalent to the three highest grades of senior secondary school and beyond. While it is possible for students to proceed from FET colleges to higher education, this currently seldom happens. Efforts are underway to increase such mobility.

FET is an important sector, especially in terms of skills development. In South Africa, it has been linked to major skills-development initiatives such as the national skills strategy and the joint initiative for priority skills acquisition (JIPSA). A major program is under way to recapitalize the FET colleges. The aim is to ensure that these colleges have the necessary infrastructure, equipment, materials, administrative systems, teaching staff, and information technology for effective teaching.

In addition to the public FET colleges, education at this level is also made available by private providers, NGOs, community organizations, and employers. The public colleges were established by merging technical colleges, manpower and skills centers, and some former community colleges. There are 50 public FET colleges in South Africa, with more than 200 college campus sites and satellite sites. These enrolled 377 584 learners in 2005 and employed 6407 educators.

The private FET sector has grown rapidly in the post-1994 period. While government has been making efforts to register and regulate private FET colleges, there appears to be no certainty yet on the size of the private FET sector. However, some officials estimate that it is substantially larger than the public sector in the number of enrolments.

Table 4 Percentage of students by degree level, 2005

<i>Degree</i>	<i>% of students</i>
Undergraduate degrees (3 years)	59.8%
Professional undergraduate degrees (4 years)	22%
Postgraduate degrees below masters	8.4%
Masters and doctoral degrees	7.3%
Occasional courses (various levels)	2.6%

Compiled from information on the Department of Education website and the higher education management information system (HEMIS) for State-subsidized Universities and Technikons.

Higher Education

There are currently 22 public higher education institutions in South Africa – 11 universities, five universities of technology (formerly known as technikons), and six comprehensive universities (a combination of universities and technikons). This new institutional landscape emerged out of a restructuring process, which included a consolidation of the 36 higher education institutions that existed previously.

Enrolment in public higher education institutions stood at 741 380 in 2006. This represented an increase from the 270 874 recorded in 1985. The majority of students in public higher education institutions were enrolled for undergraduate degrees, as shown in **Table 4**.

Of the total number of students, 29% were registered in science, engineering and technology programs, 30% in business and commerce, 13% in education, and 28% in other humanities and social sciences. In terms of racial group, 61% of registered students were African, 25% were white, 7% were colored, and 7% were Indian. In 2005, 120 000 students completed their studies in higher education institutions, an increase from 77 000 earlier in 1998. The increase in higher education enrolments has been facilitated by the establishment of a national student financial aid scheme which provides assistance to poorer students, mainly in the form of loans which are repaid after the recipient has left university and found a job.

The racial profile of academic staff in higher education institutions has not changed as much as that of students. The proportion of white academic staff in permanent posts as a whole declined from 87% to 61% between 1993 and 2006, while black staff increased from 13% to 39% (with 25% being African).

Private higher education institutions are permitted in terms of the Higher Education Act of 1997, but are required to register with the department of education. The purpose of registration is to ensure that institutions offer an acceptable quality of education, that they have the capacity to deliver what they promise, and that students will receive qualifications aligned to the NQF. The

register of private higher education institutions in 2008 records 78 registered and eight provisionally registered. None of these currently qualify to call themselves universities. They range from fairly large corporate and overseas-based institutions, offering a limited range bachelor's and even master's degrees, to fairly small specialist colleges offering various courses including, *inter alia*, business studies, advertising, theology, media studies, information technology, and tourism.

Reliable data on enrolment, staffing, and output in the private higher education sector is not currently available, but they clearly cater for tens of thousands of students.

The Teaching Profession

There were 385 860 teachers in South Africa in 2006. Of these, 5% (19 407) were in independent schools. Of those in public institutions, 173 850 were in primary schools, 111 865 in secondary schools, and 53 988 in combined, intermediate, or middle schools. Others were in special schools (i.e., schools for the disabled), ECD, and ABET centers. Approximately 7% of teachers in the public school system are employed privately by school governing bodies, mainly in the more affluent areas where school fees provide the resources for this.

In 1994, 36% of teachers were considered underqualified or unqualified (the definition of qualified is 3 years of professional, postschool training). This figure declined to 18% in 2001, and stood at 8.3% in 2004. There are moves to raise the standard for qualified teachers by one additional year of professional training. **Table 5** shows teacher qualification by gender and race in 2004.

Notwithstanding the improved qualification profile of the teaching force, indications are that the majority of teachers have not yet been sufficiently equipped to meet the education needs of a growing democracy in a twenty-first-century global environment. A research report commissioned by the president's education initiative in 1999 concluded that the most critical challenge

for teacher education in South Africa was the limited conceptual knowledge of many teachers. This includes a poor grasp of their subjects as evidenced by a range of factual errors made in content and concepts during lessons. Similar concerns are expressed in the findings of other research.

The teaching profession faces a shortage of qualified educators, especially in the fields of mathematics and science. Estimates vary, but indications are that teacher training institutions are not producing sufficient teachers to meet the demands of the schooling system. This situation is further exacerbated by the impact of the HIV and AIDS pandemic. A recent study conducted for the education labor relations council estimated that 22% of educators in South Africa were living with HIV. The highest prevalent rates were among teachers aged 24–35. Although the attrition rate for teachers was between 5% and 5.5% (i.e., equivalent to 17 000–20 000 teachers in 2004), teacher-training institutions were producing at best 9000 graduates annually, of whom 3000 were already practicing teachers.

Major plans are underway to address these challenges, and to increase the number of people who choose teaching as a career. This includes bursary schemes, efforts to improve the quality of teacher education, and mitigate the impact of HIV and AIDS on teachers.

In order to maintain high levels of professionalism in the teaching profession, a South African council for educators was established by Act of Parliament in 2000. All educators must be registered with the council, which is responsible for ensuring the maintenance of professional ethics and values in the teaching profession.

Performance Monitoring and Evaluation

A number of performance monitoring and evaluation mechanisms have been put in place. The South African Qualifications Authority (SAQA) Act of 1995 provides for

Table 5 Teacher qualifications by gender and race, 2005

REQV ^a	Total (%)	Female (%)	Male (%)	African (%)	Colored (%)	Indian (%)	White (%)
14+	53	53	52	47	55	89	88
13	38	38	39	42	35	11	12
12	6	6	6	7	7	0	0
11	2	2	1	2	3	0	0
10	1	1	2	2	0	0	0
	100	100	100	100	100	100	100

^aRequired education qualification value (REQV) refers to the qualification level of teachers. Levels 10–16 refer to the number of postmatriculation years teachers have successfully completed to achieve their qualification. For example, a teacher at REQV 13 has completed the (school leaving) senior certificate plus 3 years of additional education.

From Department of Education (2006). *The National Policy Framework for Teacher Education and Development in South Africa*. Pretoria: Department of Education.

the establishment of education and training quality assurance bodies (ETQAs) across the various sectors of the education system. The main purpose of the ETQAs is to monitor and audit achievements in terms of national standards.

Two independent quality-assurance bodies have been established by statute. The first is Umalusi – the council for quality assurance in general and further education, which aims to enhance and assure education quality in public and private schools, further education institutions, and adult education providers. The second is the higher education quality committee (HEQC), a permanent committee of the council on higher education, which has a similar function in the higher education sector. In late 2007, the government took the decision to establish another similar body, the quality council for trades and occupations (QCTO), with responsibility for occupation-specific training programs in workplaces and institutions outside of registered universities and colleges.

Twenty-three sector education and training authorities (SETAs) have been established with responsibility for promotion and coordination of skills development within their respective economic sectors. This includes a quality-assurance role. They are accredited by SAQA to quality assure qualifications in their areas of primary focus. So, for example, the quality assurance of programs aligned to bricklaying or carpentry qualifications is delegated to the Construction SETA, which must ensure that all accredited training meets approved standards.

Within the system of school administration, the department of education has created the integrated quality management system (IQMS). This system serves four purposes – to identify the specific needs of educators, schools, and district offices with a view to supporting and developing them; to promote accountability; to monitor the overall effectiveness of institutions; and to evaluate educator performance. The IQMS uses three strategies, namely developmental appraisal, performance measurement, and whole school evaluation, all of which are aimed at enhancing and monitoring the performance of the education system as a whole.

There are also systemic evaluation studies which focus primarily on assessing the achievement of learners at the various transitional stages of the system – namely, grades 3, 6, and 9. The purpose of the systemic evaluations is to assess the effectiveness of the entire system and the extent to which the vision and goals of the education system are being achieved. Two systemic evaluations have been conducted to date (among grade-3 learners in 2003 and among grade-6 learners in 2004/2005). Both have given rise to major concerns regarding the teaching of literacy and numeracy in primary schools, as pupil performance has been unacceptably low. As a result, the department of education has developed special programs to tackle the problems identified.

Conclusion

Many structural changes have reshaped the way education is organized and managed in South Africa and have increased access to education at all levels. While the system will continue to expand, the focus for the next decade will be on quality improvement. The government has already put in place a number of initiatives in this regard, including various programs for quality assurance, increased emphasis on teaching literacy (both in primary schools and in adult classes), improving mathematics teaching, enhancing the relevance and quality of further-education colleges, improving the quantity and quality of teaching materials and educational equipment, upgrading the infrastructure of educational institutions, and improving both preservice and in-service teacher education. South African education remains very much a system in transition, and systemic reform will continue to dominate the educational agenda for many years to come.

Glossary

Autonomous communities – Each of the 17 regions forming Spain. They have their own parliament and government and hold wide responsibilities in several fields, education among them.

Bachillerato – Academic upper-secondary level, noncompulsory, composed of two grades (grade 11 and 12).

Basic education – Educational period aimed at preparing all citizens for adult life, composed of ten grades in two levels (primary and *Educación secundaria obligatoria* (ESO)), compulsory and free of charge.

Childhood education – Educational level for children from birth to 6 years, equivalent to pre-primary or preschool education in other systems.

Conference of Ministers of Education – Body formed by the Minister of Education of Spain and the regional ministers and having the function of discussing all national regulations and establishing ways for cooperation in the field of education.

Early school leaving – Proportion of young people from 18 to 24 years having finished compulsory schooling at most and not continuing further studies.

Educación secundaria obligatoria (ESO) – Comprehensive lower-secondary level composed of four grades (7–10).

High Inspectorate – Body which assures that educational regulation of Spanish autonomous regions does agree with national legislation and respects central-government responsibilities.

National Agency for Quality Evaluation and Accreditation (ANECA) – National institution for the evaluation of quality and accreditation of university studies and staff.

National Professional Qualifications Catalog – National repertoire including all qualifications identified in the labor market with the necessary competencies for a professional exercise.

Popular universities – Educational institutions for adults, usually promoted by municipalities, offering formal and nonformal programs and cultural and leisure activities.

School council – Decision making and controlling body at school level, assuring the participation of

teachers, parents, and students in school governance.

Universities of the experience – University extension programs for adults over 55 years without academic requisites.

General Background

Spain is situated southwest of Europe, having an area of 505 km², most of it in the Iberian Peninsula. Its population grew from 18 594 405 inhabitants in 1900 to 40 709 455 in 2001, reaching 45 million in 2008, due in part, to the important immigration received since the late 1990s. Of the current Spanish inhabitants 8.4% are of foreign origin, mostly from Latin America, Europe, and North Africa.

Spanish economy has been traditionally based on extensive agriculture, which employed more than half of the active population until 1940. From 1960 on there were important changes in all economic sectors, producing as a result, a very significant growth of employment in industry and services and a parallel decline in agriculture. In 2001, employment in agriculture represented 4.7% of the active population, compared to 30.7% in industry and 64.6% in services. So, Spain has evolved into a typical postindustrial economy. According to Organization for Economic Cooperation and Development (OECD) data, gross domestic product (GDP) per capita in equivalent USD was 26 018 in 2004.

In the last two decades, an increasing number of women have joined the workforce, producing as a side effect a growing demand of educational services for early childhood. As the trend is likely to continue in coming years, it will be of particular influence for the development of the education system.

Spain is a diverse country, by geography, ethnics, culture, and languages. Spanish, a language spread worldwide, is the official language of Spain, but there are also some regional languages, which are co-official in their own territories, like Catalanian, Basque, or Galician. The existence of different official languages creates an obligation to offer education in all of them according to different regional regulations.

Spain is a constitutional monarchy according to the 1978 Constitution, which was the result of a broad national agreement reached after the end of the authoritarian Franco's regime. The long history of wars and conflicts in the nineteenth and twentieth centuries was closed with

the transition to democracy – a process started in 1975 and ended with the approval of the new Constitution in 1978.

The Constitution acknowledges the diversity of Spain, setting the basis for what is usually known as a ‘State of Autonomies.’ According to this system, Spain is organized into 17 autonomous communities, with their own regional parliaments and governments. Even if Spain is not a proper federal state, the autonomous regions have wide responsibilities in some fields, education among them.

The building of the national education system started with the 1812 Constitution, which obliged all towns of the Monarchy to have primary schools. The liberal governments of the first half of the nineteenth century approved the seminal rules for the national system and in 1857 the first general law for education was passed, introducing compulsory education for all Spanish children from 6 to 9 years.

The development of the education system was very slow and timid. For a long time, schools were under the responsibility of the municipalities. The national Ministry of Public Instruction was created in 1900 and extended its responsibilities into the field of public education. Nevertheless, the conflicts of the first part of the twentieth century and the negative effects they had in education were evident until the last quarter of the century. As a significant example, universal education from 6 to 14 years was only accomplished in 1984–85 and from 6 to 16 years, 10 years later.

The backwardness of the educational development in Spain was overcome in the last three decades of the twentieth century. The 1970 Act (*Ley General de Educación*, LGE) was an important step forward, reinforced by the 1990 Act. Since the late 1970s, the Spanish education system has developed very quickly, even if current indicators are not yet as positive as wished. For example, in 2005, only 49% of the adult population (25–64 years) attained at least upper-secondary education and 28%, tertiary education. Among the young adults (25–34 years) those figures increased up to 64% and 40%, for upper-secondary and tertiary education, respectively, thereby indicating the progress made in this period.

Goals of the Education System

Since the 1970 Act, a great emphasis was put on extending the right to education for all. Therefore, an immediate objective of this time was the quantitative extension of the education system, finally succeeding in making education universal for compulsory ages by mid-1980s and enlarging the proportion of young people over 16 years at school.

The main goals of education were set in the 1978 Constitution, where the following principles are stated:

- Right to education: all citizens have the right to receive education according to their will and needs, and that right must be guaranteed by public authorities.

- Freedom of teaching: all citizens are allowed to create educational institutions, which may be supported by the public authorities under certain conditions; parents may express their preferences in choosing a school for their children; teachers have academic freedom.
- Development of all capacities and talents: education is aimed at developing all aspects of human personality respecting the principles of democratic life and fundamental rights.
- Participation: all sectors will participate in the general programming of educational provision; teachers, parents, and students will participate in the controlling bodies of public and publicly funded schools (school councils).
- Religious and moral freedom: parents are entitled to ask for an education for their children which respects their own religious and moral values.
- University autonomy: universities have the right to develop an autonomous life.

These goals have been developed by several laws: *Ley de Reforma Universitaria* (LRU, 1983); *Ley reguladora del Derecho a la Educación* (LODE, 1985); *Ley de Ordenación General del Sistema Educativo* (LOGSE, 1990); *Ley Orgánica de Universidades* (LOU, 2001 and 2007); *Ley Orgánica de las Cualificaciones y de la Formación Profesional* (LOCFP, 2002); *Ley Orgánica de Calidad de la Educación* (LOCE, 2002); and *Ley Orgánica de Educación* (LOE, 2006).

Once basic education (grades 1–10) was made universal, the main goal has been to offer a high-quality education and training for all. Offering a common education in the context of attention to diversity is one of the outstanding principles concerning basic education in the Spanish legislation.

A common education implies: (1) introducing a comprehensive system from grade 1 to 10, without streaming students and leading to a single diploma of lower-secondary education; (2) defining a national core curriculum, covering 55–65% of the study time and further developed by each autonomous region; and (3) defining a set of eight key competencies to be developed in basic schooling.

Attention to diversity implies: (1) paying attention to personal differences among students; (2) introducing curricular and organizational measures to address different educational needs; and (3) offering optional subjects or ways adapted to personal projects and expectations.

After the period of basic schooling the main aim is to offer equal opportunities, giving every citizen the possibility to continue their studies regardless of their socio-economic situation. This implies the existence of a solid national grants system. In close connection, another aim of post-compulsory education is to offer high-quality education and training for coping with new social and economic demands. It also implies stressing the aim of making lifelong learning real in a national context not always sensitive to it.

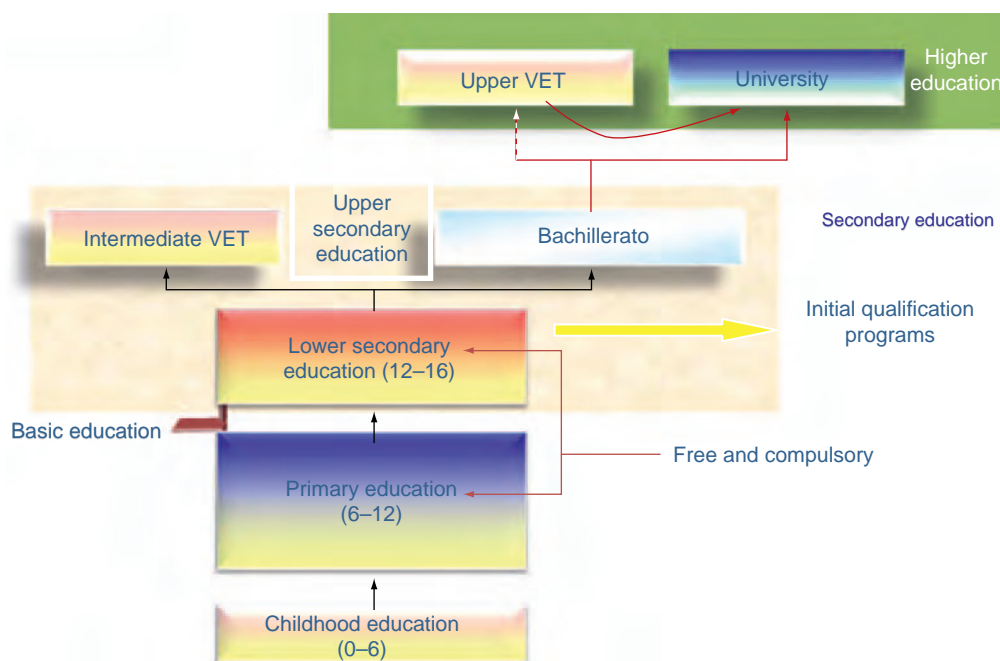

Figure 1 Structure of the formal education system in Spain.

Structure and Operation of the Education System

Figure 1 outlines the structure of the formal education system. Key statistics and indicators can be seen in **Tables 1** and **2**.

Childhood Education

Spanish law puts special emphasis on the educational purposes of childhood attention and care. This level is composed of two cycles: 0–3 and 3–6 years. Both are offered in children's schools, but the second one is also usually offered in mixed primary and children's schools. Contents and organization of the first cycle lies under the responsibility of the regions, but there is a national core curriculum for the second cycle.

In 2006, 96% of 3-year-olds were at school, schooling for 4- and 5-year-olds being almost universal. The rate of children from 3 to 6 years at school rose very quickly from the mid-1990s and now the main goal is enlarging educational provision for children younger than 3 years. A proportion of 16.6% children below 3 were at school in 2006. About 1 620 000 children attended this level in 2008.

Basic Education (Primary and Lower Secondary)

Basic education is compulsory and free of charge for all children from 6 to 16 years. It covers primary education and compulsory secondary education (*Educación*

Secundaria Obligatoria, ESO). The structure of these two levels (set in 1990 and revised in 2006) is the same for the entire country and there is a national core curriculum, even if autonomous regions are responsible for the organization and operation of schools.

Primary education consists of six grades, organized in three cycles. Normal school week covers 5 days with 5 h of tuition, usually with a break for lunch. Most of the primary teachers are nonspecialist, but some are specialized in physical education, music and arts, and foreign languages. Pupils not reaching the objectives and assessment criteria can repeat 1 year along the level, usually at the end of a cycle. In 2008, about 2 603 000 pupils attended this level. Pupils attend primary schools even in very small towns, with special provisions for rural areas (e.g., non-graded schools and associations of rural schools).

Compulsory secondary education consists of four grades. Grades 7–9 are common and grade 10 has a counseling purpose, introducing some optional subjects with different orientations. A normal school week covers 5 days with 6 h of tuition, with or without a break for lunch. Students not reaching the objectives and assessment criteria can repeat up to 2 years. Repetition is frequent in this level (25.2% of students had repeated at least once in 2003). Special programs are offered for students with difficulties. Schooling is possible in this level until 18 years. At the end of the level, students can get a lower-secondary diploma needed to continue studies at post-compulsory level. Secondary teachers are specialists in different subjects, but in some cases they may teach two or more subjects. In 2008, about 1 827 000 students attended this level.

Table 1 Students, teaching staff, and educational institutions, 2005–06

	<i>Institutions</i>	<i>Students</i>	<i>Teaching staff</i>

Madrid: Ministerio de Educación y Ciencia and Ministerio de Educación y Ciencia (2007c). *Las cifras de la educación en España. Estadísticas e indicadores. Edición 2008*. Madrid: Ministerio de Educación y Ciencia. (www.mepsyd.es) VET – vocational education and training.

Private schools offering these ten grades can receive public funds if they meet some legal requirements concerning admission policies, parents' participation, and no compulsory fees. They usually offer both levels in the same school, sometimes together with lower and upper levels. Public schools usually offer both levels in different institutions – primary schools and secondary institutes – even if some new models are being developed. A total of 23 678 institutions offered childhood, primary, and secondary education in 2008, of which 16 725 were public and 6953, private. In all, 33% of primary and lower-secondary students attended private schools in 2006 (less than 5% attended nonsubsidized ones).

Wherever possible, children with disabilities or special needs are integrated in normal schools and classrooms. Nevertheless, in 2008, a total of 29 555 children attended special schools.

Upper-Secondary Education

After basic education, students getting the lower-secondary diploma (in 2006 only about 70% of the age cohort) have two

Table 2 Selected educational indicators

<i>Indicator</i>	<i>Year</i>	<i>Data</i>
School expectancy at 6 years	2005–06	14.5 years

Edición 2008* Madrid: Ministerio de Educación y Ciencia and *Informe 2007: Objetivos educativos y Puntos de referencia 2010* (www.mepsyd.es); OECD: *Education at a Glance* (2007). OECD Indicators. Paris: OECD.

different ways to continue their studies: upper-secondary education (*Bachillerato*) or intermediate-vocational training.

Bachillerato consists of two grades, organized by specialties: science and technology, social sciences and humanities, and arts. Students take some common courses plus a number of optional subjects, depending on the specialty. The 2006 law gave it a more flexible structure, aimed at preparing students for the new model of higher education. Students passing all subjects get the *Bachillerato* diploma, allowing them to go on to higher education. Students wishing to go to university must also pass an external examination, adapted to the different specialties, whose marks serve as the basis for choosing university degrees and institutions. In 2008, a total of about 625 000 students were at this level, 25% of them in private schools.

Vocational Training

Vocational training is offered in Spain in different ways. The education system offers formal intermediate- and upper-vocational training programs, usually full time for young students. Labor administrations offer both nonformal training courses for employment and continuous training activities for employees in cooperation with

trade unions and business organizations. Different types of formal and nonformal vocational training courses are offered in integrated centers, recently created.

Formal intermediate-vocational training is offered for students holding the lower-secondary diploma or passing a specific entrance examination. It is a part of the post-compulsory secondary education and usually lasts 2 years. It includes education in a school and a training period in a workplace.

Formal upper-vocational training is offered for students holding the *Bachillerato* diploma or passing a specific entrance examination. It is a part of the higher education system and usually lasts 2 years. It also combines tuition in an educational institution and a practical training period.

Both formal and nonformal vocational training are adapted to a National Professional Qualifications Catalog, allowing the organization of modular courses and the addition of successive periods of training. The NQS is also the basis for the recognition and accreditation of competencies acquired through working and social experience.

Vocational training has been traditionally underdeveloped in Spain. This is why the number of vocational education and training (VET) students is lower than those involved in academic ways. In 2005, 45% of the young population got a *Bachillerato* diploma, but only 25% got an intermediate-VET certificate, and 32.7% got a university degree, but 17.2% got an upper-VET certificate. The proportion of students in VET programs is currently growing due to the excellent rates of employment of those professionals. In 2008, there were 235 110 students in intermediate-VET programs and 208 830 students in upper ones.

University Education

Spanish universities have been offering two types of basic official degrees: first-cycle degree (*Diplomado*), lasting 3 years, and second-cycle degree (*Licenciado*), lasting 4 or 5 years. Moreover, they offer PhD studies. Master has not been until very recently an official degree, but universities did offer a number of them with professional focus and content. From 2009 on, the implementation of the Bologna scheme will change significantly the structure of university studies, moving to a different system of three degrees: graduate, master, and PhD. It will mean an important change for Spanish universities, in convergence with European ones.

In 2008, Spain had 75 universities – 50 public and 25 private. Public ones are economically dependent on the autonomous regions, but have organizational and academic autonomy. Governing boards of public universities are composed by academic authorities, teaching and services staff, and students, and the rector is elected by university members. They are accountable for the quality of the studies they offer to a national or regional agency for evaluation and accreditation.

In 2008, a total of 1 381 749 students were following official, non-PhD studies at university level, 557 511 in first-cycle degrees and 824 238 in second-cycle degrees. Percentage of young population getting a university degree is currently higher than the OECD average.

Other Formal Studies

The Spanish education system also includes some specialized studies: arts and design, drama, music and dance, languages, and sports. They are offered, whether at basic, intermediate, or upper level, in public or private schools. In 2007, a total of 695 098 students followed these courses. The most important ones are languages (381 367 students) and music (259 132 students).

Provision of education for adult population is important in Spain. Providers of this kind of educational activities are very diverse, offering from formal, second-chance education to nonformal education, as well as cultural and leisure activities. Adults involved in formal education were 366 670 in 2007, 62.1% of them being women. A great majority (almost 80%) of persons involved in nonformal adult education are also women. Adult centers, popular universities, the so-called universities of the experience, and other similar initiatives are being boosted by different institutions and administrations.

Distance teaching is offered in Spain, both at university and non-university level and mixed programs are being developed by traditional institutions.

The Teaching Profession

In 2008, a total of 455 130 teachers worked in public schools and 168 844 in private ones. University teaching staff was of 107 905, all categories included.

Since 2009, pre-primary and primary teachers need to have a specific first-cycle university degree, to be transformed into a 4-year graduate degree, including practical training. Secondary and VET teachers need to have a *Licenciado* or a graduate degree in any disciplinary field, plus a 1-year master degree of pedagogical and didactic orientation.

Teachers in the public system have the status of civil servants, after passing a rigorous concourse. Private institutions select their teachers by themselves. Teaching is a feminized profession, women being about two-thirds of non-university teachers.

Between 1998 and 2008, the number of teachers has increased by 24.2%, while students have decreased by 4%. In consequence, the student-teacher ratio in 2005 was 14.3 in primary education, 13.4 in all secondary education, and 11.6 in all tertiary education, significantly lower than OECD averages (16.7, 14.2, and 15.8, respectively).

In the years to come an important change in the teaching force will be produced. It is expected to incorporate about 200 000 new teachers, due to retirement and the need to create new schools. Educational administrations are thus giving high priority to the development of the new model for teacher training. No shortage of teachers is expected.

Administrative and Supervisory Structure

Spanish regions have important responsibilities in the operation of the education system. Central government keeps some crucial responsibilities to assure the existence of one single system, although some significant regional differences do exist.

Central government is responsible for setting the conditions for delivering official diplomas and certificates, establishing the basic rules for the structure and organization of the education system, defining the national core curriculum for all educational levels, and assuring equal opportunities for all students in Spain. One important responsibility lies with the High Inspectorate, a body which assures that educational regulation of autonomous regions agrees with national legislation and respects central-government responsibilities.

Autonomous regions are responsible for all the organization and operation of schools and educational services. For instance, they have autonomy for setting the model of school organization, selecting and training teachers, developing school curricula and pedagogical methods and tools, assessing the quality of teaching, and approving subsidies for private schools. Some of these responsibilities should be developed under a basic national framework or regulation. According to this distribution of roles, regions have their own inspectorate services to supervise schools.

There are some national bodies aimed at fostering cooperation among central and regional administrations. The most important ones are the Conference of Ministers of Education and the General Conference for University Policy, but there are others like the General Council for Vocational Training or the Higher Council for Arts Education. Central and regional governments also develop some cooperation programs, jointly defined and financed, in fields of special interest for educational development and improvement.

Educational Finance

The quantitative expansion of the education system in Spain has implied a higher expenditure in all levels. In absolute terms, the educational public expenditure has more than doubled from 1997 (22 785.5 million €) to 2007 (45 617.6 million €). Nevertheless, the important economic growth in this period has resulted in a decrease in relative expenditure to GDP (4.52% in 1997, 4.36% in 2007). Private expenditure in education has also grown, but in a

smaller proportion, from 5528 million € in 1997 (1.10% of GDP) to 8810 million € in 2007 (0.84% of GDP).

As the number of students has decreased by almost 300 000 in this decade, expenditure per student has also increased. In 2004, expenditure per student in public institutions related to GDP per capita was higher than the European average for both primary and secondary education (22.6% and 30.3% in Spain, 20.9% and 26.5% in the 27 member states of the European Union (EU-27)), but lower for tertiary education (37.4% in Spain, 39.7% in EU-27).

As for different education levels, in 2005, 32.9% of public expenditure in education was devoted to pre-primary, primary, and special education; 30.6% to secondary education (including *Bachillerato* and VET); 19.6% to university; and 7.2% to other educational activities. The national grant system received 3.1% of public expenditure. Grants do receive big attention as one of the outstanding systems for assuring equal opportunities. Central government contributed in 2008 with 1482.26 million €.

The distribution of public expenditure in education reflects the distribution of responsibilities among central and regional governments. In 2005, only 4.6% of the total public expenditure came from the central government, while some of the biggest regions, like Andalusia or Catalonia, contributed with 16.7% or 14.7%.

Students pay no fee in public schools or in subsidized private ones. University studies are highly subsidized in public universities, students covering only about 20% of the real cost. Annual fees cost between 500 € and 800 € in public universities and can be higher than 6000 € in private ones.

Performance Monitoring, Evaluation, and Research

Performance monitoring is a shared responsibility between the Ministry of Education and the regions. Each of the 17 regions is responsible for the monitoring and evaluation of the education system and schools in its own territory. Some of them have created regional centers or institutes for evaluation and have developed school-evaluation programs. There is a national statistical plan which allows the collection of national data on education and training on a regular basis and the contribution to international statistics.

The Evaluation Institute, belonging to the Ministry of Education but governed in cooperation with the regions, sets the frame for the general evaluation of the education system and the collection of national indicators. National evaluation programs set in place in the 1990s are now developing toward a new model based on the assessment of key competencies.

The Evaluation Institute also coordinates Spanish participation in international evaluations. Most of the Spanish

regions are participating in PISA with comparable samples, allowing comparison with other countries and regions.

Universities and their teaching staff are evaluated by the National Agency for Quality Evaluation and Accreditation (ANECA) or the corresponding agencies created by some regions.

Educational research is mainly undertaken by universities, with the participation of some public or private centers or foundations. The Center for Educational Research and Documentation, belonging to the Ministry of Education, plays a significant role in fostering research and disseminating its outcomes.

Major Changes and Issues since the 1990s

In the last few years three outstanding issues have been raised: the impact of immigration on schools, the need to reduce school failure, and the necessary European convergence.

The important immigration movement since the late 1990s has provoked a number of effects in the education system and in schools. On the one hand, it has changed the trend of a decreasing student population, raising it again and demanding more resources. On the other hand, it has raised new challenges for school inclusion and multicultural education, in the perspective of future social cohesion. From 1997 to 2007 the number of students of foreign origin has multiplied 9 times, reaching a proportion of 8.4% in 2008 (in some regions is higher than 12%). For a country traditionally of emigrants, this means a big change.

School failure and early school leaving are two important problems in Spain. Almost 30% of students don't get the lower-education diploma in due time (some of them do it later through adult education), and in 2006, 29.9% of young people from 18 to 24 years had left school after lower secondary without continuing post-compulsory studies. Early school leaving implies that the Spanish population holding a post-compulsory diploma is lower than the OECD average. The Conference of Regional Ministers has taken some decisions and put in practice a set of cooperation programs to reduce these rates by 2010 and afterward.

The EU has defined a set of educational objectives for 2010. Spain is committed to them, but still below the benchmarks for early school leaving, upper-secondary education attainment, and skills level of the 15-year-old population. A national strategy has been adopted for improving those results thereby approaching the European objectives in the coming years.

Glossary

Free education policy and education subsidies –

Providing education free for all students from grade 1 to first degree (at university) level. Additionally, it is implementing a number of education subsidies programs such as: providing free textbooks for students in grades 1–11, free school uniforms for all students, mid-day meal for primary students and students in disadvantaged areas, public transport subsidies, scholarships and bursaries, special provisions for children with special educational needs (SEN) etc., and ensuring free education policy.

Generic skills – Examples are creativity, communication, problem solving, and decision-making.

Higher-order capital assets (HOCA) – Learning equipment, technology, books, reading materials, library, and computers.

Higher-order inputs – All materials, equipment and instruments used to improve the quality of education.

Higher-order learning spaces (HOLS) – Learning spaces for higher-order transferable skills of students: activity rooms, computer centers, libraries, laboratories, auditorium, gymnasium, and vocational/technical complex.

Higher-order processes (HOPs) – All services to improve students' higher-order skills.

Sri Lanka at a Glance

Background

Sri Lanka is an island in the Indian Ocean, situated to the south of the Indian subcontinent with a land area of 65 000 km², lying a few degrees north of the equator. It has a tropical climate. With nature's gifts of rain and fertile soil, the principal means of livelihood of the people from the dawn of history has been agriculture.

The proximity to the Indian subcontinent created close affinities between Sri Lanka and India. The original settlers were immigrants from India spreading principal religions (Buddhism and Hinduism) in the country. The ancient culture, language, art, architecture, technology, and social customs were of Indian origin. Political developments in

India, too, had their repercussions. The island was subjected to frequent invasion from South India.

However, Sri Lanka developed a culture of its own, with a distinct identity. Buddhism, which originated in India, remains the principal religion in Sri Lanka. Similarly, the language and other cultural aspects have developed their own distinguishing characteristics. The strategic location on the main sea routes resulted in travelers visiting this country in the past. The Greek and Arab merchant sailors described the island as Taprobane, Serendib, Ceilao, and finally Ceylon. The present name, Sri Lanka, is used with the promulgation of the Republican constitution in 1972. The European explorers conquered the island in the sixteenth century and ruled for four-and-a-half centuries.

Sri Lanka gained independence from the British in 1948. After independence, the country was governed by a democratically elected, Westminster type of government. In 1972, it became a Republic, and, in 1978, an executive presidency model was adopted. At the center, there is the Legislature, the Parliament, and the Executive President, but power is substantially devolved to elected provincial councils, and the local government system assures people's participation in managing their local affairs.

People, Society, and Economy

The population of Sri Lanka in 2006 was 19.5 million and the annual growth rate was 1.2%. It is estimated that by the year 2020, the population will stabilize at 22 million. The decline in the rate of population growth will enable the authorities to divert more resources for quality improvement in the education sector.

Sri Lanka is a multiethnic, multireligious society, with 74% Sinhalese, 12.6% Sri Lankan Tamils, 5.5% Indian Tamil, 7% Moors, and 0.8% others. It is predominantly an agricultural country; 72% of the population lives in rural areas, 21% in urban areas, and 6% in the plantation sector.

According to the United Nations Organization (UNO) Human Development Index (HDI), Sri Lanka enjoys a high quality of life in comparison to countries having a similar or a higher level of per capita income. Some of the components taken into account in the compilation of the HDI, such as literacy at 92%, life expectancy of 74 years, and infant mortality at 13 per 1000, are impressive achievements in social development. These are the results of the social welfare measures pursued by successive

governments after independence, to which free education has made a remarkable contribution.

On gender issues, the country has followed an enlightened policy. The right to vote, irrespective of any restrictions, granted with universal suffrage in 1931 and the provision of educational facilities for women have established gender equity in Sri Lankan society. Women outnumber men in enrolment in secondary education and in professions such as teaching.

Sri Lanka is a developing country with a per capita income of US\$ 1030 per person. The economy has been expanding at a real gross domestic product (GDP) growth rate of 7.4% in 2007. According to the World Bank, the economic progress of the country has been the result of market-oriented development policies that enable private sector participation in the industrial and service sectors.

Historical Evolution of Education

Ancient Period

The ancient period is divided into three eras: pre-eras of the arrival of Vijaya; period from Vijaya to King Devanampiyatissa; and period from the Arhanth Mahinda to year AD 1500. As the early history (543 BC to AD 1500) of Sri Lanka reveals, close affinity and cultural relationship with India from the Vedic times have had their impact on Sri Lanka. The introduction of Buddhism to Sri Lanka by Arhanth Mahinda during the reign of King Devanampiyatissa laid a firm foundation for Buddhist civilization that led to the establishment of Pirivenas – monastic institutions that were intended for the education of clergy but also enrolled lay students.

The Buddhist temples in villages became the institutions for primary education, while the Pirivena, where the Bhikkus received their teaching in the Dhamma, became the institution for secondary education, and the Mahavihara turned out to be the center for tertiary education. During the Polonnaruwa period (AD 1073–1215), more Pirivenas were started and the curriculum included Sinhala, other languages, and art. Nonformal education (NFE) provided an education of a high standard in subjects like handicraft, fine arts, and engineering.

Pre-independence Era

Portuguese period (AD 1505–1658)

When the Portuguese invaded Sri Lanka in 1505, the country was ruled by the kings of Kotte, Kandy, and Jaffna for about 150 years. The Portuguese introduced an education system in the provinces and started many schools, the main aim of which was conversion of local population to the Catholic religion. The curriculum consisted of Catholic religion, reading, writing, arithmetic, and languages, and the teachers were mostly Catholic priests.

Dutch period (AD 1658–1796)

The Dutch conquered the maritime provinces of Sri Lanka. The aims of their education system were to convert local people to Christianity and to suppress the spread of Catholic religion; teach reading and writing to new converts; and train local people to assist them in administration. Under the Dutch with their system of free compulsory education, large numbers of girls attended school. During the Portuguese and Dutch occupation, the state of affairs was not favorable for Buddhist education, which largely disappeared.

British period (1796–1948)

The British had their influence in the maritime provinces since 1796, before they conquered the Kandyan Kingdom. The period from 1805 to 1824 was known as the missionary period. Various Christian missionary societies started schools in all provinces of the country, and the large number of Christian schools led Buddhist, Hindu, and Muslim organizations to establish schools in premises donated by the community. As many different organizations were involved in education during this period, there was no proper supervision or administration. In 1841, a school commission was established but was replaced in 1869 by the Department of Public Instruction responsible for the supervision of schools. The curriculum was secularized, and several higher education colleges were established.

In 1931, Dr. C.W.W. Kannangara became the country's first minister of education. His efforts cleared the way for the establishment of a system that would ensure equal opportunities for all children. In 1942, a special committee recommended providing free education from the kindergarten to the university; using mother tongue as the medium of instruction in the primary schools; teaching English in all schools from standard III; and introducing a curriculum for the child which would develop its "head, heart, and hands."

Postindependence Era (1948–present)

Since independence, the government has given the highest priority to education. Within a period of less than 60 years, the number of schools increased by over 50%, the number of students increased by more than 300%, and the number of teachers increased by more than 400%. The literacy rate has grown correspondingly and by mid-1980s, over 90% of the population was literate.

The difficulties of educational planning in the past caused by the system of dual control and lack of coordination were finally removed by the nationalization of schools in 1960. The National Education Commission (NEC), in 1961, recommended a system of school zones, and the establishment of regional education departments and district education offices.

In 1970, there were 2.7 million students in 9928 government schools. Due to the increasing demand, government of

Sri Lanka (GoSL) faced the problem of improving the quality of education and the mismatch between education and the labor market. Therefore, GoSL implemented a range of reforms in 1972, and the 1981 White Paper on education recommended a new subject (life skills) in place of the two pre-vocational subjects; a dual system of evaluation; and a school cluster system. The 1997 education reforms covered major policy areas such as extending educational opportunities; improving the quality of education; developing practical and technical skills; education and training of teachers; and management and resource provision.

Present Education System and Administrative Structures

Sri Lanka faces all the political, economic, and social problems common to all developing countries. Despite these problems, experienced during the past 60 years since independence in 1948, the literacy rate increased to 91.6% in 2006. The government has accepted that education is a right of each citizen, and the Sri Lankan

constitution ensures everyone the right to universal and equal access to education at all levels.

This principle of providing equal opportunities has been a prominent characteristic of the policies of all governments that came to power since independence. Changing the medium of instruction from English to the mother tongue (Sinhala/Tamil) and the provision of financial aid to less-privileged students are other measures along regulations enforcing compulsory attendance for all children. However, Sri Lanka has not attained equity in education. Economic backwardness, climatic conditions in certain regions, the cultural traditions of certain ethnic groups, and problems in the employment and deployment of teachers in the school system have caused difficulties in achieving education-for-all targets.

Organizational Structure and Operation of the Education System

The education sector is organized into four major stages (see **Figure 1**). Sri Lanka has a 13-year schooling system that provides general education where age of admission to

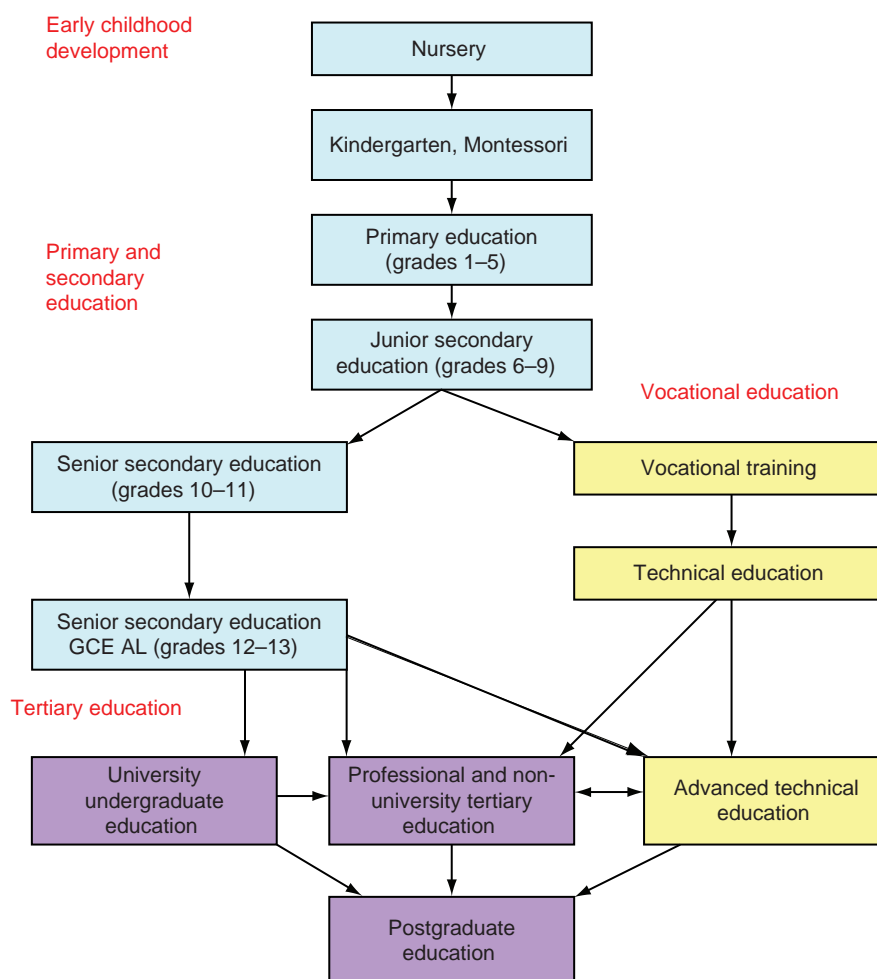

Figure 1 Organizational structure: National system of education in Sri Lanka.

grade 1 is 5 years. The education system is divided into three main levels as primary, secondary, and tertiary. The system has a compulsory phase from grades 1 to 9. The public sector accounts for 93% of schools and 95% of student enrolment.

Preschool/early childhood care

The earliest stage, catering to children aged 3–5, is that of early childhood development. It is not included in the formal public education system as virtually all preschools are in the private sector.

Primary and secondary education

The second stage includes formal primary, junior secondary, and senior secondary education. The primary school from grades 1–5 enrolls about 1.6 million students (50% are female). There are 3034 exclusively primary schools. Except for a few 1AB schools, all other schools offer primary education. The student–teacher ratio in primary grades is 1:26. The primary school curriculum is an activity-based curriculum and there is a reasonable level of equity in achievement levels. Annually, around 300 000 students enrol in grade 1. Net enrolment ratio has been 98% and the net completion ratio at grade 5 is 95%. The completion ratio at the end of compulsory basic education, at grade 9, is 83%.

The secondary school includes grades 6–13; the grades 6–11 form the junior secondary school; and grades 12–13 are the senior secondary school. The grades 6–13 have about 2.3 million students (50% are female). At the end of grade 11, students sit for the General Certificate of Education Ordinary Level (GCE OL) examination to qualify for senior secondary schooling.

The junior secondary school curriculum from grades 1–9 is oriented to provide all basic skills before one leaves school. Grades 10 and 11, leading to GCE OL examination, have core and optional subjects. The senior secondary school curriculum is streamlined to offer specializations in science, arts, and commerce streams. At the end of grade 13, a student sits for the General Certificate of Education (Advanced Level) (GCE AL) examination.

Tertiary education: Vocational and university education

The tertiary education system consists of the public and private universities, technical colleges, and tertiary-level institutions. Examination performance at GCE AL serves as the basis for admission to the public universities. Only about 34% who complete grade 13 get access to tertiary-level courses. There are 15 universities, including the Open University of Sri Lanka (OUSL) and the Sri Lanka Institute of Advanced Technological Education, 17 national colleges of education (NCoEs), 31 teacher training colleges (TTCs), and many other public and private sector higher education institutions (HEIs) providing tertiary education. Sri Lanka has a widely spread apprenticeship training system with three national-level institutes, five regional centers, and 52 vocational centers that absorb only about 10 000 trainees.

Public School System

In 2006, the total number of government schools was 9714, educating nearly 3.84 million students, and these schools are classified as:

- 1AB – classes up to grade 13, with GCE AL science, arts, and commerce streams;
- 1C – classes up to grade 13, and with GCE AL arts, and/or commerce streams;
- Type 2 – classes up to grade 11; and
- Type 3 – classes up to grade 5/8.

In addition, there is another category of government schools called national schools, mainly type 1AB. These schools are directly administered and financed by the Ministry of Education (MoE), whereas the administration and finance of the other schools are functions of the Provincial Education Authorities (PEAs). The total numbers of schools, teachers, and pupil enrolments in 2006 are given in **Table 1**.

Thirty-three percent of schools in the country are type 2, and 40% are type 3 schools. Types 2 and 3 schools are predominantly found in the rural areas where multi-grade teaching takes place with few teachers. Out of the

Table 1 Numbers of schools, teachers, and pupils by types of schools, 2006

<i>Type of school</i>	<i>No. of schools</i>	<i>No. of teachers</i>	<i>No. of pupils</i>	<i>Student–teacher Ratio (STR)</i>
National (1AB or 1C)	327	31 088	681 510	22
1AB	367	24 872	541 080	22
1C	1 820	62 474	1 220 456	20

Type 3	2 971	19 054	337 852	18
Total	9 714	204 645	3 837 548	19

From Ministry of Education (2006a). *School Census–2006*. Battaramulla: Ministry of Education.

9714 schools, 4906 are small schools (less than 200 students). Most of the types 1AB, 1C, and type 2 schools include primary sections. However, schools in remote areas lack human and physical resources. Further, some schools are situated in tea and rubber estates where 6.3% of the population live and the level of human poverty is the highest.

Semi- and Nongovernment Educational Institutions

In addition to the government schools, there are three other types of educational institutions: pirivenas, private schools, and international schools (see **Table 2**).

Pirivena education

Pirivenas are functioning under the legal provision of the Pirivena Act, No. 64 of 1979. State-funded Pirivenas provide formal education from the primary level to higher education for Buddhist monks and lay male students. They are run by the head of each institution under the supervision of MoE. Every Pirivena is entitled to a per-pupil subsidiary grant provided by the government. From 2006, that the government has provided capital grants to improve their infrastructure facilities and provided learning resources enabling them to increase access and participation in education.

Private schools

Private schools are run by the management board of each school, and charge pupils for education. They fall under three categories (see **Table 3**).

The first category does not receive any funds from the government, while the second and third categories receive free textbooks, free school uniforms, and funds for the purchase of learning materials. Additionally, the third category is provided with salaries for its academic staff.

The government does not provide capital budgets for any of these categories. They are directed to follow the national curriculum.

Special education schools

GoSL does not provide capital budget for these schools, but the salary bill for teachers is paid. In addition to the pupils in these schools, 58 626 pupils (1.5% of enrolled students) were on the rolls in the mainstream of normal schools.

International schools

International schools offer English-medium education and charge fees for tuition. These schools have been established as companies and are registered with the registrar of companies and the Board of Investment in Sri Lanka. Around 200 international schools with a student enrolment of about 70 000, which prepare students to sit overseas examinations, were functioning in the whole country in 2007. GoSL does not provide any financial assistance to these schools. In 1999, the government has made the legal provision for pupils in international schools to take public examinations, but the autonomy of these schools keeps them outside the purview of MoE.

Nonformal Education

NFE initiatives of the government could be traced to the early 1970s. Then, NFE offered vocational training courses in some schools after school hours, adult education programs, weekend English courses for adults, and literacy courses for children of school-going age who were out of schools. However, the NFE program did not expand, given the relatively small number of school dropouts (lower than other countries in the region).

One of the main focuses of the 1997 reforms was to provide education for all children of the school-going age. The intention was to provide facilities for every child in the age group of 5–14 years to obtain education in schools or through suitable NFE programs. Approximately 8500

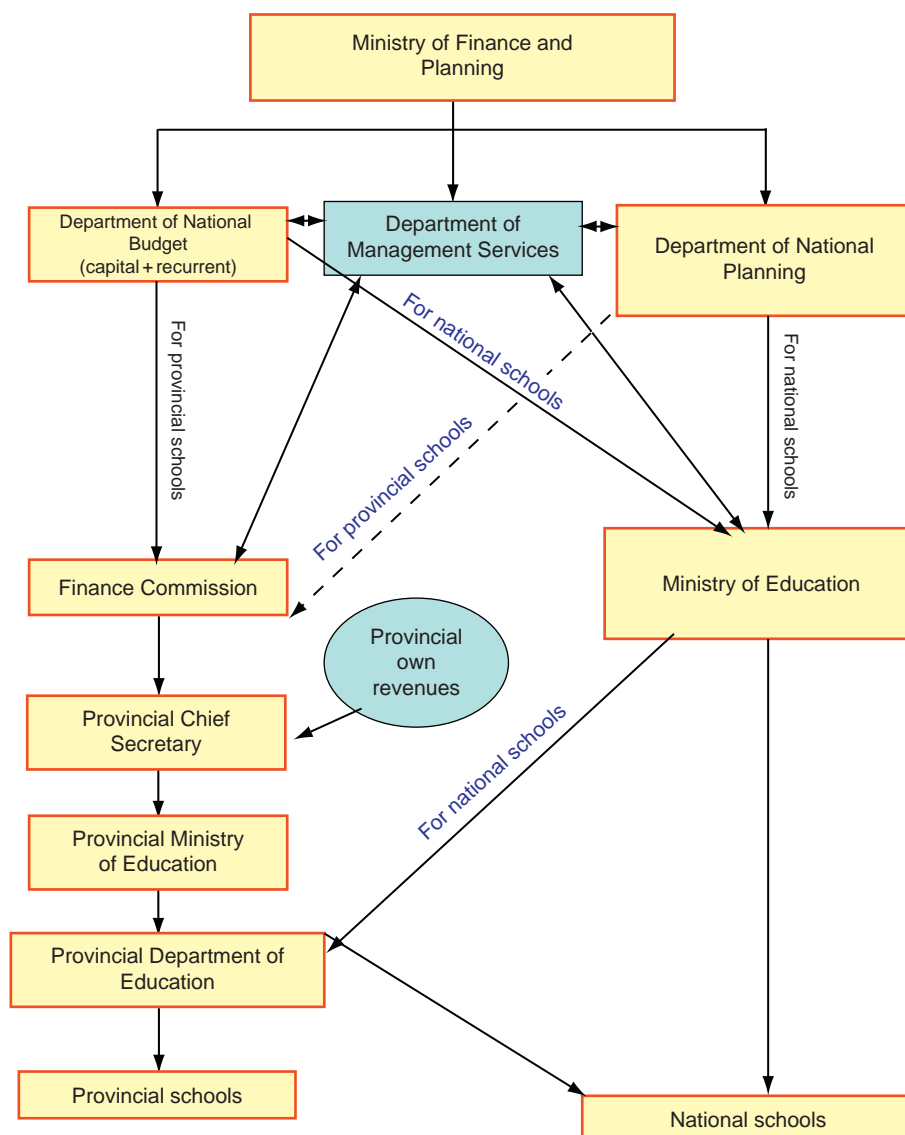

Figure 2 Education financial allocation flow in Sri Lanka, 2007.

school attendance committees were established for monitoring the attendance of children. NFE programs include career guidance programs; literacy classes; income generating programs; and programs for street children. Community learning centers also conduct NFE programs, and the NIE has introduced an open school to provide opportunities for persons who obtain basic literacy and pre-vocational training to receive recognized certificates.

Teacher Education

At present, 17 NCoEs provide preservice training to all teachers to be recruited. As many as 8692 students were trained as cadet teachers by 504 teacher educators. Continuing education will be provided through a network of 100 teacher centers (TCs). In addition, there are ten TTCs with the 1922 teacher trainees and 156 academic staff

operating in the system. Recently, teacher educators have promoted school-based teacher development programs.

Education Management and Administrative Structures

The governance framework for education is somewhat complex and combines elements of deconcentration, delegation, and devolution of functions and power. The central government is responsible for national education policy at all levels. However, PEAs play an important role in the administration of the school system.

Current policy thinking is to further devolve education management to empower frontline service providers (i.e., principals, section-heads, and teachers), and involve local communities. The present decentralized management

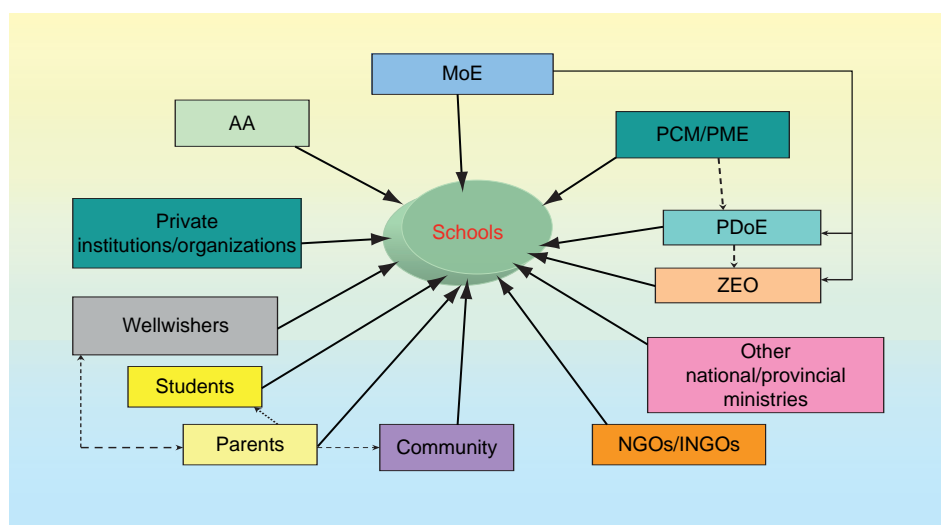

Figure 3 Pattern of provision of school financing and resources: Sri Lanka. Balasooriya, B. M. J. (2004). *An Evaluation of the Impact of School-Based Resource Management and Formula Funding of Schools on the Efficiency and Equity of Resource Allocation in Sri Lanka*. (Unpublished), London: Institute of Education, University of London.

structure consists of two interlinked layers: national and provincial (see **Figures 4 and 5**).

National level

The Ministry of Education is the national policymaking body with regard to general education in Sri Lanka. It is vested with legislative and executive authority to: formulate and ensure the implementation of national policy on education, and management of schools and education institutes; manage national schools, and control the functioning of private schools; planning, monitoring, evaluation, supervision, and research and development; donor coordination; review and coordinate policy implementation; set standards; provide incentives and subsidies; and exercise other powers relevant to education.

The National Education Commission, established in 1991, is mandated to identify and recommend policies in education for declaration by the President of Sri Lanka.

The National Institute of Education was established in 1986 and is responsible for providing leadership for the development of general education and curricula for general and teacher education, providing professional development, and spearheading change through research and innovation.

The Department of Examinations, established in 1968, conducts all types of national evaluations, and public and other local and foreign examinations.

The Department of Education Publications (DEP) was established as a separate budgetary entity for the production and publication of textbooks for use in schools. The main objective of the DEP when it was first established was the production and distribution of textbooks in national languages. This became necessary due to the

need for textbooks in Sinhala and Tamil following the change in the medium of instructions in the school system from English. Since 1980, DEP has published free textbooks for grades 1–11 in all schools for all subjects.

Provincial level

Provincial councils play an important role within the school system. The provincial education structure consists of: Provincial Ministry of Education (PME), Provincial Department of Education (PDoE), Zonal Education Offices (ZEO), Divisional Education Offices (DEO), and National and Provincial Schools. PEAs develop education plans and budgets, and deploy education administrators, principals, and teachers at the provincial level.

Provincial Ministry of Education is responsible for the implementation of national education policies, and formulation and implementation of provincial education policies in line with the national education policies.

Provincial Department of Education is responsible for the management and administration of all education programs of the province while being accountable and responsible for both the MoE and the PME.

Zonal Education Offices are responsible for administrative work of the schools and teachers in the zone, and the quality improvement of education. At present, 93 ZEOs are functioning island-wide.

Divisional Education Offices are responsible of supervision, monitoring of schools, and divisional administration. At present, 295 DEOs are functioning in the system.

National and provincial schools

Although the national schools are directly administered and financed by the MoE, many administrative powers are

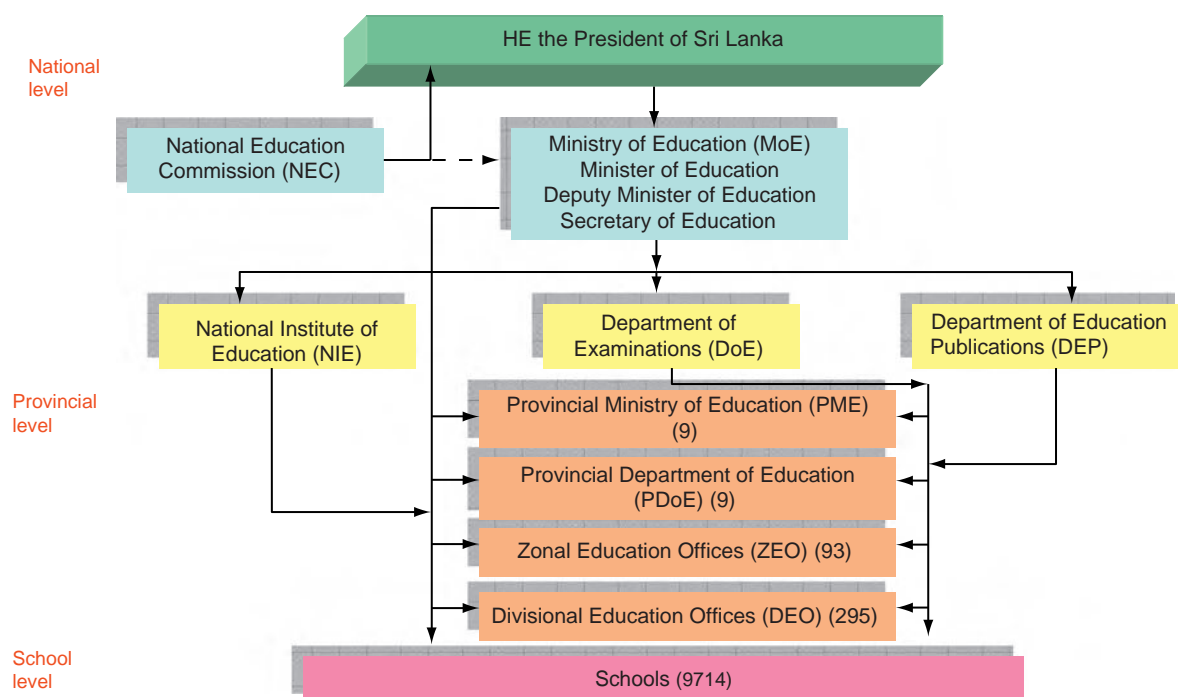

Figure 4 Administrative structure of education system: Sri Lanka.

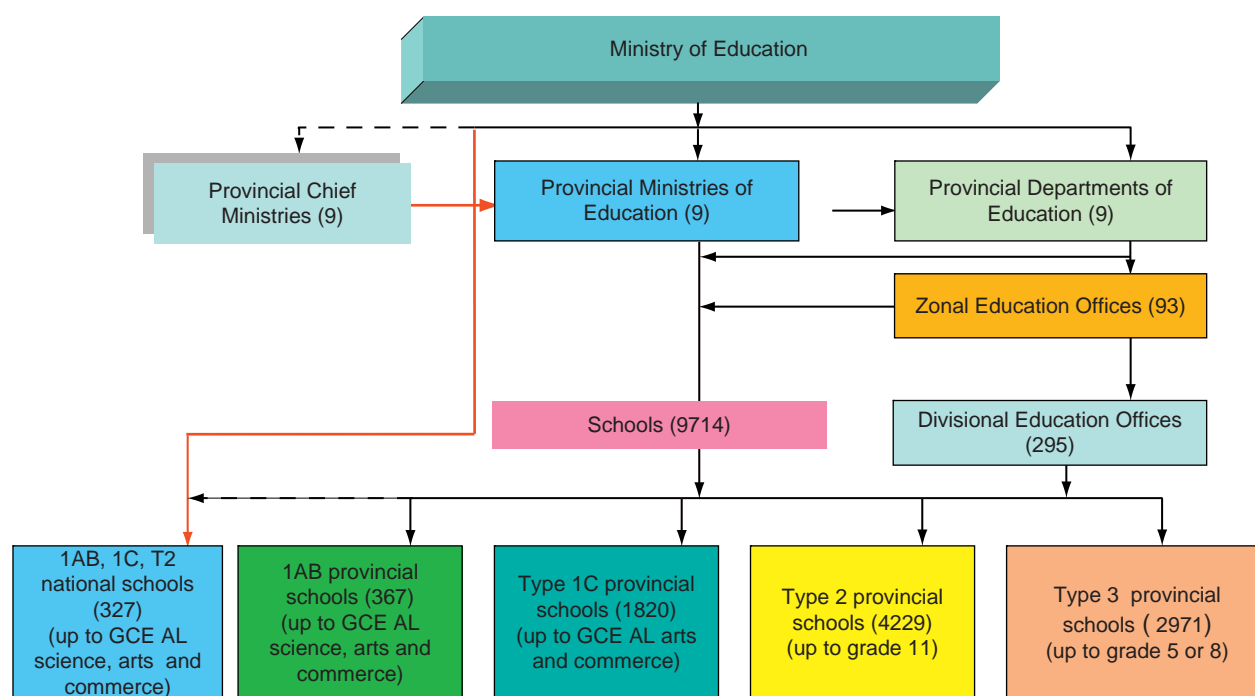

Figure 5 Implementation structure of education system: Sri Lanka.

being devolved to the provincial level. School principals act as heads of management and accounting officers for the schools and are accountable to the government through PEAs.

Education Financing

There are two main sources of expenditure on education: first, government expenditure and second, private/household

expenditure. Public expenditure on education for the period 2001–08 is shown in **Table 4**.

As **Table 4** shows, the government's expenditure on education has increased annually, although as a percentage of GDP, it has varied. In spite of its impressive achievements, by international standards Sri Lanka has spent small amounts on education. World Bank (1996) estimates the international average as 5% of GDP and 20% of total public expenditure. Asian averages range from 4% to 8% of GDP and 11–18% of total expenditure. Though the educational expenditure in Sri Lanka has increased with the expansion of the school system, it has remained between 6% and 10% of overall public spending since 1978. This may however, reflect both positive and negative features in the provision of education. First, it may reflect low unit costs and second, it may reflect less than desirable quality in the sector. Consequently, for further development of education financing, the Presidential Task Force on General Education in 1997 recommended that while current expenditure on education was around 2.5% of GDP, the allocation should be increased within the next few years to above 4.5% of GDP. PEAs have the main responsibility for providing education for children in schools, although there are many national schools located within the provinces which receive funding directly from the central government. The education sector has a complicated governance framework in relation to financial powers and authorities. The allocation flow for education in Sri Lanka is shown in **Figure 2**.

Assessing expenditure on primary and secondary education separately has been difficult due to the way that the school system has been organized. In 2000, recurrent public education expenditure was approximately 38% on primary education, 53% on secondary education and 9% on higher education.

Table 4 Expenditure on education, 2001–08

Year	Education expenditure SLRs m	Education exp. as a percentage of total government exp.	Education exp. as a percentage of GDP
2001	28 286.00	7.30	2.00
2002	33 575.38	9.20	2.40

Household Expenditure on Education

The second-largest financial contribution to education is made by individuals, but these expenditures have not been computed at school, zonal, provincial, or national levels. These expenditures fall into two types. The first is expenditure contributed directly to school budgets. The second is expenditure incurred by the students and parents that does not necessarily go to the school budget. Sri Lanka has achieved high levels of school participation with low costs compared to other Asian countries. This depends on the household contributions. In Sri Lanka, both poor and rich parents aspire to obtain good quality education for their children. Their contributions have not been computed, and little attention has been paid to them when decisions are taken on school financing or education policies in general.

Output-Oriented Education Budgetary Approach

Currently, the resource mechanism is moving from an input-oriented approach toward an output/outcome-oriented approach; the budgeting approach followed medium-term budgetary framework (MTBF) for resourcing schools and other educational agencies. Within the MTBF, performance-based budgeting (PBB) and formula-based funding mechanisms have been implemented, ensuring equity and efficiency of resource allocation.

School Revenues

The entire financial requirements of schools are born by the government. Schools have been given permission to collect a very small amount as school facilities fees and for the school development society. Most of the schools have their own alumni associations (AA). Although statistics are not available, the total amount of these funds is not negligible. School revenue flow is given in **Figure 3**.

New trends: Education Sector Development Framework and Program (ESDFP)

Sri Lanka now faces the challenges of expanding equitable access to basic and secondary education and establishing a high-quality education system. The country has passed regulations on compulsory education for all children aged 6–14 years, but participation in basic education is only 81%, and needs to be increased.

The achievement tests show substantial shortfalls in languages and mathematics. Therefore, the government set priority to improve learning achievement levels and

skills, to revise and update curriculum, develop teacher development framework (TDF) and modernize testing mechanisms. Issues remain in relation to equitable and efficient distribution of resources, service delivery, governance, and capacity building.

To face these challenges, the government developed ESDFP as a way forward. Initially, ESDFP was developed for the period of 2006–10 within the multiyear planning and is organized following four themes and result-based monitoring (see Table 5).

Theme 1: Increase Equitable Access to Basic and Secondary Education

The objectives of this theme are to ensure that all students complete the compulsory basic education cycle, and have access to secondary education (grades 10–13). Sri Lanka has performed well in attracting and retaining students in the primary cycle (grades 1–5), with a net enrolment rate of 96% and a net completion rate of 95%. With better implementation, Sri Lanka will be able to reduce the number of out-of-school children.

Theme 2: Improve the Quality of Basic and Secondary Education

The objectives are to improve the quality of basic and secondary education by supporting initiatives to improve learning outcomes and orient the education system to the world of work. Current policy objectives are to promote the development of generic skills; to reform the curriculum; to improve the content, quality, and delivery of textbooks and examinations; and to strengthen professional development.

Theme 3: Enhance the Economic Efficiency and Equity of Resource Allocation

Investment in education in the past has been based on a single year budgeting framework, with resources allocated to various expenditure heads on a historical basis. Several policy initiatives have been introduced to improve the efficiency and equity of resource allocation. The government has agreed to meet financial performance targets in actual spending from 2006 to 2010, and to allocate additional funds for accelerated learning campaigns in disadvantaged provinces/regions.

Theme 4: Strengthening Education Governance and Service Delivery

This theme is implemented under the three key outcomes set out in Table 5.

Result-Based Monitoring and Evaluation

ESDFP has a strong focus on the monitoring and evaluation of agreed results/outcomes. Outcome indicators and targets for 2006–10 have been developed for each outcome indicator. It is noteworthy that all external and internal assistance can be accommodated within this policy framework.

Tertiary Education

The tertiary education system is a three-tier system, which consists of: public universities, public advanced technical institutions, and private postsecondary institutions.

Public University Education

Beginning with a single university in 1942, the university system has now grown to 14 conventional universities and one open university operating under the primary legislative enactment, the Universities Act. The University Grants Commission (UGC) is responsible for planning and coordination of university education, allocation of public funds to HEIs, maintenance of academic standards, and regulation of admission to the HEIs. Present student enrolment of conventional universities is about 40 000 students and the OUSL has an enrolment of 20 000 students. This represents a participation rate in university education of less than 3% of the age cohort.

Postgraduate and Higher Education Institutions

Six postgraduate institutes and seven state-owned and 53 private HIEs are functioning. Up to 50 000 students are enrolled in these HIEs. They spend over SLRs 5.00 billion per annum.

Technical and Vocational Education

The technical education and vocational training (TEVT) sector is currently made up of an extensive system of public, private, and NGO sector training providers. Public sector TEVT providers used to function under different ministries up to the mid-1990s.

A considerable number of Sri Lankan students study abroad. The annual outflow of students is approximately 1000 and annual foreign exchange outflow is SLRs 2 billion.

Conclusion

The historical initiatives show that planned interventions are not new to the education system. However, some interventions had only partial success. The Sri Lankan

Table 5 Main education development programs and outcome indicators (ESDFP)

<i>Theme</i>	<i>Key operation (KO)</i>	<i>Project/key activities</i>	<i>Outcome indicator</i>
Increasing equitable access to basic and secondary education.	KO-1: Provide equal educational opportunities ensuring free education policy.	-Mid-day meal program. -Free textbooks and school uniforms. -Public transport subsidies. -Grade 5 scholarship program.	Number and percentage of children aged 6–14 years enrolled in formal schooling, special education, and NFE programs.
	KO-2: Expanding the network of secondary schools to relax constraints on geographically equitable access to good quality secondary education.	-Isuru colleges. -Model primary school development project. -Project on development of selected primary and secondary schools in urban areas.	
	KO-3: Development of special education programs for children with SEN.	-Special education programs. -Enrol out-of-school children.	
	KO4: Development of NFE programs for out-of-school adolescents.	-NFE programs. -Implementation of compulsory education act	
Improving quality of basic and secondary education.	KO-5: Curriculum reforms at primary and secondary levels and facilitate curriculum implementation.	-Curriculum reforms and implementation. -Provision of essential and HOCA, and inputs. -Provision of financial allocation for HOP.	Learning competencies over the basic and secondary education cycles clearly specified and communicated to schools.
	KO-6: Establishment of a TDF, which would include school-based/on-site teacher development systems.	-Acquisition of basic and HOLS. -School-based/on-site TDF.	
	KO-7: Examination reform to promote acquisition of higher-order transferable skills.	-Capacity building of teacher educators.	Schools staffed with trained and certified teachers, and supported by a high-quality teacher development system.
		-Establish item bank.	
		-Develop examination guidelines.	
	KO-8: Production and timely delivery of textbooks.	-Research and development. -Implement HRD programs.	Examination item bank, guidelines specified and communicated to schools and stakeholders.
		-Improve quality and content of textbooks.	
		-Develop timely delivery mechanism of textbooks.	
	KO-9: Promoting values, ethics, civic consciousness, and social cohesion in schools.	-Maintain and publish standards of textbooks.	Quantity, timeliness of delivery and quality of textbooks available to children.
		-Peace education and social harmony.	
	KO-10: Forging synergy between curriculum reforms, school-based TDF, and examination reform.	-Establish mechanism to improve forging synergy between NIE, Teacher Education Section, DoE, and DEP.	

Continued

Table 5 Continued

<i>Theme</i>	<i>Key operation (KO)</i>	<i>Project/key activities</i>	<i>Outcome indicator</i>
Enhancing economic efficiency and equity of resource allocation.	KO-11: Development of an over-arching education sector development plan.	-Develop/revise medium-term education sector development plans.	
	KO-12: Establishment of MTBF.	-Strengthen national- and provincial-level planning capacities and EMIS. -Establishment of MTBF.	Recurrent education budget prioritized to support HOP and inputs. Capital education budget prioritized to support the development of HOLS and HOCA. Resource allocated for replacement of the education capital stocks, on the basis of funding formulae.
Strengthening education governance and service delivery.	KO-13: Establishment of PEQETS.	-Establishment of PEQETS.	
	KO-14: Program for school improvements (PSI).	-Awareness programs and principal training programs.	PSI pilot tested and evaluated, and, if successful, established countrywide after incorporating lesson from the pilot program.
	KO-15: Human resource development strategy for the education system. KO-16: Organizational analysis and capacity building.	-Develop plan and the policy on HRD. -Organizational review. -Revise organizational structure.	A long-term HRD plan produced and which forms the basis for staff development in the MoE, and among the PEAs. Organizational capacity review of the MoE, provincial, zonal and divisional education authorities conducted and organizational activities completed satisfactorily.
Results-based monitoring and evaluation.	KO-17: Results monitoring and evaluation.	-Implement result-based monitoring mechanism. -Policy analysis, research, surveys, and studies.	

From Ministry of Education (2006b). *Education Sector Development Framework and Programme (2006–2010): Policies and Expected Results*. Battaramulla: Ministry of Education. and Ministry of Education (2007). *Education Sector Development Framework and Programme*. Atul-Kotte: Graphics Systems.

education system has achieved success in providing wide-spread access to formal education enabling the country to attain a high level of human development relative to a low-income economy. Up to the early 1990s, Sri Lanka enjoyed the highest basic social development outcomes relative to per capita income among virtually all developing countries. This achievement was the result of strategic policy decisions over several successive governments to invest resources in education, health, and other social services. Sri Lankan policymakers who designed the basic framework of the education system in the 1930s and 1940s were far ahead of their time in perceiving human capital as a promising investment.

Currently, a number of policy initiatives have taken place to improve learning outcomes of students in line with the education quality development principles. It should be noted that the focus of present ESDFP is outcome oriented, and the reform program follows medium/long-term planning and budgeting horizons.

General Background

Suriname is situated in the north-east coast of South America, just north of the Amazon Delta. Its borders are the Atlantic Ocean in the north, Guyana in the west, French Guyana in the east, and Brazil on the south. The size of Suriname is approximately 163,820 km² and almost 90% of Suriname's surface is covered by tropical rainforest. The capital of Suriname is Paramaribo. This is the largest city in Suriname and is also the major import/export port as well as the major economic center. It is located on the west bank of the Suriname River and has about 250 000 inhabitants. The city is famous for its historical wooden architecture. The historical inner city has been placed on the United Nations Educational Scientific and Cultural Organization (UNESCO) World Heritage List as of July 2002.

The surface of Suriname is mainly covered by dense tropical rainforests, and you could find mainly lowland and marshes in the coastal area. The average temperature is 30°C and the humidity is approximately 90%. The annual average rainfall is above 2000 mm, and the south-west district has an average rainfall of 3000 mm annually.

The multi-ethnic population with their heartwarming hospitality is a token of the diversity of cultural traditions that exist side by side in harmony. The population is formed by several ethnic groups including Amerindians, Creoles, Maroons, East Indians, Javanese, Chinese, etc. Dutch is the official language as Suriname was a former colony of the Netherlands. The common spoken language is Sranan Tongo (*lingua franca*). Most of the people in Suriname can speak English as well.

Suriname has many natural resources that have to be developed and an enormous, particularly unexploited rainforest with many attractions for ecotourism. The world is nowadays discovering Suriname as an ecotourism destination, as well as a cruise-tourism destination. Suriname has many natural resources such as aluminum, gold, crude oil, etc. Most of the gold-mining projects in Suriname are outsourced to Canadian companies. Recently, more and more Chinese companies are investing in the wood industry of Suriname as well. The major countries to which natural resources are exported to are USA and the Netherlands. Approximately 18% of the population of Suriname is in the farming industry. Farmlands are located in the coastal area and in the district of Nickerie (one of the 10 districts in the country). The major farm products include rice, coconut, banana, tropical fruits, flowers, etc. Apart from this, there is also a huge market for seafood resources from

Suriname, including shark fins, fish maws, and shrimps. Most of them are exported to Hong Kong and China where these are very popular. One could also discover a lot of species that are only found in the Amazon River region. There are also fish and shrimp farms.

Goals of the Education System

In the twenty-first century, there has been a broad agreement about the basic goals of the education system and the responsibilities of government. These are generally set out in legislation and are supplemented by more detailed policy documents. In accordance with the Constitution and the Ministry of Education and Community Development (MOECD) policy document, the following mission has been formulated:

to create and maintain conditions, facilities and means of formal and informal education and community development for the benefit of every citizen and resident of Suriname for the acquisition of knowledge, skills, standards and values aimed at participating efficiently in our democratic society and the modern world, and participating freely in the multi-cultural life with a strongly developed environment awareness and participating optimally in socio-economic life of our country (Policy document 2000–05, MOECD).

The mission is based on the principles of quality, equality and equity, continuity, diversity, and also focuses on actors, in order to accomplish its objectives. The objectives at the macro-level have been set out as follows:

- a more effective and efficient educational system;
- a just educational system offering equal opportunities to all;
- an internationally competitive working population; and
- an educational system offering services that meet the quality standards set.

The government aims to create a seamless, high-quality, world-class education system in Suriname which will contribute to a highly skilled, talented, and knowledgeable workforce and the development of a people characterized by excellence in innovation. It is within this context that the MOECD is working diligently, along with other key stakeholders, in restructuring and developing the educational system in Suriname.

The national educational plan builds on much prior work that has been carried out in Suriname as well as in

different international for a in which Suriname has been involved. So, in addition to the national education plan benefiting from the Suriname documents referred to above, it has also benefited from international educational strategies such as those put forward in the Educational for All (EFA) campaign and the Caribbean Task Force which emerged from the Caribbean Development Strategy and is planned till the year 2020. Five strategies are outlined in the national education plan:

1. reducing the knowledge gap between and within countries;
2. turning the school and the classroom into the focus of the educational system;
3. undoing inequalities in the education system;
4. improving educational finance and management; and
5. strengthening regional cooperation.

The ministry has developed this national educational plan for the period 2005–10 which identifies several strategic priorities: focus on schools, change/reform the ministry, and involve the community. This plan establishes the framework within which educational goal setting, policy development, strategic planning, research, program development and implementation, establishment and management of quality standards, and monitoring and evaluation are conducted by the ministry's central administration.

The Aims and Purposes of Education at Each Level

The MOECD is in the stage of transforming the basic education system for 4–15-year-old children in the basic education improvement project (BEIP). The goal of the project is to contribute to the development of human capital in Suriname and its objective is the improvement of the quality and internal efficiency of basic education by means of updating the educational contents and processes, providing inputs to schools, and supporting institutional reforms to strengthen the MOECD. Therefore early childhood development (ECD) is combined with preschooling and primary junior secondary schooling into a new 11-year basic education cycle model. The underlying goals of early childhood care and education are to provide young children with opportunities to succeed in all areas of development utilizing the constructivist learning theory. Primary education serves to ensure the transmission of culture and values, deepen cognitive and social development, and prepare students with literacy and numeracy skills to successfully pursue a quality secondary-level program.

The core objective is to improve the quality and internal efficiency of basic education by introducing (1) updated curricula and educational processes, (2) the provision of inputs for schools, and (3) the establishment of several institutional amendments aimed at strengthening the

MOECD and hence build management capacity at the school level in Suriname. The BEIP includes four key components, with some components comprising several major subcomponents. They can be summarized as follows:

- support the establishment of a revised basic educational cycle and quality improvement;
- renovation of schools and MOECD infrastructure;
- strengthening of management capacities at school level; and
- modernization and strengthening of MOECD and the school system.

Structure and Operation of the Education System

General

The MOECD provides the general-education system for children from age 4 years and older. Children are legally bound to participate in education up to the age of 15 years. The Suriname's educational system includes (pre)primary, junior secondary, senior secondary, and tertiary schooling. Schooling for young children (ages 4 and 5) is integrated with primary education, and is optimal until age 6. Roughly half (48%) of all schools in the country are operated by religious bodies that are mostly financed and regulated by the MOECD; also, they follow the same national curriculum as those in the public schools (51%) and other private education (1%). The education system uses tracking based on pupil performance, which results in a primary school-leaver's certificate based on the sixth-grade final exam. For students who pass this exam, their entry into one of the six streams of junior secondary education is granted, based on the results.

Suriname's (pre)primary schools have relatively high enrolment rates of 90%, with approximately 90 000 children enrolled in 320 (pre)primary schools. Approximately 35% of the schools are located in the capital city Paramaribo and 55% are situated in surrounding (semirural) districts and 10% are found in the interior.

The ministry provides four levels of education: pre-primary, primary, secondary, and tertiary levels of education. All education is included within these four levels.

Preprimary and Primary Education

Nursery education is intended to offer preschool children of ages 4 and 5, basic education and teach them basic knowledge and basic skills. This is necessary with a view to their further development and to prepare them for primary education (GLO). Except for a few private schools, all nursery schools are accommodated at GLO-schools. Although most preschoolers in the age group 4–5 years go to school, compulsory attendance does not apply to this

group and there is no law on nursery education. This will be changed in the new law on the 11-year basis education law. The compulsory education age will be changed from 7–12 years to 4–15 years. Suriname is now in the stage of implementing the integral ECD approach (age 0–8) with special attention being paid to early childhood stimulation.

Children must have reached the age of 6 prior to 1 January of each calendar year in order to be admitted to primary education. Primary education is characterized by a very high degree of inefficiency. The percentage of repeaters is approximately 25% and also the drop-out percentage is rather high (8%). Only 50% of the pupils who start school, leave with a certificate.

The causes of this degree of inefficiency may be attributed to, among other things, the shortage of educational tools, obsolete curricula, deficient refresher and supplementary training of teachers, and high percentage of teacher absenteeism. At the end of the sixth year, pupils take the national primary test. On the basis of the test results and the school marks for the sixth year, pupils are admitted to one of the various types of junior secondary education (VOJ). At the moment, no diagnostic test or formative tests are taken prior to enrolling in secondary education. The interest and the capacity of the pupils should be and will be taken into account in the new 11-year basic cycle education program.

Education in the Interior

Education in the interior demands special attention. The development of the educational sector in the interior has always been hindered by the fact that the village communities are scattered over large geographical distances and moreover, are often difficult to reach and are accessible only by dugout or airplane. The percentage of repeaters and drop-outs in the interior is about 50%. Due to their isolated conditions, education in the interior is confronted with some specific problems: shortage of qualified teachers, expensive transport for teachers, deficient physical infrastructure, shortage of educational tools and adjusted curricula, insufficient guidance and inspection from city, and language problems. Many qualified teachers do not wish to work in the interior because of the geographic isolation, the lack of possibilities for further study, and the incidence of malaria disease.

Special Education

Special education targets children with a handicap and special educational needs. This type of education is provided in various schools and institutions at primary-education levels. This type of education is strongly differentiated according to the type of handicap and is intended for children with: visual, auditory, communication, physical, and/or mental

handicap; serious behavioral disturbance or psychiatric problems; and learning and behavior difficulties.

At primary level (GLO), dependent on the nature and intensity of the handicap, this type of education is provided in/at several school: classes for special education at primary schools and schools for children with learning difficulties, multiple disabilities, motor disabilities, visual and auditory disability.

Over 1800 pupils are involved in some form of special education. Almost all schools and institutes for special education fall under the management of private foundations and institutions, while the teachers are subsidized by the government. A few institutes provide secondary education.

Special education is characterized by numerous problems. Some of these are: the absence of adapting the international development (Salamanca Declaration, 1994), the lack of implementing new instruments (diagnostic systems, assessment aid, research centers), insufficiently qualified teachers and assistants, and insufficient opportunities to move back to regular education.

MOECD needs to develop a guiding philosophy on inclusive education which will address the provision of support and services to all learners, regardless of their physical, intellectual, social, or emotional conditions, and regardless of the ethnic group, religion, socioeconomic status, or gender. All children have a right to become all they are capable of becoming. The government successfully achieved universal primary-education capacity since the mid-1970s. The ministry is in the starting process of developing a policy on inclusive education which will address the provision of support and services to all learners regardless of their physical, intellectual, social or emotional conditions.

Junior Secondary Education

There are two levels of secondary education: junior secondary (VOJ) and senior secondary education (VOS). The junior secondary education consists of several streams: junior secondary general education (MULO, 4 years), junior vocation-oriented education (LBGO, 4 years), junior technical education (LTO, 4 years), junior domestic science and technical education (LHNO, 3–4 years), elementary technical education (ETS, 3 years), elementary vocational education (EBO, 3 years), and advanced special education (VSO, variable duration) (See **Figures 1 and 2**).

Pupils (12 years) are admitted to the different types of schools mainly on the basis of their primary-education test results, as well as a certain priority of performance and prestige. In MULO especially, there is a greater demand in view of the possibilities it gives to move up to various forms of senior secondary education. Of the pupils who participated in the primary education test in the past 10 years, 46.9% was referred to MULO, 30.3% to LTO, 14.4% to
