Education externalities are the public benefits of education that spillover to benefit others in the society, including others in future generations. External benefits are distinguished from private market benefits to earnings and from the private nonmarket benefits beyond earnings such as those to own health, longevity, and the quality of life. Education externalities can be either positive or negative. But with a few exceptions, the evidence is that they are overwhelmingly positive.

The external benefits of education include education's direct benefits to the development of civic institutions that contribute slowly over long periods of time to the rule of law, democracy, human rights, and political stability. Externalities also include direct benefits to longevity, reduced poverty, lower crime rates, lower public welfare and prison costs, environmental sustainability, contributions to happiness and social capital, and effects from new ideas and adaptation of the results of research.

External benefits of education also include indirect effects of education that are over and above these direct benefits. Indirect effects operate through other variables and feed back over time to increase the private market and nonmarket benefits. Examples include the contribution of education to better governance, political stability, and trade that then indirectly increases growth. Indirect effects aid productivity and set the stage for new rounds of growth in the future, benefiting others and future generations. The reverse side of the coin is that earnings and well-being today are larger due to external social benefits of education from prior generations. The analysis of the dynamic process involved provides a basis for their measurement. External social benefits today continue to set the stage for growth within families and within nations.

The social benefits of education are normally defined to include the total benefits of education, including the external benefits. Therefore, private market and private nonmarket benefits, which are part of this total, must be identified so that they can be distinguished from the externalities. That is, to arrive at the total value of the external social benefits the value of each must be estimated, including the indirect effects!

In what follows, each of these concepts will be further explained as will the method of estimating their value. This is followed by a review of the empirical evidence for each, and estimates of their monetary value. The method of valuing the indirect effects will be explained, followed by considering those studies that have sought to measure

the value of aggregate education externalities without identifying each.

Distinguishing Private Market, Private Nonmarket, and Social Benefits

The external social benefits of education are not the same as nonmarket benefits. Some nonmarket benefits are private benefits, such as better own health, and some public benefits raise market earnings, such as political stability. These concepts and the methods of measuring each need to be distinguished.

The Market Benefits of Education

The market benefits of education are the additions to earnings, or in the aggregate the additions to per capita economic growth, that are due to education. These are increments to earnings above the amount earned by those with less education, measured either by a Mincer earnings function or by the full method that computes a pure internal rate of return (see McMahon, 1991). Increments to aggregate per capita growth are measured using a growth equation based recently on Lucas' (1988: 18) endogenous growth theory. His production function, including investment in human and physical capital, is normally augmented to include trade, the rule of law or political stability, life expectancy, and shocks. The direct market benefits of education that this reveals are illustrated in **Figure 1**, panel A-1. The indirect effects in panel B-1 result from feedback effects as education contributes through trade openness, political stability, and longevity (see McMahon, 2009: ch. 3 and Appendix D). Difference equations that incorporate lagged effects reveal these feedback effects on per capita growth over time.

The Private Nonmarket Benefits of Education

The private nonmarket benefits of education are private benefits to the student and his or her family as shown in panel A-2. (The relevant decision-making unit is regarded here to be the household. Intrafamily benefits to children, therefore, are private benefits. When individual pupils are regarded as independent decision-making units, as in Haveman and Wolfe (1984), benefits to children are externalities and increase the size of the externalities

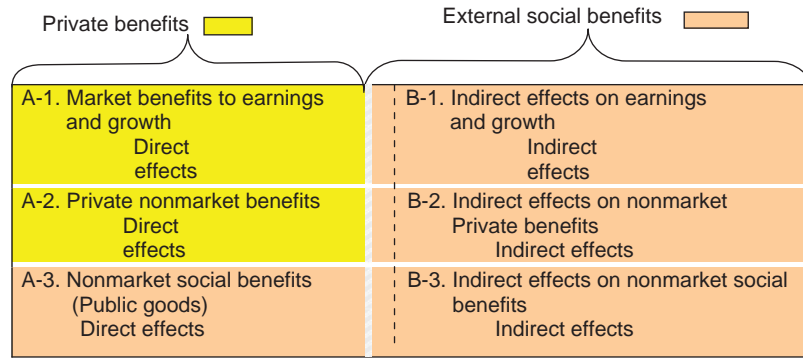

Figure 1 Total benefits of education. From McMahon, W. W. (2006). Education finance policy: Financing the non-market and social benefits. *Journal of Education Finance* 32(2), 264–284, with permission from University of Illinois Press.

reported here. Similarly, the firm is regarded as the relevant decision-making unit so intrafirm spillovers are also private benefits.) They are not external benefits but instead private benefits to own health, spousal health, longevity, lower infant mortality, child health, child education, child cognitive development, lower fertility leading to smaller families, and happiness or well-being. The value of each of these nonmarket private education has a monetary value that is estimated in McMahon (2009) by methods explained below and estimates of their value are just as legitimate as estimates of the value of the earnings due to only education. The nonmarket private benefits are measured using a household production function attributable to Becker (1965). It includes per capita income since market goods are also needed to produce final outcomes. The income term in the regression controls for the market benefits of education, which permits the value of the nonmarket benefits in addition to income to be valued. There are many studies in the literature that do not include this important control, although there are hundreds of studies that do use the household production function rationale, and therefore, include per capita income. Students, families, and policymakers generally have very poor information about these nonmarket benefits and their value, leading to significant market failure (see McMahon, 2009: ch. 4).

Some of these private nonmarket benefits are indirect. For example, education contributes to own health, which in turn, contributes to child education and child health (panel B-2).

The External Social Benefits of Education

The portion of direct social benefits that are public benefits are externalities because they benefit others in the society or in future generations. Public goods in public finance mean that consumption by one person does not reduce the consumption by others. Romer (1990) calls these public goods nonrivalrous. World events analysis offered by public broadcasting (PBS) is a public good,

for example, because consumption of it is not limited as others tune in. It is supported by donations but about 90% of all listeners do not contribute and are free riders. Hence, some contribution from these persons must be obtained through taxes or too little of the public service would be produced. Education is partly a public good, with external social benefits, and partly a private good, generating purely private benefits. Lucas (1988) proves analytically that with education externalities, the growth rate is higher and that this is required for overall economic efficiency (the optimal solution). He suggests that the individual's investment in education is small relative to the average level in the community so the individual takes these community benefits for granted. The individual or family will not invest more in education to receive external social benefits because of this and because they spillover to benefit others and future generations. Therefore, insufficient investment in human capital formation through education is the outcome. (This discussion assumes that government failure is limited, which is sometimes challenged. However, government failure in the United States and Organization for Economic Cooperation and Development (OECD) is relatively small in these democracies compared to massive government failure in providing basic education in authoritarian regimes, for example, in sub-Saharan Africa, Pakistan, Nepal, and Haiti.)

This has important public policy implications and is a second source of market failure. The value of the external benefits of education as a percent of the total benefits is a guide to the extent to which government must finance education through taxes if the system is to be economically efficient. However, efficiency is a term that is thrown around with wild abandon. Economic efficiency includes external efficiency, or how well education serves the needs and demands of society, as well as internal efficiency, and to achieve it requires providing for the production of the external social benefits of education. (Economic efficiency includes production efficiency and exchange efficiency. In the education literature, the former is usually referred to as internal efficiency, and the latter as external efficiency.

Overall economic efficiency requires both). A private for-profit college with no endowment and vocational offerings might be internally efficient, but not externally efficient, with few requirements in history, the humanities, or social sciences that encourage citizenship and public service. At the other extreme, government supported public universities with little tuition as in Europe may also not be very economically efficient. With lower resource recovery from parents and lower resources per student than in the United States, either quality or access must be sacrificed. In the latter case, there may be too few graduates to serve society's needs efficiently. A related policy implication involves how far private versus public financing of higher education should go if higher education is to remain economically efficient. That is, if the external benefits of education are to be realized, then some government investment will be necessary to encourage private families to invest more. Apart from equity, this is the primary economic rationale for public support of the schools, colleges, and public universities. (Equity is an important part of the rationale for public support, but distributional issues are not externalities and so are not considered further here.)

The Indirect Effects from Education

The indirect effects from education are those that operate through intervening variables. They are part of the total market benefits, of the private nonmarket benefits, and of the social nonmarket benefits in panels B-1, B-2, and B-3 above. For example, private earnings and the quality of life are higher in part due to the education of others and the education of prior generations. Looking forward, the education of current graduates benefits the earnings and quality of life of others in future generations. However, future benefits cannot be measured directly. Instead, they can be measured based on the benefits received from the past using simulations with difference equations that have been estimated by regression methods and contain parameters that then generate time paths into the future. Estimates and simulated outcomes for many countries worldwide and for internal US Deep South states are presented in McMahon (2002, 2007), respectively.

Why Are Indirect Effects Externalities?

The indirect effects from education are externalities not only because the effects of the individual's investment in education on intervening variables such as, say, the rule of law, is small and taken for granted, the Lucas (1988) rationale, but also because many of the benefits flow to others in the society and future generations and cannot be captured by the individual, the standard definition of externalities. Therefore, families have no incentive to invest more in education in order to receive either free public benefits or indirect benefits, which are also free.

Yet, these indirect effects are a significant portion of education's total benefits. The best estimate available so far is that they are about 42% of the total benefits of education (McMahon, 2002: ch. 13). Their value, shown in panels B-1, B-2, and B-3 of **Figure 1**, must be added to the value of the direct social benefit externalities shown in panel A-3 to arrive at the total value of the external benefits of education.

The Evidence: Identifying and Valuing the External Social Benefits

Studies quantifying and valuing the external social benefits of education will be discussed first, followed by studies that estimate the value of aggregate education externalities. Once the quantity of external benefits is estimated, there are four methods for estimating their monetary value:

- First is the income-equivalent method developed by Haveman and Wolfe (1984). This method finds the amount of income the typical household would be willing to pay for the increase in the social benefit that results from one more year, or one more level, of education. It is based on the standard economic proposition that individuals typically adjust until the ratios of the marginal products of each good including education to their respective prices are equal. For public benefits, the income-equivalent value is interpreted as the amount of income the typical household is willing to give up or vote for in support of civic institutions.
- Second is the dynamic simulation method in McMahon (2002: ch. 13, 2007). This is needed to value the indirect effects, which then can be added to the value of the direct effects to obtain total education externalities. This is explained following **Table 1** below where it is used, and more extensively in McMahon (2009: ch. IV). Then the difference equation model estimated by regression methods, which contains many control variables is used to generate the total benefits of education by means of dynamic simulations. These methods are widely used in astronomy, physics, meteorology, and macroeconomic forecasting. From this is subtracted the values at each point in time given by a simulation generating only the direct effects to obtain the indirect benefits as a residual. The latter can be expressed as a percentage of the total market benefits, thereby establishing their value.
- The third method is to value the aggregate external benefits of education as in Breton (2008). This is done by estimating a growth equation based on international data to arrive at the total social benefits, public and private, from which are subtracted the private benefits estimated using Mincer earnings functions based on micro data. Aggregate external benefits have also been estimated using panel data for US states or US cities,

including a variant that uses the average level of education in the community to represent externalities based on Lucas (1988). This approach has been used by Rauch (1993), Acemoglu and Angrist (2000), Moretti (2003, 2004), and Ciccone and Peri (2006). But these have also been criticized by Lange and Topel (2006), although for reasons that Breton's (2008) newer study avoids.

- The fourth method is to examine the total social accounts in Eisner (1989). They estimate total income and total consumption that include the value of the nonmonetary qualities of life. They include the value of housewives' services, and build on earlier work by John Kendrick. However, the total accounts provide no method for separating the social benefits of education from the private benefits, or for isolating the value of the quality of life that is only due to education. For these reasons, this approach will not be pursued further here.

The Value of the Direct Nonmarket Public Benefits of Education

To place a monetary value on each of the direct external social benefits based on the Haveman and Wolfe (1984: 395) method, a standard proposition in economics is that households will tend to substitute among inputs until they find relatively cost-effective ways of producing each final satisfaction. Better health, for example, can be produced by earning a bachelors degree, which leads to more effective use of time in sustaining health, or it can be produced

by using time in the labor market to produce income and then to purchase doctors' services and drugs, or by some combination. As households balance these alternatives, the ratio of the marginal product of education for achieving health, $MP_{\text{education}}$ below, to its value, P_E , will approximately equal the ratio of the marginal product of income in purchasing medical services, $MP_{X \text{ market}}$, to their price, P_X :

$$\frac{MP_{\text{education}}}{P_E} = \frac{MP_{X(\text{market goods})}}{P_{X(\text{income})}} \quad [1]$$

By cross-multiplying and moving P_E to the left, this value of education for producing better health becomes equal to the ratio of the marginal product of education to the marginal product of market goods (i.e., income), times the marginal cost of the market goods, P_X , needed to produce an equivalent amount of better health. These marginal products, $MP_{\text{education}}$ and MP_X , are the regression coefficients for education and for income in a regression where the dependent variable is democratization, human rights, or some other external benefit shown in **Table 1** below. The education and income coefficients are shown in columns 3 and 4, control variables that are significant in are shown in column 5, and the source of each regression is shown in column 6, so the reader can interpret each estimate.

The estimates of the value of education in **Table 1** apply to the annual benefits generated by a college bachelor's degree, which is also interpreted as one more

³ Definitions of Control Variables: (For data sources see article or book cited)

Y = GDP Per Capita

M = Military Expenditure as % of Govt Budget

P = Primary Gross Enrollment Rate lag 10 years

S = Sec. Gross Enrollment Rate lagged 10 years

H = Higher Education Gross Enrollment Rate

D = Democratization, Freedom House (2007)

G = Government Consumption as % of GDP

U = Unemployment Rate lagged two years

GI = GINI Coefficient: inequality in the distribution of income

I = Investment in Phys.Cap.as % of GDP

T = Trade Openness; exports + imports as % of GDP

PS = Political Stability, International Risk Guide

Y(70) = Initial GDP per capita in 1970

lnY = log of GNP Per Capita

PV = Poverty Rate

p = Population Growth Rate

⁴ No regression in the survey.

⁵ Not included in average because income coefficient is not significant.

⁶ Not included in average because education coefficient is not significant.

⁷ Helliwell's income and other controls contribute to this. See McMahon (2009, Ch. IV).

⁸ To get the effects of only higher education when only a secondary education coefficient is available and when there is no control for higher education, the assumptions are made that this secondary education coefficient captures both, and that four years.

⁹ No income variable in the paper.

¹⁰ Government consumption (reflecting social security and aging) as a percent of GDP.

¹ Gross Enrollment Rate includes replacement investment (65% of total)

² GDP Per Capita

percentage point on the per capita enrolment rate. Attention is given to this in part because, in the past, some have asserted that externalities at the college level are negligible since college graduates earn so much. But this assertion avoids analyzing the specific direct external benefits shown in **Table 1**, as well as the research on these, and also ignores consideration of the indirect effects from education that increase earnings. If most of the benefits listed have a roughly linear effect for one more year of schooling, whether it be at the high-school or college level, then the values in **Table 1** could be interpreted alternatively as also an approximation of the external benefits from high-school graduation. The valuation must relate to some level of education if they are to be relevant to policy. To include comparable tables for primary and junior secondary education and for masters and PhD levels would expand the scope beyond that of a short article.

To illustrate how these values are estimated, the ratio of the education coefficient to the income coefficient in columns 3 and 4 of **Table 1** is first calculated. This is the ratio of the marginal product of higher education in producing refinements in democracy, D , in the typical OECD country, for example, which is the $MP_{\text{education}}$ in eqn [1] above or 0.0101 empirically in **Table 1** below, to the marginal product of \$1 of income, $MP_{X(\text{income})}$ or 0.05, in producing the same amount of democratization. It is this ratio that is used to obtain the income-equivalent values of the net effects from more education. So using household income as the basis for the imputation, the average annual increase in the Freedom House (2007) index for D achieved in the OECD countries from 1975 through 2004 of 0.0017 is taken to be the amount of D to be produced, either through increased education enrolments or through purchases or votes in financial support for civic institutions. Using the income coefficient in the regression, it can be estimated how much income it would take to produce the 0.0017 typical increase in D based on past experience. This turns out to cost \$55 per capita. Taking this therefore to be P_X , the price or marginal cost of achieving the typical improvement in D in the OECD countries, the income equivalent value of achieving this same outcome through increased education is estimated to be \$1726 as shown. This is fairly close to the \$1830 average of the three studies that contain education and income coefficients that are both significant. The work of skeptics is considered later.

The imputations for the value of education in improving human rights, political stability, and almost all of the other social benefit outcomes in **Table 1** are made on the same basis. That is, the value of the social benefit of education is the income equivalent of achieving either by more education or by spending more income, the average annual improvement in each of the other indices in the OECD from 1975 through 2004. The details for

standardizing the studies in **Table 1** to convert everything to 2007 dollars and to make them comparable in other respects as well as further details for each imputation appear in McMahon (2009, Appendix E).

It must be stressed that these are the direct effects, calculated directly from the regressions, which usually apply to 5-year periods, and do not include the indirect effects that feed back and build up over time to make total education externalities larger. These are considered further below. The control variables that often remove these indirect effects that are listed in column 4 and footnote 3 of **Table 1** are only those that are significant at the 0.05 level. Other control variables thought to influence each dependent variable are often mentioned, but the data generally will not support their significance. There are also many studies not included in **Table 1** simply because both education and income are not in the regression, or if they are, both coefficients are not significant. Another constraint is that basic research does not exist in appropriate form to value all social benefits, so there are gaps and the total value in **Table 1** is conservative. Most studies have either checked for simultaneity or used instrumental variables or two-stage least squares methods. Nevertheless, this is the first effort to standardize the many studies and estimate the value of individual social benefit externalities comprehensively. Total precision is not claimed, and as gaps in the research pointed out here are filled further refinements will become possible. (All regressions control for heteroscedasticity. Those not using IV have been checked for simultaneous bias. For those from McMahon (2002), alternative specifications are reported there.)

Evidence Concerning Specific External Social Benefits

The empirical evidence on direct specific social benefits follows, with both indirect effects and efforts to estimate aggregate education externalities considered later.

Democratization

Democratization is the degree of development of political institutions at the national, state, and local levels as measured by the Freedom House (2007) index. Democratization worldwide is empirically determined as shown in line 1 of **Table 1** primarily by access to education, growing per capita income, and lower military expenditure as a fraction of public budgets (McMahon, 2002: 97–101; Diamond, 1992; Clague *et al.*, 1996). Other factors are empirically less significant. Clague *et al.* find that an additional variable for Muslim religion is negatively related to democracy. But it becomes insignificant whenever literacy is included, indicating that completion of basic education displaces Muslim's role. Secondary education enrolments are especially important, although for

the most developed OECD member nations, the effect is smaller (see rows 2 and 3 of **Table 1**). The reason is relative homogeneity; the variation in the democracy index is very small, the variation in enrolment rates is also small, and the result is statistically less dependable. Using worldwide data, Keller (2006) controls for per capita income and secondary education and finds investment in higher education lagged 10 years to be a highly significant determinant of democratization ($t = 3.22$). However, her income coefficient is not significant. In contrast to her result showing a large education impact, Acemoglu *et al.* (2005a) find no effects whatsoever from education on democratization. The methodology of their study, however, is not based on a dynamic view of the process since it includes no lags in education's impacts, includes year dummies which eliminate most of the effects of technology embodied in human capital, and uses school achievement that also eliminates effects from new technology embodied in replacement investment in human capital. It also uses lagged democracy as an explanatory variable that eliminates what little variation is left in 5-year movements in the very-slow-moving process of democratization. Therefore, with these problems, their study is not averaged in. The Beasley and Case (2003) study cannot be included because there is no control for income.

The best estimate therefore averaging the first three studies is the \$1830 value per year of a bachelor's degree to the development and operation of civic institutions shown on line 1 in **Table 1**. The evolution of democratic institutions is a long, slow process. The most difficult context for showing the relation of education to democracy is within the relatively homogeneous OECD or among states within the United States both because of this and because of the spatial equilibrium involved.

There are also contributions of education to behaviors such as voting that are important to democracy. The empirical evidence on this is strong and strengthens the case, but the value of these behaviors cannot be added to the value of education's contribution to overall democratization measures without double counting. Therefore, the important effects of education on contributing behaviors are not included in **Table 1**. To mention a few, those with more education voluntarily give twice as much of their time and twice as much of their money at each income level to civic institutions as do those with a high-school education or less, where only 12% give (Hodgkinson and Weitzman, 1988; NCES, 2005). There are also large positive effects on voter participation, support for free speech, and the quality of civic participation, the latter as indicated by the frequency of news readership (Dee, 2004). Tastes are shifted away from drag racing, dog fighting, and TV game shows, and toward world affairs. UK college graduates have also been shown in tracer studies of graduates to exhibit greater racial tolerance, less cynicism, and less unquestioned support

for authority than those with only high-school education (Byner *et al.*, 2003). These graduates engage in more life-long learning about public affairs' importance to good citizenship and social capital. More education also increases support for democracy in Muslim countries based on micro data by Shafiq (2009).

Human rights

Human rights are a public good that is very important to the quality of life. As measured by Freedom House's (2007) index of civil rights, it includes freedom of the press, freedom of speech, freedom of assembly, the legal protections of *habeas corpus*, trial by jury, freedom from unlawful searches, freedom from unlawful incarceration, protections from torture, reasonable equality of opportunity, and limited corruption. All require an effective criminal justice system and civic institutions. In worldwide data, human rights depend significantly on secondary education, higher per capita income, lower military expenditure as a percent of the government's budget, and on democracy (McMahon, 2002: 103). The highly significant effects from democratization mean that human rights are important benefits of democracy.

The value of education's contributions to human rights is estimated to be about \$2865 per year for each bachelor's (or high-school graduate) in **Table 1**. Other studies of education's contribution to human rights are very limited and also do not control for income (e.g., IHEP, 2005). Contributing behaviors discussed above also contribute to human rights. But their value cannot be added to the total without overlap.

Political stability

Political stability is measured by the comprehensive index from the International Country Risk Guide (2007) that includes both political and economic risk. Stability is generally agreed to be an important determinant of economic growth (Barro and Sala-I-Martin, 1995: 426; McMahon, 2002; Oliva and Rivera-Batiz, 2002). Political stability is significantly dependent on education, per capita income, lower military expenditure as a percent of government budgets, and democracy (McMahon, 2002: 105–110). However, although growth depends on political stability, stability is not 100% dependent on democracy in the regressions. Singapore, China, and Dubai, for example, are all authoritarian and yet growing rapidly. However, as growth continues and education spreads, the pattern may follow South Korea and Taiwan. Both were authoritarian after World War II; extended basic education and promoted growth; and both became full democracies in 1980. In contrast, Pakistan grossly underinvested in basic education to the point that a majority of the labor force and 95% of rural women are illiterate. From 1980 to 2008, it remained a military dictatorship, with low per capita income.

The value of each bachelor's contribution to political stability after controlling for income is estimated to be \$5813 per year in 2007 dollars in **Table 1**.

Life expectancy

Increased life expectancy is a positive private benefit of education in many studies (McMahon, 2009: ch. 4). However, the contribution of education to longevity in aggregate data can also be regarded as a social benefit. This is most obvious in the poor countries where life expectancy is very low, and many die before reaching the most productive years in their life cycle. The value of the net effects from more of education is estimated to be \$3110 per year in **Table 1**. But from this has been subtracted the negative effect on economic growth of increasing longevity in the OECD countries, estimated to be the average of the \$590 and \$539 estimates shown. The latter is a negative externality. The \$537 estimate uses Barro's government consumption, a proxy for life expectancy because it reflects the social security and health expenditures for an aging population. (The per year value is estimated by spreading out the value of the number of years of increased life expectancy over an average of 65 years remaining in the life cycle.)

Reduced inequality and lower poverty

Inequality in the distribution of income is increasing dramatically in the United States and in other OECD countries. It is related to inequality earlier in access to education as shown by Psacharopoulos. More recent studies also show that remarkable increases in earnings inequality in the United States, United Kingdom, and OECD since 1980 is linked with human capital skills in dealing with new technology (Faggio *et al.*, 2008).

Reducing high-school dropout rates also reduces inequality (Levin, 2006: 9). In higher education, Leslie and Brinkman (1988) conclude that increased access in the United States reduces inequality except in states where the tax systems are regressive as in Florida and Mississippi. In the OECD countries, however, higher education contributes to greater inequality as shown in **Table 1**. Admissions are restrictive in many European universities, 2-year associate degrees are far less widespread, and need-based aid is less available. Therefore, although increased access to higher education reduces inequality in most states in the United States, it probably does not in Europe because of policies related to less need-based aid and proportionally fewer in associate degree programs.

Poverty is reduced, however, by economic growth, increased high-school completion, and increased access to higher education. The value of this direct effect is estimated to be \$3110 per year for completion of college degrees in **Table 1**.

Lower crime rates

The effect of education in reducing crime rates and criminal justice system costs has received more attention than other externalities. Witte's (1997) review reveals that further education of those who have started on a life of crime is of limited effectiveness, whereas reducing high-school dropout rates and increasing 2-year college enrollments that cause young males to be under supervision in school (and in employment later) are effective. The value of high-school or college graduation in reducing murder rates (violent crime) and property crime (all other crime) after controlling for per capita income, lagged unemployment, inequality, and poverty is estimated to be \$719 per year per graduate for lower murder rates, and \$4928 per year per graduate for all of the many other kinds of crime. Higher education contributes to white-collar crime, a negative externality, but this has been netted out against education's positive benefits in reducing overall crime. Lochner and Moretti (2002) do not control for income.

Lower public health, welfare, and prison costs

Education reduces public welfare costs. Only 0.5% of all college graduates receive public assistance or Aid to Families with Dependent Children (AFDC) compared to 5.6% of all high-school graduates. The percentage of college graduates on welfare is 16.6 percentage points lower than those that stop short of high-school graduation (NCES, 1992). Muennig (2000: 28) estimates the lifetime savings in public costs of uninsured populations to be \$11077. When converted to 2007 dollars, his present value (he uses a 3.5% discount rate) is \$544 per year over 45 years after graduation as shown in **Table 1**. (His present value for each student completing 2 years of college is \$6317.) Muennig's estimate means that welfare costs to state governments could be reduced by about two-thirds if all students completed high school. They would be reduced by 91% if all high-school graduates completed a bachelor's degree. Education policy would dramatically augment welfare reform that has sought to move welfare recipients into often unskilled work.

The decrease in criminal justice system costs, and larger state and federal tax revenues from increased high-school completion are also found to be enormous in studies reported by Levin (2006). This evidence of external benefits from public support of schooling in poor districts benefits residents of wealthier districts by lowering their public welfare, prison, and health care system tax costs while also increasing tax revenue from others.

Increased tax receipts

Education dramatically increases income, sales, and property tax receipts in estimates by Rouse (see Levin, 2006). They are external social benefits, but not included in **Table 1**, which is confined to nonmarket benefits. Taxes

are already included in standard social rates of return based on earnings.

Environmental benefits

Many effects of education on the environment are indirect. There are direct effects of secondary education in reducing water pollution, but the indirect effects of education through lower poverty and increased democratization are greater. Together, they offset the adverse effect of income growth, so that education's direct effects plus indirect effects on balance reduce water pollution. The per graduate annual value of education's contribution to cleaner water is estimated to be \$136 in **Table 1**.

Similarly, although growth has adverse effects, there are net positive contributions of education to reduced air pollution and slower deforestation. The value of education's annual contribution to reduced air pollution, and probably, global warming is estimated to be \$1482 in **Table 1**. Education's contribution to reforestation and wildlife habitat is estimated to be \$3991. However, the coefficient for education's net effect has a lower level of significance, so this estimate may be too high. Most of education's net effects after controlling for income growth on the environment are indirect through lower fertility, slower population growth, and more democratization.

Happiness and social capital

There are many studies that show that education has a positive effect on happiness, known earlier as subjective well-being. But few of these control adequately for per capita income. Happiness not only is a private benefit of education, but it also is known to benefit others by contributing to greater social cohesion and social capital (Helliwell, 2005). The latter are external social benefits.

Happiness is now measured cardinally based on brain waves. It is known to increase with income up to about \$20 000 per capita, or \$80 000 for a family of four, but not beyond that (Layard, 2006). Education contributes to earnings and therefore indirectly to happiness up to this point. But beyond that, the basic research on education's effects on happiness and social capital at family incomes above \$80 000, where the income effect flattens out, is missing.

However, some informal inferences can be made. This is because education is well known to contribute to most of the major sources of happiness, and hence to social capital. These sources include genes; some persons are born to be happy, and others to be unhappy. However, beyond this, happiness increases with the better selection of a mate, less unemployment, lower divorce rates, better civic institutions, better human rights, less crime, better health, and a better work environment, all of which are positive functions of the level of education (Layard, 2006). The bottom line, however, is that there must be further research, especially on education's effects on happiness

and social capital through these intervening variables and also at family incomes over \$80 000.

Dissemination of technology

Probably the largest external social benefit of higher education is left to last. It is the benefit to the broader society from the embodiment in graduate students and undergraduates of new knowledge created by research and development (R&D) in all academic fields and disseminated by them as they take teaching jobs in other institutions or jobs engaged in creating new ideas (Jones and Romer, 2009). Utilization of most modern knowledge and technology in production is very complex, requires advanced education, and has little effect on the economy unless the means to use it are disseminated. Knowledge from throughout the world is accessed by faculty engaged in research and embodied in students at masters, PhD, professional, and undergraduate levels, who later disseminate it to other colleges, government agencies, and firms. This basic complementarity between human capital and R&D is stressed by Griliches (2000: 88) and fundamental to Romer's (1990) endogenous growth model. Unfortunately, it is too often overlooked in studies of the relation of education to growth. However, an important fraction of the external social benefits from research are also external social benefits from higher education. It is not possible to place a value on these, but the value of the knowledge embodied in the number and skill levels of postgraduate students may be a promising approach.

The Value of External Indirect Effects

The total value of the direct external social benefits of education in **Table 1** is estimated to be \$27 726 per year. These direct benefits per year per degree are not the total benefits from the average level of education in the United States, and also do not include the indirect effects.

The indirect effects of education operate through other variables to set the stage for growth of earnings and non-market benefits later. To estimate these, a dynamic simulation is first run using regression equations that control for other significant variables to generate the total benefits of education over the rest of the life cycle, say 40 years. Then a second simulation is run with the indirect effects suppressed, giving only the direct effects (i.e., the cross partial derivatives are set to zero). These direct effects then are subtracted at each point in time from the total benefits leaving only the indirect effects. Expressing the indirect effects as a percent of the market benefits (and as a percent of the value of the private nonmarket benefits as in McMahon, 2009: ch. 4) which establishes their value. Based on McMahon (2002: ch. 13, pp 228–242) where this is done, the value of the indirect benefits is about 42% of the value of the market benefits – 42% of the market benefits is \$10 540 in 2007 dollars (panel B-1), and 42% of the value of

the private nonmarket benefits is \$15 993 (panel B-2). Therefore, the total value of the market plus nonmarket indirect benefits is estimated to be \$26 533 per year.

The Total Value of Education's External Benefits

Adding the \$27 726 of direct public-good-type benefits from **Table 1** to the \$26 533 of indirect benefits (part of which are future values) gives a total estimated value of all of education's external benefits of \$54 259. This addition is possible because all regressions considered control for per capita income so the direct public good benefits do not overlap the market benefits. Indirect benefits, however, do overlap private benefits since some private benefits are due to the education of others and the education of earlier generations. (It is assumed that the indirect social benefits (panel B-3) are included in the other indirect effects.)

External social benefits, as a percent of the total benefits from education, is a matter of interest to public policy. If the total benefits are \$90 902 per year for a bachelor's degree in 2007 dollars, composed of \$25 096 in earnings increments (the average over the life cycle for males and females based on Census data from McMahon (2009: ch. 3)), \$38 080 in private nonmarket benefits (McMahon, 2009: ch. 4), and \$27 726 in direct social benefits from **Table 1**, then the external benefits of \$54 259 are 59% of this total. If the indirect effects simulated over a 40-year period were discounted back to their present value, they would be smaller. However, the total net effects of education would also have to be discounted back to the present. Therefore, the 59% would not be much affected.

Studies of Aggregate Externalities

The third method of estimating the value of the external benefits through studies of aggregate education externalities involves macro regressions of education's effects on growth. Either a social rate of return is estimated using a macro growth equation and the private Mincer return estimated from micro earnings data is subtracted to obtain the net externalities, or else a macro growth equation is estimated that contains the average education level in the community that represents the externalities. Obviously, if education is found to contribute nothing to growth in the macro growth equation, there are no externalities. Therefore, either of these aggregate approaches involves getting into the education and growth literature.

The results of various growth equation estimates are summarized in **Table 1** (continued). Benhabib and Spiegel (1994), Acemoglu *et al.* (2005a), and Pritchett

(2000, 2006) cannot find that education contributes anything to growth, and there are therefore no externalities. The details of these studies are reviewed elsewhere. (See McMahon (2009: chs. 3 and 4) and the cross-referenced growth entry below.) However, briefly, there are many other studies that show significant contributions of education to growth, six of which are summarized in the continuation to **Table 1**. The three zero-return studies mentioned in common use a static conceptual view, eliminating education's role in the dissemination of new technologies. They do this by using time dummies, using school attainment measures that exclude technology embodied in human capital replacement investment, which is about 68% of the total, and using controls eliminating education's indirect effects through democracy and political stability. The further severe problems with the Acemoglu *et al.* study were discussed above under democratization. Lange and Topel (2006: 479) in their thorough recent review conclude that there is "little evidence in favor of *negative* external returns to education," and that recent studies "cast doubt on the earlier studies by Benhabib and Spiegel and Pritchett who argue for small or even zero aggregate returns to schooling."

The aggregate approach to externalities has most frequently been applied using differences among US states or US cities. But questions can be raised as to whether externalities can ever be found using this type of data. There are two problems: there is little variation because of homogeneity within countries in slow-moving variables such as democratization, human rights, and stability. Second, Lange and Topel (2006: 505) conclude "that this type of evidence is inherently flawed as it does not sufficiently account for endogeneity issues implied by the spatial equilibrium in Rauch, 1993; Acemoglu and Angrist, 2000; and Moretti, 2003." In other words, worker mobility among localities responds to exogenously imposed differences in demand and earnings differences are not just due to prior human capital investments.

Studies based on differences among nations such as Breton (2008) or those as in **Table 1** are not subject to these problems. There is less worker mobility among nations and greater differences in democratization, human rights, political stability, and education since some countries are at earlier development stages. So with proper controls for other factors there is enough variation to estimate statistically meaningful coefficients. Using cross-country data, Topel (1999) and Heckman and Klenow (1997) estimate aggregate education externalities by first estimating a growth equation and then subtracting the private returns to schooling based on Mincer regressions from individual earnings data. Topel's estimate is a 23% social rate based only on market returns and Heckman and Klenow's is 30%. After the average private Mincer return of 8.3% is subtracted, this leaves 14.7% and 21.7%, respectively, for the external benefit. This offers useful insight but has two

problems. It is biased upward because it does not control other things that affect growth; and it is biased downward because it does not include the externalities related to nonmarket private and social benefits. They seek to correct the former by introducing life expectancy and time dummies as proxies for technology. The problems are that life expectancy subtracts from growth in the OECD countries because an aging population shrinks the labor force and increases social security costs. Moreover, time dummies again imply a static interpretation that rejects the role of education in disseminating technology. With these very debatable controls, no externalities are left.

In his later eclectic review of world data, Pritchett (2006) considers OECD data. He does not recognize this role of life expectancy, control for oil shocks, or include the role of technology through replacement investment in human capital. He again finds no positive contributions of education to growth and hence no externalities. Larger positive and roughly comparable effects of education on growth are found by Keller (2006), Barro (1998), Barro and Sala-I-Martin (1995: 426), Oliva and Rivera-Batiz (2002), and McMahon (2009: Appendix D), all in **Table 1** (Continued), and also by McMahon (1998), the World Bank (1993), and many others.

In a recent thorough study Breton (2008) using international data that avoids twin problems of spatial equilibrium and of homogeneity within a single country that plagued earlier studies estimates the market-based social rate of return to be 22% in the United States and 24% in the United Kingdom. He uses instrumental variables to avoid simultaneous bias, with the percent of the population that is Protestant as the somewhat debatable instrument for education. He uses cumulative investment expenditure on education to reflect quality and not just quantity that dominates attainment measures. Subtracting the private Mincer return based on micro earnings data, he finds the residual pure external social benefit rate to be 10.6% in the United States and 16.2% in the United Kingdom, close to Topel's 14.7% and Heckman and Klenow's 21% above. However, Breton's study is also confined to only earnings benefits. So if an imputation is made for the private nonmarket benefits, then his external social benefits as a percent of the total benefits is 57% for the United States and United Kingdom. This is almost identical to the 59% external benefits as a percent of the total that we have independently obtained above through analysis of the specific external social benefits and indirect effects.

Implications

With the cautions mentioned earlier, these estimates suggest that public support of education should be a little over 50% of the total costs on average to provide for these

external social benefits. Total investment in human capital formation includes foregone earnings costs borne primarily by parents as they support room and board costs and not just institutional costs. At the high school level, public investment is very close to this, a little over 50% on average, although the public share is lower for private schools and higher for public schools (where foregone earnings costs are less than half the total). At higher education levels, public support is less than 50% on average. This suggests overall that the trend toward privatization in financing higher education through higher tuition and fees may have gone far enough if overall economic efficiency that includes external benefits is to be maintained. Of course, there is wide variation. Public support of community colleges is above 50% when Pell Grants and Stafford Loans are considered. Some private universities have large endowments support external social benefits. But for most 4-year public colleges and universities and for the less-well-endowed private institutions, public support plus endowment support has fallen significantly below 50% in recent years.

In conclusion, education externalities are not the same as nonmarket benefits; some externalities raise monetary market benefits, and some nonmarket benefits are purely private and not social externalities. Many specific non-market external social benefit externalities are poorly understood and undervalued. When corrected social rates of return are calculated, they are much higher than conventional rates based only on earnings benefits. Poor information about what they are and their value is a significant source of market failure and underinvestment in education, both by households and by governments.

From a dynamic perspective, the external social benefits from education set the stage for each new round of growth and broader development within families and within nations over time. The process is cumulative so that the short-term effects of education, including the external benefits, are smaller. But they grow as interactions and feedbacks occur to the point that they can be extremely important to the future of both individual families and of nations.

Glossary

Human capital theory – Investment in higher levels of educational attainment improves labor market outcomes through improved productivity.

Private returns to education – The benefits accruing to individuals from obtaining additional education. These include higher earnings and reduced likelihood of unemployment. 'Returns' to education are causal impacts rather than associations.

Skill-biased technical change – Changes in technology lead to increases in the productivity which differentially favors high-skilled workers. This is in part responsible for increases in inequality as earnings for high-skilled workers rise more quickly than the earnings of lower-skilled workers.

Social returns to education – The benefits of an individual obtaining additional education for other members of society. These can include higher productivity, reduced impacts from crime, a healthier workforce, and more civic engagement.

Introduction

This article considers the interplay between education and inequality. We have structured this into two-related-parts. First, we consider the extent to which educational achievement is unequally spread through the population. Second, we look at the implications of inequalities in education for economic and social well-being. The analysis we present studies several dimensions of inequality in educational experiences and achievement: social background; ethnicity and immigrant status; and gender. In doing so, we gauge the magnitudes of these inequalities at different educational levels in the main industrialized countries and comment, as far as possible, on their changes over time.

Attainment gaps are so important because education is crucial in determining individuals' prospects and life chances. Even the attainment of low-level qualifications can substantially reduce the probability of unemployment or worklessness (the major cause of poverty), and higher level qualifications increase individuals' earning power. The second part of the article reviews the size of these returns to education, and once again considers their evolution over time. We also briefly note the importance of education for individuals' noneconomic well-being, low education levels are closely linked to poorer health outcomes, a higher likelihood of committing crime, and even an early death.

* This article builds upon, and in parts reproduces, some of our related work in this area, including Machin (2005, 2008a, b).

Figure 1 Estimated effects of family background on students' test scores across countries. Family background effects are based on reported measures of the number of books at home; test scores are average mathematics and science scores from TIMSS. The family background effects are estimated from statistical regressions explaining standardized test scores based on the number of books at home. As standardized test scores have an international standard deviation of 100, these effects can be interpreted as percentages of an international standard deviation by which test achievement increases if the number of books is raised by one category. The authors validate these estimates by also looking at other measures of family background from the 2001 Progress in International Reading Literacy Survey (PIRLS). From Schuetz, G., Ursprung, H., and Woessman, L. (2005). *Education Policy and Equality of Opportunity. CESifo Working Paper 1518*.

Inequalities in Educational Outcomes

Inequalities by Social Background

The observation that children from poorer backgrounds do worse in terms of educational outcomes has a long history, for example, being highlighted by Rowntree's investigation into poverty in York, England at the turn of the twentieth century (Rowntree, 1901). Gaps in educational attainment between children from richer and poorer backgrounds continue to be marked at the start of the twenty-first century.

A large literature indicates that gaps in attainment emerge very early in children's lives. Substantial gaps in test-score attainment are found by income group before children start school (see Carneiro and Heckman 2004, for the United States, and Blanden and Machin, 2008, for the United Kingdom).

Some evidence links these differences to the sizable disparities in preschool enrolment between children from high- and low-education parental backgrounds (Meyers *et al.*, 2004).

Evidence suggests that early gaps in test-score attainment tend to widen as children age (Carneiro and Heckman, 2004; Feinstein, 2003). Recent international surveys that test school-age children enable comparisons to be made of the strength of the influence of family background on achievement across many countries. For example, **Figure 1** shows family background effects on test scores from an interesting recent paper by Schuetz *et al.* (2005). This uses cross-country data from the Third International Mathematics and Science Study (TIMSS) from 1995 and its repeat survey from 1999. In 53 out of 54 countries, the family background effect (in this study measured by the number of books at home) is statistically

Figure 2 Comparison of students' fathers' educational level with other men of their generation. 1. England and Wales. Data refer to the parent (male or female) with the highest income. From figure 15, EUROSTUDENT 2005.

significant and the implied gaps in test scores are large. Moreover, the estimates are internationally comparable and show very large family background effects in some countries. The largest family background effects are in England and, while all show an important family background gradient, there is a fairly wide range of estimates. (Of course, some of the relative positions may well be sensitive to the use of TIMSS data as compared to other survey data on pupil achievement.)

Unsurprisingly, these substantial gaps in test scores lead to inequality in final educational attainments. This includes a higher probability of dropping out of school and lower qualification attainment. Indeed, there is evidence that inequalities continue to grow so that parental background influences final educational outcomes even once earlier achievements are taken into account.

Figure 2 compares the proportion of higher education (HE) students' fathers who have tertiary education with the proportion of all men of the same age with this level of education. Provided fathers are not substantively different from other men, this should provide a measure of the parental educational advantage of students in HE. In all of the countries that were included, fathers of university students are better educated. Once again, the United Kingdom stands out as among the most unequal countries.

Inequalities by Race, Ethnicity, and Immigrant Status

Gaps in educational performance between ethnicity, race, or immigration status are of interest because of the inequalities observed between different groups in the labor market. In the United States, the focus of this debate has tended to be around differences in performance between

blacks and whites (and to a lesser extent Hispanics). Cameron and Heckman (2001) find that minority groups are actually more likely to attend college, given their test scores; hence, it seems that the source of education inequality between whites and minorities in the United States is present in test scores (Jencks and Phillips, 1998).

In a recent contribution, Carneiro *et al.* (2005) have sought to investigate the time path of differences in cognitive and noncognitive skills by race. The authors find that differences open up as early as ages 1 or 2. There is evidence that this gap widens somewhat with age between blacks and whites, but with gaps appearing so early, it is difficult to state that the school system is the major source of racial inequality in the United States. Their conclusion is that adverse early environments have a long-term impact on the educational achievements of blacks and that early-age intervention is likely to be the most powerful tool in reducing inequality.

The debate on the educational differences between whites and minorities tends to reach rather country-specific conclusions, depending on the groups involved and the historical patterns of migration experienced. Platt (2007) finds substantial differences in educational attainment among the UK's 16- to 24-year-olds in 2001, with young people from Chinese and Indian backgrounds exceeding the performance of whites. Young black people perform more poorly than whites, although the gaps are not as stark as between whites and Bangladeshi and Pakistani groups. Evidence from the Millennium Cohort Study shows that all ethnic minorities are performing more poorly than whites in school readiness and vocabulary tests at age 3, with Bangladeshi and Pakistani children performing particularly badly (Hansen and Joshi, 2007). As these cohorts are separated by 20 years, it is not possible to combine this information to form an assessment of inequalities as children age.

Figure 3 Differences in mathematics performance by immigrant status (2003). Statistically significant differences are marked in darker tones. From table A6.1a. in OECD PISA 2003.

Given the diversity of the racial and ethnic dimensions pertinent in different countries, it is difficult to provide a concise summary across countries. **Figure 3** attempts this by considering the differences between mathematics test scores in the Programme for International Student Assessment (PISA) between both first- and second-generation immigrants and native students (that is third generation or higher). In almost all countries (Canada being the exception), natives are outperforming immigrant groups at age 13 and, in most, gaps are larger for first-generation immigrants than second-generation immigrants, this suggesting assimilation. Card (2005) looks in detail at the performance of second-generation immigrants in the United States and finds that in many cases that they are outperforming whites. Worrying exceptions to this pattern in **Figure 3** are Germany and Denmark where second-generation groups appear particularly disadvantaged.

Inequalities by Gender

The relative performance of women compared to men in terms of qualifications gained has improved across the world in the past three or four decades. For example, in 1970, 42% of all US college undergraduates were women, whereas by 2000 this had risen to 60% (Bae *et al.*, 2000). Figures from the Organization for Economic Co-operation and Development (OECD) Education at a Glance show women's relative improvement in terms of

HE is widespread internationally, by comparing education rates for men and women in different age groups. Among the 30 countries studied all but six have higher graduation rates for men among the 55–64 age group; this reverses among the 25–30 age group so that women are outstripping men's HE performance in all but five countries. (Figures are from Education at a Glance 2007 Tables A1.2b and A1.2c.) Exemplar figures for the United States, United Kingdom, and Germany are given in **Figure 4**.

Jacob (2002) uses a decomposition approach to analyze why women in the United States are now more likely to go to college than men. He finds that 90% of the attendance gap can be explained by women's higher returns to degrees and women's greater noncognitive skills. Noncognitive skills are measured as middle school grades, grade retention, and the number of hours spent on homework – a measure of behavioral problems. The idea is that measures of school-based attainment will reflect effort and application once cognitive test scores are also taken into account. Jacob does not find any differences in cognitive scores between girls and boys conditional on other characteristics.

The PISA and TIMSS surveys reveal a fairly consistent pattern of differences in test-score achievement between girls and boys. As shown in **Table 1** (taken from Dustmann, 2005), figures from PISA reveal that in the majority of OECD countries, girls outperform boys in reading, while boys (although generally to a less extent) outperform girls in mathematics. Differences in science are much less pronounced.

Figure 4 Proportion of population holding tertiary education qualifications by gender and age: United Kingdom, United States, and Germany. From tables A3.1b and A3.1c in OECD (2007). *Education at a Glance*. Paris.

Machin and McNally (2005) review the evidence on gender gaps in English schools from the 1970s to the turn of the century. They find evidence that while gaps in mathematics performance at the end of primary school

are slight, those for reading strongly favor girls and appear to have grown at least until the mid-1990s. Achievement at age 16 (the end of compulsory schooling) has an even larger gender bias with 10 percentage points more girls achieving 5 A–C grades at the General Certificate of Secondary Education (GCSE; the minimum grades required for progress into further academic education). The evolution of the gender gap at age 16 indicates that it is linked to the introduction of the GCSE assessment regime in 1988, which includes more continuous assessment, a change which appears to favor girls. This impression is confirmed by the most recent UK GCSE results, as coursework assessment ended and boys results in mathematics immediately outstripped that of girls.

Recent data from the Millennium Cohort in the United Kingdom allow us to consider gender gaps before school; as with gaps by socioeconomic status, the evidence suggests that they start early. Table 2 presents figures from a number of standardized test scores at ages 3 and 5. In all cases, girls tend to perform better in these test scores than boys do. In the vocabulary test, which is completed by children at both ages, the evidence is that the gap closes somewhat over the 2 years between the surveys. This might indicate that part of girls' better performance at age 3 is due to their higher level of maturity at that age.

To summarize this section on the dimensions of inequalities in education, we can say that inequalities by family background are large, persistent, and show little sign of reducing, while the picture for race/ethnicity and gender is more positive, at least in some countries.

Education and Economic Outcomes

Higher levels of educational attainment are strongly associated with higher earnings and better employment prospects. Much of the empirical work studying the labor market impact of education has its roots in the highly influential and pathbreaking work done in the economics of education field by American economists in the 1960s, especially Jacob Mincer (1958) who popularized the earnings function that relates wages to the number of years of schooling:

$$\log w = a + bS + c_1X + c_2X^2 + u$$

where w is earnings, S measures schooling, X denotes years of experience, and u is a random error term. Psacharopoulos and co-authors have written numerous papers comparing the coefficient b across the world and have found evidence that earnings returns to schooling are widespread and tend to be higher for primary education and in countries with lower levels of development (see Psacharopoulos and Patrinos, 2004, for the latest work).

Table 3 shows OECD evidence on educational wage differentials that accrue to people with tertiary education levels relative to post-secondary nontertiary levels in 15 countries. The existence of sizable gaps in earnings is seen

for all countries. According to these earnings differentials, acquisition of more education leads to significantly higher earnings.

As well as being associated with increased earnings, workers with educational qualifications also tend to correlate with improved employment probabilities. **Figure 5** compares the employment rates of those who do not complete upper secondary schools (equivalent to US high school) with employment rates for those who have high school education but no college education. It is very clear from these statistics that obtaining at least the typical level of education increases employment probabilities.

Causality

The empirical study of education-related earnings differentials was developed in tandem with human capital theory (see inter alia Becker, 1964); the idea is that educational attainment has a casual impact on labor market

Figure 5 Employment rates by educational attainment (2005). From table A8.3a OECD (2007). *Education at a Glance*. Paris.

outcomes through improved productivity. Of course, the fact that more educated workers tend to be more productive does not prove that education is the cause of their higher productivity. Indeed, many commentators have noted that interpretation of positive earnings differentials for the more educated as a causal impact of education may not be correct due to differential selection into HE by more able individuals and those from higher-income families. As such, it may be that higher-ability/income people select into education more so that the positive coefficient on education in a wage equation is actually upward biased. The existence of ability bias of this form has been studied in detail, from the highly influential work of Griliches (1977) onward, and confirmed in research since. Empirically, it is the case that the education coefficient falls once ability proxies are included (this is because ability is positively correlated with both earnings and education).

Conversely, one may think that the education variable included in the earnings function may not be measured perfectly. This causes a downward bias in the estimated coefficient of education variables in earnings equations. Card (1999, 2001) considers the impact of ability bias and measurement error on estimated returns to education. In particular, Card carefully considers the interpretation of instrumental variables estimates, which are designed to purge endogeneity and measurement error bias.

In the recent literature addressing these issues, a number of what Card (2001) refers to as supply-side instruments are used to identify the causal impact of education, where researchers try to ensure that variations in education are driven by factors that do not

directly impact on wages. Estimated returns from this approach are above the basic uncorrected differentials. (Examples are changes in compulsory school leaving laws and differences in the accessibility of schools. Formally, these enter an education equation, but not the earnings equation, and so their impact on earnings is assumed to operate only through education acquisition.) **Table 4** summarizes some of the key papers in the field that identify the causal impacts. Moreover, differences between the basic and causal returns are of similar magnitudes for the studies considered in this table (they, of course, differ across studies owing to different data, different countries, and so on). Hence, there is robust cross-country evidence that the more educated get higher monetary rewards in the labor market.

Based on this, we can have a degree of confidence that education is causally associated with higher earnings. Moreover, it seems that the simple least squares regressions, which estimate human capital earnings functions provide a reasonably good idea of how big the education effects on earnings actually are. From this, it seems reasonable to conclude that there is a significant and sizable average rate of return in the labor market to HE.

Wider Benefits of Education

Social science researchers have considered the wider benefits of education by studying connections between education and a broader range of outcomes outside of the labor market. These are often thought of as picking up social returns to education and include health, crime, civic engagement, and intergenerational effects on chil-

Table 4 Evidence on the causal impact of education on earnings

Study	Data	Basic return (%)	Causal return (%)	Means to generate causal estimate
Angrist and Krueger (1991)	US Census	5–7	6–11	Variations in years of education generated by different quarter of birth
Card (1995)	1966 Cohort of Young Men, United States	7	13	Variation in years of education from proximity to college when growing up
Conneely and Uusitalo (1997)	Finnish men in the army in 1982	8	11	Variation in years of education from proximity to college when growing up
Harmon and Walker (1995)	Family Expenditure Survey, United Kingdom	6	15	Variation in education induced by raising of compulsory school leaving age
Ashenfelter and Rouse (1998)	1991–93 Princeton Twins Survey	7	9	Variation in education within twin pairs
Miller <i>et al.</i> (1995)	Australian Twins Register	3	5	Variation in education within twin pairs

Examples taken from Card's (1999) review.

dren's outcomes. From this work, there is evidence of important externalities, in that education significantly improves health outcomes (Grossman and Kaestner, 1997; Lleras-Muney, 2005), is associated with lower crime levels (Lochner and Moretti, 2004; Machin and Vujic, 2005), and enhances the extent of civic engagement and participation (Brehm and Rahn, 1997; Bynner and Egerton, 2001; Dee, 2004). Moreover, there are important intergenerational effects of education of adults on the education of their children (Black *et al.*, 2005).

Changes over Time

We have so far reviewed the evidence that differential educational attainments can lead to substantial differences in earnings, employment probabilities, and other outcomes that matter to individuals' welfare. It is clear that employers are prepared to pay higher wages to more educated workers; this reflects in part their scarcity value. As simple demand and supply analysis indicates that, *ceteris paribus*, as more workers become highly educated, the earnings returns to being educated will decline.

Figure 6 shows the proportion of the populations of 36 countries with tertiary education in two age groups, 25–34 and 45–54. In almost every case, the proportion of educated workers is higher in the younger group – attainment has risen over a generation. If demand had remained steady, we would expect this to have resulted in a fall in earnings (and indeed employment) differentials over time. However, the most recent survey by Psacharopoulos and Patrinos (2004) finds that while returns to each additional year of education have slightly declined worldwide, the returns to higher education have increased.

In the United Kingdom and United States, the rising educational wage differentials generated have made an important contribution to rising wage inequalities (Katz and Autor, 1999). Understanding why these changes have occurred is essential to understanding the relationship between education and inequality.

An increase in the supply of educated workers will lead to a decline in the wage premium they receive unless demand for them increases further. This seems to have been what has happened in practice. Large increases in the demand for graduates have occurred so that wage differentials related to education have stayed constant or increased in the face of the expansion of tertiary education in many countries. Researchers have studied what lies behind the increase in the demand for educated workers in the United States and the United Kingdom. In both countries, wage premia have risen despite a massive expansion in the supply of graduates with a tertiary education.

The leading explanation for the rise in demand for skilled workers is skill-biased technical change (SBTC).

This hypothesis states that the rise in demand for more skilled workers has been driven by new technologies in the workplace. The critical idea is that these new technologies lead to higher productivity, but that only some workers possess the necessary skills to use them. As such, employers are prepared to increase the wages of the skilled workforce who complement the new technology. However, at the same time, less-skilled workers do not possess enough skills to operate the new technologies and their wages are lowered or they lose their jobs. Relative wages and/or employment of the more skilled, therefore, rise.

The SBTC hypothesis has received substantial empirical support (see the survey of Machin and Van Reenen, 2008). At the risk of being somewhat simplistic, the approach generally taken to investigating SBTC is to model the demand for skilled workers (measured by their share in the wage bill) as a function of technology. A strong positive relationship is found, and the fact that similar industries are affected across the world, makes other competing explanations (such as increased international trade) less convincing (see Berman *et al.*, 1998, or Machin and Van Reenen, 1998, for international evidence in line with this).

Autor *et al.* (2003) have lately proposed a more sophisticated version of the SBTC hypothesis. Their argument is that computerization reduces the demand for routine tasks (for manual and nonmanual workers) but results in an increase in demand for analytic or nonroutine skills. Thus, routine nonmanual tasks (e.g., clerical work) may be replaced by computers, while some nonroutine tasks done by manual workers (like cleaning) are largely unaffected. Thus, one sees increased demand for workers with the skills and capabilities to do jobs involving nonroutine tasks. Again, this shows that education that confers these skills on workers is likely to have a bigger payoff in the labor market and generate earnings returns.

Conclusions

Education and inequality are closely related. It is evident that education acquisition is related to family background and that different demographic groups acquire different levels of education. Since education yields a private return in the labor market and there are social returns to education, it is clear that the uneven patterns of education acquisition have the potential to generate inequalities in economic and social outcomes. Depending on how these uneven patterns of acquisition are distributed across the population, it is evident that education can have an equalizing or disequalizing effect on outcomes. The recent experience of increased labor market inequality being linked to changing patterns of educational attainment suggests that it has, at least in this recent time period,

been disequalizing, and therefore, had a tendency to raise inequality.

Human Capital

E R Eide and M H Showalter, Brigham Young University, Provo, UT, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Human capital refers to the intrinsic productive capabilities of human beings. These capabilities can be increased through investment in things such as education, on-the-job training, and health. Human capital is viewed as an asset that generates a flow of services, most often measured as earnings, although broader measures of output are also used.

Adam Smith in *The Wealth of Nations* (Smith, 1776) set the stage for the study of human capital. Although he does not use the phrase human capital, he identifies the acquired and useful abilities of individuals as a fundamental source of wealth and economic progress of a country. Writing more than a century later, Alfred Marshall notes in his *Principles of Economics* (Marshall, 1920) the long-term nature of investments in human capital and the family's role in undertaking them. Additionally, Marshall expands the notion of returns on human capital to include non-monetary considerations. However, Marshall is also credited with delaying the study of human capital due to his reluctance to put it on the same footing as physical capital.

The modern study of human capital coincides with two developments in economics. The first was a resurgent interest in understanding why economies grow. It was apparent to researchers that national output was growing at a much faster rate than the rates of growth of inputs – land, labor, and physical capital (Denison, 1962). A leading hypothesis to explain the anomaly was that labor was mismeasured: a day of work from a typical worker in the 1950s was substantively different than that of a worker in the 1920s.

The second development dovetailed with the first – the availability of large datasets that allowed exploration of worker productivity and earnings and how they related to characteristics such as the years of education and age. The data revealed that education levels were increasing dramatically and that the higher levels of education might explain rising productivity and wages.

Three authors deserve particular note amid the flurry of theoretical and empirical work in the late 1950s and early 1960s. Jacob Mincer (1958) stimulated a vast literature measuring the returns to education. Using census data, he documented the now-classic result that the years of education has an inverted U-shape on the rate of earnings growth. Theodore Shultz focused on the role of education and general investments in human capital in explaining the increased productivity of labor. His monograph

The Economic Value of Education focused attention on education as a subject worthy of concentrated study by economists, thus beginning the field of the economics of education. Gary Becker (1964) organized the emerging threads of empirical and theoretical work into a coherent framework that provided a guidebook for future research.

The study of human capital has proven to be an exceptionally fruitful vein of research with implications for individuals, firms, and nations. The general topic has resulted in an enormous quantity of research. Several comprehensive surveys have been done and are listed under the section titled 'Further reading'. This article will of necessity be very selective in its coverage. The primary focus is on education as an investment in human capital. In what follows, the private returns to education are first addressed. Returns are generally measured in monetary units, but some evidence on nonmonetary returns is also discussed. This is followed by a discussion of the social returns to education. As early as Adam Smith, the potential externalities of education were noted, and this section discusses some of the more prominent findings in the empirical literature. The final section summarizes the conclusions.

Private Returns to Education

Theoretical Issues and Modeling

This section begins with a brief overview of the theoretical underpinnings of the study of human capital. The terminology of capital is instructive: human capital and decisions involved with it are the same type as decisions involving physical capital, such as equipment and buildings. A business executive invests in new equipment if the expected benefit derived from the equipment exceeds the cost. Human capital theory uses the same construct: an individual invests in education with an expectation that the investment will provide a benefit in the form of higher earnings.

More generally, human capital theory assumes that individuals take actions that will likely increase their future earnings and overall well-being. Such investments are costly: they might involve direct costs such as tuition and fees for school, and indirect costs such as foregone earnings during the period spent in school. These investments result in some expected future benefits. The benefits might include a higher wage, but can also be anything that the individual values, for example, better working

conditions or a longer life. Human capital theory typically models investment decisions such as those resulting from an optimization process: an individual will invest in such activities in order to maximize well-being over the course of a lifetime. Observed outcomes in the marketplace will be the result of an equilibrium process where the demand for specific skills and abilities is balanced with its supply.

Human capital theory offers numerous useful insights and testable hypotheses about human behavior. One of the first to be explored is that observed differentials in earnings can be explained in part by differences in training costs. Adam Smith noted that professions that require years of training tend to have annual higher earnings than professions with no such restrictions. Using human capital theory, the explanation for this empirical observation is that a rational individual would only be willing to incur the costs of tuition and lost earnings during the training period if that investment has a sufficiently high rate of return in the form of higher earnings post training. This insight also suggests that lifetime earnings is a more appropriate measure when evaluating inequality: two individuals, one who invests in professional training and one who does not, can have identical lifetime earnings, but very different earnings at each point during their lives.

Human capital theory undergirds most of modern labor economics. It offers explanations and insights on topics as diverse as discrimination, inequality, unemployment, fertility, marriage markets, immigration, and productivity. This brief survey focuses on the relatively narrow slice of empirical work that touches on topics in education.

Empirical Estimates and Methodology

Although human capital theory suggests that individuals invest in education in anticipation of a wide range of benefits, most empirical work has focused on the monetary rewards of increased earnings. Such data have tended to show rates of return of about 10% for an additional year of education, with some variation by gender and race/ethnicity (Psacharopoulos and Patrinos 2004). These return measures ignore nonmonetary and consumption benefits of education, and they also ignore any externalities associated with education. There has been substantial work done on these latter topics which are discussed later in this article.

Several methodological issues arise in estimating the returns to education. The goal of most empirical work is to establish a causal link between education and measures of return, which tends to be much more difficult than simply measuring a correlation. Early work compared lifetime earnings profiles for groups with different levels of educational attainment. More advanced analysis based on multiple regression analysis has attempted to account for a host of technical estimation problems such as omitted variables,

nonrandom samples, incorrectly measured variables, and jointly determined outcomes. These issues are discussed briefly in what follows.

A key omitted variable in much empirical work is innate ability (e.g., natural intelligence, work ethic) which can also include unobserved effort. The fundamental difficulty is that high-ability individuals are likely to obtain more years of schooling than low-ability individuals, but high-ability individuals would also tend to earn more for any given amount of schooling than low-ability individuals. This makes it difficult to disentangle the effect of schooling versus innate ability.

A large literature is devoted to investigating and overcoming this particular problem. Ideally, a researcher would like to observe otherwise identical individuals who differ only in their level of education. Although this approach is impossible in practice, clever research strategies using advanced econometrics have been employed with varying degrees of success.

Nonrandom sampling is often a problem with estimating returns to education for individuals with weak attachment to the labor market. For example, in contrast to most college-educated males, a substantial fraction of women who graduate from college will exit the workforce for extended periods of time. This implies that estimating returns to college will rely on a subset of the available data (women who work) that might not be representative of the full population of women. As with accounting for unobserved ability, a large literature has developed to account for this type of problem, again, with varying degrees of success.

Measurement error can afflict several variables of interest in empirical models. One example is earnings: earnings can be misstated in surveys because of carelessness by either the responder or the person (or machine) coding the information; or, responder wariness toward the survey instrument might lead to inaccurate data. Another example is in the measurement of school quality: a year of schooling from an Ivy League college might be very different than a year of schooling from the local junior college. Such problems cloud the measurement of the causal relationship between schooling and earnings, and the relationship between human capital accumulation and outcomes more generally. Several approaches have been used to account for this problem, the simplest of which is the development of better data sources.

The problem of jointly determined variables, also known as endogeneity, arises in situations where multiple outcomes are simultaneously decided upon. For example, household fertility decisions are likely to be made jointly with decisions about the level and type of education to obtain. This makes it difficult to measure a causal impact of one endogenous variable on another, although such causal links are theoretically possible. For example, it seems likely that having additional children makes it

more costly and therefore less probable that a person will pursue additional years of education. But measuring the independent effect is confounded by the joint-decision process. The typical strategy to deal with endogeneity is to use an econometric technique known as instrumental variables estimation. Alternative complex estimation techniques have also been used in the empirical literature.

Topics in Empirical Estimation

Research on the development of human capital tends to have a three-pronged focus: (1) childhood and adolescence, with a heavy emphasis on kindergarten through high school completion; (2) young adulthood, emphasizing formal post-secondary education; and (3) adults, highlighting on-the-job training and general experience. Each is discussed in turn.

Primary and secondary education

Economic research on the effects of K-12 education is usually organized around the notion of an education production function. This approach posits that inputs such as teacher quality, class size, school policies, family demographics, and general aptitude of students determine observable outcomes such as test scores and high school completion.

A large empirical literature attempts to quantify the empirical relationship between inputs and outputs. One of the earliest and most influential studies was directed by James S. Coleman (Coleman *et al.*, 1966). This government-sponsored study documented a significant Black–White achievement gap in test scores, and it came to the controversial conclusion that family background characteristics were much more important in explaining outcomes than school-controlled inputs such as class size and teacher quality. Subsequent research critiqued both the methodology and the data of the Coleman report, but an acknowledgment of the weak association between school inputs and student outcomes has been the dominant view among economists since the 1980s (Hanushek, 1986; Burtless, 1996).

However, a small but growing set of research is reexamining the production function relationship using data generated by experimental and quasi-experimental designs. A notable example is the Tennessee student teacher achievement ratio (STAR) project that performed an experiment to measure the impact of class size on student outcomes (Word *et al.*, 1994; Krueger, 1999; Krueger and Whitmore, 2001). The results suggest a significant effect of class size on test scores and on the likelihood of taking a college-entrance exam.

An important set of related research employs quasi-experiments. A quasi-experiment refers to data generated without an explicit experiment such as the STAR project, but includes institutional details that allow researchers to

treat the data as if it were. An interesting example of this approach is a paper by Angrist and Lavy (1999) that uses the institutional rule of a 40-child maximum class size in Israeli public schools to examine the effects of class size on test scores. They find that smaller class size leads to higher test scores in some situations.

A variety of policy experiments designed to improve and evaluate student-learning outcomes are currently underway throughout the United States, and past policy innovations are currently being studied to determine their effects, if any. Examples include the following: (1) High-stakes testing where administrators and teachers can be punished if aggregate test scores are too low, or where individual students can be retained in a grade or be subject to remedial education if their test scores are not sufficiently high. (2) Vouchers where individuals receive government funding to be spent on the school of their choice, including private schooling. (3) Charter schools that are fully government funded, but have less-direct oversight than typical government schools. (4) The effects of peers on student outcomes. Peer effects are fundamental in evaluating policies like tracking where students are segregated by ability measures such as test scores, or combining children of different grades in the same classroom. (5) The role of teacher quality on student outcomes. Quality can refer to experience, education level, and type, or measures of teacher performance. (6) Direct incentives to students for performance on standardized tests, such as monetary payments for high test scores.

Many of these topics and research agendas are discussed in greater detail elsewhere in the encyclopedia.

Post-secondary education

A substantial amount of work has been done over the past two decades focusing on postsecondary formal education. In the early 1990s, researchers documented a substantial rise in the return to completing college relative to completing high school. A number of explanations have been given. The rising demand for skilled labor due to the forces of international trade and specialization has received some empirical and theoretical support. (Acemoglu, 2002)

Another area of research has focused on variations in quality of education. Noting that there are large discrepancies in college tuition across institutions, a natural question arises whether higher tuition results in correspondingly higher earnings. An interesting strand of research compares outcomes from individuals attending elite private institutions (e.g., Ivy League Schools) with less-prestigious universities. The empirical results are mixed. A widely cited work by Brewer *et al.* (1999) suggests earnings tend to be as much as 40% higher for students from elite institutions compared with their peers at less-selective universities. But using different data and different methodology, Dale

and Krueger (2002) find a much smaller effect on earnings from attending an elite university.

A related literature examines the returns to attending a community (junior) college. This literature notes that a majority of first-year college students enrol in a community college. The empirical evidence to date suggests that the returns to a year of community college are similar to the returns to a year of college at a 4-year institution (Kane and Rouse, 1995).

Returns to particular college majors has also been an active area of research. The literature documents substantial differences in the returns to various majors, with math-oriented and technical majors earning approximately 30% more than nontechnical majors. Large differences remain even after accounting for the ability bias that leads innately more capable individuals into technical majors.

On-the-job training and work experience

Becker's (1964) seminal book notes a difference between firm-specific and general human capital. In his model, firms would not invest in general human capital – general literacy, for example – because workers might leave the firm after they receive the training. But recent work suggests that there might be conditions under which firms do invest in general training (Acemoglu and Pischke, 1999). A growing body of empirical evidence supports this work. For example, Autor (2001) documents the workings of temporary help firms providing training in general skills.

A final area of inquiry deals with the depreciation of human capital. While formal education and work experience can build human capital, detachment from the labor force and general inactivity can deteriorate it. This is one of the major economic concerns arising from extended spells of unemployment. Work by Mincer and Ofek (1982) examines the implications of interruptions of labor-force participation by married women. They find that the longer the period of interruption, the lower the wages upon reentry into the labor force. However, they also find rapid growth in wages after these women return to work.

Nonmonetary Returns to Education

As noted by Marshall, human capital investments might have payoffs beyond increases in earnings. There is an expanding research agenda attempting to measure such returns. For example, recent work by Lleras-Muney (2005) examines the causal impact of education on longevity. Using variation in education level induced by compulsory education laws, she estimates that a year of schooling leads to an increased life expectancy at age 35 of 1.7 years.

A second example is the interaction of human capital investment and family interactions. Higher marketplace returns reduce the demand for children and lead to relatively higher labor-force participation by married women. Divorce rates, wage inequality, and occupational segregation by gender exemplify topics where human capital theory has extended its reach. It is often difficult to conclusively show causal relationships between educational attainment and these nonmonetary outcomes due to data constraints, but research continues to explore these topics and circumstantial evidence continues to mount.

Social Returns to Education

Research evidence suggests there exists substantial private gain to investment in education, but it is also an important question whether gains accrue to individuals other than the person actually investing in human capital: is there some social return to education over and above what any given individual obtains? In economics, such a phenomenon is known as a positive externality and its existence justifies government involvement in the promotion of education. Without such externalities, the rationale for government provision of education becomes much weaker.

Two general approaches have been used to measure the extent of externalities. First, macroeconomists have tried to identify aggregate human capital externalities. A recent focus of this literature has been to determine whether skilled (high human capital/education) workers tend to raise wages for unskilled workers (Ciccone and Peri, 2006). More generally, this aggregate approach attempts to measure whether there are monetary benefits to entire economies that are not fully reflected in wages. There is no consensus on the magnitude of this aggregate effect.

The second approach is a more narrowly focused search to identify specific externalities from education, usually involving nonmonetary outcomes. A few examples include the following:

- *Citizenship.* An educated citizenry is often argued to be necessary for a functioning democracy. Such fundamental tasks as voting and filing taxes require some basic level of cognitive function. Recent work has attempted to measure whether education has a discernable, causal effect on voting behavior. Milligan *et al.* (2004) find that schooling increases civic participation in the United States. They also find that higher levels of education are positively associated with individual awareness of campaign issues and that educated individuals are generally more involved in the political process.
- *Crime.* Criminal activity offers an interesting case study in externalities. Criminal acts almost by definition cause harm to people other than the person committing the crime. Hence the reduction in crime due to higher

education levels is *de facto* an externality of education. Human capital explanations for a link between education and crime usually involve opportunity-cost arguments. Individuals with few marketable skills have a low opportunity cost in the commission of crime and in the possible time cost of incarceration. Such arguments are used to explain the widely noted age profile of criminal activity: property and violent crimes increase through adolescence for males, peaks in the late teens, and declines markedly thereafter. On the other hand, white-collar crime, which tends to require somewhat more sophistication, peaks at a much later age and declines more slowly. An interesting study by Lochner and Moretti (2004) attempts to measure the causal effect of schooling on criminal activity. They estimate that an extra year of schooling results in a 0.37 percentage point reduction in the probability of incarceration for blacks, and a 0.10 percentage point reduction for whites. They estimate that the social savings per additional high school graduate is between US\$1170 and US\$2100. They also find that nearly a quarter of the difference in the black–white gap in incarceration rates can be accounted for by differences in years of schooling.

- *Health.* The case for externalities in health is theoretically compelling but empirically weak. A key example involves vaccinations. Vaccinating an individual against communicable diseases benefits the individual (a private return), but also lowers the incidence of the disease in the population (a social return). If education has a causal effect that increases vaccination rates, this would imply the existence of an externality. Although a strong positive correlation exists between education and vaccination rates, a definitive causal link has not been established.

Other possible health links include educational effects that lower rates of smoking and drunk driving. Both of these activities have the potential to harm individuals other than the one engaged in the activity. But as with vaccinations, solid empirical support is currently lacking.

Some recent work argues that individuals do not adequately account for the addictive nature of products like cigarettes and alcohol and that the resulting unintended harm to an individual from their own actions ought to be considered as an externality. This work is in its early stages and no definitive empirical work has yet been produced.

Finally, some authors have argued that insurance pooling results in an education externality on health (Manning *et al.*, 1991). The empirical evidence suggests that education leads to healthier lifestyles, but with insurance pooling, healthy individuals are not rewarded with lower health insurance premiums in employment-based insurance pools, despite the reduction in medical expenses resulting from better health. In not being rewarded,

healthy individuals confer a positive externality on the less-healthy individuals in the pool. The empirical magnitude of the potential effect is uncertain.

Conclusion

Human capital theory forms the basis for most of the empirical work in the economics of education. It has proved to be a powerful tool for conceptualizing how individuals make educational choices and for guiding how the implications of those choices are measured. Empirical work establishing causal relationships is often difficult, fraught with problems of limited and inadequate data. But exciting new work continues to refresh, refine, and occasionally refute previous theoretical and empirical conclusions.

Glossary

Ability differences – Refer to innate ability differences as measured by tests before children enter school, but in most economics literature is usually the measured test performance differences among individuals on a school-based test.

AFQT – Armed Forces Qualifying Test—a test developed to screen individuals for service in the military.

Cognitive skills – Mental skills that are used in the process of acquiring knowledge, such as attention, memory, reasoning, symbolic thinking, perception, and self regulation.

Cross-section data – Data collected at one point in time on a sample of individuals.

Educational quality – Refer to the quantity of schooling inputs per student, the quality of inputs per student, such as teacher content knowledge or teacher experience, or the measured outputs of schooling, such as test score gains from year to year.

Ethnic group – A group of people that shares a self-identity, which can be based on language, national heritage, culture (often mixed with religion), and usually a combination of all these.

Labor market discrimination – Differences among race, ethnic, and gender groups in employment, wages, and promotion due to differential treatment of individual characteristics associated with productivity, such as education, experience, and measured ability.

Longitudinal data – Data collected on a sample of a cohort of individuals over a number of years in a series of follow-up questionnaires.

Noncognitive skills – Skills such as persistence, reliability, self-discipline, the ability to work with others, and the capacity to listen.

Racial group – Although controversial for scientific and political reasons, this usually means a category of individuals based on heritable characteristics such as skin color and facial features, but also on self-identification and social construct.

Test score gap – Refers to the difference in average performance on national tests by identifiable social class, gender, ethnic, and race groups.

Earnings differentials between racial or ethnic groups exist in most societies. To the extent that they persist over time in democratic political conditions, they are of considerable concern, since they suggest that different groups are not getting either equal access to human capital investment opportunities or equal treatment in labor markets, or both.

The literature on such earnings differences (and more generally, unequal economic and educational opportunities) have been of interest to economists for almost 70 years, especially in the United States, where, in 1944, a Swedish economist, Gunnar Myrdal, published the path-breaking *An American Dilemma: The Negro Problem and Modern Democracy*, and where the civil rights movement in the 1950s and 1960s continued to draw attention to the unequal education and income of African-Americans and Latinos. The pressure exerted by the movement enabled the collection of detailed census statistics that helped researchers estimate the existence of wage and schooling differences and to posit explanations for them. In other countries where such data are collected, the results also show distinct differences in economic performance between ethnic and race groups, suggesting that discovering differences is largely a function of data-collection politics.

More recently, in the 1990s, a major debate was held over whether racial/ethnic discrimination in labor markets has disappeared, and whether the main problem is that African-Americans and Latinos earn lower incomes for a given level of education because their academic achievement is lower. This then raises the issue of why different race/ethnic groups achieve differently in school (e.g., the Black–White test-score gap), and how important those differences are in explaining earnings differences.

Although the discussion in this article focuses on the United States, this is primarily because of the richness of the data available and the highly developed debate about the explanation of differences. The methodology is applicable to other economies with minor changes of local conditions. Such a comparison is made with Brazil, with a large Black and mulatto population, and Israel, where European immigrants and those of Afro-Asian origin differ considerably in education and cultural background, and a large minority of Israeli Arabs, representing 19% of the population, that faces major barriers to entry into private and public sector jobs and are discriminated against for ideological reasons.

Race and Ethnic Earnings Differences in the United States

Data on race, ethnicity, and earnings in the United States are available for the period 1939–2006, and can be analyzed by native- and foreign-born percentage (see Chiswick, 1984 for the 1970 census breakdown). It is important to analyze the data by gender since earnings differ by gender across groups, and female labor force participation rates also differ among groups and over time.

The data suggest that certain ethnic groups, regardless of race, earn more than average and more than the dominant White Anglo (non-Latino) majority. Therefore, for example, Japanese Americans, Chinese-Americans, and Jewish-Americans all earn more than Anglo-Whites and this has been the case since at least the 1960s. African-Americans, Latinos, Filipinos, and Native-Americans are all examples of groups that earn considerably less, on average, than Anglo-Whites and have done so for as long as data have been available on such differences.

Among Latinos there is also variation, with Mexican and Puerto Rican Latinos earning much less than those of Cuban origin.

Table 1 presents earnings data for the period 1939–2006 according to ethnic group, race group, and gender group. The Asian-American and Latino groupings are broad and contain distinct subgroups that earn significantly more or significantly less than the group average. Estimates of earnings of Latinos of Mexican origin, Puerto Rican origin, and Cuban origin show that Cuban-origin Latinos earn more on an average, than Latinos of Mexican or Puerto Rican origin. Part of the subgroup variation is due to large differences in the socioeconomic origins of different national groups that immigrated to the United States. For example, the first wave of Cuban Americans who came to Florida in the late 1950s and early 1960s were professionals leaving Castro's Cuba. That group of immigrants was markedly different from the unskilled laborers from Mexico who immigrated throughout the same period, and especially after immigration laws changed in 1965.

Table 1 United States: Annual median earnings by education, race/ethnic group, and gender, 1939–2006 (full-time workers, current dollars, and percent)

Category	Year 1939	1949	1959	1969	1979	1989	1999	2006
All schooling (males, 25–34 years)								
White	1356	3001	5438	8633	17 389	28 578	35 603	40,964

From US Department of Commerce, Bureau of the Census, Public Use Census Sample, 1940, 1950, 1960, 1970, 1980, 1990, 1996, and 2007.

Yet, despite this variation within broad groups, **Table 1** suggests that: (1) there are important and persistent ethnic/race differences in earnings in the United States labor market, (2) these differences cut across gender, and (3) they are subject to historical change. In the period 1939–79, non-Anglo men and women made large gains relative to Anglos, and after 1979, these gains leveled off, with some notable continued gains (Black male high school graduates), and notable reversals for Black and Latina women. Even with the large gains over four decades, African-Americans and Latinos have remained at a lower level of median income than either Anglos or Asian-Americans. It also should be noted that these data are reported for full-time, full-year workers, so they do not reflect the higher rates of unemployment among minority workers, and that, in real terms (adjusted for inflation), the average earnings reported for White male high school and college graduates, 25–34 years old declined, from US\$14 830 in 1979 to US\$12 369 in 2006 in the case of high school graduates, and from US\$18 394 in 1979 to US\$18 155 in 2006 for college graduates. Female high school graduates also had a 12% decline in real earnings in this period. Thus, except in the case of Black male high school graduates, after the 1970s, Blacks and Latinos generally maintained a constant or declining share of declining real earnings. It is also fairly evident from **Table 1** that once education and age are accounted for, Latinos earn relatively more than African-Americans with a college education, but males earn less at the high school graduate level.

The two important questions that the literature has addressed about these earnings differences, logically, are:

- (1) Why do some groups do better or worse than others?
- (2) What causes them to change over time?

A Model for Explaining Earnings Differences

The human capital model has typically been used to understand race and ethnic differences in earnings (Becker, 1957; Freeman, 1973, 1976; Hanushek, 1981; Welch, 1973; Chiswick, 1984). This model characterizes individual earnings as a function of education and experience in the labor force. The premise is that earnings of various groups would be explained largely, if not entirely, by their average education and experience. This still leaves the issue of why average education differs among different groups. Is the difference voluntary, or the result of discrimination in the supply of educational services? However, leaving this issue aside, if the human capital model is a correct representation of the market for labor, then race or ethnicity should play no significant role once

the human capital of individuals is controlled for, that is, the coefficients of education and experience in the earnings function should be equal of all ethnic groups. The model is as follows:

$$\ln Y_i = a + b_j \sum_{j=1}^m S_{ij} + C_k \sum_{k=m+1}^n E_{ik} + e_i$$

where Y_i = income of the individual i ; S_{ij} = dummy for schooling level j ; E_{ik} = dummy for experience level k ; and e_i = unexplained variance.

Other models are more elaborate, including the possibility that earnings for different groups vary because of employment in different industries (with significantly lower or higher pay), in public versus private employment, different parts of the country, and because of differences in civil status, and in native versus foreign parentage, which could represent English-language skill differences (Carnoy *et al.*, 1976; Farley, 1986; Bean and Tienda, 1988; Carnoy *et al.*, 1990). Time worked per week or per year is also an important potential factor affecting earnings differences, since some groups may have higher average levels of voluntary unemployment and part-time employment than others.

Most recently, in the 1990s, the argument on race/ethnic earnings differences focused on the achievement score differences between these groups even when they have the same number of years of schooling and similar experience in the labor force (Herrnstein and Murray, 1994; Murnane *et al.*, 1995; Neal and Johnson, 1996; Thernstrom and Thernstrom, 1997). Such achievement differences can reflect varying initial endowments, varying family and community investments in children's academic ability, and possible differences in the quality of schooling available to different race/ethnic groups. Some analysts are persuaded that the Black–White and Latino–White test gaps are the main obstruction to Black and Latino economic progress. In their view, the test gap indicates that the cognitive ability of many Blacks and Latinos is weak and therefore the main reason their wages and income lag behind whites. In the human capital explanation, academic ability among those with the same number of years of schooling needs to be added to the model to measure human capital more fully.

We take these arguments step by step; first, we use cross-section data over a long period of time to estimate how much school attainment and other variables (not including academic ability) may contribute to earnings differences between race/ethnic groups. Then we look at studies that use longitudinal data to test the contribution of ability differences to these earnings differences. We also comment on how the contribution of various factors to earnings differences may be changing over time.

Explaining Earnings Differences with Cross-Section Data

Empirical results of cross-sectional studies in a single year show that schooling level attained is a significant correlate of earnings differences among groups. African-Americans, Latinos, and Native-Americans take significantly less schooling than Anglo Whites and, particularly less than, Asian-Americans. The importance of education in explaining differences in income between various ethnic/gender groups can be simulated with log income equations, estimating how much equalizing education differences would equalize income between groups. For each year and each ethnic/gender group shown in **Table 2**, the figure in the table represents the percentage point increase in average income the group would have had if its education were equal to that of White males in the same year. For example, in 1939, Black males would have had 27 percentage points higher income if their education were equal to White males', taking account of age differences. White females, on the contrary, would have had 9 percentage points lower income if their education were equal to White males', implying that that working White females were more educated than males in the 1930s. Adding work-experience differences changes these percentages marginally, except for Latinos in the 1970s, when the Latino labor force became significantly younger than other groups. The additional effect of Latino experience decreased sharply in the 1980s.

Observable factors other than the quantity of schooling and age may explain part of the gap in the earnings of

Black and Latino workers compared to Whites. Some of these factors are industry and region worked in, English-language limitation (foreign birth/language spoken at home), and the quality of education taken by different groups, including differential investment in education at home.

Excluding measures of ability differences, which are not available in the census cross-section census samples, the graphs in **Figure 1** show the percentage points of income difference remaining when all the observable factors (school attainment, work experience, region of work, marital status, foreign/native birth, and industry of work) of each group are equalized by simulation to that of White full-time employed adult males (see Oaxaca (1973), Carnoy *et al.*, (1990), and Carnoy (1994), for the standard model of such a simulation). This residual fell significantly for full-time-employed Black males between 1939 and 1982 and for Latino and Asian-American males between 1939 and 1969. The residual shown in **Figure 1** is measured as percentage points of the earnings gap for each group that is not explained when minorities are made to look like White males educationally and in terms of experience and of place of work. In the 1980s, the residual rose for all three groups. The residual was essentially zero by the end of the 1940s for Asian-Americans, and has been, until the new Latino immigration after 1965, much lower for Latinos than for Blacks. In the 1980s, it represented about 16 percentage points of White male income for Blacks and 13 percentage points for Latinos. It is probable that the residual continued to rise for Latinos and may have fallen for Blacks between 1989 and 2006 (see **Table 1**). Part of the residual for

Table 2 Percentage points of income gain that would result from equalizing minority education to White male education, by ethnicity and gender, full-time employed, 1939–89^a

Year	Latino males	Latina females	Black males	Black females	White females
1939	29	18	27	22	-9
1949	17	12	18	11	-8
1959	15	10	15	9	-2
1969	12	9	14	7	0
1973	16	9	12	5	0
1979	16	8	11	6	2
1982	15	10	11	6	2
1985	15	10	11	6	2
1987	15	8	10	6	1
1989	20	14	10	7	0

^aThe education variable is measured in 1940, 1950, 1960, 1970, 1974, 1980, 1983, 1986, 1988, and 1990; incomes refer to the previous year – hence, the years in the table refer to the income year. The education gap is estimated from a simulation using a regression equation with human capital variables (years of schooling, labor-force experience, and, in census years, native or foreign born). The percentages in the table should be read as the number of percentage points that a given group would have gained just from getting the same distribution of education in its labor force as White males. A negative sign means that White females would receive lower incomes, all other variables equal, were education equalized with that of White males (White females in the labor market in those years had higher education than White males).

From Department of Commerce, United States Census, Public Use Sample. 1940, 1950, 1960, 1970, 1980 and Current Population Survey, 1974, 1983, 1986, 1988, 1990.

Figure 1 Minority-White income gap explained by wage discrimination (does not include adjustment for ability differences), 1939–89.

Latinos is associated with foreign birth, and this, in turn, may be a function of English-language capability. When Latinos of Mexican origin are separated into native- and foreign-born, the corresponding residuals for the native-born are 3 percentage points in 1960, 3 in 1970, and 6 in 1980, and for foreign-born, 27 percentage points in 1960, 14 in 1970, and 14 in 1980 (Carnoy *et al.*, 1990). The low residuals for native-born Latinos of Mexican origin suggests that the main explanation of lower incomes for Latinos, once English-language capacity is accounted for, is observable differences in educational attainment, experience, and place and type of work.

The residual can be interpreted as reflecting lower-quality education taken by minorities (Welch, 1973; Card and Krueger, 1992a, 1992b), lower returns to experience, such as in the choice of or access to jobs that have a smaller training component, hence flatter experience-earnings profiles, and possibly a strong interaction between the quality of schooling and access to training in jobs. The differences in quality of education received may not only reflect differences in the quality of schools attended by different groups, but also the amount invested in them by their families and the interaction between family background and school performance, which is discussed in detail below. Eliminating discriminatory practices in school access does not necessarily equalize outcomes (the quality of an individual's education) because of the cumulative nature of learning before and during school and also because of interaction effects. Differences in returns to education and in access to jobs with more training for different groups may also simply be the result of discriminatory practices in the labor market.

Why labor market discrimination occurs has been the subject of considerable controversy. In his pioneering work on racial discrimination, Myrdal (1944) argued that it was historically institutionalized in the fabric of society and required public intervention to change. Becker's (1957) model of discrimination focused on the taste for discrimination on the part of White workers and consumers, which drives the earnings of Black workers down relative to White workers. Reich (1982) refutes the claim by Becker that White workers profit when there is discrimination, showing that the lowest White earnings are in those states where the greatest discrimination exists. He argues that labor-market discrimination serves owners of capital, since it keeps all workers' wages lower.

Earnings Differences for Minority Women

Racial and ethnic earnings differentials vary by gender. **Table 1** suggests that full-time-employed minority women in the United States had, by the late 1960s/early 1970s, come to earn approximately the same income as full-time-employed White women when the level of schooling was the same, and, on an hourly basis, may actually have earned more than White women (Chiswick, 1987). By 2006, Black male high school and college graduates earned about 90% and 80% of the annual income of Whites, and Black women graduates earned about 90% of full-time White female incomes at both levels of schooling. Latino men high school graduates earned a much lower fraction of White male incomes than did Latina women relative to

White women, but only slightly lower at the college graduate level – this is the opposite of the pattern for Blacks.

If Black women and Latinas are subject to the same race/ethnic discrimination as men, why should they earn higher relative incomes with compared to their White gender counterparts? The answer lies partly in the gender segregation of the labor market and the willingness of White male employers to group minority and White women in the same category of labor. This was not always the case, and, recently, differences in pay are beginning to emerge again in favor of White women, perhaps for somewhat different reasons than in the past. Black (but not Latina) female earnings were much lower than those of Whites in the 1940s and 1950s, when Black women were highly concentrated in domestic service. As Black women moved into manufacturing and clerical jobs and received much more schooling, the differences between White and Black female earnings tended to disappear, at least until the 1970s. After that time, with the steady increase in the labor-force participation of White women, the ratio of Black and Latina women's earnings to White female earning has gradually declined. Even so, Neal (2004) argues that the measured wage gap between Black and White women continues to be too small because of the failure to correct for differential labor-force participation.

Besides the continued gender segregation of the labor market, one reason that Black women may continue to earn a higher ratio of White salaries than Black men, particularly among college graduates, is that a higher fraction of college graduate Black women work in the public sector, where female salaries are much higher than in the private sector. Public sector employment was especially important in the late 1960s and in the 1970s, when such employment was at its peak.

Do Ability/Educational Quality Differences Explain Race/Ethnic Earnings Differences?

The most recent debates center on whether discrimination has been eliminated or still exists in US labor markets (see, for example, Thernstrom and Thernstrom, 1997 vs. Brown *et al.*, 2003). The discussion centers in part on whether earnings differences not explained by education and experience differences are the result of continued discrimination or of race/ethnic differences in ability as measured by test-score differences (Neal and Johnson, 1996) – in part such test-score gaps are the result of family education differences (initial endowments) and, in part, of differences in the quality of schooling taken by Blacks/Latinos and Whites.

Estimates of the contribution of higher ability, as measured by scores on mathematics tests taken in high

school, to individual earnings later in life suggest that its value is significant even when years of schooling are accounted for (Murnane *et al.*, 1995), and that the return to academic skills may have increased in the 1980s (Blackburn and Neumark, 1993; Murnane *et al.*, 1995). (However, this is not a universally held view. Some economists, such as Samuel Bowles and Herbert Gintis have long argued that cognitive skills explain relatively little of the variance of earnings and productivity (Bowles and Gintis, 1975; Bowles *et al.*, 2001)).

Those estimates paid little attention to the role of race/ethnicity, but Carnoy and DeAngelis (1999) used the National Longitudinal Survey of Youth (NLSY) and High School and Beyond data to estimate the role of mathematics achievement and race/ethnicity in wages by gender group for the 1972 and 1982 high school senior cohorts in various years after graduation. They made these estimates separately for high school graduates, those who had completed some college, and for college graduates. They found that in the 1972 cohort, mathematics test score in high school had little direct effect on the wages of high school male graduates. Being Hispanic had no significant effect on earnings, but being Black had a strong negative effect; about 20–25% lower wages when education, mathematics achievement, and work experience were controlled for. The race effect was somewhat smaller but significant for those with some college, but was negligible for college graduates, whereas one standard deviation higher mathematics test score was worth 3–4% for those males with some college and 8–9% higher wages for college graduates. Higher mathematics score had a similar size effect for female college graduates, but neither race nor ethnicity had a significant relationship to wages.

For the 1982 cohort, only annual earnings (not wages) were available as the dependent variable. For male high school graduates, mathematics score is related to earnings in the 1991 follow-up, but so is race (being Black), although less so (10–18% lower earnings) than for the 1972 cohort. For those males with college education, race is unrelated to earnings when education and mathematics score is accounted for, but math score is related to earnings for college graduates to about the same degree as in the 1972 cohort. For females with college education, mathematics score is related to higher earnings, but race is generally not.

This analysis suggests that the labor market for high school graduates placed relatively less value on ability differences in the 1970s and 1980s and paid Black males considerably less even when all these human capital variables were accounted for. This did not appear to be the case for Hispanics with high school degrees or Hispanic/Black college graduates even in the 1970s, and by the 1980s and early 1990s, was not the case for even those males with some college. For females, race and ethnicity

do not seem to have been correlated with wages or earnings even in the 1970s.

Thus, race discrimination for Blacks seems to have been important in the labor market for males with lower levels of schooling even in the 1980s and early 1990s, whereas it seems to have played little role in the labor market for college-educated males by the late 1980s and for females with both high school and college education. For the latter groups, mathematics ability was related to earnings; so if Blacks and Latinos had lower mathematics ability, they would have received somewhat lower earnings (about 10% lower earnings for one standard deviation difference in mathematics test score). If we extrapolated these results to the earnings differences in **Table 1**, most of the differences observed in Black/White male high school graduate earnings in 1989 and 1999 could be attributed to racial discrimination, and most of the observed Black/White differences in college graduate earnings for males and females, to mathematics achievement differences.

An analysis of yet another data set, the NLSY, which includes the armed forces qualifying test (AFQT) as a measure of ability among a sample of 16–23-year-olds in 1979, Carneiro *et al.* (2005) explores wage differences between Blacks and Whites and Hispanic and Whites, males and females, in that sample followed over the period 1991–2000. When the AFQT scores are corrected for the level of schooling attained by the test taker in order to get a purer ability effect, one standard deviation higher AFQT score is associated with 9–10% higher male wages whereas being a Black male is associated with 14–19% percent lower wages than White males. Once AFQT scores are taken into account, Hispanic and White males do not have significantly different wages. Being a Black woman is associated with 7–8% lower wages than White women earn when ability is taken into account, and being a Hispanic woman is associated with a wage premium of 7–14% compared to White women. The payoff to ability is somewhat higher than for men, about 9–13% for one standard deviation higher AFQT score. These results are generally consistent with the results for the High School and Beyond Survey, but the test-score effect is somewhat larger in the NLSY, and being Black seems to have a negative effect on men and women's wages, although the coefficient is not large for women.

What Are the Sources of the Black/White Test-Score Gap?

Although it is beyond the scope of this article to provide a comprehensive review of the literature on the Black/White test-score gap, the overall question of race/ethnic difference in earnings merits at least some discussion of whether Blacks and Hispanics choose to invest less in

themselves academically, hence achieve less, or whether the schools they attend and the society around them are the main source of their lower achievement – hence, it is the civil society and state that makes them less productive (this would be akin to the discrimination argument in labor markets).

Earlier Jencks and Phillips (1998) and more recently Rothstein (2004) summarized the empirical research on this issue. Rothstein argues that much of the achievement gap between Blacks and Whites exists at age 5 years when children enter kindergarten. His main point is that the achievement gap is largely the result of differences in the social context in which most Blacks and Latinos live in the United States and that the potential for schools to overcome achievement gaps is relatively limited. Thus, he concludes that a more productive strategy to reduce the achievement gap would be improving minorities' social conditions – nutrition, healthcare, and sense of being full participants in American society.

Part of those conditions is also the degree to which Blacks feel discriminated against in labor markets. A number of opinion surveys suggest that Whites believe that the United States is free of racial discrimination, and Blacks believe that despite great improvement in race relations over the past 40 years, racial discrimination is still a major feature of their lives (Brown *et al.*, 2003). This could influence their desire to perform well in school and their test performance (Steele, 1997).

Evidence from national- and state-level data on whether the Black–White test score changes during schooling is contradictory:

Data from [longitudinal] ECLS-K and SECCYD suggest the gap is large at the start of kindergarten, and grows in the early elementary grades (particularly from first to third grade in ECLS-K), though the patterns differ somewhat depending on the gap metric used. Data from NAEP suggests that the gap continues to grow from age 9 to 13 (fourth to eighth grades, roughly), but [longitudinal] state-level data from Texas and North Carolina seem to contradict this finding, at least during the late 1990s and early 2000s, suggesting that the gap grows relatively little in standard deviation units over the latter half of elementary school. Finally, data from NAEP and NELS suggest the gaps change relatively little following eighth grade, though there is some uncertainty in these estimates, since most are based on analysis of repeated cross-sectional data (Reardon, 2007: 8).

Reardon (2007) does a careful analysis of changes in the Black–White test-score gap between kindergarten and fifth grade and concludes that the gap in both math and reading scores widens between kindergarten and fifth grade, and that the gap grows faster among higher-scoring students, suggesting that part of the widening gap may result from "... black students with high skill levels in kindergarten

being more likely than equally high-scoring white students to be in schools where the median skill level is far below their skills (because they are more likely to be in schools with predominantly black student populations)” (Reardon, 2007: 31). Thus, the increasing Black–White test-score gap might be the result of poorer schools, but schools whose quality is derived from the concentration of low-income students, in turn the result of residential segregation. Even so, the Black–White test-score gap at kindergarten entrance explains the bulk of the gap at grade five.

Carneiro *et al.* (2005) also argue that early environment rather than poor schooling is likely the most important reason that Blacks have lower test scores (academic skills) than Whites.

Minority deficits in cognitive and non-cognitive skills emerge early and widen. Unequal schooling, neighborhoods and peers may account for this differential growth in skills, but the main story in the data is not about growth rates but rather about the size of early deficits. . . . The failure of the Hispanic-white gap to widen with schooling or age casts doubt on the claim that poor schools and bad neighborhoods are the reasons for the slow growth rate in black test scores. (Carneiro *et al.*: 21).

Explaining Changes in Earnings Differences over Time

Why has the gap in earnings between Whites and minority groups changed over time? **Table 1** shows that full-time-employed Black males and females made large gains in relative earnings in the period 1939–79, especially in the 1940s and 1960s. The gains in the 1980s were negligible (the relative earnings of Black male college graduates fell), and Black males high school graduates made some gains in the 1990s, whereas Black female college graduates saw a decline in their earnings relative to White females. Latino males and females also made big gains in the period 1939–69, but then lost ground, particularly male high school graduates. Asian-Americans made large gains in the 1940s, 1950s, and 1960s, and college graduates continued to make gains in the 1990s and early 2000s.

The principal debate that has developed over these changes is whether they are the result of supply side forces, specifically changes in the relative investment in human capital made by the different groups, or demand side forces, specifically legal and direct employment intervention by government. Freeman (1976) maintained that the large gains in relative earnings of Blacks in the 1960s came as a result of the passage of the 1964 Civil Rights Act and subsequent federal employment legislation in 1965. Others (Heckman and Payner, 1989; Donohue and Heckman, 1991; Card and Krueger, 1993) have supported this explanation. Smith and Welch

(1989), on the contrary, have argued that the single best explanation for the gains in the period 1939–79 was the relative increase in Black education, and that federal intervention had only a minor effect, primarily in raising the earnings of young Black college graduates in the early 1970s. Card and Krueger (1992b) claim that about one-fourth of the gain in Black earnings attributed to government intervention in labor markets in the 1960s and 1970s is the result of improvements in Black education in the South in the 1930s and 1940s. Juhn *et al.* (1991) argues that the slowdown in Black–White convergence in the 1980s was due to unmeasured skill effects, namely that the payoff to educational quality increased in the 1980s, and Blacks still received lower-quality education than Whites.

If the analysis is done decade by decade in the 50-year period 1939–89, the supply-side argument is weakened. **Table 2** suggests that education gains by Blacks between 1939 and 1979 were correlated with a reduction in the Black–White earnings gap in those four decades. But other factors appear to have been much more important than education in that reduction. For example, **Table 3** corrects that contribution of education differences to the income gap estimated in **Table 2** for changes in the income distribution (specifically the income weights attached to different levels of schooling) in each decade. Wage compression in the 1940s was much more important than Black male educational gains in reducing the

Table 3 Change in education gap adjusted for changing income weights, by decade, full-time workers, 1939–89 (percentage points of income)

Year	Latino males	Latina females	Black males	Black females
1939	29	18	27	22
1949	23	16	24	15
1949	17	12	18	11
1959	16	10	16	9
1959	15	10	15	9
1969	12	9	14	7
1969	12	9	14	7
1979	16	8	11	6
1979	16	8	11	6
1989	19	13	9	7

From See **Table 2** for figures based on the education gap estimated using same-year White male income weights. Figures in this table compare the education gap in 1939 with the gap in 1949 figures based on average education differences between ethnic groups in 1949 weighted by White male coefficients estimated using 1939 census data; compare the 1949 figures from **Table 2** with 1959 figures based on average education differences in 1959 weighted by White male coefficients using 1949 census data, and so forth, for various census years. This permits comparison for each decade of the effect on income of the education gain net of changes in the distribution of income among education groups in that particular decade.

Black–White income gap, and was as important as education for Latinos. Although Black males' education did not increase much relative to Whites in the 1940s and racial discrimination declined only slightly, the enormous increases in incomes for all low-income earners relative to high-income earners – irrespective of race – during that decade lifted Black male relative incomes more than in any decade since. In the 1940s, there was also a job shift from agriculture to manufacturing that had a power effect on Black male incomes. As a point of comparison, in the 1950s – a period of significant educational gains for minorities but no reduction in overall income inequality, much-reduced sectoral job shift, and no reductions in job discrimination – gains in relative incomes for Blacks were minimal. In the 1960s and particularly, the 1970s, Blacks made large education gains, but the major gains in income for Blacks came from the reduction in wage discrimination. In the 1980s, when the political climate on affirmative action changed, Black male and female incomes stopped rising relative to Whites' (particularly for Black male college graduates), and in the 1990s, when the climate became more favorable again, Black male relative earnings rose again. Another possible influence on Blacks' relative incomes in the 1990s may have been the relative increase in fourth- and eighth-grade mathematics test scores in the late 1970s and 1980s, which could have been reflected in the higher relative test scores of both 25–34-year-old high school and college graduates in the 1990s and early 2000s.

A similar analysis for Latinos and Asian-American males and females suggests that education is a more important explainer of their relative income gains than for Black and White females, although changes in sector of work (shifts from agriculture to manufacturing) are also crucial in understanding their gains in the 1940s (Latinos and Asian-Americans) and 1950s (Latinos). Both groups also profited from reduced labor-market discrimination in the 1940s and 1960s.

The recent work focusing on the relation to relative wages of pre-market skill differences between minorities and Whites has been interpreted by many as a mandate to improve the quality of education taken by Blacks and Hispanics (e.g., by Thernstrom and Thernstrom, 2003). However, both Carneiro *et al.* (2005) and Rothstein (2004) make convincing cases that most of the ability differences between Blacks and Whites as measured by teenage test scores of those with similar levels of schooling occur before children enter school and persist through the schooling process. This is apparently not the same pattern for Hispanics, who are able to close the ability gap as they acquire more schooling. Furthermore, almost all studies with longitudinal data show that even in the 1990s, at least for Blacks, education and test-score differences compared to Whites do not explain even part of Black–White wage differences, particularly for males.

Comparing Results for Brazil and Israel

Brazil has a large Black (*preto*) and mulatto (*pardo*) population. For many years, the official ideology in Brazil was that its racial inequality was softened by the acceptance of intermarriage. In the past 10 years, however, research has identified large earnings differences between Whites and both *pretos* and *pardos* in the Brazilian labor market. The most recent of these studies uses 1996 household survey data for urban male workers and a rough proxy for the educational quality received by the individual worker (teacher–pupil ratios by state of birth and year of birth) to estimate wages of male household heads as a function of education, age, parents education, and industry worked in (Arias *et al.*, 2004). The study finds that the bulk of wage differences between Whites and workers of color is explained by productivity-related worker characteristics, but unexplained wage differences remain large at higher-income levels. In the fifth quintile of income, the residual wage gap is 15% for *pretos* and 12% for *pardos*, and this increases in the top-income decile to 25% for *pretos* and 16% for *pardos*. This is reflected in lower rates of return to education for males of color than for Whites. Nevertheless, whereas *pretos* face a larger gap in education returns at the top of the income distribution, the opposite is true for *pardos*. Apparently, the common belief in Brazil that in higher socioeconomic levels, interracial marriage softens racial discrimination probably holds true.

Similar estimates have been made for Israel, where ethnic origin (European-origin vs. North African-Asian-origin immigrants) and being an Israeli Arab are potentially a source of wage discrimination (Amirs, 1983, 1988; Margalioth, 2005). The results of such estimates show that in the 1970s, the wage differential between the foreign-born males of the two ethnic groups in the Jewish population fell substantially from 25% to 16% mainly because of demographic factors such as a change in the relative age structures and period of immigration of the two groups. Unexplained differentials (wage discrimination plus quality of schooling differences) also fell from 15% to 12%. When the same estimates are made for first generation Israeli-born of North African-Asian and European extraction, the wage differential is shown to have become larger than for the foreign-born in the 1970s, rising from 26% in 1970–72 to 30% in 1980–82. This is explained mainly by an increasing age difference over the decade, with European-origin Israelis becoming increasingly older in relative terms. Nevertheless, the results also show that educational differences (larger than between the foreign born of the two ethnic groups) continued to persist even though average levels in both groups rose significantly relative to their parents. The results also show that wage discrimination fell during the decade and was relatively low (about 6% in 1980–82). Other estimates of wage differences between Israeli Arabs and

Jews suggest that it is mainly the segregation of the labor market that contributes to the wage gap between the two groups. The gap is quite large: Israeli Arab employees earned about 28% less than Jewish employees. Arabs are highly overrepresented in low-paying industries such as agriculture and construction, whereas they are underrepresented in financial and business services (Margalioth, 2005). Although education differences, particularly a lower likelihood that Israeli Arabs attended university, contribute to wage differences, there is considerable evidence that an important source of wage differences is discrimination against Arabs in access to jobs on security threat and ideological grounds. Arabs also face a number of other barriers to entry, such as the requirement that potential employees have completed military service (Arabs normally do not serve in the Israeli defense forces).

Glossary

Ability bias – The bias to the returns to schooling that can result from the fact that people who acquire more education may have greater innate skills that would allow them to earn more even without additional schooling.

Causal returns – The returns to education that are induced or caused by additional education rather than simply correlated or associated with additional education.

Endogeneity of education – The fact that education is a decision variable in that the amount of education acquired may be a function of factors such as ability, motivation, family background, income, proximity to school, and compulsory school laws.

Instrumental variables – In the context of education decision making, instrumental variables are variables that affect the amount of education acquired but do not affect the education outcomes or the returns to education (e.g., compulsory school laws or proximity to schools).

Measurement error – The possibility that collected data, like education, may be measured with error since people may not accurately report their education.

Returns to education – The financial rate of return to investing in an additional year of schooling, obtained by comparing the additional earnings from an additional year of education with the cost of acquiring the additional education; it shows how average earnings increase with added education.

Selection bias – In the context of returns to education, it is the bias that can be created by the fact that education may be a function of conventionally unobserved factors such as ability or motivation.

Sheepskin effect – The credential effect or additional returns associated with the credential of completing key phases of education like graduating from high school or university (sheepskin was used historically to make the parchment for diplomas).

importance. What are the private returns that individuals can expect from investing in education? How do those returns vary by factors such as level of education, field of study, and individual background characteristics? How have those returns varied over time and across different countries? Is there an extra effect from a year of education if that year provides the credential of completing a phase of study such as graduating from high school or university? If potential dropouts are compelled to stay in school longer by compulsory school laws, do they receive returns that are higher or lower than the average returns? Are the returns the result of education enhancing the productivity and skills of individuals or are they the result of signaling of such conventionally unobserved factors such as ability, motivation, and time-management skills? What are the appropriate methodologies for estimating the returns to education, especially for dealing with factors such as measurement error, ability bias, credential effects, and financial constraints?

The purpose of the article is to address these practical and methodological questions. The emphasis here is on the causal returns to education after controlling for other observable and unobservable factors such as innate ability or motivation that may affect the outcomes associated with higher education. Understanding the underlying causal relationship process is important for policy purposes so as to ascertain the effect of policy interventions, for example, to reallocate resources from fields of low returns to fields of high returns or raise the age of compulsory schooling or institute policies to deter dropping out. It can also be important for predicting future changes as the underlying causal factors change.

The article moves from the simple to the more complex. It starts with estimates of the return to education based on basic schooling equations where education is not exogenous but can be correlated with other factors that can affect outcomes. It then moves to a discussion of refinements to the basic model: the appropriate measure of earnings and the inclusion of nonwage benefits; measurement error in the schooling variable; corrections for ability bias, omitted variables, and selection bias; and the possibility of heterogeneous returns and credential or sheepskin effects.

Introduction

Understanding the causal relationship between education and the financial returns to such education is important for addressing a range of questions of practical and policy

Estimating Returns to Education via Schooling Equations

A wide range of methodological issues are associated with estimating the economic returns to education. (Reviews of

many of these issues include Card (1999, 2001); Chamberlain (1977); Chamberlain and Griliches (1975); Griliches (1979); and Lemieux (2002). Heckman *et al.* (2006) provide a critical review of much of the literature, emphasizing the heterogeneous returns to education and the importance of psychic costs in explaining such heterogeneous returns. Here, we have cited articles that illustrate the issues and that contain references to related articles.) In this section, the main methodological issues are outlined in a nontechnical fashion, generally referencing more technical treatments of the issues.

Basic Schooling Equation

Estimates of the private returns to education essentially build on the human capital earnings function of Mincer (1974) where the (natural) log of earnings is regressed on years of education and other control variables including years of labor-market experience. The latter is often entered in a quadratic form to capture the nonlinear relationship whereby earnings tend to advance rapidly for early years in the labor market, flatten in later years, and decline slightly thereafter. Higher-order polynomial functions for experience have also been recommended so as to better capture the more rapid earnings growth early in an individual's career and the slower decline in wages later in an individual's career, although Heckman *et al.* (2006: 333) indicate that such higher-order polynomials did not improve their estimates.

The estimated coefficient on the education variable has a convenient interpretation as the average percent increase in earnings from an additional year of schooling (e.g., a number like 0.10 or 10% which can be compared to the returns to other investments). For interpretation, Mincer and other social scientists often assume that tuition and psychological costs from schooling are negligible, individuals do not work much while in school, and schooling and years of experience have separate effects on earnings. Under these assumptions, the coefficient from the Mincer equation can be interpreted as the return to investing in the cost of an additional year of education and compared to alternative investments. In this case, the monetary benefits of an additional year of schooling are the additional earnings from such schooling, while the costs are the forgone income. Since both the benefits and the (opportunity) costs are in this way factored into the estimates of the earnings equation, the coefficient on the education variable yields an internal rate of return to investments in education. (Heckman *et al.* (2006) provide more detailed discussion on estimating internal rates of return from schooling and alternative approaches to assessing returns from education when the mentioned assumptions do not hold.) Since data sets often have different categories of highest level of education achieved, these are often entered in place of years of schooling so that the

returns can vary by different categories of completed education.

Estimates from a basic Mincer schooling equation tend to yield estimates around 0.07–0.10, being slightly higher for females and lower for males. The returns are slightly higher for general academic streams compared to technical vocational streams, and they are higher in the more professional fields such as engineering, medicine, business, and sciences and lower in social sciences and humanities and especially in fields such as fine arts. These can be thought of as the simple benchmark returns to education against which to gauge the effect of the myriad of procedures (discussed subsequently) to improve on those estimates and to consider how returns differ across particular groups of individuals.

Hourly Wages Versus Measures That Include Hours of Work

The appropriate measure of earnings is one that approximates the hourly wage so as to reflect the productivity effects of education and to control for differences in hours worked given that persons with higher education tend to work longer hours. To the extent, however, that higher education leads individuals to work more hours, the additional time is an endogenous part of the returns to education. Measuring increased earnings per hour may therefore underestimate the true returns to education over a fixed period of work. Card (1999: 1809), for example, estimates that slightly more than two-thirds of the returns to education based on annual earnings in the United States in the mid-1990s reflects higher wages while one-third reflects longer hours. More specifically, he estimated returns to education of about 10% for males and 11% for females based on hourly wages, and 14.2% for males and 16.5% for females based on annual earnings. The fact that the change was higher for females than males highlights the facts that higher education is also associated with longer hours of work (both hours per week and weeks per year in his data) and the effect on longer hours was greater for females than males.

Measurement Error in Schooling

Returns to schooling are typically estimated from survey data where individuals report their highest level of schooling. This reported schooling can be subject to measurement error or misreporting of education. Estimates indicate that about 10% of individuals misreport their level of education, and this is true in administrative data as well as survey data. (Misreporting is discussed, for example, in Ashenfelter and Rouse (1998) and Card (1999)). If the misreporting is random or unrelated to the level of education, then such classical measurement error leads to a downward bias in the estimated returns to

education. However, if the measurement error is systematically related to the level of education, then the bias can go in either direction. Persons with low levels of education may be prone to overstate their actual education and persons with higher education may be more accurate in their reporting, yielding an upward bias to the returns to education. However, there is also the possibility of higher-educated people having more opportunities to inflate their education given the multiplicity of different types of degree-granting institutions. In essence, the biases from measurement error in schooling can go in either direction. Overall, based on his assessment of the literature, Card (1999: 1834) concludes that measurement error in education leads to a downward bias in returns to education, with the estimated returns understating the true returns by about 10%. That is, if the estimated returns were 0.10, the true returns would be 0.11.

Ability Bias, Omitted Variables, and Selection Bias

The potentially most severe bias that can occur in estimating the causal returns to education occurs because educated people can have other characteristics that are associated with higher earnings, and those other characteristics are not controlled for in the estimating procedures. Indeed, models that attempt to explain differences in school attainment often do so by noting that costs and benefits from additional schooling are not the same for everyone. Individuals may differ by innate ability, motivation, organizational skills, entrepreneurship, time-management skills, and willingness to work hard. To the extent that these factors lead to higher earnings as well as higher education, and they are not accounted for in the statistical analysis, then omitting them from the estimating equation means that some of the higher returns to education may be reflecting the effect of these factors. That is, the estimated returns to education are biased because the higher education is capturing the economic returns to these omitted variables as well as the pure causal effect of education. Alternatively stated, higher-educated people may be a select group in terms of not only observable characteristics that can be controlled for in the regression analysis but also unobserved traits as indicated above that are not conventionally controlled for in the analysis. The returns to education can reflect a return to these traits as well as to education itself.

The literature on estimating the causal returns to education has been a growth industry in recent years based largely on devising ways to control for this ability or selection bias, often involving imaginative ways of obtaining exogenous variation in education that is independent of ability or selection bias. The following illustrate such procedures.

Include proxy measures of ability

A number of empirical studies have been able to include proxy measures of ability such as IQ scores or test scores designed to measure innate ability. (Studies that deal with test scores as a measure of ability are referenced in Card (1999, 2001) and Griliches (1977)). Such studies tend to find the ability bias to be small in that the estimated return to education drops only by about 10% (e.g., from 0.10 to 0.09) after controlling for the effect of ability.

Family characteristics such as the education of a parent or sibling are also sometimes included to control for factors that may help a person obtain more education and affect their earnings. Such studies also generally find the return to education to drop very slightly (by around 0.01) after controlling for such family characteristics. (Family background controls are used in Ashenfelter and Rouse (1998); Ashenfelter and Zimmerman (1997); and Card (1995b)). Studies that have also examined how the return to education varies by the ability of the individual or his/her family background have yielded inconclusive results (Ashenfelter and Rouse, 1998, and the literature cited therein).

Twin studies

Another way to control for ability bias, and perhaps some of the other potentially important omitted variables, is to use twins since they presumably have the same natural ability (especially if they are identical twins from the same egg as opposed to fraternal twins from two different eggs). Differences in their education are assumed to occur for random reasons (a possibly questionable assumption), and in this way this procedure approaches the ideal random-assignment procedure for estimating treatment effects (in this case the treatment being more education). Using same-sex twins also controls for the possibility that parents may favor one sex or the other in devoting family resources to them to improve their labor-market outcomes.

Studies that utilize differences in education between twins to identify education differences while controlling for ability and other differences generally lower the return to education slightly (suggesting a slight upward ability bias) but this tends to be offset by the measurement error bias from mis-measuring education so that on net the true returns are about the same as those estimated in the conventional regression of earnings on education without controlling for ability bias or measurement error. Estimates of returns to schooling using US twins generally range between 0.06 and 0.12. (Earlier twin studies are reviewed in Griliches (1977, 1979) with more recent twin studies reviewed in Ashenfelter and Rouse (1998) and Miller *et al.* (2006)).

Natural experiments based mainly on features of the education system

A number of empirical studies have used institutional features of the education system or the environment to generate differences in education that arise for reasons

beyond an individual's control. A policy change that lowers the cost of college in one state, for example, affects some individuals but not others depending on when and where they are born. Forces that cause differences in education for reasons outside individuals' control are called exogenous. Using exogenous forces to estimate returns to schooling helps address ability bias because differences in education that arise from exogenous forces are unlikely due to differences in individual ability. Returns-to-schooling estimates from this approach apply only to individuals affected by the exogenous force (e.g., policy change). (Such studies are reviewed in Ashenfelter *et al.* (1999); Ashenfelter and Rouse (1998); Card (1999, 2001); and Carnoy (1997) and critically assessed in Heckman *et al.* (2006)). Exogenous variation can be caused by various factors:

- Geographic proximity to educational institutions can generate exogenous variation in education in that those close to a university are more likely to attend university and hence acquire more education than those who are far away from a university (e.g., Cameron and Taber, 2004; Card, 1995).
- Differences across regions or over time in financial costs to attending school (e.g., through tuition) can also lead to differences in education attainment (e.g., Kane and Rouse, 1995; Chen, 2009)
- The Vietnam draft lottery generated exogenous increases in schooling because many persons enrolled in school in order to defer military service (Angrist and Krueger, 1994).
- Local labor-market earnings for persons at the age of 17 years have generated exogenous variation in education in that higher earnings may increase the opportunity cost of education and thereby induce dropping out (Cameron and Taber, 2004).
- The GI bill in Canada gave rise to exogenous variation in education in that the cohort of males from English-speaking Ontario received additional education due to the GI bill and not to the decision, say, of higher-ability people to acquire more education. The earnings of this treatment group were compared to the earnings of a control group from French-speaking Quebec who were less likely to have served or to have taken advantage of the bill (e.g., Lemieux and Card, 2001).
- Day of birth can interact with compulsory school laws. For example, persons born earlier in a year (e.g., January) tend to have less education than those born later in a year (e.g., December) because they are older when they start school (from missing the school entry age cutoff) and hence reach the compulsory school-leaving age with a lower level of education, many of whom then drop out (e.g., Angrist and Krueger, 1991).
- Differences in compulsory school laws and changes to these laws over time can also generate differences in

education attainment since some persons in jurisdictions with higher ages at which it is compulsory to remain in school will acquire more education because they cannot drop out until the compulsory age (e.g., Oreopoulos, 2006a, b).

- Exogenous variation in education has also been found in situations where an additional year of schooling has been added or subtracted to the high school or university curriculum (Webbink, 2007; Krashinsky, 2007).

Studies using the natural experiments from features of the education system or environment to obtain exogenous variation in education tend to find such causal returns to education to be in the neighborhood of 0.06–0.15, and sometimes higher. As emphasized in Heckman *et al.* (2006: 392), however, the returns are often imprecisely estimated, with large standard errors. These estimates are somewhat higher than the returns when conventional years of schooling are used.

Heterogeneous Returns

It is important to view returns to schooling as being individual and context specific. Gains from schooling depend upon the individual's background, motivation, and the quality and type of schooling. An individual's decision to take more schooling depends on both expected gains and costs. Estimates of returns to schooling using exogenous policy variation can often be interpreted as average returns to schooling among individuals affected by the policy variation. Sometimes the policy variation identifies particularly interesting parameters, such as the average gains to schooling among those forced to stay on in school because of more restrictive compulsory schooling laws or the average gains to schooling among those who entered college because tuition costs were lowered. As discussed in Card (1999, 2001), many of the natural experiments used to estimate returns to education identify average returns for more disadvantaged groups. The fact that increase in the education of such persons tends to generate higher-than-average returns suggests that increasing the education of such marginalized groups can have both desirable efficiency effects (high returns) as well as distributional effects (high returns to otherwise more-disadvantaged groups). This suggests the viability of increasing the education of such groups through policy initiatives such as increases in the compulsory school age, funding assistance, expansion of accessibility (e.g., by facilitating transfers from colleges to universities), and campaigns against dropping out.

A number of researchers have tried to model an individual's schooling decision by assuming more structure to the decision-making process (e.g., schooling only affects wealth, people have rational expectations, and discount the future geometrically). The models are simplified enough to

allow estimation of a few unknown parameters, such as an individual's time discount rate and return to schooling. A correctly specified model with enough structure permits estimation of a wide set of returns-to-schooling measures for individuals under different circumstances (e.g., faced with different costs or benefits or different schooling-level decisions). The advantage of this approach is that it emphasizes the economic content of what is being estimated and offers a potential approach to measuring individual rates of return in situations where an experimental approach cannot. Studies using this approach typically estimate returns around 0.04–0.07, which are lower than those from experimental approaches (Bezil, 2007, provides a review). If the assumptions of these models are incorrect, however, the returns-to-schooling estimates can be off significantly. Unfortunately, this is difficult to determine.

Annual Returns, Signaling, and Sheepskin Effects

An important issue to address is the extent to which the estimates of returns to schooling reflect not only the productivity-enhancing effect of schooling but also an effect on earnings of the underlying set of skills that schooling signals. There is a fundamental difficulty in unraveling the extent to which schooling is a signal of existing productivity as opposed to enhancing productivity: both theories are observationally equivalent – they both suggest that there is a positive correlation between earnings and schooling, but for very different reasons. If the rate at which employers learn an employee's correct set of skills is slow, or if early job placements influence long-term job opportunities, the effects of signaling can be long lasting.

The empirical literature generally finds evidence of such signaling or sheepskin effects (see Weiss, 1995; Chatterji *et al.*, 2003; for examples and reviews).

Ferrer and Riddell (2002) provide estimates of the credential effects and review much of the earlier literature, as do Heckman *et al.* (2006). The returns to an additional year of education that involves completion of a stage (e.g., graduating from high school, or university) is higher than the return to a year of education that does not involve the credential of the completion of a phase. For example, based on the 1996 Canadian census, Ferrer and Riddell (2002) estimate rates of return to an additional year of schooling to be 6% for males and 9% for females. These are averages of both the credential effects associated with milestones of completing various phases as well as the returns to years within the different phases. When the returns to completing the phases are calculated and annualized over the period of education necessary to complete the degree, the annual rates of return that are implied by completing university relative to high school are 9% for males and 11% for females.

While most researchers would agree that schooling affects earnings both by improving skills and by signaling skills, the relative importance of these effects is not well understood. One paper estimates that the contribution of signaling to the returns to schooling is less than 25% (Lange, 2007). Understanding the relative importance of signaling in explaining returns to schooling remains an important area for further research.

Trends and Some International Evidence

Returns to education in the United States have been increasing steadily in recent years likely reflecting the widening skill differential in wages (Card and Lemieux, 2001), in spite of the dramatic increases in education that would normally be expected to depress returns. Returns have also been increasing in Canada and European countries even though the wage structure there is more compressed when compared to the United States. (e.g., Bingley *et al.*, 2005). Obviously, the demand changes favoring higher-educated personnel have more than offset the supply changes.

International comparisons of the return to education are obviously difficult because of differences in the data sets and methodologies. In spite of this, reviews of the international evidence in general find similar results as those in the United States and Canada. (The international generalizations given here are based mainly on Psacharopoulos and Patrinos (2004), earlier studies are cited therein. Similar generalizations for some of the issues are given in Trostel *et al.* (2002) with further international evidence provided in OECD (1998)).

Summary

The following points sum up the returns to education:

- Returns to education tend to be in the neighborhood of 10%, typically ranging from 6% to 15%. **Table 1** illustrates the main approaches used to estimate these returns and their general findings.
- Returns to education tend to be in the 6–10% range when based on ordinary least-squares (OLS) estimates from conventional schooling equations and the 10–15% range (and sometimes higher) when based on instrumental variables (IV) and other procedures used to identify exogenous variation in education. As such, the 10% estimate is at the upper end of the OLS range and lower end of the IV range.
- The returns tend to be higher for
 1. females as opposed to males;
 2. obtaining the credentials associated with completing phases such as high school or university;

Introduction

Earnings of workers classified by some dimension have been at the core of empirical economics, as well as of sociology, since the dawn of the discipline. Up to the middle of the twentieth century the main dimensions according to which earnings were classified were sector of economic activity, industry, occupation, and formal versus informal sector in developing countries. From about 1960 onward, following the human capital revolution in economic thought (Schultz, 1961; Becker, 1964; Mincer, 1974), the educational level of the worker was added as a classificatory variable.

Earnings differentials by level of education reflect the monetary incentives for someone to invest in education. Earnings differentials by education represent the intersection of supply and demand curves for educated labor. Differences in relative earnings between countries reflect a number of factors, for example, the demand for skills in the labor market, minimum wage legislation, the strength of unions, collective agreements, the supply of workers with various levels of educational attainment, the work experience of workers with high and low levels of schooling, the distribution of employment among occupations, and the relative incidence of part-time and seasonal work (OECD, 2007).

The study of earnings by schooling has led to a number of empirical works testing hypotheses on a great variety of social issues. These include, for example, racial and ethnic discrimination (McNabb and Psacharopoulos, 1981; Chiswick, 1988; Psacharopoulos and Patrinos, 1994); gender discrimination (Psacharopoulos and Tzannatos, 1992; Goldin and Polachek, 1987); income distribution (Mincer, 1958; Marin and Psacharopoulos, 1976); and the determinants of the demand for education (Freeman, 1976; Psacharopoulos and Soumelis, 1979; Psacharopoulos, 1982). Under certain assumptions, earnings differentials by level of education have been used to identify the sources of economic growth (e.g., Denison, 1967; Psacharopoulos, 1972). However, perhaps the application *par excellence* that has used earnings by level of education is the estimation of the rate of return to investment in schooling.

In what follows we give a taste of earnings differentials by education in developing countries, and compare them to those in advanced industrial countries. The section titled 'Returns to education' provides a review of the returns to education for developing countries. Empirical estimates of

the returns to education date from the late 1950s and thus range from one decade after the post-war years (after World War II) to the beginning of the twenty-first century. As the number of empirical studies increases, compilations of the rate of returns to education start to emerge in the early 1970s (Psacharopoulos, 1973) and have continued to the present (Psacharopoulos and Patrinos, 2004). The final section tries to draw policy conclusions from the empirical work based on earnings differentials by education.

Earnings Differentials by Education

It is a universal fact that, in all countries of the world, the more education one has the higher his/her earnings (Table 1). Age-earnings profiles by level of education behave as predicted by the seminal theoretical and empirical work of Mincer (1974), taking the general shape depicted in Figure 1.

To set a perspective, Table 2 presents earnings differentials in the Organization for Economic Co-operation and Development (OECD) countries. Note that the university premium amounts to a factor of 2 only in the case of Hungary. As shown in Figure 2, using readily available data from Latin America to serve as illustrative example, the earnings premium by level of education is steeper in developing countries. Out of the many factors responsible for the intersection of the supply and demand for educated labor taking place at different points in the two sets of countries, the main one must be that human capital is scarcer in developing, less-developed countries (LDCs), relative to industrial or developed countries (DCs).

Returns to Education

Using an appropriate methodology, the above earnings differentials can be used to estimate the returns to investment in education. Most published estimates of the rate of return to schooling rely on the Mincerian earnings function (Mincer, 1974), the most widely used estimation in economics (for a review of the Mincerian earnings function see Heckman *et al.*, 2006). However, the most correct methodology is what is known as the full discounting method that is based on the actual shape of the age-earnings profiles, rather than be smoothed out by an earnings function (Psacharopoulos and Mattson, 1998).

Based on this methodology, Tables 3 and 4 present the private and social rates of return stemming from the

earnings differentials presented above, for selected Latin American and OECD countries. A private rate of return takes into account only the costs and benefits realized by the individual, that is, earnings are after taxes and, because of the public subsidization of education, the main part of the cost is foregone earnings while studying. A social rate of return is based on pretax earnings and takes into account the full resource cost of education.

The returns to primary education are highest in the developing countries set, a finding giving a taste of diminishing returns. It should also be noted that in both sets of countries the private returns are higher than the social returns because of the public subsidization of education. In fact, the difference between the private and social rates of return offers a handy measure of the degree of such subsidization. As shown in **Table 5**, the highest level of education is subsidized more heavily relative to the lower ones, raising a major issue of perverse equity.

Table 6 reports results from a wider set of developing countries using the Mincerian earnings function. The average rate of return in developing economies is almost 11%, slightly higher than the 10% for the whole world. The returns are highest at the primary level, but the returns to higher education are also high. A typical pattern in developing countries is the dip in returns at the secondary level. This has been attributed not only to low quality of schooling (but without any empirical justification), but also to the option value of secondary schooling (Weisbrod, 1964). It could also be that the most successful secondary school students go on to higher education.

Among a few economies, there appears to be an increase in returns to education over time. With regard to educational attainment, there appears to be increasing returns to education in developed economies. While this conforms to the observations made in prior research, Schultz (2004) also mentioned that there are now increasing returns to education (by levels) in African economies. Developing transition countries, such as China, start from a low base (in terms of the rate of returns to education), and have experienced substantial increases in rates of return to education over the years.

In **Figure 3**, we break down the rate of returns to education by gender. We find that for developing

Figure 2 Based on education-earnings differentials are steeper in developing countries.

economies, the rate of return to education for men is highest for primary education (14.3%), decreases for secondary education (9.2%), and increases for university education (12.3%). For women, the rate of returns to education is lowest for primary education (7.2%), highest for secondary education (13.1%), and falls to 10.1% for university education. That is, in developing economies, on average, rate of return to primary education for women is lower than that of men but women overtake men by secondary education. For university education, on average, men's rate of returns to university education is 2.2 percentage points higher than that of women.

It is possible that there may be differential returns in education by gender due to the different job opportunities available to men and women at each educational level. For example, Hawley (2004) finds that in Thailand, women have higher returns to secondary education than men. He reasoned that this is because occupations, such as those in manufacturing, that pay more and require secondary education, have grown more rapidly for women than for men (Phananiramai, 1996; Kurian, 1999). Conversely, in jobs that may require only primary education (such as construction), the proportion of men may be higher because of tradition or labor intensity. Consequently, men may have higher returns to primary education.

A major policy concern, therefore, is the relatively lower returns to education for women at the primary education level in developing economies. It is a major concern because families in poor countries may decide to send sons rather than daughters to school. The lower returns to females at the primary level in developing countries is puzzling, given the fact that the rate of return to years of schooling is two percentage points greater for females than for males in developing countries, as well as transition countries. Dougherty (2005) considers various explanations. The most important involves the detrimental impact of discrimination and other factors that cause women to accept wage offers that undervalue

Figure 3 Based on private returns to education by gender and level. From Patrinos, H. A. and Psacharopoulos, G. (2007). Returns to education: An international update. World Bank, Working Paper Series (processed).

their characteristics. It is hypothesized that the better educated is a woman, the more able and willing she is to overcome the sex handicaps and compete with men in the labor market. He also considers the possibility that part of the differential could be attributable to male–female differences in the quality of educational attainment. Moreover, women may choose to work in sectors where education is relatively highly valued. The lower return to primary education in developing economies may be evidence of discrimination – such that women need to achieve more schooling in order to garner sufficient wages – or the option value of schooling – that is, since women are likely to perform better, stay in school longer, and experience higher returns for each year of schooling, the most able go beyond primary schooling, thus depressing the returns at that level.

Turning to the broader picture, the rate of return to education has fallen over the decades, while average years of schooling have risen. The returns to different educational attainments have fluctuated over the years, but it is also clear that amid the fluctuations, there has been a downward trend since the 1980s. The proportions of the population that are secondary educated and university educated have all risen markedly over the decades, while the proportion of the population that is primary educated has declined slightly. The rate of return to primary education has fluctuated over the decades. For secondary education, the rate of return has risen until the 1980s.

For university education, the private rate of return has declined as the proportion that is university educated increases (Patrinos and Psacharopoulos, 2007).

Causality

It is also worth noting that estimates of the returns on education based on advanced econometric techniques that control for different characteristics come to an average rate of return that is very similar to the global average presented in reviews: 10%. To estimate the true effect of education on earnings, some authors have employed instrumental variables (IVs) estimates. A useful instrument should be correlated with schooling, but uncorrelated with unexplained variation in earnings. Various variables on family background are frequently used. However, they are not expected to meet the requirement that they are uncorrelated with earnings (among other possible reasons, due to intergenerational effects).

Recently, information on the costs of schooling and supply-side sources of identifying information, such as various types of education reform, are increasingly sought after as instruments. Costs are important because people make decisions about investing in schooling on perceived costs and benefits. Therefore, loan policies, tuition changes, and distance are possible sources of instruments. Institutional constraints are also important. Therefore, supply-side

changes, such as the extension of compulsory school laws or making education facilities more accessible by reducing the distance to school, provide the researcher with the sort of natural experiment that allows one to say that the instrument is correlated with schooling but not earnings. One could argue, for example, that extending compulsory school age results in more people enrolling in school because of the legal change rather than their individual ability to generate more earnings. Such instruments will fail if they are corrected with earnings – as is sometimes the case with family background variables; in other words, the approach will fail when the researcher chooses bad instruments.

The IV estimates are often higher than ordinary least-squares (OLS) estimates, although it is unclear to what extent this is due to measurement error or inadequate instrumentation (see Trostel *et al.*, 2002). There are very few studies for developing countries dealing with the issues surrounding the endogeneity of education and the implications of estimating returns to education from IV. The rate of return estimates from IV is not only different from OLS, but it is also generally higher. Since the IV estimate is supposed to be the true return, this contradicts the standard ability bias intuition: OLS should be upward biased if higher ability individuals have more schooling. This approach uses sources for exogenous variation in educational attainment, such as institutional changes in the schooling system in the form of changes in compulsory schooling laws (Patrinos and Sakellariou, 2006), and reducing the distance to school (such as school construction projects; see Duflo, 2001) affecting the schooling decision, to estimate a causal return to education. The interpretation (Card, 2001) is that the returns to schooling vary across individuals. Institutional changes affect the schooling decision of a subset of individuals who, otherwise, would not have pursued a higher level of education and not the average individual. Furthermore, individuals affected by such reforms tend to have a higher return to education than the average individual. There is a distribution of returns, and OLS and IV correspond to different weighted averages of this distribution, and OLS can be below IV (see also Heckman and Li, 2004; Arabsheibani and Mussurav, 2007; Sakellariou, 2006).

Cognitive Ability

Beyond the returns to increasing the quantity of schooling, recent research has thrown light on the returns to improving the quality of schooling, the latter being measured by the cognitive skill of the student or graduate. Ability, or school quality, matters for earnings attainment (Leuven *et al.*, 2004). **Table 7** summarizes research results to increasing cognitive skills.

Conclusions and Policy Considerations

The empirical returns to schooling literature have proven to be a useful standard. The global average rate of return to schooling, estimated at 10%, is used as a global benchmark. Empirical evidence on returns on investment in education is a useful indicator of the productivity of education, and it serves as an incentive for individuals to invest in their own human capital.

More research is needed, however, on estimating the social benefits of schooling. After all these years, it is still an underdeveloped theme in the literature and remains a research priority. Still, existing evidence suggests that social returns and externalities are likely high.

Several important papers over the last decade on establishing causation between education and earnings have made the case for schooling as an investment. It is also clear that there is a need for more evidence on the impact of education on earnings using quasi-, and where possible, experimental design. Evaluation techniques are usefully applied in analyzing education and earnings, and providing evidence on the effectiveness of projects, programs, and reforms. Thus, more research along the lines of Oreopoulos (2006) and others' analysis of changes in compulsory schooling laws and other reforms is warranted. Such analyses allow one to provide not only estimates for those likely affected by reforms (i.e., the local average treatment effect, or LATE), but also estimates that come close to population average treatment effects (or ATEs).

Recent research shows that skills – ability and learning outcomes – matter for earnings attainment. Overall, in several countries, a one standard deviation increase in school

Table 7 Estimated returns to a standard deviation increase in cognitive skills

Country	Estimated effect	Source
Chile	0.17	Patrinos and Sakellariou (2007)
Ghana	0.14–0.30	Glewwe (1996)
Ghana	0.05–0.07	Jolliffe (1998)
Kenya	0.19–0.22	Boissiere <i>et al.</i> (1985), Knight and Sabot (1990)
Pakistan	0.12–0.28	Alderman <i>et al.</i> (1996)
Pakistan	0.25	Behrman <i>et al.</i> (forthcoming)
South Africa	0.34–0.48	Moll (1998)
Tanzania	0.07–0.13	Boissiere <i>et al.</i> (1985), Knight and Sabot (1990)
Average	0.17–0.22	

performance results in about a 12–15 increase in earnings. Although more work is needed in this area, clearly, learning outcomes are important determinants of earnings. Therefore, a policy priority is to empirically establish which policies and programs lead to learning outcome gains.

Evidence of heterogeneity in the returns to education exists. From the evidence available, in most high-income and middle-income countries, higher returns at the upper ends of the wage distribution have been observed. Overall, in low-income countries the returns tend to be higher at the lower ends of the wage distribution. Although more research is needed, such differences between countries could be due to: more job mobility in DCs allowing individuals to improve their position by changing jobs; scarcity of skills; differential exposure to market forces and the link between pay and productivity; or differential access to quality education or distribution of quality outcomes. What is clear is that average returns to the average individual will not suffice for policy purposes. We need to know more about which interventions are more likely to affect which parts of the distribution, and to establish at the same causality. In the above review, we noted that a major policy concern is the relatively low private rate of return to primary education for women in developing economies.

School Quality and Earnings

J R Betts, University of California, San Diego, La Jolla, CA, USA

Glossary

Endogeneity – A situation in which one variable, Y , is being modeled as a function of a second variable X , but variable X is determined by other variables that also influence Y . In such a situation, X is said to be endogenous, and standard statistical methods of fitting the best line between Y and X will tend to give the wrong answer because both X and Y are being determined by other variables.

What factors contribute to high-quality schooling? A large literature studies the relation between class size, teacher qualifications, spending per pupil, and other measures of school inputs with gains in student achievement. This literature is quite useful, in part because it uses an outcome close in time to when the student enjoys the benefits of additional resources, and because one could reasonably expect better school resources to boost test scores.

A shortcoming of this approach is that test scores are only weakly linked to adult outcomes that policymakers really care about, such as employment and earnings. For this reason, social scientists have attempted to estimate a link between school resources and earnings of students once they leave school and enter the labor market.

This article briefly summarizes the methods used in this literature, the findings, alternative explanations for the variation in findings across studies, and weaknesses of the methods used thus far in the literature.

Several patterns emerge:

1. Most of the studies that find no link or a weak link between school inputs and student outcomes measure school inputs at the level of the actual school attended; studies that do find a strong effect typically measure school resources at the level of the US state.
2. Studies that find that school inputs have a strong link tend to examine workers schooled before the 1960s. The opposite holds for studies that find no link.
3. Studies that find no significant link often examine workers who are in their early 30s or their 20s at the time earnings are observed.

Estimation Methods Typically Used

The typical study estimates a variation of the following log earnings equation for person i whose wage is observed

in year t , who attended school s in region b and who currently resides in region r :

$$\ln W_{isbtr} = \alpha + \beta \text{Qual}_{is} + X_{ist}\Gamma + V_{ib}\Phi + Z_{irt}\psi + u_{isbtr} \quad [1]$$

where the natural log of earnings (annual or hourly in most work) is assumed to depend on one or more measures of school characteristics Qual_{is} ; personal characteristics X_{ist} such as age, gender, race/ethnicity; characteristics of the area where the student grew up V_{ib} ; characteristics of the area where the person currently resides Z_{irt} ; u_{isbtr} is an error term that captures unobserved factors, and the Greek letters indicate coefficients or vectors of coefficients to be estimated.

Several important variants of this equation have been estimated. Some authors have included years of schooling ED_{it} on the right-hand side of this equation, and interacted it with the measure(s) of school resources Qual_{ist} , in the belief that school resources should have a bigger effect on earnings the longer one stays in school (see for instance Card and Krueger, 1992a, b). However, to the extent that years of schooling and earnings are jointly determined, such models will be biased because years of schooling ED_{it} is an endogenous variable, that is, a variable chosen by the person and influenced by other factors in eqn [1] as well as by unobserved factors. Such models will tend to be biased because of correlation between ED_{it} and u_{isbtr} .

Researchers have measured observed school resources Qual_{is} at different levels of aggregation. Equation [1] assumes that the researcher has data on the actual school attended, but many researchers have proxied for Qual_{is} with measures of spending per pupil, pupil–teacher ratios and other measures of school resources measured at the district level, or even the level of the US state in which the worker was born.

A third important source of variation derives from alternative approaches to modeling characteristics of the place b where a person attended school and the place r where the person resides at the time of the wage observation. Again, authors alternatively measure characteristics of local areas at a disaggregated level such as counties or cities, or more at a more aggregated level, typically US states. Further, other researchers who observe workers in a wide range of years add fixed effects for states in which students attended school and currently reside. These fixed effects control for anything observable and unchanging over time from the regions b and r .

Methodological Weaknesses

The literature as a whole shares numerous weaknesses which make it difficult to treat estimates of β from eqn [1] as estimates of the causal effect of the given measure of school resources on students' earnings years later. The first challenge to a causal interpretation is omitted variable bias: the error term u_{isbrr} likely contains many omitted personal, neighborhood, and regional characteristics that directly influence wages. If these are correlated with the explanatory variables such as school resources, then we will obtain biased estimates. Closely related to this concern is endogeneity bias. Economists have shown that people self-select into neighborhoods that offer the mix of taxation and public services that they most prefer. School quality, or perceptions of school quality, clearly is related to families' choice of where to live. This creates a strong positive link between average student achievement in a school and various measures of socioeconomic status of people living in a given neighborhood or city.

Two potential but partial solutions to this problem are to control for family and neighborhood demographics as much as possible, or to aggregate up beyond the neighborhood of residence to the school district or even the state. Neither of these methods is likely to yield causal estimates. The first method can at best only partially control for unobserved determinants of families' choices of school. The second method, involving aggregation, risks creating aggregation bias if the causal effects of school resources are nonlinear. Another potential bias in models that observe school resources at the state level is the possibly nonrandom-measurement error due to systematic differences between the location in which one was born (the most commonly used proxy for the state in which a student attended school in the many studies that use census data), the state in which one attended school, and the state in which one lived at the time of the wage observation.

A problem that potentially afflicts the school-level studies is random-measurement error in the measures of school resources, which will bias findings toward conclusions of a zero link to earnings. Small sample size is a second potential issue.

Summary of Findings

The literature review below, unless stated otherwise, discusses the relatively large US literature.

Testing for a Significant Relation between School Resources and Earnings

When a researcher asks "Does school quality matter for earnings of students?" this question can be interpreted in several ways. One response is to ask whether students who

attend certain high schools tend to earn more than students who attend other schools. Both Betts (1995) and Grogger (1996a) find that earnings of adults vary significantly by US high school attended, even after controlling for a host of personal characteristics.

However, the literature that instead tests for a relation between school resources and earnings of students typically finds either a zero or only a small link between earnings and measures of school resources.

The measure of school resources most typically used is school spending per pupil in the district attended, or in the worker's state of birth. Other measures of school resources include the pupil-teacher ratio, or its reciprocal, various measures of teacher education, teacher salary, and in a few studies, teacher salary, books per student, or length of the school year.

Betts (1996a) reviews the US evidence in detail. As the patterns in the literature are fairly similar across measures of school resources, below we focus mainly on the evidence regarding spending per pupil and the teacher-pupil ratio (or its reciprocal).

Most of the state-level estimates (83%) found a positive relation between spending per pupil and earnings, compared to 51% of the estimates based on district-level spending per pupil. The single existing estimate based on school-level spending per pupil found no significant link. This pattern, of more positive findings when one proxies school resources based on the worker's state of birth rather than based on the actual school or district attended, extends to most of the other measures of school resources. For example, Betts (1996a) reports that the percentage of estimates that found a positive association between earnings and the teacher-pupil ratio when the teacher-pupil ratio was measured at the state, district, and school level were 19, 0, and 0, respectively.

Figure 1 shows, for the US studies, the patterns of statistical significance across studies. Black bars indicate studies in which lesser than a third of results suggest a significant positive relation between school resources and earnings, while gray and white bars indicate cases where one-third to two-thirds and more than two-thirds, respectively, of estimates suggest a positive relation. The horizontal axis indicates the years in which the adults in the study were likely to have enrolled in grades 1 through 12. Vertically, the studies are arranged to display differences between studies that measure school resources at the school level, the district level, or by state of birth.

Figure 1 shows that school-level studies are much more likely than the district-level studies, and especially the state-level studies, to find no statistically significant effects of school resources on earnings.

Figure 1 also suggests that studies of workers who attended US public schools in the late 1950s onward are much more likely to find no significant effects of school resources than are studies of earlier cohorts.

Figure 1 Patterns of statistical significance across years students were enrolled in grades 1–12, and across level of aggregation of school characteristics in the given study. The bars indicate the range of years in which adults in the given study would have attended grades 1–12. The shading indicates the percentage of estimates of the relation between school resources and earnings are significant. Dark bars (insignificant) indicate studies in which none to 32% of estimates were significant; gray bars (mixed significance) indicate that 33–65% of estimates were significant; and white bars (significant) indicate that 66–100% of estimates were significant.

Results for US women and workers in the United Kingdom

The literature that Betts (1996a) reviews includes only American studies. Remarkably, up to that point, the American literature had studied only men's earnings but not women's earnings. A number of studies since then partially fills in these voids.

For instance, Harmon and Walker (2000) and Dearden *et al.* (2002) test for an association between earnings and school resources in the United Kingdom. Harmon and Walker find that in England and Wales, there is no significant link between earnings and various measures of school resources such as pupil–teacher ratios, actual class sizes, teacher salaries, or spending on textbooks. Similarly, Dearden, Ferri, and Meghir find that in Britain

pupil–teacher ratios are not significantly related to adult men's wages.

Dearden *et al.* (2002) model outcomes for British women find some evidence that pupil–teacher ratios are significantly negatively related to women's earnings at age 33, but only for women of lower academic ability, as measured at age 11. Betts (2001) provides the first study of the relation between school resources and the earnings of women in the United States. For white women, no significant connection between school resources and wages emerges. But the pupil–teacher ratio and library books per student are significantly and positively related to black women's wages, even though overall spending per pupil in the district and teachers' salaries bear no relation to black female students' subsequent earnings.

Estimating the Size of the Relation Between School Resources and Earnings

As we have seen, the level of aggregation at which school resources are measured appears to be related to the likelihood that a statistically significant relation to wages emerges. A second and perhaps related pattern is that the size of the estimated relation between resources and earnings tends to be bigger when the researcher proxies the school resources that workers received based on their state of birth, than when resources are measured for the district or school actually attended. For example, the elasticity of earnings with respect to spending per pupil averages 0.128 in the state-level studies but only 0.096 in the studies that measure actual spending per pupil at the district level. (Elasticity is a measure of how much one variable is predicted to change given a change in a second variable. The state-level elasticity of 0.128 implies that a 1% increase in spending per pupil is associated with a 0.128% increase in earnings of workers once they leave school.)

This pattern applies to all of the school resources studied in Betts' review. For instance, the average elasticity of earnings with respect to the teacher–pupil ratio in state, district, and school studies is reported to be 0.099, 0.024, and –0.037, respectively.

In an absolute sense, are the elasticities discussed above big or small? To assess this, one can think of education as an investment. Just as a firm invests in equipment and worker training at a new plant with the expectation that the plant will generate revenues in future periods, one can think of an increase in spending per pupil today as an investment that will pay dividends in the future, as students who benefited from this spending graduate, enter the labor market, and earn more.

A difficulty with evaluating the returns to either type of investment is that all of the costs are upfront, while the benefits do not accrue until the future. A dollar today is worth more than a dollar a year from now because if the discount rate (which can be thought of as an interest rate) is 10% ($r = 0.1$), then a dollar saved today yields $(1 + r)$ dollars a year from now, or US\$1.10. The solution to this is to calculate the present discounted value of the investment project. The stream of benefits (higher wages less the costs of higher school spending) are expressed in today's money by discounting them to the base period. For example, consider a project which costs US\$1 today and produces benefits next year and the year after of US\$1.21 and US\$1.33. Then with a discount rate of $r = 0.1$, the present discounted value (PDV) is:

$$\text{PDV} = -\$1 + \$1.21/(1 + 0.1) + \$1.33/(1 + 0.1)^2 = \$1.20$$

The higher the PDV, the better is the investment project. A project with a negative PDV should not be undertaken.

Figure 2 shows estimates by Betts (1996a) of the present discounted value of increased spending per pupil, estimated at the state and district level, plotted against the discount rate. To provide a comparison, Figure 2 also shows estimates of the PDV to society of an individual staying in high school for 1 year longer or attending college for 1 year. The present value of staying in school or college is far higher than the estimates of the present value of increased spending per pupil. Indeed, as the discount rate increases, the PDV of increased spending per pupil quickly becomes negative.

One way of comparing the returns to spending of the given types is to calculate the internal rate of return, that is, the discount rate at which the present value equals zero. At discount rates beyond the internal rate of return, no rational investor would undertake the project because it would produce a negative rate of return. Thus, better investment projects will have a higher internal rate of return. But what is a reasonable internal rate of return? One reasonable point of comparison is the average real rate of interest, that is, the interest rate minus the rate of inflation.

Figure 3 plots the internal rate of return to increasing spending per pupil (based on both state- and district-level studies), with the average real interest rate overlaid as a horizontal line. Figure 3 makes clear that a student who stays in high school or college for an extra year is making a good investment. Conversely, even the more optimistic estimate of the effects of increasing spending per pupil suggests produces an internal rate of return below real interest rates. Betts (1996a) also estimates the internal rate of return to reducing the pupil–teacher ratio, and finds even lower rates of return.

One infers that policies to keep students in school longer, such as raising the school-leaving age, are likely to be more cost effective than increasing spending per pupil. This of course raises an important question: Are increases in educational resources associated with increases in years of schooling? This question is beyond the scope of this article. However, Betts (1996a, 2001) suggests either a weak or no relation between resources and educational attainment for men and women in the US, respectively.

Explanations for Variations in Results

Figure 3 suggests that the level of aggregation of the school resources matters, and that studies of American cohorts educated from the late 1950s onward are much less likely to exhibit a positive relation between school resources and earnings. Betts (1996a) also observes that many of the school-level studies focus on earnings of relatively young workers. What might explain these patterns?

Figure 2 Net percentage return to various types of educational investments plotted against discount rate. Based on results from Betts, J. R. (1996a). Is there a link between school inputs and earnings? Fresh scrutiny of an old literature. In Burtless, G. (ed.) *Does Money Matter? The Effect of School Resources on Student Achievement and Adult Success*, pp 141–191. Washington, DC: Brookings Institution.

Figure 3 Comparison of internal rates of return to increased spending per pupil (from district- and state-level studies) and increased time spent enrolled in high school or college. The real interest rate was calculated as the average yield on 10-year US treasury bonds minus inflation in the US consumer price index, averaged over 1962–2008. It averaged 2.64% over this period. Historical data on treasury bond interest rates and the consumer price index were downloaded from, respectively, http://www.federalreserve.gov/releases/h15/data/Annual/H15_TCMNOM_Y10.txt and <ftp://ftp.bls.gov/pub/special.requests/cpi/cpiat.txt>.

Age Dependence

First, suppose that the effects on wages of attending schools with ample resources do not manifest themselves until workers are well into their careers. This alone could explain the general lack of significant results in the school-level studies. Betts (1996b) addresses this question using census data and also by projecting mid-career earnings of younger workers based on their occupation, and finds no evidence of positive age dependence. Betts (2001), which provides the first US evidence on school resources and women's earnings, uses a very long panel that observes women's wages from ages 18 to 50. This article finds no positive age dependence, and if anything, the effects of school resources appear to weaken as women become older.

Structural Changes?

The observation that studies focused on those educated in the late 1950s and later years are less likely to find positive relationships between school resources and earnings raises questions about whether some type(s) of structural change(s) might have occurred in American public schooling. Such changes could have arisen from diminishing returns, increasing bureaucratization and centralization of public schools, and rising teacher unionization. Betts (1996a) provides an overview of each of these ideas, in particular examining whether the returns to increased school resources may be diminishing as levels of school resources have risen over time.

Hoxby (2000) provides evidence that workers who attended large districts that face little competition from other districts tend to earn less than otherwise similar workers, and that these districts, by a variety of measures, are less productive than other districts. These findings could hold relevance for the structural change hypothesis because of a rapid consolidation of school districts that took place in the United States between 1945 and 1970 (Betts, 1996a).

Hoxby (1996) studies the relation between school resources and earnings of former students, and how the unionization of teachers mediates this relation. She replicates Grogger's (1996a) results from the same dataset that there is no significant link overall between school resources and earnings. But when she divides the sample into students who attended unionized versus nonunionized schools, she finds that some of the school-resource measures do become significant predictors of adult outcomes in the nonunionized schools. Given that the percentage of US public school teachers who were unionized tripled between 1960 and 1984, this finding could account for the apparent structural change that may have weakened the relation between school resources and earnings.

Hoxby and Leigh (2005) extend this teacher-union argument, focusing on the incentives for female graduates of selective universities to become teachers. They argue that unionization has compressed the variation in teachers' pay related to measures of teacher ability. This tendency, combined with the gradual opening of more career opportunities beyond education for women led to a sharp shift in the composition of the new female teacher labor force, toward women who graduated from the lowest tier universities.

Specific Problems Potentially Afflicting State-Level and School-Level Studies

One reason why the school-level studies may find no effects are that the sample sizes are small, in which case the studies might have little statistical power. Betts (1995) finds evidence against this hypothesis in the case of the pupil-teacher ratio and teacher education, but evidence in the case of teachers' relative salary that a lack of variation in this variable could explain the insignificant results.

A second potential problem with the school-level studies is that the school inputs are measured with error, so that their coefficients will be biased toward zero. State-level analyses might reduce this problem, since they use an average taken across schools. One can test this hypothesis directly by rerunning the school-level analyses using two-stage least squares (2SLS), with state-level school resources serving as instruments for the school-level variables. Both Grogger (1996a) and Betts (1995) take this step and find that the instrumented school inputs remain insignificant. This finding reduces the plausibility of the existence of significant measurement error. Grogger (1996b) tests for measurement error in a slightly different way and concludes that it is minor.

What issues may affect the validity of the state-level estimates?

Aggregation bias could be an issue if there is a nonlinear relationship between school resources and student outcomes. Hanushek *et al.* (1996) develop this argument in detail, and Betts (1996a) surveys evidence in other studies to this effect.

Omitted variable bias seems likely in studies that proxy the resources at the school a worker attended by using average resources in that worker's state of birth. Both Rizzuto and Wachtel (1980) and Akin and Garfinkel (1977) report that in some of their state-level models school resources become insignificant once one controls for income per capita. Betts (1995) finds that state-level resources do sometimes enter significantly in his sample, but whatever association there is does not work through correlation with the resources at the actual school attended. This raises concerns that state-wide averages of

school resources can sometimes proxy for other characteristics of a state.

Heckman *et al.* (1996) provide two key criticisms of the state-level literature. First, they show that once one allows for the returns to a year of schooling to be nonlinear, then the only workers whose earnings appear to remain correlated with state-level school resources is university graduates, who in the time frame they study constituted a distinct minority of the population. Second, these authors raise questions about nonrandom migration from state of birth, which could influence the coefficient estimates in studies that proxy school resources based on workers' state of birth.

Issues That Require Further Research

The literature suggests a fairly narrow range of estimates of the relation between school resources and earnings of students once they leave school. Some patterns emerge. In the United States, school resources may have become less strongly associated with earnings of workers over time. Moreover, studies that measure school resources at a finer level of geographic aggregation are less likely to find a positive association.

But the entire body of work appears to agree that the relation between school resources and earnings of adults ranges between none and small but positive. Even the most positive results, based on studies that measure spending per pupil based on each worker's state of birth, suggest an internal rate of return far below the rate of return to an extra year of high school or university, and below the real rate of interest.

Should we interpret these anemic effects as a sign that policymakers have been wrong to increase spending on schools, or that increased resources can never have an effect on adult earnings? The answer to both questions is probably no. There may be policy reasons for increasing school resources more generally that relate to student outcomes quite distinct from earnings. For example, suppose that increased school resources improve student attitudes along lines that society values. This could fruitfully be studied. Similarly, it would be inappropriate to extrapolate from the historical studies reviewed here to reach the conclusion that more spending can never matter. It could be that if policymakers increased spending in different ways than has been done historically, the benefits could be greater.

For example, the recent trend in the United States of coupling infusions of money with student testing and school accountability provides a distinct shift from that nation's past trends in educational spending.

Finally, note that none of the studies establishes a causal relationship between resources and students' subsequent

earnings as adults. Rather, they study correlation. Increasingly, researchers use actual experiments to examine whether an educational intervention affects test scores, or quasi-experiments that try to minimize the possibility that school resources and student outcomes are codetermined by some other set of variables or policy influences. In some experimental studies of various school interventions, it may soon become possible to study the long-term consequences of these interventions on adult outcomes including earnings.

Signaling in the Labor Market

M E Page, University of California-Davis, Davis, CA, USA

The Signaling Model

The signaling model of education, usually attributed to Michael Spence (1973), is distinguished from the human capital theory of education by its premise that individual workers' innate productivity levels are identified by their years of schooling rather than enhanced by them. An implication of the model is that more-educated workers receive higher pay because education provides them with a credential, rather than because of acquired skills. Important variations on the signaling model include theories that have been developed by Arrow (1973), Layard and Psacharopoulos (1974), Riley (1975, 1979), Spence (1974, 1976), Stiglitz (1975), and Wolpin (1977). The terms signaling, screening, and sorting are often used interchangeably to describe variants of the same basic model.

Signaling theory is based on the following assumptions. (1) Individuals have different innate levels of productivity, which are not affected by their education. (2) Additional education incurs additional costs, which differ for high- and low-productivity workers. In particular, the psychic cost of schooling is higher for individuals with lower productivity levels. Those who learn easily can acquire the signal more cheaply than others. For example, they may need to spend less time studying. (3) There is asymmetric information with respect to workers' productivity: individual workers know their skill level, but potential employers do not. (4) Schooling levels can be observed without incurring a cost. As employers cannot observe potential workers' actual productivity, they instead use educational qualifications to predict productivity, make hiring decisions, and set wages, based on the assumption that individuals who have more years of education are more productive. In order for this assumption to be accurate, more productive workers must, in fact, choose more schooling. The model is based on the premise that individuals are rational and that they invest in education as long as the benefit of an additional year of schooling exceeds the cost. The benefit of an additional year of schooling is the same for high- and low-productivity workers, but the costs are higher for low-productivity workers. If the wage gain associated with education is sufficient for high-productivity workers to select into more schooling but not large enough for low-productivity workers to select more schooling, then education may sort differently skilled workers so that the employers' beliefs are ratified and equilibrium exists.

The signaling model hinges on the assumption that worker productivity is negatively related to the cost of acquiring the signal. As long as cost differences across workers result from differences in cognitive ability or tastes for learning, they may be indicative of differences in on-the-job productivity. However, if costs vary because of differences in family contributions toward tuition, etc. then individuals who face higher schooling costs may be no less productive than those who face lower schooling costs, and education will not allow employers to distinguish between high- and low-productivity workers.

An example to substantiate this is mentioned here which is based on Michael Spence (1973).

Suppose that there are two types of workers: more-productive workers have a productivity level equal to 2, and less-productive workers have a productivity level equal to 1. Suppose further that employers believe that job applicants with schooling levels equal to or greater than S^* will be type 2 workers and that those who have less than S^* years of education will be type 1. Firms pay workers according to their expected productivity level; so those with S^* or more years of schooling are paid a wage equal to 2, and those with less than S^* years of schooling are paid a wage equal to 1. Workers care about the (present discounted) value of lifetime earnings, which is E_1 for those with less than S^* years of schooling and E_2 for those with more than S^* years of schooling. The relationship between lifetime earnings and schooling is depicted in **Figure 1**.

Individuals will choose to invest in the level of education that maximizes their net benefits (total benefits minus total costs). For simplicity, assume that the only benefit that workers care about is their earnings. Then individuals will choose the level of education that produces the biggest difference between the (present) value of lifetime earnings and the cost of education. If education were costless then all workers would want to acquire the signal of S^* , but the signaling model hinges on the assumption that costs vary across individuals. Suppose as in **Figure 2**, that type 1 workers face a cost of C for each year of schooling but that type 2 workers, who find school easier, face a cost of $C/2$. It is easy to see that for type 1 workers the difference between lifetime earnings and C is maximized when they choose 0 years of education. On the other hand, for type 2 workers, the difference between lifetime earnings and $C/2$ is largest at S^* . Thus, type 1 and type 2 workers sort into different levels of schooling that

Figure 1 Lifetime benefits associated with education. Adapted from Spence, A. M. (1973). Job market signaling. *Quarterly Journal of Economics* 87, 355–374.

Figure 2 Lifetime benefits and costs associated with education. Adapted from Spence, A. M. (1973). Job market signaling. *Quarterly Journal of Economics* 87, 355–374.

are consistent with the employers beliefs, and S^* works as a valid signal.

Note that not all years of education necessarily provide valid signals. For example, in **Figure 3**, employers use S' years of education instead of S^* to differentiate between high- and low-productivity workers. Therefore, the earnings structure is now depicted as the distance AEGH. Here, both type 1 and type 2 workers maximize the difference between lifetime earnings and the cost of education by choosing S' . Since all job applicants choose the same level of education, S' does not signal anything about workers' productivity.

As stressed by Weiss (1995), the human capital and signaling models of education are not necessarily mutually exclusive. Education may simultaneously enhance

workers' productivity and act as a signal about their innate abilities. In such a case, signaling can be thought of as an extension of a human capital model in which some productivity differences that firms cannot observe are correlated with schooling costs.

Empirical Evidence

Empirically disentangling the relative importance of the human capital model and the signaling model has proven to be difficult. Both models predict that more-educated workers will earn higher wages, so the positive relationship that we observe between schooling and earnings does not provide useful information. There is no universally accepted method for separately identifying education's productivity-enhancing role from its signaling role.

One approach that has been used is to compare educational wage gaps for workers of different ages or years of work experience assuming that over time, it will become easier for employers to directly observe their employee's actual productivity (Cohn *et al.*, 1987; Layard and Psacharopoulos, 1974; Mendes de Oliveira *et al.*, 1989; Psacharopoulos, 1979; Rao and Datta, 1989; Wolpin, 1977). The idea is that if education is just a signaling device then it serves a useful function early in a worker's career, but as direct information on workers' actual productivity accumulates, the relationship between schooling and earnings should diminish. In fact, earnings differentials between more- and less-educated workers increase with age, which may be taken as evidence in favor of the human capital model. On the other hand, advocates of the signaling model argue that continued growth in earnings differentials occurs because the signal inherent in

educational attainment is an accurate predictor of individuals' productivity.

Another set of studies compare earnings across industries or professions where signaling is likely to be important, to industries or professions where it is not. Cohn *et al.* (1987), De Wit and Van Winden (1989), Katz and Ziderman (1980), Riley (1979), and Wolpin (1977), for example, compare the education and earnings of self-employed and salaried workers, based on the assumption that signaling should be irrelevant to the self-employed. Since self-employed workers do not have to invest in educational signals for potential employers, they will invest in less schooling. These studies have produced mixed evidence on the relative importance of the two hypotheses.

A third set of studies focuses on sheepskin effects, or wage returns to particular credentials and/or diploma years. The argument is that the productivity-enhancing part of education should be proportional to the time spent in school; therefore, a wage return to the diploma itself, controlling for years of education, may be interpreted as evidence in favor of the signaling hypothesis. Groot and Oosterbeek (1994), Hartog (1983), Hungerford and Solon (1987), Jaeger and Page (1996), Layard and Psacharopoulos (1974), and Weiss (1983) have all estimated variants of sheepskin models. The studies by Hungerford and Solon, and Jaeger and Page both find that relative to a year of high school or college schooling, there are higher wage returns associated with high school and college graduation. However, both of these studies note that the existence of sheepskin effects is not necessarily a corroboration of the signaling model: it is impossible to tell whether the observed differences result from a signal about completers' versus noncompleters' abilities or whether those who actually complete their degree increase their productivity more than those who do not.

Tyler *et al.* (2000) address this issue when estimating the signaling value of the general equivalency diploma (GED) by comparing the earnings of individuals who had the same GED test scores but lived in states with different passing standards. Individuals with the same test score are assumed to have acquired equal amounts of human capital and to be equally productive. They find that whites who obtain a GED have earnings that are 10–19% higher than whites with the same test score who do not get the credential because they live in a state with a higher standard. This suggests that the GED has an important signaling effect on earnings. On the other hand, Cameron and Heckman (1993) and Heckman and LaFontaine (2006) find that the wages of those with a GED are no higher than the wages of high school dropouts, which suggests that the GED is not a substitute for high school.

Lang and Kropp (1986) test the signaling model by comparing enrolment rates of age groups that are bound by compulsory schooling laws to the enrolment rates of age groups that are not directly affected. The idea is that

under the signaling model, a state compulsory school attendance law should increase the educational attainment of high-ability workers who are not directly affected by the law, because it lowers the average ability (and thus the wage) associated with the compulsory level of education. This gives high-ability individuals an incentive to get more schooling. Human capital theory predicts that such laws should only affect those individuals who are directly constrained. Lang and Kropp find that compulsory schooling laws do increase enrolment rates for age groups that are not directly affected, which supports the notion that education acts as a signaling device.

In a similar vein, Bedard (2001) compares high school dropout rates in labor markets with differential university access. The signaling model predicts that an environment in which more individuals are constrained from entering college will be characterized by higher high school graduation rates: when there are fewer barriers to college, then some previously constrained but relatively high-ability students will become university enrollees, and the average skill of high school graduates who do not go on to college will fall. There will be a commensurate decline in the wage associated with a high school diploma, which will reduce the incentive to obtain one. As a result, the least-able high school graduates will choose to drop out instead. Bedard finds evidence of such responses.

Kroch and Sjoblom (1994) suggest that if education acts as a signal, then within a cohort, the signal should be related to an individual's position in the distribution of education. They estimate models that include both absolute and relative years of education and find that while years of education are always positively associated with earnings, one's rank in the education distribution is not statistically significant. They interpret this as evidence that the value of schooling is not primarily due to signaling.

Weiss (1995) summarizes a number of additional studies that provide indirect evidence on the prevalence of signaling in education, including detailed discussions of Altonji's (1995) and Kang and Bishop's (1986) papers on the earnings effect of course work in school, and Card and Krueger's (1992) paper on the effects of school quality on wage returns to education. He concludes that labor economists have been unreasonably skeptical of signaling theory, given its ability to explain empirical regularities that are not explained by other models – such as why wage returns to education seem to be so much larger than the returns to courses taken in secondary school, and why the variance of wages increases with education.

In summary, empirical tests of the signaling model were most prevalent during the late 1970s and 1980s, but many of these tests were of questionable validity. Since the late 1980s, there have been fewer studies that have attempted to identify the role that signaling plays in the labor market, but the literature has laid more emphasis on finding external sources of identification. Recent studies that use

plausibly random variation in degree receipt while controlling for observable measures of productivity (such as the study by Tyler *et al.*, 2000) find evidence in support of signaling for certain degrees (such as the GED). There are also labor-market relationships such as those discussed by Weiss (1995) that seem to provide indirect evidence in support of the signaling model. However, the number of studies that use convincing empirical strategies to test the signaling model is short, and the evidence to date is mixed.

Conclusion

More than 30 years have passed since the signaling model first gained attention; yet, much is still unknown about the relative importance of signaling versus human capital theories. Many of the implications of the two models are the same, thus it has proven hard to empirically distinguish between them. The results of existing research do not conclusively reject the signaling theory, and more recent work has produced evidence that signaling does play a role in the labor market. Nevertheless, the extent to which education acts as a sorting device in addition to (or instead of) augmenting productivity, is still unknown.

The Economics of High School Dropouts

R W Rumberger, University of California, Santa Barbara, Santa Barbara, CA, USA

Introduction

One of the major educational challenges in virtually all industrialized nations is ensuring that all students graduate from high school. Although many countries allow students to leave school prior to completing upper secondary school, a high school diploma is increasingly viewed as a minimal requirement for entry into the labor market and for further postsecondary education. In fact, with the economy generating an increasing number of jobs that require at least some postsecondary schooling, students who earn no more than a high school diploma will likely have diminishing economic prospects.

Despite the increasing importance of graduating from high school, a large segment of the student population in many countries leave high school prior to graduation. This article provides a brief review of the research on who drops out of high school, the economic and social consequences of dropping out, the causes of dropping out, and what can be done to improve high school graduation rates. The article relies primarily on literature in the United States.

Who Drops Out of High School?

Identifying the number of students who drop out of school and graduate each year is complicated by the difficulty of tracking students over time, and the sources of data currently available to track them. There are also a number of measures of dropout and graduation rates that are used to gauge the extent of the problem.

One measure is the annual dropout rate. According to US Census survey data, 414 000 students dropped out of grades 10–12 in 2004–05, or about 3.8% of the students enrolled (Laird *et al.*, 2007, Table 1). This is no doubt an undercount because it excludes students who dropped out before grade 10. Dropout rates are higher for some demographic groups: males have higher dropout rates than females; Blacks and Hispanics have higher dropout rates than Asians and Whites; and students from low-income families have higher dropout rates than students from high-income families. Annual dropout rates have been falling steadily over the last 25 years, from a high of 6.7% in 1979 to the current rate of 3.8% (Laird *et al.*, 2007, Table 4).

But annual dropout rates understate the likelihood that a student will drop out sometime during his or her

educational career. A better gauge is the proportion of dropouts in the population, which is referred to as the *status* dropout rate. Again according to US Census survey data, there were 3.5 million dropouts aged 16–24 years in October 2005, representing 9.4% of the population (Laird *et al.*, 2007, Table 6). These rates too are higher for the same demographic groups mentioned above, and they too have declined over the last 25 years, from a high of 14.6% to the current rate of 9.4% (Laird *et al.*, 2007, Table 7).

Yet, dropout rates alone may not be sufficient to reveal the extent of the problem. Census data have been criticized because they rely on respondents' self-reported educational status, which respondents may overstate. Moreover, the Census considers persons who earn equivalent high school credentials by taking the general education development (GED) examination as completing high school even though there is extensive evidence that alternative credentials do not provide the same economic benefits as a traditional diploma. Thus both federal and state governments are attempting to measure the proportion of entering ninth-grade students who earn a regular diploma within 4 years, which is known as the ninth-grade cohort graduation rate. Such a rate is particularly difficult to measure because it requires tracking students over several years. This is problematic, in part, because students often transfer from one educational setting to another during their high school careers. In addition, some students are retained, especially in the ninth grade, when they fail to earn enough credits to be promoted to the next grade level. A number of specific measures are currently used to estimate the ninth-grade graduation rate, and all have limitations. Recently, the federal government has adopted one measure known as the averaged freshman graduation rate, and has produced estimates for the nations' public schools and for the public schools in each state. These estimates show an averaged freshman graduation rate of 75% for all public schools nationally in 2003–04, with state rates varying from a low of 61% in South Carolina to a high of 88% in Nebraska (Laird *et al.*, 2007, Table 12). Other measures and data sources suggest the national high school graduation rate, especially when it includes students who earn a diploma after the normal 4 years of high school, exceeds 80%.

The Organization for Economic and Cooperative Development (OECD) computes the percentage of upper secondary graduates to the population at the typical age of graduation. The average graduation rate among OECD

countries in 2004 was 81%, ranging from 38% in Mexico to 100% in Norway, with the US rate at 75% (OECD, 2006, Table A2.1)

What Are the Consequences?

Dropping out of school has economic and social consequences both for dropouts themselves and for the country as a whole. First, dropouts have difficulty finding jobs. Government data show that more than 33% of 16- to 24-year-olds in October 2005 who dropped out of school the previous year were unemployed (Snyder *et al.*, 2007, Table 382). Among all 16- to 24-year-olds in October 2005, the unemployment rate for dropouts was 18.5%, compared to 12.1% for high school graduates and 5.0% for 4-year college graduates (Snyder *et al.*, 2007, Table 375). Second, even if they find a job, dropouts earn substantially less than high school graduates. In 2005, the median annual earnings of high school dropouts were almost 25% less than the income of high school graduates (Snyder *et al.*, 2007, Table 378). Over their working lives, the Census Bureau estimates that dropouts will earn about US\$200 000 less than high school graduates (Day and Newburger, 2002, Figure 3).

One reason for dropouts' poor economic outcomes is their low levels of education. Yet, dropouts can return to school. Almost half of 1988 eighth-grade students who dropped out of school completed either a regular high school diploma (16%) or a GED or alternative certificate (29%) within 2 years of their scheduled graduation date in 1992 (Berkthold *et al.*, 1998, Table 1). Dropouts who completed high school were more likely to enrol in postsecondary education than students who did not complete high school (42% vs. 14%) (Berkthold *et al.*, Table 15). Nonetheless, dropouts as a group are much less likely to enrol in postsecondary education than high school graduates, even though most states allow dropouts to enrol in community colleges without a high school diploma.

Dropouts experience other negative outcomes (Belfield and Levin, 2007). Dropouts have poorer health and higher rates of mortality than high school graduates; they are more likely to engage in criminal behavior and be incarcerated over their lifetimes compared to graduates. They are also more likely to require public assistance and less likely to vote. Although the observed relationship between dropping out and these economic and social outcomes does not necessarily imply a causal relationship, a growing body of research evidence has, in fact, demonstrated one. This suggests that efforts to reduce dropout rates would, in fact, reduce these negative economic and social outcomes.

The negative outcomes from dropouts generate huge social costs. Federal, state, and local governments collect fewer taxes from dropouts. The government also

subsidizes the poorer health, higher criminal activity, and increased public assistance of dropouts. One recent study estimated that each new high school graduate would generate more than US\$200 000 in government savings, and that cutting in half the dropout rate from a single cohort of dropouts would generate more than US\$45 billion in savings (Belfield and Levin, 2007).

A number of economic, demographic, and educational trends could exacerbate these problems in the future. As the US economy moves toward a higher-skilled labor force, high school dropouts will have an even harder time surviving economically. The numbers of students who are generally at greater risk of school failure – students from poor and low-income households, and racial, ethnic, and linguistic minorities – are increasing in the nation's schools. Finally, the growing push for accountability in the nation's public schools that has produced policies to end social promotion and to institute high school exit exams could increase the number of students who fail to complete high school.

Why Do Students Drop Out?

Understanding why students drop out of school is the key to addressing this major educational problem; yet, identifying the causes of dropping out is extremely difficult. Like other forms of educational achievement (e.g., test scores), the causes of dropping out are influenced by an array of proximal and distal factors related to both the individual student and to the family, school, and community settings in which the student lives.

Dropouts themselves report a variety of reasons for leaving school, including school-, family-, and work-related reasons (Rotermund, 2007). The most specific reasons cited by tenth-graders of 2002 who dropped out were “missed too many school days” (44%); “thought it would be easier to get a GED” (41%); “getting poor grades/failing school” (38%); “did not like school” (37%); and “could not keep up with schoolwork” (32%). But these reasons do not reveal the underlying causes of why students quit school, particularly those causes or factors in elementary or middle school that may have contributed to students' attitudes, behaviors, and school performance immediately preceding their decision to leave school. Moreover, if many factors contribute to this phenomenon over a long period of time, it is virtually impossible to demonstrate a causal connection between any single factor and the decision to quit school. Despite this difficulty, two types of factors have been identified that contribute to or increase the likelihood that students drop out of school: (1) individual factors associated with students' characteristics, attitudes, behaviors, and experiences; and (2) contextual factors associated with students' families, schools, communities, and peers.

Individual Factors

A variety of individual factors are associated with dropping out (Rumberger, 2004a), including several demographic factors. Generally, dropout rates are higher among males, Blacks and Hispanics, immigrants, and language-minority students. Attitudes also affect dropout rates. Dropout rates are also higher among students who have low educational and occupational aspirations. Several activities and behaviors also predict dropout rates, including absenteeism, misbehavior in school, and pregnancy. Finally, poor academic achievement is a strong predictor of dropping out. Together, these factors support the idea that dropping out is influenced by both the social and academic experiences of students.

In addition to these proximal factors, a number of distal factors are associated with dropping out, such as student mobility. Both residential mobility (changing residences) and school mobility (changing schools) increase the risk of dropping out of high school. Student mobility may represent a less-severe form of student disengagement or withdrawal from school. Another distal factor is grade retention. Although retention may have some positive impact on academic achievement in the short run, numerous studies have found that it greatly increases the likelihood that students will drop out of school. Finally, a number of long-term studies have found that lack of early academic achievement and engagement (e.g., attendance, misbehavior) in elementary and middle school predicts withdrawal from high school.

Institutional Factors

While individual factors clearly contribute to students' decisions to drop out of school, individual attitudes and behaviors are shaped by the various settings or contexts in which students live – families, schools, communities, and peer groups. The importance of context in shaping behavior, including dropping out, was acknowledged in a report by the National Research Council Panel on High-Risk Youth (1993) that argued that too much emphasis has been placed on high-risk youth and their families, and not enough on the high-risk settings in which they live and go to school. A number of factors within students' families, schools, and communities (and peer relationships) predict dropping out.

Families

Family background is widely recognized as the single most important contributor to success in school. Socio-economic status, most commonly measured by parental education and family income, is a powerful predictor of school achievement and dropout behavior. Parental education influences students' aspirations and educational support; while family income allows parents to provide more resources to support their children's education,

including access to better-quality schools, after-school and summer-school programs, and more support for learning within the home. In addition, students whose parents monitor and regulate their activities, provide emotional support, encourage independent decision-making (known as authoritative parenting style), and are generally more involved in their schooling are less likely to drop out of school. Additionally, students in single-parent and step-families are more likely to drop out of school than students in two-parent families.

Schools

It is widely acknowledged that schools exert powerful influences on student achievement, including dropout rates. Four types of school characteristics influence student performance: social composition of the schools, structural characteristics, school resources, and school policies and practices.

1. The social composition of schools – the characteristics of students attending the schools, particularly the socioeconomic composition of the student body – predicts dropping out even after controlling for the individual factors that influence dropping out.
2. The second characteristic has to do with the structural characteristics of schools, such as size, location, and school control (public vs. private). Dropout rates from Catholic and other private schools are lower than dropout rates from public schools, even after controlling for differences in the background characteristics of students. Yet, students from private schools typically transfer to public schools instead of or before dropping out, so that student turnover rates in private schools are not statistically different from turnover rates in public schools. Smaller schools also have lower dropout rates. What is less clear is whether structural characteristics themselves account for these differences or whether they are related to differences in student characteristics and school resources often associated with the structural features of schools.
3. The third type of characteristic concerns school resources. Resources, in particular student/teacher ratios and teacher quality, appear to influence dropout rates even after controlling for a host of individual and contextual factors that might also influence dropout rates.
4. The final type has to do with school policies and practices. In particular, academic and social climate – as measured by school attendance rates, students taking advanced courses, and student perceptions of a fair discipline policy – predict school dropout rates, even after controlling for the background characteristics of students as well as the resource and structural characteristics of schools.

School factors contribute to student withdrawal in two ways. One way is indirectly, by creating conditions that

influence student engagement and their voluntary withdrawal from school. Another way is directly, through explicit policies and conscious decisions by school personnel that cause students to involuntarily withdraw from school. These rules and actions may concern low grades, poor attendance, misbehavior (such as zero-tolerance policies), or being overage, and may lead to suspensions, expulsions, or forced transfers. This form of withdrawal is school initiated and contrasts with the student-initiated form mentioned above. Some schools, for example, contribute to students' involuntary departure from school by systematically excluding and discharging troublemakers and other problematic students.

Community and peers

In addition to families and schools, communities and peer groups can influence students' withdrawal from school. Differences in neighborhood characteristics can help explain differences in dropout rates among communities, apart from the influence of families. Some evidence suggests that there is a threshold or tipping point on the quality of neighborhoods that results in particularly high dropout rates in the most disadvantaged neighborhoods. Poor communities may influence child and adolescent development through the lack of resources (playgrounds and parks, after-school programs) or negative peer influences. Community residents may also influence parenting practices over and above parental education and income. Students living in poor communities may also be more likely to have dropouts as friends, which increases the likelihood of dropping out of school. Another way that communities can influence dropout rates is by providing employment opportunities both during or after school. Relatively favorable employment opportunities for high school dropouts, as evidenced by low neighborhood-unemployment rates, appears to increase the likelihood that students will drop out, while more favorable economic returns to graduating, as evidenced by higher salaries of high school graduates compared to dropouts, tend to lower dropout rates. Working long hours in high school can increase the likelihood of dropping out, although the impact of working in high school depends on the type of job held and on the student's gender.

What Can Be Done?

Knowledge about why students drop out suggests several things about what can be done to design effective dropout-intervention strategies (Rumberger, 2004b). First, because dropping out is influenced by both individual and institutional factors, intervention strategies can focus on either or both sets of factors. That is, intervention strategies can focus on addressing the individual values, attitudes, and behaviors that are associated with dropping out without

attempting to alter the characteristics of families, schools, and communities that may contribute to those individual factors. Many dropout-prevention programs pursue such programmatic strategies by providing would-be dropouts with additional resources and supports to help them stay in school. Alternatively, intervention strategies can focus on attempting to improve the environmental contexts of potential dropouts by providing resources and supports to strengthen or restructure their families, schools, and communities. Such systemic strategies are often part of larger efforts to improve the educational and social outcomes of at-risk students more generally.

Second, because dropping out is associated with both academic and social problems, effective prevention strategies must focus on both arenas. That is, if dropout-prevention strategies are going to be effective, they must be comprehensive by providing resources and supports in all areas of students' lives. As dropouts leave school for a variety of reasons, services provided them must be flexible and tailored to their individual needs.

Third, because the problematic attitudes and behaviors of students at risk of dropping out appear as early as elementary school, dropout-prevention strategies can and should begin early in a child's educational career. Dropout-prevention programs often target high school or middle school students who may have already experienced years of educational failure or unsolved problems. Dropout-recovery programs must also attempt to overcome longstanding problems in order to get dropouts to complete school; yet, such programs may be costly and ineffective. In contrast, early intervention may be the most powerful and cost-effective approach to dropout prevention.

The longstanding interest in the problem of school dropouts has spurred a great deal of effort in designing dropout interventions. Unfortunately, there is little scientific evidence on the effectiveness of these dropout interventions. One reason is that there have been relatively few rigorous evaluations of dropout-intervention programs. Another reason is that the scientifically rigorous evaluations that do exist, often fail to demonstrate program effectiveness. The US Department of Education established the What Works Clearinghouse in 2002 to review scientific evidence on the effectiveness of a variety of educational interventions (US Department of Education, 2007). To date, only 11 dropout-prevention programs have been identified that meet rigorous scientific standards. Although 8 of the 11 programs have demonstrated to be effective in reducing dropout rates, improving students' progress toward graduation, only one has been demonstrated to improve graduation rates. Despite the dearth of research evidence, evaluations of proven or at least promising programmatic and systemic approaches to dropout prevention suggest some important features that contribute to their apparent effectiveness.

Programmatic Approaches

Programmatic approaches to dropout prevention do not attempt to change existing institutions serving most students, but rather create alternative programs or institutions to target students who are somehow identified as at risk of dropping out. Although evaluations show that dropout-prevention programs differed in the types of students they enrolled, the curricula and services they provided, and the way they were structured, there appear to be several common features among effective programs (Rumberger, 2004b):

- a nonthreatening environment for learning;
- a caring and committed staff who accepted personal responsibility for student success;
- a school culture that encouraged staff risk-taking, self-governance, and professional collegiality;
- a school structure that provided for a low student-teacher ratio and a small size to promote student engagement.

Creating successful alternative programs presents two challenges. First, alternative programs can have difficulty in attracting students because of negative perceptions by students, parents, and educators that such schools are a dumping ground for bad students and that they symbolize the failure of the regular system. Second, because of their low regard, such programs often have a hard time competing for resources with regular school programs.

Systemic Solutions

Systemic solutions have the potential to reduce dropping out in a much large number of students by improving some of the environmental factors in families, schools, and communities that contribute to dropout behavior. Although the promise of systemic solutions to the dropout problem is great, the reality is not. The reason is simply that systemic changes are extremely difficult to achieve because they involve making fundamental changes in the way institutions work individually and within the system in which they are a part. For example, improving existing high schools requires changing two basic features of schools: the commitments and competencies of the people (teachers, administrators, and staff) and the organizational structure (size, staffing ratio, curriculum design, services, etc.). Yet, it is extremely difficult to identify the resources, technical support, and incentives to transform or restructure existing schools in order to create those features.

Despite the difficulties of designing and implementing systemic solutions, a number of whole-school reform models have been developed and shown to improve student achievement and high school graduation rates. A recent review of these programs identified a number of challenges that these programs have been able to successfully address (Herlihy and Quint, 2007):

- assisting students who enter high school with poor academic skills;
- improving instructional content and practice;
- creating a personalized and orderly learning environment;
- providing work-based learning opportunities and preparing students for the world beyond high school;
- stimulating change in overstressed high schools.

Efforts to reform other institutions that serve at-risk youth have proved more difficult. One ambitious systemic reform effort was the New Futures Initiative, promoted and funded by the Annie E. Casey foundation beginning in 1988 (White and Wehlage, 1995). New Futures was an attempt to build new collaborative structures among existing public and private institutions in five cities (Dayton, OH; Lawrence, MA; Little Rock, AR; Pittsburgh, PA; Savannah, GA) to address the problems of at-risk youth, including school dropout. The key strategy was to establish an oversight collaborative in each city with representation from public and private sector agencies to 'identify youth problems, develop strategies, and set timelines for addressing these problems, coordinate joint agency activities, and restructure educational and social services.' Evaluations of this ambitious, systemic-reform effort found that it did little to reduce dropout rates and other problems of at-risk youth. As with other systemic reform efforts, the evaluations found little incentive or support from the intervention for changing the fundamental functioning of schools.

Conclusions

Successfully addressing the dropout problem in the United States will require both capacity and will. Capacity requires technical expertise to develop and implement effective dropout-prevention and recovery programs, as well as more ambitious systemic school reforms. While some schools have such capacity, most require additional resources, technical expertise, and incentives to restructure existing schools. The development of such capacity will require political will; but even with the will to reform schools, it is unlikely that the United States will ever eliminate disparities in dropout rates among racial and ethnic groups without eliminating disparities in the resources of families, schools, and communities.

Introduction

Can we improve public schools by promoting competition between them? In 1955, Milton Friedman published an article that questioned the role played by government in the provision of education (Friedman, 1955). Friedman promotes the idea that while government involvement is important, it reduces competition. Without this competition, schools have an incentive to waste resources resulting in the provision of a less than optimal quality of education. The underlying concept is as follows: Assume a single community provides education via a single school. If the government requires that all children under a certain age attend this school and there are no other options for schooling, the school has a group of students that have no choice in schooling. Any choice depends on the willingness of parents to move neighborhoods. If parents are reluctant to move, the school has an incentive to behave like a monopoly resulting in the wasting of resources.

This scenario is more complicated in most school systems. Over the last century, single school districts have consolidated into very large school districts resulting in many schools providing similar levels of education. Historically, these school districts have given schools defined catchments, lessening any competition between schools affiliated with the same district. It is this threat of a potential monopoly that has been the basis of many arguments that encourage more choice in schooling, be it through the subsidization of private schools (e.g., vouchers or tax

credits) or through the provision of more choice in public school (e.g., charter schools). What is less clear is whether schools exert monopoly power and, if they do, the extent to which this exertion diminishes school quality.

The purpose of this article is to discuss the key features of the research that has been conducted to understand better the question of whether schools engage in this monopoly behavior and its effect on student achievement. This article focuses on the research that has studied competition within the public school system with some reference to the effects from competition from private schools (e.g., Catholic schools) and/or charter schools. Much has been written on this topic. This article highlights the research that helps to explain why understanding the effects from competition is difficult to measure.

Concepts and Empirical Background

The notion that competition could promote better achievement starts first with a consideration of the choice of schooling by a parent for his/her child. A parent is expected to take into account things such as the quality of the school, the distance from the parent's home to the school, and the teaching philosophy of the school. If a parent can choose from a set of schools, this choice should encourage school administrators to use their resources efficiently to provide a quality level of education. The school

administrators, however, must be motivated to react to this potential competition. What motivates the school administrators can be a range of things such as receiving more resources upon meeting some level of performance or having resources tied to the school's enrolment. Card *et al.* (2008) expound on this theoretical framework to illustrate that areas in which parents have choice in schooling should result in better student performance in all schools relative to areas that have less choice in schooling.

To assess whether competition affects school quality, we can study school resources or student outcomes. Competition can impact the allocation of resources to their use by schools. If resources are used more efficiently in areas where schools face greater competition, then we should observe stronger student performance by students in these areas, after controlling for things such as student ability and characteristics of the neighborhood in which the school is located. The basic idea behind the analysis of competition would be to use data to run a regression that looks something like

$$Y = \alpha + \beta C + \gamma Z + \epsilon$$

where Y represents a measure of school resources (e.g., funding per student) or student outcomes (e.g., high-school dropout rate, test scores), C (or competition) is a measure that reflects the degree to which a school or set of schools face competition from other schools, Z is a set of measures to control for factors that could explain variation in the Y measure such as socioeconomic neighborhood characteristics, and ϵ is a residual term to capture other factors that affect the Y measure. This analysis may be done at a student, school, neighborhood, or school district level. Ideally, the analysis is done with data that are measured over time, allowing the researcher to control for both time-varying changes within each level of analysis (student, neighborhood, or district) and time-invariant characteristics of the area under study.

The purpose of the analysis is to focus on the coefficient β to identify the effect of competition on the decisions taken by the school or school district and/or on student performance. In the ideal study, students are randomly assigned to the school and one can compare the outcomes for areas with greater competitive pressures (e.g., greater school choice) with less competitive pressures. For example, if we were to study the potential effects of school competition on student outcomes, we would want to capture the outcomes of two groups of students. Both groups of students would have similar characteristics in terms of their parental background, socioeconomic characteristics, and their motivation for learning. The groups would differ based on the degree of competition faced by the schools attended by the students. Unfortunately, constructing this type of experiment can be difficult. Because parents can choose where to live and competition might be driven by the presence of

a private school, in any study that seeks to study whether competition matters one has to be concerned with parents' house location and/or schooling decision being made in a nonrandom fashion.

Sorting associated with household location is commonly referred to as Tiebout choice based on the work of Tiebout (1956). Under this notion, parents may choose the neighborhoods based on their preferences or tastes for education and other characteristics. If some parents have stronger preferences for education over other parents, this could result in a sorting that is positive or negative. If parents are willing to move to switch schools if a school is not providing a level of service expected by the parent, schools may seek the best use of their resources because they can attract new students and reduce the risk of losing existing students. A more efficient use of resources should result in a higher quality of education and, thus, better student performance. Sorting, however, could have negative effects. If the sorting is based on taste for education, some school districts might end up with students who are less interested in educational pursuits than other districts. The districts with less interested parents may end up with fewer resources which can result in a more limited ability of the school to deliver a quality education. In addition, if students perform differently based on their peers or other spillover effects, the overall effect from promoting competition through Tiebout sorting could result in students underperforming in the areas with students that are less interested in school.

What can be difficult to disentangle is whether observations on variations in school resources are attributable to the sorting/taste for education, due to the constraints a given school or school faces because of a lack of resources, or associated with being in a more or less competitive environment. Similarly, it is difficult to rely on casual observation to understand whether districts that are spending more resources are doing so because of a sorting issue or because they are inefficiently wasting resources as a result of monopoly power. Barrow and Rouse (2004) study whether school expenditures are valued by potential residents. Their overall finding is that school expenditures are valued by residents and there is no evidence of overspending on education by school districts. They conclude that increased competition across school districts may account for the lack of a finding of overspending by school districts.

This sorting issue can bias the coefficient on a measure of competition. The coefficient can also be biased for other reasons. These reasons include endogenous changes in the measure of competition or the exclusion of measures in the analysis that are correlated with both the competition measure and the outcome measure (omitted variable bias). As discussed below, the competition measure could be endogenous if a change associated with competition is linked to the demand for quality

education, for example, if a new school opens in response to an increase interest in schooling. This new school opening would increase the competitive environment. But if the new school opening is in an area where there is an increase interest in education, any observed gains in student outcomes could be attributable to either this change in interest in education or increase in competition. Disentangling the degree to which a change in performance is attributable to a change in competition is difficult. Thus, when estimating the effect of competition on school resources or on student achievement, one should consider carefully whether there are sorting or endogeneity issues or omitted variables in the estimation that could bias the measured effect of competition.

A common method used to address this problem is to identify a set of measures that directly affect the competition measure but not the outcome measure (Y). These measures are then used to predict the portion of the competition measure that can be viewed as exogenous to the outcome measure using an estimation technique known as instrumental variables or two-stage least squares. This allows the researcher to identify an unbiased effect from competition (β) on the outcome (Y). A second method is to use a policy change that affects the competition measure and measure the difference in outcomes before and after the policy change. A third method is to identify stark differences (discontinuities) in the rules that can affect the level of competition and then compare the effects of competition on the outcome around the area of the discontinuity. Examples of these methodologies are provided below.

Competition Associated with the Presence of Private Schools

Hoxby (2000) points out that it is important to understand the role played by Tiebout choice as any type of reform should consider the nature of sorting that occurs across neighbors given that parents are free to choose where to live. One approach taken by researchers is to study the performance of students in public schools relative to the fraction of students in private schools within a school district. The underlying basis for this approach is based on the notion that greater private school presence provides parents with alternatives, encouraging public schools to use their resources efficiently. An early study by Couch *et al.* (1993) and a study by Dee (1998) found a positive correlation on test scores and high-school graduation rates, respectively. Studies, however, by Newmark (1995), Sander (1999), and Geller *et al.* (2006) failed to find significant effects.

Demand for private schools, however, is correlated with the quality of the public schools in the area. If the quality of public schooling is low, parents may opt to send their

children to private schools. Yet, only those parents with the financial resources will be able to opt out of the public schooling system. Using measures of the demand for private schools (e.g., private school enrollment) as a proxy for the degree of competition one faces could suffer from a downward bias given the potential endogeneity between demand for private schools and public school quality.

Hoxby (1994) seeks to correct for this potential endogeneity bias by using the share of Catholics in an area as an instrument for private enrollment. If Catholic parents are more likely to send their children to a private school for reasons other than school quality (e.g., to provide their children with an education within a religious environment), then one should expect to observe more private (Catholic) schools in areas where there is a greater share of Catholic residents. Using the share of Catholics in an area, thus, provides a potential source of exogenous variation that can be used to identify the extent to which private schools provide a competitive threat to public schools. Hoxby's analysis suggests a positive effect on test outcomes. More recent studies, however, suggests a weaker and fairly small effects when this type of variation is used to predict the degree of potential competition (e.g., Arum, 1996; Jepsen, 2002, 2003). Altonji *et al.* (2005) also raise into question the use of measures that reflect the share of Catholics as instruments for competition. There are several extensions that use similar empirical methodologies that compare the effect of mechanisms such as vouchers for private schooling, publicly funded charter schools, and a comparison of performance of students in both public and private schools.

Competition Among Public Schools

Another way to explore the potential effects of competition is to study competition between public school districts within a geographic area. Given that parents can choose to where to live, if the size of the district is small enough, a parent potentially can choose to live in one of a number of school districts and these districts will compete with each other for that parent. Borland and Howsen (1992) develop a Herfindahl index of enrolment shares at different school districts to compare the performance of students based on the degree of market concentration of the school districts within a US county. Assume, for example, there are three school districts within a given area. The total enrolment across all districts is summed and shares of total enrollment for each school district is calculated. The Herfindahl index is the sum of the squares of these shares. The index ranges between 0 and 1. A higher index suggests less competition and a lower index suggests greater competition. If each of the three districts had approximately one-third of the students in

the area, the index would be approximately 0.33. If, however, one district had 80% of the students in the area and the other two districts had 15% and 5%, respectively, the value of the index would be 0.665.

Borland and Howsen (1992) find that third-grade students perform worse in counties with more concentrated school districts. Millimet and Rangaprasad (2007) extend this research by testing for strategic interactions across the input choices of nearby school districts in Illinois. Their approach assumes that a given district will react to the decisions taken by neighboring school districts if these districts compete for students. They find positive effects from nearby choices on things such as pupil/teacher ratios, spending per pupil, and average school size.

The concentration of districts within a county, however, is also arguably endogenous and could bias results downward to not finding a competitive effect in areas that have more school districts. Hoxby (2000) illustrates the importance of identifying exogenous measures that control for the potential endogeneity associated with the degree of market concentration within a county. Our observation of any given school district represents a combination of decisions made about the district with respect to the level and use of resources and decisions by parents to locate within the geographical boundaries of the school district. For example, an area that has many rivers or mountains will constrain the size of a school district. Hoxby (2000) exploits the natural contours of the land to identify the number of school districts in a given area. She relied on the measures related to the number streams located within a metropolitan area to identify the level of concentration of school boards within the metropolitan area.

At the time the paper was written, Hoxby did not have access to machine readable information about the location of streams. She relied on maps provided from the US Geological Survey's 1/24 000 quadrangle maps. From these maps she developed two measures of streams: a count of the larger streams and a count of the smaller streams. Her results suggest a strong association between the stream measures and the degree of concentration of school districts. Hoxby (2000) represents a creative way to address the endogeneity associated with some US counties having higher levels of market concentration relative to other US counties.

Rothstein (2007) comments on his replication of the Hoxby (2000) results. Rothstein (and subsequently addressed by Hoxby (2007)) identified some coding and software program errors that affected the assignment of students to school districts. Using machine readable data on streams, Rothstein created a set of instruments that differ from Hoxby's instruments but seek to capture the same types of exogenous variation in school district competition. His results fail to find a significant effect from competition on student performance.

Another way to study the potential effects from competition is to focus on the differences in student performance between students with choice and students without choice. Cullen *et al.* (2006) undertake such an approach. Similar to the discussion above, any study that compares different options of choice available to students must use a choice variable that is exogenous. An example of this exogenous variation is the lottery system undertaken by the Chicago public school system to allocate students across different public high schools. Students were eligible to attend a non-neighborhood high school if space was available. Because the space for these schools was limited, the school system assigned interested students based on a lottery. Cullen, Jacob, and Levitt compare various outcomes for the winners and losers of these lotteries. In effect, the winners get to choose to attend their home school or another school within the school district and so have greater choice in schooling than do the losers. Thus, if choice matters, we should expect to observe stronger student outcomes by the winners.

Cullen *et al.* (2006) fail to find much evidence that supports the argument that greater school choice results in stronger student performance. Their results suggest that the argument that competition through more choice results in better student performance may reflect only part of the story on how best to improve the delivery of education. If parents are not well informed about the role that schools can play in promoting better outcomes, this can result in a mismatch between students and the schools they attend. Cullen *et al.* (2006) provide limited support for this hypothesis.

Lessons from Research Using Non-US Data

Most of the current research in the US has focused on understanding the degree to which contiguously situated school boards compete with each other and whether this competition affects resource allocation and/or student performance. (There is also a literature that considers how school quality and changes that affect access to public schools across neighborhoods can affect housing prices. Reback (2005) studies a policy change that allowed students from nearby school catchment areas to attend a school in a different catchment area in Minnesota. He shows that house prices change as a result of this policy change. House prices rose in areas where there was a tendency for students to attend a school in a different catchment area and house prices fell in areas that attracted students from the neighboring catchment areas.) In other countries, however, there are institutional features that can add to our understanding of the potential effects from competition. Relying on Canadian data,

Card *et al.* (2008) exploit a feature of the public schooling system that provides choice in schooling to Catholic parents and their children. In Ontario and other provinces, a student of Catholic descent can choose between schools operated by two different types of publicly funded school boards: one operated solely for Catholic students (separate school boards) and one operated for all students (public school boards). Approximately 40% of the Ontario population is Catholic. Thus, for any given area within the province, there are two distinct publicly funded schools from which to choose if one is Catholic. In their paper, the authors first demonstrate that the two systems can be expected to compete with each other. Both systems are publicly funded, with the bulk of their funding being driven by enrolment figures. If there is a shift in enrolment from one system to the other system, the system losing enrolment suffers financially and the system gaining enrolment gains financially. Card *et al.* (2008) demonstrate that if one system opens a new school, the enrolments in neighboring schools affiliated the opposite system decline. These enrolment shifts are closely linked to the share of Catholics residing in the neighborhood.

Card *et al.* (2008) then explore the effects of these two systems on student performance by studying the performance of grade 6 students in a neighborhood, relative to the performance of the students in the neighborhood 3 years earlier (grade 3 test scores) and relative to the proportion of Catholics in the neighborhood. Their research suggests that students in neighborhoods with a high proportion of Catholics perform better than students in neighborhoods with a low proportion of Catholics. Their results are strongest in neighborhoods that are growing, as measured by the share of new housing in the area.

Gibbons *et al.* (2006) use a set of primary schools in England to study how competition may affect student achievement. They exploit discontinuities in school district boundaries to identify the competition effect. Their study finds limited gains in student performance at schools facing more competition than at schools facing less competition. Burgess *et al.* (2004) study England's choice-based education system to understand better the extent to which students sort across schools and whether this sorting affects student outcomes. After demonstrating that most students have different options for schooling, the authors demonstrate that rules that do not rely on the residential location of students affect the degree to which students are sorted across schools based on their ability.

Lavy (2005) explores a policy change in Tel Aviv to study the effects on student performance. The policy change introduced a program that allowed students to choose schools in and out of their assigned district. Lavy finds the policy affected high-school dropout and graduation rates, especially among disadvantaged children. He, however, fails to find any significant differences in the

achievement levels of the students that took advantage of the program.

In 1981, Chile introduced a program that provided vouchers to any student attending a private school. Similarly, in 1992 Sweden introduced a program that provided equivalent public funding to private schools. Both of these programs resulted in a dramatic increase in the number of private schools. Hsieh and Urquiola (2006) study the effects of the Chilean program. They compiled a panel data set that covered 150 municipalities to study the effects of the program on test scores and other student outcomes. The program resulted in a dramatic increase in private school enrolment ($\sim 10\%$). Sandstrom and Bergstrom (2005) study the Swedish reform. This reform dramatically increased the number of private schools (from 90 to 400), although the share of students attending private schools was still small ($\sim 4\%$). Sandstrom and Bergstrom study the effects of the reform on student performance using mostly cross-sectional data from a small sample of Swedish municipalities (33 of 288).

For both studies, the authors had to address issues concerning endogenous location of private schools and the potential of a nonrandom switch by students from public to private schools. They both seek to study the effect of increased private school enrolment on public school performance. In both studies, the authors use as instruments for private school enrolment measures that capture different characteristics of the municipalities in which the schools are located. Hsieh and Urquiola (2005) and Sandstrom and Bergstrom (2005) find, at best, a small positive effect of an increased private school enrolment on public school student performance. Hsieh and Urquiola (2005) push their analysis further and find evidence of a nonrandom switching by students from public to private school which illustrates the difficulty associated with finding a strong effect from increasing potential competition.

Summary

The research on whether schools compete with each other and how this affects student outcomes and school resources teaches us many things. First, there are many potential ways to measure potential competition. Competition could come from the ownership of schools (private, public), the structure of public schools within a school district (choice in selection of schools or assignment to a neighborhood school), and/or the structure and geographic boundaries of school districts. With each method, however, there are identification issues that could result in a downward bias of the effect of competition on performance and resources. Dealing with these identification issues requires creativity, quality data, and a clear understanding of the statistical issues.

The existing research suggests that there is limited evidence of the effect of competition on either performance or school resources. More recent research, most using data from outside of the US, is demonstrating a modest effect on measures of student performance from competition. There is no evidence at this stage, alas, that schools or school districts waste resources or results in substantially lower student achievement given a monopolistic position.

Educational Privatization

C Belfield, Queens College, City University of New York, Flushing, NY, USA

H M Levin, Teachers College, Columbia University, New York, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Educational privatization is a term that has become widely used in the early part of the twentieth century. To those unfamiliar with the term, it may connote a shift to private schools. However, the term has come into wider usage largely because of a variety of forms of increased involvement of nongovernment entities in the sponsorship, financing, and provision of education. For example, one dimension of this trend is that of charter schools in the US, where some 4000 public schools have been given considerable autonomy in operation and management, including maintaining their own governing boards. However, there are many other examples of privatization including government schools operated under contract by private entities which include for-profit firms and universities or private schools that receive government funding. At the same time, many countries require private fees as well as other private expenditures by parents to attend public schools. All share in common some dimension of privatization in contrast to a purely public concept of education where schooling is provided and funded exclusively by public authorities.

In this article we delineate a range of different forms of privatization and set out criteria for evaluating their consequences. We begin by referring to four different forms of schooling: home schooling, private schools, charter schools, and public schools.

Privatization of Different School Types

Home schooling refers to the education that parents provide in the home, both informally and as an official form of schooling (Belfield, 2008). In some countries, such as the United States, home schooling that meets certain standards can satisfy compulsory attendance laws of the states, even when the children are not attending formal schooling institutions for any part of their education. In fact, in the US, about 2% of students are home schooled. In many respects, home schooling is the most privatized form of education with the least public intervention. The public involvement extends only to requirements that parents meet broad standards for curriculum, hours of instruction, and, in some cases, testing, but accountability for these standards is often lax.

Private schools are the most common form of educational privatization, schools that are founded and sponsored by private entities, including religious groups, independent organizations, and for-profit organizations. Such schools may be independent or operated by organizations with an educational or spiritual mission or operated as a business. In the US, private schools are mostly religiously affiliated and not for profit. In other parts of the world, particularly in Asia and Latin America, private schools were started by missionaries, but the major growth has been that of for-profit businesses. Private schools were founded in most countries long before the advent of universal and government-provided schooling, but only to serve particular religious or social groups.

In some countries, private schools are funded strictly by parental fees and philanthropy. In other countries, they are fully or partially funded by government funds, even though they are operated privately. Two of the best examples are Holland and Chile. In Holland, a school that meets specified standards in personnel, curriculum, class size, and other requirements can receive the same amount of funding whether it is a private or government-sponsored school. In Chile, the national voucher system also provides similar funding for religious, for-profit, or government public schools. In Europe, in general, it is also common to provide substantial government funding for private schools (McEwan and Carnoy, 2000).

Charter schools are a unique development in the US that mixes both public and private elements. They are public in receiving public funding and being required to meet some public requirements, but private in terms of governance and sponsorship and in being provided autonomy and release from many of the state and local laws (Bifulco and Bulkley, 2008). Charter schools, started in 1992, have proliferated among nearly 40 states to where there are about 4000 of them serving more than 1 million students in the elementary and secondary grades. Charter schools are expected to augment their public support by obtaining private funding through the philanthropic community, and a significant segment obtains a substantial amount of support through this source.

Public or government schools represent the most common form of schooling around the world. However, even these schools have many private components. For example, in many countries, public schools draw upon students in particular residential areas where students from wealthier families are segregated in their own government

schools and those from poorer families are segregated in schools with high concentrations of poor children. In other cases, parents must pay fees or provide other private costs for their children to attend public schools. In this respect, there is privatization of at least part of the costs and segregation of students that enables the schools to provide a different type of education as the public schools attended by students from good families are able to attract better teachers and other resources.

What can be demonstrated is that pristine categories of public versus private tend to oversimplify the educational privatization phenomenon. Most educational systems support schools that have both components (Belfield and Levin, 2005). Further, to the degree that all schools must produce not only individual learning and skills, but also preparation for citizenship in a society, even the most privatized schools in terms of finance or sponsorship are contributing to public goals.

Privatization of School Services

However, privatization can also take other forms beyond differences among major school types. For example, both public and private schools can produce their own services or make arrangements for those services to be provided by private suppliers. In many countries, construction, furnishings, text books, food services, and transportation are provided by outside contractors to public schools. In general, the view is that competitive markets for these types of school resources can provide greater choice and variety and lower costs than if governments produce these services. Of course, these decisions also have employment consequences as well which make them politically contentious where public employee unions are strong.

Nevertheless, even more controversial has been the shift to private educational management organizations (EMOs) to operate public schools (Miron, 2008). EMOs are firms that have arisen to contract with public school authorities to manage their schools. In general, there has been relatively little controversy over whether government or private entities should provide material goods or services to public schools. However, the expansion of such efforts to instructional services has brought great controversy, at least in the US where there has been the greatest development of this approach. In general, it takes the form of public entities such as school districts contracting out the management of schools to firms that hope to make a profit from such endeavors. These enterprises are given a set amount of revenue for each student and are required to provide educational services at least comparable to those of the government-managed schools.

School districts generally have contracted with EMOs for their poorest-performing schools with the hope that the private-sector effort can solve low-achievement problems

that have not been solved by government management. Typically, these schools enrol students from economically disadvantaged, minority, and immigrant families. The EMOs promise to outperform comparable public schools by hiring better teachers and administrators and using more efficient business practices. However, two decades of experience in the US have neither shown that EMOs can outperform public schools or be consistently profitable.

A similar story can be said about contracting for particular instructional services such as the tutoring of students who lag in academic achievement. In the US, under the No Child Left Behind legislation of the federal government, states are required to provide funding for students in failing public schools to receive tutoring and other instructional services from outside vendors. The rationale for opening these options to private vendors is that the public authorities have failed these students and should not be entrusted with additional funding for remedial services when the private sector has the capacity to outperform the public schools. However, after 7 years of experience there is virtually no evidence of private contractors providing better academic outcomes.

Financing Education and Privatization

Privatization of education is supported by many different financial approaches. The most general of these is that of educational vouchers.

Educational vouchers refer to a school financing approach where families are provided with a certificate or voucher that can be used to pay a certain level of tuition at any approved school, public or private (Levin, 2002). Schools compete for students and their vouchers and redeem them with the state to finance operations. Chile has had a national voucher scheme since 1980, and much has been written about it and many evaluations have been done with respect to performance (McEwan and Carnoy, 2000; Zimmer and Bettinger, 2008: 456–457). One of the major claims for vouchers is that by introducing competition into the schooling system in place of a government monopoly, schools will become more productive and efficient in order to attract enrolments. Thus far, there is no evidence of rising efficiency for the Chilean educational system, although it appears that the private schools receiving vouchers do slightly better in raising achievement than public schools, at least for middle-class students. However, Chile also permits schools to establish additional private family payments beyond the government voucher, and these higher costs may account for any higher achievement.

In the US, there is also a strong push for increasing educational privatization with educational vouchers. Both free-market advocates and those who simply see market competition as a stimulus to raising public school performance have supported vouchers in the US. Milwaukee has

had a voucher system since 1990 and Cleveland since 1995. Washington, DC, has had a voucher system since 2006, and Louisiana has just adopted one. In all of these cases, the number of students funded by vouchers is limited, and eligibility or preference is given to low-income families. In general, evaluations show that the families who seek and obtain the vouchers indicate a higher level of satisfaction with their schools of choice than comparable families in public schools, but there is little evidence that achievement of students using vouchers is higher (Zimmer and Bettinger, 2008).

A special version of vouchers has also been adopted by such states as Arizona, Florida, and Utah. In the US, there are laws that require public schools to provide appropriate educational services for students with disabilities in the least-restrictive environment. Often, the small student-teacher ratios and facilities requirements for such students necessitate high funding costs by school districts, sometimes 2–3 times the average pupil expenditure for nondisabled students. If a school district is unable to provide satisfactory services in the view of the parents, the parents can seek private school services at public expense through a hearing procedure. However, the more recent use of vouchers for students with disabilities makes them available to fund private student placement directly by giving the parent the option of accepting the public school's individual educational plan for their child or getting an equivalent amount of funding to send the child to a private school.

Tuition tax credits refer to a different mechanism for covering private costs of education (Huerta and d'Entremont, 2007; Zimmer and Bettinger, 2008). At least seven states in the US sponsor tuition tax credit plans. Under this approach, a portion of family tax liability is forgiven for paying tuition at a private school, or in some states, for other private educational expenses. For example, a family might be given a tax credit of \$1000 in reduced state tax liability for paying at least that amount toward tuition at a private school. Libertarians and many advocates of market competition prefer tuition tax credits to educational vouchers because they require less government involvement in the operations of schools. Educational vouchers require many detailed regulations in terms of what kinds of schools are eligible and what information they must report annually and other operating details to be able to redeem vouchers. With tuition tax credits it is only necessary for a parent to gain the tax benefit by providing a receipt of payment from a private school or from some other private educational service.

There are several variants of the tuition tax credit for parents. Several states allow nonparents and businesses to contribute to funds that will provide scholarships for students to attend private schools. Since the willingness to take a tax credit simply reduces one's tax burden, such a decision is virtually costless for the taxpayer, although tax

credits obviously have a cost to the state in terms of foregone tax revenues. Another variant is that of a tuition tax deduction. The tax deduction simply allows the taxpayer to reduce taxable income and save the tax on that reduction, a much smaller tax benefit than a tuition tax credit.

Private costs in public schools represent a prevalent form of privatization in the sense that families must contribute substantial resources to participate and ensure success for their offspring in the educational system. In some countries, such as Tanzania, the fees to attend public secondary schools are so substantial that they are an important reason for one of the lowest secondary school participation rates in East Africa. Many countries allow government schools to charge fees to students. In Bangladesh, India, and Pakistan, it is common for teachers to require students to pay for private tutoring sessions for curriculum topics that are deliberately not covered in class, but required for passing the examinations. In addition, many schools in the developing world require families to pay for textbooks, study guides, uniforms, writing supplies, transportation, and pay other special fees that are assessed during the year. The shifting of school finance from public sources to private ones is a form of privatization with the consequences that it may limit school enrolments or shift enrolments of the poor who cannot afford the private costs into schools with more limited learning resources.

Philanthropic resources are also important funding sources for privatizing education. Normally, these are provided by organizations or movements that are committed to a particular mission or population. Religious organizations, in particular, may subsidize the costs of private schools of their denomination in order to ensure that the costs to families are not a barrier to attendance. A different motive may be evident when philanthropic resources are applied to schools with relatively high-performing students or those from families of high status. By adding resources they can assure salaries and facilities that will attract the best teachers, increasing the appeal of the school and allowing the school to discriminate in admissions.

Evaluating Educational Privatization

Many advocates of educational privatization support it because they believe that it may be more efficient than public forms in promoting competition and choice. Opponents often argue against educational privatization because it leads to segregation by family income, race, ethnicity, and other distinctions that create inequities and inequalities. Although these are broad-stroke assumptions, the different forms of privatization must be evaluated according to their specific consequences, and different forms of privatization have different consequences. For example, in the case of educational vouchers, a high voucher (relative

to existing school costs) that is given to all students with supplements for special need students, such as students from immigrant and impoverished families or with disabilities, will tend to promote more equal outcomes than if the voucher is set at a low level with parental contributions supplementing it. In the latter case, wealthier families will be able to spend more on the education of their children, sequestering them in schools with other children from high-income families and better salaries and working conditions that will attract the best teachers away from the poor.

Evaluating Educational Privatization Approaches

Educational privatization is not just a single phenomenon, but comprises many different phenomena. Privatization can occur in the sponsorship, governance, funding, contracting, and many other aspects of schooling. Even what we call public schooling often has many dimensions of privatization. These conclusions suggest that being precise about what is meant by educational privatization is important in evaluating it.

Clearly, there is no perfect system as much as a quest for a best system in providing a balance among competing aims. In this context, one can denote four major criteria, which are detailed below, for addressing an effective educational system (Levin, 2002):

1. *Freedom to choose.* This criterion places a heavy emphasis on the private benefits of education and the liberty to ensure that schools are chosen by parents who are consistent with the child-rearing practices of families. Just as families wish to set the types of conditions that will influence their children's growth and development overall, they wish to choose schools that reinforce those values. Privatization advocates typically place great weight on this criterion.
2. *Productive efficiency.* This criterion refers to the maximization of educational results for any given resource constraint. Educational privatization advocates assume that competition among schools for students and the greater use of parental resources will create strong incentives for schools to meet student needs and to improve educational productivity. Privatization opponents believe that the assumptions that make competition effective will not be present in the educational marketplace.
3. *Equity.* This criterion refers to the quest for fairness in access to educational opportunities, resources, and outcomes by gender, social class, race, language origins, disability, and geographical location of students. Educational privatization advocates argue that many forms of privatization can be used to expand school choice and open up possibilities for students who are locked into inferior neighborhood schools and that a

competitive marketplace will have great incentives to meet the needs of all students more fully than existing schools. Challengers argue that educational privatization, and particular vouchers and tuition tax credits and increasing private costs, will create greater inequities because parents with education and income are better informed and have greater resources to cover school costs and to have access to transportation. In addition, they believe that the choices, themselves, will further segregate the poor and disenfranchised as those with power and status will select schools with students like themselves and schools will also select students by such criteria.

4. *Social cohesion.* This criterion refers to the provision of a common educational experience that will orient all students to grow to adulthood as full participants in the social, political, and economic institutions of our society. This is usually interpreted as necessitating common elements of schooling with regard to curriculum, social values, goals, language, and political institutions. Privatization advocates believe that social cohesion will develop in schools without making special provisions or that it will only require minimal regulations, such as common curriculum requirements. Opponents argue that it will take place only if schools adopt a common set of objectives and educational experiences through societal agreement and mandated policies.

More fully meeting some criteria may reduce the ability to meet others, so that any system of educational privatization must acknowledge trade-offs. Some goals cannot be attained without sacrificing others. Although some design provisions would improve outcomes along more than one criterion, almost all would also reduce outcomes on other criteria. Provision of information and transportation will improve choice options for all participants, especially for those from families with the least access to information and transportation, the poor. However, such provision would also raise the costs of the overall educational system and decrease resources available for instruction, probably reducing productive efficiency unless academic gains from competition due to better information and access offset the costs of the transportation and information. As another example, the establishment of extensive regulations on curriculum, admissions, and finance with continuous monitoring and enforcement could be used to increase equity and social cohesion, but only by creating more uniformity among schools which will undermine freedom of choice.

This means that there is no optimal system that provides maximal results among all four criteria. Ultimately, the choice of design features will depend upon specific preferences and values as transmitted through democratic institutions. Those who place a high value on freedom of choice will probably be willing to sacrifice some equity and social cohesion provisions by minimizing regulations,

stressing school autonomy, and giving parents the ability to increase private spending on the schooling of their offspring through permitting fees in government schools or private supplements to government vouchers. Conversely, those who place a high value on social cohesion will be willing to sacrifice some freedom of choice through establishing a common curriculum core and other standardized features of schools. Ultimately, much of the debate over the specifics of educational privatization plans revolves around the political power and preferences of the stakeholders.

Tools of Educational Privatization

How a society uses educational privatization will depend on its priorities in balancing the four criteria that were set out above. There are three tools for addressing these criteria, finance, regulation, and support services, which are described below:

1. *Finance.* How an educational system is financed will have strong implications for such goals as choice, efficiency, and cohesion. For example, if funding is kept low, whether for use at public or private schools, the range of choices will be limited for those who must depend upon public funding. As one finds in many countries of the developing world where government schools are funded minimally, middle- and upper-income families circumvent the government schools by using their own funds to send their children to private schools that charge additional tuition which the poor cannot afford. This means that the educational system will foster segregation of the poor from those who are financially more privileged. In contrast, if more funding is provided overall to make government schools more attractive to the middle and upper-middle class and additional funding is given for services for students from poverty backgrounds and those with disabilities, it is possible to provide a more equitable system of education with less stratification.
2. *Regulation.* Governments can use regulation of admissions, curriculum, and testing requirements as well as school performance criteria to promote educational goals. By requiring schools to accept students by lottery, establishing a common curriculum, and ensuring that school performance is measured through standard testing requirements, both an emphasis on equity and social cohesion can be sought. The use of a common rubric for measuring results may also increase efficiency of competition. However, regulation produces greater uniformity which reduces the range of schooling options and freedom of choice.
3. *Support services.* Governments can provide transportation, information, on school alternatives, and instructional support such as tutoring to expand educational choice

and equity. These services are especially likely to help those with the greatest economic disadvantage by providing access to more potential schools, information on school performance, and instructional assistance beyond the school. However, they may also reduce the instructional resources available to schools for providing educational services.

Summary

Educational privatization is not a singular phenomenon, but one that can take many different forms. Thus, simple generalization about the phenomenon is not useful. Different countries utilize educational privatization in different ways with enormously differential consequences with respect to the impact on choice, efficiency, equity, and social cohesion. Even in the same country there may be many different forms of educational privatization. The specific impacts of any form of educational privatization can be evaluated according to their consequences for different educational outcomes. Unfortunately, the goals, themselves, are often in conflict so that designing an approach that uses privatization may enhance one outcome at the expense of sacrificing others. In particular, the careful design of educational finance, regulation, and support services can be used as policy tools to obtain the mix of outcomes that is most desirable.

Student Incentives

E R Eide and M H Showalter, Brigham Young University, Provo, UT, USA

Introduction

A fundamental principle of economics is that people respond to incentives. They change behavior in ways that promote their well-being when faced with new circumstances. Many education reform policies rely on incentives to change student, teacher, and principal behavior in ways that increase their effort and improve student outcomes. For example, some school districts in the United States have implemented high-stakes testing that determines which students are promoted to the next grade or allowed to graduate high school. In principle, students faced with the possibility of a disruption in their educational progress will work harder in order to meet the required standards.

A strand of research has recently emerged that assesses the ways, both intended and unintended, in which incentives have changed student achievement and educational progress. This article provides an overview of this research agenda. It includes a discussion of how education economists conceptualize and estimate the association between incentives and measures of student learning and educational progress, and it summarizes the research findings on this relationship.

Conceptual and Empirical Issues

Economists use a conceptual framework called an education production function to model the educational process that leads to improved student outcomes. In these models, a student's educational outputs, such as test scores, are a function of the quantity and quality of a variety of school and teacher inputs. Common educational input measures include class size, per-pupil expenditure, teacher education, and teacher experience. Education policy variables specific to a particular research objective, such as incentives to raise student performance, are also included as inputs.

Education production functions usually include non-school inputs that are theorized to affect student outcomes. Such measures include the students' family background (parents education and income), demographics (race/ethnicity, gender), and peers. Including nonschool inputs together with school inputs provides a deeper understanding of the factors that influence student outcomes.

While conceptually straightforward, statistically evaluating education policies, such as the effectiveness of incentives, is fraught with challenges. There are often multiple ongoing policies at the national, state, and local

level that simultaneously affect the educational process, making it difficult to assess the effectiveness of any one particular policy. Changes over time in the types of students who are being measured, for example, the demographic composition or the percentage of students who are classified under special education, pose another obstacle. Furthermore, if one of the research goals is to assess whether improved student outcomes are a result of increased student effort, a difficulty arises because student effort is not usually observed or measured. In most cases, researchers must take an indirect approach such as measuring the difference in student achievement before and after a policy is implemented.

Strategies for overcoming these estimation issues include the use of longitudinal data that follow students and school districts over times to cover both pre- and post-policy implementation, as well as the use of sophisticated statistical models. While these fixes are not perfect, they go a long way toward improving the validity of the estimates.

Incentives to Increase Student Effort and Performance

Numerous education policies incorporate incentives to raise student learning. For exposition purposes, here policies are grouped into three areas: standards-based accountability, direct monetary rewards to students, and incentives to teachers.

Standards-Based Accountability

The prominence of standards-based accountability in the education reform arena began in the United States in 2002 when President Bush signed into law the No Child Left Behind Act (NCLB). Standards-based accountability provides incentives to students, parents, teachers, and principals to improve student performance. Schools and school districts must develop curriculum and achievement standards, and measure student learning through tests that are aligned with the standards (Betts and Costrell, 2001). A key feature of standards-based accountability is that consequences are associated with how well students and schools progress toward their learning objectives. For students, consequences include high-stakes tests that determine whether or not they graduate from high school or are promoted to the next grade. For schools, consequences for failing to make adequate progress can include dismissal or reassignment of teachers and school administrators.

In principle, these incentives provide the motivation for students and schools to change behavior and improve. Betts and Costrell (2001) explore the possible incentive effects of high-stakes testing on student performance, and how student response to the test cutoff depends on where the student is in the distribution of ability and attitudes toward study. For example, for students who are just under the margin of passing, it would only take a small increase in their effort in order to raise performance enough to pass the test. Hence, in comparing the cost (i.e., effort) and the benefit (i.e., passing the test) of trying harder, students at the margin of passing would respond to the incentive and work harder to pass the test. Students who are far below or far above the cutoff have little incentive to change their effort.

While advocates of standards-based accountability believe these incentives will yield benefits to students and schools, critics argue that the incentives result in strategic behavior by teachers in ways that bring about unwanted changes. For example, teachers may shift resources away from low-stakes subjects toward high-stakes ones that will be explicitly tested, and they may teach to the test. There may also be a discouragement effect as students who fail high-stakes exams, such as high school graduation exams, choose to drop out of school rather than retake the exam in the future in an effort to pass (Martorell, 2004).

In addition to high-stakes testing, some schools elicit greater student effort and performance by raising grading standards. While the consequences of higher grading standards may not seem as direct or severe as high-stakes testing, the consequences can be considerable because grade point average is a main determinant of college admission and scholarships. Economic models of grading standards (Becker and Rosen, 1992; Betts, 1998) predict that, as with high-stakes testing, increasing grading standards may have uncertain effects on student achievement as more academically proficient students increase effort in order to reach the new standard, while less-proficient students, who must work harder in order to meet the higher grading standard, give up instead. Students at the extremes of the achievement distribution may be unaffected by increased grading standards.

Evidence

Studies examining the relation between standards-based accountability and student performance yield mixed conclusions. Results differ according to the city or state studied, and the type of policy that was implemented. For example, some studies relating high school exit exams to student achievement find a positive association, while studies with more extensive data do not find higher achievement (Jacob, 2001). Martorell (2004) used data from Texas to examine how high school exit exams affect a number of student

outcomes. He found that failing the exit exam reduces the probability of normal high school graduation and increases the likelihood of acquiring a general educational development (GED) degree. Martorell also found that failing the high school exit exam lowers earnings, but only among individuals whose work experience indicates a strong attachment to the Texas labor market.

Jacob (2005) studied the effectiveness of an accountability policy implemented in the Chicago public schools in 1996–97. The accountability policy consisted of two parts. One part was holding students accountable by ending social promotion, where students are advanced to the next grade regardless of their academic achievement level, and in its place instituting grade retention, where students repeat a grade if they are not achieving at grade level. Students were required to pass standardized tests in math and reading, or else be required to take a 6-week summer school program. They were tested at the end of summer school, and if they still failed the test, they would not be permitted to advance to the next grade.

The second part of the accountability policy was designed to hold teachers and schools accountable for student achievement. Schools in which fewer than 15% of students scored at or above national norms on the standardized reading exam were placed on probation. If they did not show adequate improvement, these schools could be reconstituted, which involved the dismissal or reassignment of teachers and school administrators.

Using longitudinal student-level and administrative data, the study found that math and reading achievement increased sharply following the introduction of the accountability policy, in comparison to both prior achievement trends in the Chicago district and to changes experienced by other large, urban school districts in the mid-Western United States. The results suggest that the observed achievement gains were driven by increases in test-specific skills and student effort. Moreover, the study found that teachers responded strategically to the incentives along a variety of dimensions – by increasing special education placements, preemptively retaining students, and substituting away from low-stakes subjects such as science and social studies.

A related study by Jacob and Lefgren (2004) examined the effect of the Chicago accountability policy on summer school and grade retention using a sophisticated statistical technique called regression discontinuity. The intuition behind regression discontinuity in this paper is that students who are just under the test cutoff must attend summer school, and those who are just past the cutoff do not have to attend, and these two groups of students who are just on either side of the cutoff are likely similar in their individual characteristics and background. Provided there is some randomness in the test outcomes, differences in future performance between these two groups of students can be attributed to the accountability policy.

Using this statistical technique, the study found that the Chicago accountability program substantially increased academic achievement among third graders, but not among sixth graders.

Other studies have examined the effects of accountability systems on student achievement using cross-state analyses, and have found positive effects. Research by Hanushek and Raymond (2005) and Carnoy and Loeb (2002) show that the introduction of accountability systems led to significantly higher student-achievement gains as measured by the National Assessment of Educational Progress (NAEP).

Research on the effects of increasing grading standards on student outcomes finds that students do indeed respond to higher grading standards. Betts and Grogger (2003) find that higher standards raise test scores across the distribution of achievement (low-performing, average, and high-performing students all improve achievement), but the greatest increase is found among students at the top of the distribution. They also find, however, that higher standards have no positive effect on educational attainment, and in fact have negative effects on high school graduation among some racial/ethnic groups.

Overall, research suggests that standards-based accountability can raise student effort and performance, depending on the context and type of accountability policy implemented. Moreover, students and teachers sometimes respond in unintended ways when faced with new incentive structures.

Student Financial Incentives

Monetary rewards to students for good academic performance are another incentive used to raise student effort and achievement. Financial incentives typically include scholarships to pursue higher education, and in less-frequent cases, direct monetary rewards to use for education purposes during primary grades. Critics of financial merit awards posit that rewarding students for educational performance may weaken the intrinsic motivation for learning, and is subject to gaming.

Evidence

In recent years, state governments have become increasingly involved in providing merit financial aid, allocating billions of dollars in merit-based college scholarships. States have undertaken these efforts in an attempt to promote academic achievement, increase college enrolments, and keep the most able high school graduates in state for college (Cornwell *et al.*, 2006).

One of the most influential of these state programs is Georgia's Helping Outstanding Pupils Educationally (HOPE) Scholarship, which began in 1993 and is funded by the state lottery. The scholarship covers major expenses for all eligible high school graduates attending Georgia postsecondary institutions. Eligibility includes graduating

from a Georgia high school since 1993 with at least a B-average, and being a resident of Georgia. Analysis of the HOPE scholarship program shows that it is effective in raising college enrolments. Cornwell *et al.* (2006) find that total college enrolment was about 6% higher in Georgia than other comparable southern states as a result of the HOPE scholarship program, which amounts to an increase of about 2889 freshmen per year increase in Georgia colleges. These figures suggest that more students are meeting the eligibility requirements in order to receive the scholarship.

Another state-based merit award for higher education is the Michigan Merit Award and the Michigan Promise Scholarship. The Michigan Merit Award was established by the Michigan legislature in 1999 for the high school classes of 2000 through 2006. The award provides up to US\$3000 to high school graduates who meet or exceed standards on reading, math, science, and writing tests. The Michigan Promise Scholarship, which was signed into law in 2006, provides up to US\$4000 to high school graduates for successfully completing 2 years of post-secondary education beginning with the high school graduating class of 2007. Analysis of the Merit Award program suggests that it does increase student effort and learning (Bishop, 2001). Not only did the number of students taking the exam go up after the introduction of the merit award, but also the number of students demonstrating that they met or exceeded Michigan's education goals rose dramatically.

The studies discussed so far have focused on the relation between monetary rewards and student outcomes in the US. There is also international evidence that students respond to monetary incentives. Kremer *et al.* (2007) report results from an evaluation of a merit scholarship program in Kenya in which girls who scored well on academic exams at the end of the sixth grade received scholarships to pay for their school fees and cash grants to cover the cost of school supplies for the next 2 years. The authors find that girls who are eligible for the scholarship show substantial gains in academic exam scores. There is also evidence of additional indirect benefits as girls with low pretest scores, who were unlikely to receive an award, showed test-score gains that appear to be comparable to the test-score gains for higher-scoring girls who were more likely to receive an award.

In sum, the evidence on financial incentives to students suggests that, as expected, students respond positively to financial merit rewards. Students perform at a higher level academically, and more students attend postsecondary education.

Teacher Financial Incentives

A relatively recent approach to raising student achievement is to offer financial awards to teachers whose students demonstrate improved academic performance.

The prospect of receiving a financial award leads teachers to change their effort and performance level, and to motivate their students to do the same.

Two of the most common teacher-incentive policies are individual teacher merit pay and school-based group bonuses. Merit pay is provided to individual teachers when their students demonstrate improved academic performance. Most merit-pay plans are a combination of time-based pay and output-based pay. Teachers continue to earn a base annual salary, but may receive special pay increases or bonuses that are dependent on the output of their students, typically measured by improved performance on standardized tests. A variation of individual teacher-merit pay is school-based rewards. School-based plans are similar to merit-pay plans in the sense that rewards are based on student performance. The difference is that the rewards in school-based plans are awarded on a school-wide basis and shared by all teachers in the school, rather than being awarded to individual teachers.

Evidence

Podgursky and Springer (2007) review the literature on the relation between teacher-incentive plans and student achievement. In most of the reviewed studies, the teacher-incentive policy yields positive student-achievement results.

Figlio and Kenny (2007) combine nationally representative data on schools, students, and their families with their own survey on the use of teacher incentives to document the relationship between individual teacher-performance incentives and student achievement. Their survey on teacher incentives has data on frequency and magnitude of merit raises and bonuses, teacher evaluation, and teacher termination. They find that test scores are higher in schools that offer individual financial incentives for good performance. Moreover, the estimated relationship between the presence of merit pay in teacher compensation and student test scores is strongest in schools that may have the least parental oversight.

Lavy (2002) studies the relation between school-based performance incentives and student performance. This article examines the effect of an Israeli program that provided monetary incentives to schools and to teachers as a group according to the relative improvement in their students' academic performance. The program offered incentives to schools in the form of performance awards, part of which were distributed to teachers and school staff as merit pay and the rest used for the well-being of teachers in the school. The competition was based on various achievement criteria, with the awards going to the top third of performers. The study finds that schools' and teachers' group monetary incentives caused significant gains in many dimensions of students' outcomes. Moreover, providing schools with more resources also led to improvement in student performance.

Muralidharan and Sundararaman (2006) report results from an experiment on performance pay in rural Indian schools. This study included both individual teacher-merit pay bonuses and school-wide group bonuses, both of which were linked to gains in student test scores. The authors found significant gains in both math and languages in response to the incentive programs, and found no significant difference in the effects of the incentive programs for individual teachers and the school-wide group bonuses.

The literature on teacher-incentive plans suggests that providing incentives to teachers leads to better student outcomes. Moreover, both individual teacher-merit plans and school-wide group bonuses are effective at raising student test scores.

Conclusion

Much of education policy relies on incentives to induce greater student effort and performance. The policies reviewed in this article suggest that students respond to changing incentive structures. When faced with high-stakes exams that determine their promotion to the next grade or graduation from high school, students tend to work harder in order to meet the test cutoff. When offered the possibility of a merit scholarship based on good grades to pay for further schooling, student outcomes tend to improve. When teachers are offered merit awards based on their students' academic performance, student test scores tend to rise.

Taken together, the evidence to date suggests that the incorporation of appropriate incentive structures within education policy holds promise as a driving force for improving student learning outcomes.

Glossary

Actuarially fair insurance – An insurance policy is actuarially fair if the expected payout is equal to the premium.

Asymmetric information – When one party to a transaction has more or better information than another, there is asymmetric information. The field of information economics identifies various manifestations of asymmetric information, such as adverse selection, moral hazard, hidden action, screening, and signaling.

Division of labor – By breaking down industrial production into simple, repetitive tasks, each worker is able to specialize and become more productive. The division of labor increases economic efficiency.

Externalities – When the private actions of one individual or firm affect others, there exist either positive or negative externalities.

Government failure – When government action leads to an inefficient allocation of resources, there is a government failure. Government failure is a common focus of public-choice economists.

Market failure – There is a market failure when certain characteristics of the market lead to an inefficient allocation of resources. These characteristics may include the existence of a monopoly, asymmetric information, externalities, transactions costs, or poorly defined property rights.

Private – In economics, private refers to individual consumers and firms as opposed to government.

Public choice – Neoclassical economics is often criticized for giving short shrift to the role of government. Public choice is an area of economics that focuses on government by looking at the private motivations of bureaucrats and politicians in the public sector.

Public spending – Economists refer to government expenditure as public spending.

Rent-seeking – Rent-seeking occurs when economic actors manipulate the regulatory, economic, or political situation for their own benefit instead of earning a profit through production and trade.

Risk aversion – The unwillingness to accept an uncertain future payoff instead of a certain payoff with a lower value.

State monopoly – When a government agency is the sole provider of a good or service, economists call it a state monopoly.

The economic and political importance of education has increased dramatically over the course of the past century. Education is the largest item of public expenditure in countries around the world, and formal schooling consumes an ever-larger quantity of young people's time. The centrality of education in modern societies is mainly a consequence of state action. The state has built and expanded national education systems, encouraged and sometimes compelled young people to attend school, and fostered rewards systems that make adult success increasingly contingent on academic persistence and performance. In this article we question why this should be so, and discuss the economic factors that help to explain why the state finances and often provides schools.

Constructing Education Systems

Modern states constructed national education systems in the service of political, economic, and military goals (Archer, 1982). In France, for example, the state extended the public school system to all corners of the nation in order to foster a sense of national identity by encouraging fluency and literacy in French and familiarity with canonical knowledge and civic traditions (Weber, 1976). Following the opening of Japan in 1853, the state created a new education system, modeled on those in Prussia and the United States, in an effort to keep up economically and militarily with its Western rivals (Passin, 1965). In the US, state action supported the expansion, integration, and standardization of previously local educational systems (Tyack, 1974). More recently, the United Nations and the World Bank have encouraged and financed the construction and expansion of national education systems in countries around the world, in an effort to guarantee the right to education and to achieve the goal of education for all by 2015 (UNICEF, 2000).

National education systems grew inexorably in the nineteenth and twentieth centuries, in two distinct ways. On the one hand, the state worked systematically to extend educational opportunities both socially and geographically, to incorporate previously excluded groups

including rural children, girls, linguistic and ethnic minorities, and the disabled. On the other hand, the state sponsored and supported policies that required young people to spend an ever-increasing share of their time within the education system. These have evolved from the introduction and enforcement of child labor and compulsory education laws (which at first typically required 4 years of schooling, and now often require 12 or more) to current initiatives aimed at ensuring universal access to preschool and postsecondary education.

As in nineteenth-century Japan, state action to expand and improve national education systems has been and continues to be justified by reference to the imperatives of economic and military competitiveness. In the United States, for example, successive waves of state-sponsored educational reform have gained their impetus from public anxieties about keeping up with the Germans, the Russians, the Japanese, the Chinese, and the Finns (e.g., Reich, 1992; Marshall and Tucker, 1993). The competition among states for positional advantage in the global economy has spawned an educational arms race; the putative need for more and better education is called upon to justify increased state involvement in the education of its citizens.

Economics and the State's Role

Is Education a Public Good?

One generally acknowledged role for the state in the economy is the provision of public goods (Musgrave and Musgrave, 1980; Stiglitz, 2000). Consumption of these goods is nonrival: the amount consumed by one person has no effect on the amounts available for consumption by others. For example, adding more listeners to a radio broadcast does not diminish the value of the service to any of the existing listeners. Consumption of public goods is also nonexcludable: once a radio signal is broadcast there is no practical way to exclude additional listeners.

Private goods are both rival and excludable. The gallon of gas that a driver puts in his/her car is not available to other drivers, and the owner of the service station is readily able to exclude prospective consumers by demanding payment in advance. Private goods are efficiently provided through the familiar institutions of the market. Buyers and sellers have powerful incentives to reveal their true preferences, and their interactions determine how much of the good will be produced and sold.

Pure public goods must be financed by the state, as the price mechanism on which markets rely fails when goods are nonrival and nonexcludable. When consumption of a good is nonrival, it is not scarce to consumers; allocation of the good no longer depends on who has a stronger preference for it. When consumption of a good is nonexcludable, it is impossible to prevent consumers from

making use of the good, whether they have paid for it or not. Under these circumstances, consumers will not reveal their true preferences. The incentives they face instead push them to become free riders, consuming as much as they like of the good while paying little or nothing to support its provision (Olson, 1971). As a result, reliance on markets to produce public goods will result in too little (or no) production of these goods.

Stiglitz (2000) classifies education as a publicly provided private good because there is a large marginal cost associated with educating each additional child, which makes education rival. Education is also excludable, as can be readily observed in private schools or in tuition-funded colleges and universities. Since education does not satisfy the economist's definition of a public good, it could in principle be bought and sold in a market much the same as other private goods. The argument for public provision must therefore be sought elsewhere, in the failure of markets to produce an optimal level of educational output or an equitable distribution of educational opportunities and outcomes.

Market Failure in the Market for Education

Competitive markets may fail to deliver the optimal level of a good or service for a variety of reasons, including the presence of positive or negative externalities, information asymmetries between buyers and sellers, economies of scale, and risk aversion. Defenders of a strong state role in funding and providing schools argue that significant market failures in the market for education justify the state's involvement in the education system.

Externalities

Externalities exist when the private actions of one individual or firm affect others, either positively or negatively. For example, a farmer at the headwaters of a river decides how much water and fertilizer to use based on a private calculation of costs and benefits, without regard to the costs his/her decisions impose on fishermen and municipal water systems downstream. These external costs may be substantial, and state action may be the best way to ensure that they are taken into account (Coase, 1960).

Private decisions about education produce a number of mostly positive externalities for the broader society, above and beyond the benefits that the individual student receives. In considering how much education to consume, however, individuals base their decisions on their own private calculation of costs and benefits, taking no account of external benefits that may accrue to others. In consequence, leaving choices about education to individuals in a private market may result in a suboptimal level of educational investment for the society as a whole.

Economists have long recognized a number of positive externalities associated with an educated citizenry. In the

Wealth of Nations, for example, Smith (1937) described two external benefits of education. First, he argued that education is a necessary antidote to the mind-numbing repetition that results from the division of labor into the narrowly specialized tasks performed by each worker. Workers lacking in education would eventually become unable to converse, formulate emotional sentiments, or perform the normal duties of private life, rendering them unable to defend the country in a time of war. In addition, Smith argued that modern education, including science and mathematics, would provide a constant source of innovation in the production process.

More recent work has identified a wide variety of additional external benefits to educational investment. In general, a literate society functions more smoothly, with reduced communications costs, stronger democratic institutions, and a higher degree of social cohesion (Belfield, 2000; Stiglitz, 2000). Education also has a strong positive impact on health and fertility, both within and across generations. Educated mothers have fewer, healthier children, and the children of educated mothers are more likely to enrol and remain in school (Becker, 1991; Colclough, 1993; Schultz, 1988). Barnett (1985, 1996) has documented the effect of education on reducing crime and welfare payments.

There is a vast macroeconomic literature that suggests that education is a key input that drives technological change and economic growth (Barro, 1997; Hall and Jones, 1999; Krueger and Lindahl, 2001; Mankiw *et al.*, 1992; Romer, 1990). To the extent that this is so, state action to expand and improve the education that citizens receive and thereby raise the rate of economic growth may be fully justified (and even financed) by the increased productivity and gross domestic product (GDP) growth produced by educational investments (Hanushek and Kimko, 2000).

Realizing the external benefits of education may require state action; the economic and social gains produced by an educated citizenry and workforce may justify the state in encouraging individuals to acquire more education than they might otherwise prefer. In a contrasting view, however, increasingly powerful private incentives to invest in education may be sufficiently strong to produce high levels of external benefit even in the absence of state action. The fundamental question with regard to externalities is therefore the extent to which they are extra-marginal: Does state subsidy or state provision produce external benefits in addition to those that would be produced through private action alone?

Information asymmetry

One of the conditions for the efficient operation of markets is complete information. In a perfectly competitive market, buyers and sellers are on equal footing; both have full information on the quality and price of the product.

In some markets, however, including for instance the market for used cars, sellers have more and better information about the product than prospective buyers. Markets in which the distribution of information is asymmetric may produce inefficient outcomes (Akerlof, 1970; Stiglitz, 1996).

The education system is clearly characterized by asymmetric information between the consumers of education services (parents) and the producers (schools). Education is a complex bundle of services that involves a large commitment of time, a cumulative instructional process, and uncertain future payoffs. The production process is poorly understood and output measures are ambiguous, which makes interschool comparisons difficult. As a result, parents face great difficulties in accurately assessing the quality of the education services provided by the various schools available to their children.

There are two main ways to address the problem of asymmetric information in the education system. On the one hand, the state may provide schools itself, seeking to standardize educational services and guarantee minimum quality standards across schools. For example, the state may regulate curricula, require certification for teachers, or equalize funding across schools or school districts (Brown, 1992). On the other hand, the state may seek to increase the information available to parents by publishing data on the character and performance of different schools. Recent advances in assessment and information technology make the latter choice increasingly feasible (Gintis, 1995).

Uncertainty and risk aversion

Brown (1992) applies the economics of uncertainty and information to education to show why the public provision of education is so widespread and why schools are so similar. Parents face uncertainty about their children's abilities and the future payoffs to investments in their education. Schools are better able to shoulder risk than their more risk-averse students, enabling them to offer actuarially fair insurance (Mas-Colell *et al.*, 1995; Kreps, 1990). There are two components to this insurance. First, the vast majority of schools offer a comprehensive and broadly similar curriculum, giving all students access to a wide array of courses and programs. In addition, schools generally allow their students to accumulate a diversified portfolio of educational experiences, rather than requiring them to specialize in a specific course of study. Private and charter schools must compete with public schools in providing this form of insurance, which results in the observed similarity between curricula in state and other schools.

More fundamentally, parents and students may not fully know their own preferences for education due to the complex and cumulative process of schooling. Students' consumption of education services often relies critically on the goodwill and competence of the parents, which cannot be assumed (Gintis, 1995; Stiglitz, 2000).

As it is difficult to collateralize loans for primary and secondary schooling, parents may face credit constraints as well. In light of these circumstances, public provision may be warranted as a protection against the long-term private and social costs of bad choices or constrained resources.

Economies of scale

Economies of scale arise when producers' average total cost falls as output increases (Mankiw, 1998). In education, this suggests that larger schools and districts may face a lower per-pupil cost. For example, larger schools have a greater ability to provide science laboratories and libraries by spreading the cost over more tax-paying households. There are also potential scale economies in information gathering, organization, and in the development of a curriculum (Belfield, 2000). To the extent that there are economies of scale in the delivery of education services, market forces may result in a monopoly, as smaller schools are driven out of business by established state schools. Faced with this tendency for the market to drive out small schools, the state has two options: either run large schools as state monopolies, or actively encourage competition by leveling the playing field for smaller schools.

Equity and Equal Opportunity

The state may also have an interest in making the distribution of educational opportunities and attainments more equitable. State actions to advance equity goals may take either of two forms. On the one hand, the state may seek to ensure that all young people are provided with an education of sufficient duration and quality to equip them for productive citizenship and protect them from poverty (e.g., Colclough, 1993). On the other hand, the state may seek to alter the distribution of wealth and status in favor of previously disadvantaged groups through the provision of targeted subsidies or other forms of affirmative action (e.g., Fiske and Ladd, 2004).

The state can in principle pursue equity objectives through public financing rather than public provision, by targeting subsidies to specific groups. As Davis (1998) points out, however, the government may be more effective than private markets at ensuring the fair allocation and distribution of resources, equal access to services, nonprofit decision making in the best interest of consumers, appropriate personnel policies, and cooperative labor relations (Belfield, 2000).

In the US, education is primarily a local responsibility, which has led to large differences in the resources devoted to education. Where these differences solely related to consumer preferences for education, there would be very little need for government intervention. In fact, however, a number of state supreme courts have ruled that reliance on local property taxes to finance education violates the

provisions of state constitutions that guarantee equal access to public education (Odden and Picus, 2004; Stiglitz, 2000).

Critique of State Provision

The claim that the state should finance the education of its citizens is rarely subject to argument. Controversy arises over whether the state should provide schools itself, or underwrite the provision of schools by other actors including for-profit firms. The argument turns on questions of the relative efficiency and equity effects of state and private provision.

Friedman (1962) revived the libertarian argument against government provision of education, which dates back to Thomas Paine (West, 1964) and Smith (1937). Friedman acknowledged two justifications for government involvement in education. First, he described the positive externalities produced by schools, which include the basic skills and core values required for social stability. Second, he noted the state's paternalistic concern for the welfare of children, whose parents may not always act in their best interest. Friedman argued that these concerns warrant state funding and minimal regulation in the education system, but not a government monopoly in the provision of schooling.

Public Choice and Government Failure

In the decades since the publication of Friedman's seminal essay, economists and others have developed a comprehensive critique of state provision, closely associated with a call for greater reliance on markets in the education system (e.g., Chubb and Moe, 1990). Just as the case for state provision relies on claims of market failure, the case against state provision relies on claims of government failure (Tullock *et al.*, 2002), including inefficiency in production, inequity in provision, the institutionalization of low expectations, and rent-seeking by educators who exploit positions of authority and trust to increase their own utility at the expense of their students.

Inefficiency in production

State provision of schools may be less efficient than market provision for two main reasons. First, the absence of competition in the state education system undermines incentives for innovation and improvement. In a market where schools are obliged to compete with one another for the patronage of parents, in contrast, schools receive meaningful market signals about quality from consumers. The attendant challenge to compete for students should drive schools to lower costs, improve quality, and innovate (West, 1997). In the short run, competition might be expected to induce educators to work harder, to allocate

resources more efficiently, and to make better staffing decisions. In the long run, a competitive market for education could make schools more receptive to parental involvement, give them incentives to provide better student achievement information, reward more productive teachers with higher wages, lead schools to abandon unproductive pedagogical techniques, and ultimately affect the size and number of schools (Hoxby, 2003).

To the extent that state action in the provision of education replaces private production, consumers of education must rely on political institutions to voice their preferences. With the specification of the educational production function uncertain, the use of resources is determined through political interaction, according to criteria that bear no necessary connection to valued outcomes including student learning (Downs, 1957; Hanushek, 1986). The interplay of interests in the political system can easily lead to allocations of resources that are suboptimal from the standpoint of economic efficiency. For example, the free-rider problem may become a tax avoidance problem, as taxpayers seek to minimize the cost of educating other people's children (Tullock *et al.*, 2002). At the same time, the state's obligation to exercise strict control over the use of public resources may result in excessive regulation and high administrative costs, without commensurate gains in productivity (Hanushek, 1986; Stiglitz, 2000).

Inequity in opportunities and outcomes

Advocates of market-based policies in education argue that greater reliance on markets could also improve the overall equity of the education system (Coons *et al.*, 1970; Howell and Peterson, 2002). Wealthy parents are able to choose the schools that their children attend, either by moving to a desirable school district or by sending their children to private schools. It is only the children of the poor who are deprived of choice under the current system of state provision, and these children are often obliged to attend the least-salubrious and lowest-performing schools (Ladd, 2002; McEwan, 2000). Opening up the system to additional providers would serve to increase the number and variety of schools available to poor households (e.g., Tooley and Dixon, 2005), giving parents more and better choices about the schools their children attend and increasing the chances of educational and subsequent economic success for poor children (West, 1997).

Standardization and enforced mediocrity

State efforts to standardize educational services and guarantee minimum educational standards for all students may reduce the quality of instruction for young people attending state schools (Finn, 1993; Ravitch, 1985). The state's obligation to protect parents from risk and to ensure at least minimally equitable opportunities for students may prevent schools from accomplishing or even

seeking ambitious goals, preferring instead to institutionalize low expectations and low standards in an effort to ensure success for all of the children under their care. For example, the performance of American students on international assessments of reading and mathematics is often adduced as evidence of the disadvantages of state provision, to be remedied by the introduction of more choices and increased competition in the education system (e.g., Chubb and Moe, 1990; Walberg, 2007).

Rent-seeking and corruption

In the education system, as elsewhere in the public sector, individuals and groups may have opportunities to divert public resources to their own private benefit. Examples of rent-seeking may include widespread absenteeism among educators, who regard their jobs as sinecures and frequently fail to show up to teach their students or run their schools (Banerjee and Duflo, 2006; Castro and Fletcher, 1986). Transfer programs can be used to solicit political patronage rather than to improve the access to education of those in need (Plank, 1995). In similar fashion, unions may be more concerned with protecting the interests of their adult members than with the education of the children in their charge (Hess, 2004; Moe, 2001). Under some circumstances rent-seeking may give way to corruption, as educators employed by the state offer private instruction, passing grades, and diplomas for sale to students and households that are able to pay (Hallak and Poisson, 2007).

A Role for the State?

Under some circumstances, the state may supply education more efficiently than private markets (Belfield, 2000). First, it can bundle other services with education, such as health screening for vision and hearing. As the government offers unemployment insurance and welfare benefits, public provision of education that reduces these fiscal obligations could also be seen as bundling education and social services. Second, if people perceive the state as having a long-term commitment to the education of its citizens, then the state may be trusted more than private firms that come and go in a competitive market. As Shleifer (1998) has argued, if consumers have a difficult time identifying quality then producers will struggle to build their reputations and be unable to increase demand for their services. Third, economies of scale could lead to an education monopoly, which might be better run by the state than by a profit-seeking firm. Fourth, government providers can mediate the asymmetry of information and bargaining power between schools and individuals.

Gintis (1995) acknowledges that markets may be more efficient and more responsive to parents' preferences. He simultaneously argues that extensive state action may be required to ensure that markets work efficiently and fairly.

He proposes some regulatory interventions aimed at expanding school choice while mitigating market failures caused by violations of five fundamental assumptions:

Many producers. First, the state could subsidize student transportation costs. Second, it could either offer low-interest loans to new schools or construct the buildings and rent them to providers. Third, the state could force schools to share classrooms, athletic facilities, or other resources in order to decrease the minimum feasible school size.

Product quality is known. In order to be accredited to accept public tuition, schools could be required to provide standardized measures of school performance such as test scores, retention rates, and graduation rates. Schools could also be required to provide data on teacher accreditation, building safety and instructional techniques.

Consumers know their preferences. A guardian should be appointed when parents are found legally incapable of making sound decisions for their children. Unscrupulous schools that mislead parents should be sanctioned and schools should be prohibited from pandering to selfish parents who place their personal interests before the best interests of their children (e.g., by accepting kickbacks).

The price is set so that supply equals demand. The price of schooling is the tuition fee, which is set and paid by the government. Economists worry that because parents do not pay for education, they may consume more than they would in the absence of a government subsidy. In the presence of positive externalities, however, it is widely assumed that parents consume too little education on behalf of their children, rather than too much.

Education is a private good. As education confers both private and social benefits, some worry that parents will focus exclusively on the private benefits when making schooling decisions. Regulation can increase the social benefits to education by requiring schools to develop a curriculum that reflects social values and providing incentives to schools that encourage a diverse student body.

Education and the Shrinking State

After more than a century of steady growth, there are signs that the state's role in national education systems may have begun to shrink. As ever, there is little dissent from the idea that the state should finance the educational opportunities available to its citizens, but the benefits traditionally ascribed to state provision have been subjected to increasingly overt challenge. This is especially visible in higher education, where reduced public support for universities and their students has been matched by dramatic increases in the number and variety of private and for-profit higher education institutions (e.g., Altbach and Levy, 2005). Strong political pressures bolstered by arguments and evidence from economists

(e.g., Heckman and Masterov, 2007; Barnett, 1985) to expand the state's role in early childhood and preschool education have run into significant opposition, based in part on resistance to increased taxes and public spending, and in part on aversion to the idea that very young children should be placed under the care of the state rather than their families and communities (Fuller, 2007). In Europe and elsewhere, groups defined by communal, religious, and linguistic affinities have begun to demand increased control over the education of their own children, including the right to establish their own schools (Plank, 2006). Whether this marks a genuine turning point in the history of education or a brief pause in the steady expansion of the state's role in the education system remains to be seen.

Glossary

Error term – A variable that is created when the model does not fully represent the actual relationship between the independent variable(s) and the dependent variable.

Exogenous variable – A factor in a causal model or causal system whose value is independent from the states of other variables in the system.

Instrumental variable – A method that is used to estimate causal relationships when controlled experiments are not feasible.

Self-selection – A term that is used to indicate that individuals select themselves into a group causing a biased sample.

Standard deviation – A measure of variability or dispersion.

Introduction

This article examines Catholic schooling in the United States. The article is organized as follows. First, an overview of Catholic schooling in the United States is given. Second, the determinants of the demand for Catholic schools are reviewed. Third, literature on the effects of Catholic schooling is presented. Although the focus of this article is on Catholic schooling in the United States, some attention is also given to Catholic schooling in other countries.

Overview

History and Enrolment

The establishment of Catholic schools in the United States was partly a result of the nature of public schooling in the nineteenth century. At that time, many public schools promoted Protestantism and some were overtly anti-Catholic. This resulted in Catholics establishing their own parochial schools. In 1884, Catholic bishops in the United States asked Catholic parishes to support at least one Catholic school and Catholic parents to send their children to them. By 1900, about 5000 Catholic schools had been established serving around 1 million students. The increase in enrolment in Catholic schools

was also due to the massive waves of immigration of Catholics to the United States. According to Finke and Stark (2005), between 1890 and 1906, the Catholic population increased from 7 million Catholics (12% of the population) to more than 14 million Catholics (17% of the population). Catholic schools continued to increase both in number and the percentage of the population served until about 1960. By 1960, there were almost 13 000 Catholic schools serving over 5 million students. Catholic schools at that time accounted for about 90% of private-school enrolment. Since 1960, Catholic schools have declined in number and the percentage of the population served. Many Catholic schools especially in big cities in the East and Midwest regions have closed. For example, about half of the Catholic schools in Chicago have closed over the past three decades. Enrolment has declined even more from about 132 000 in 1976–77 to 52 000 in 2004–05 (McDonald, 2007).

By 2000, about 11% of elementary and secondary school students attended private schools. Although the percentage attending private schools has not changed too much since 1960, only about half of this population is now in the Catholic school sector. Other religious schools and nonsectarian private schools account for the rest of the private school sector. The most recent data indicate that there are 7498 Catholic elementary and secondary schools that serve over 2 million students. Although Catholic schools have declined overall, there has been some growth in demand in the West and Southeast. This is a result of high rates of economic growth in these areas that has resulted in more Catholics living in these regions (McDonald, 2007).

Teachers

If one goes back in time, most of the teachers in Catholic schools were in religious orders. For example, in 1960 about three out of four Catholic school teachers were members of a Catholic religious order. Over time, this percentage has declined markedly. Recent data indicate that only about 5% of Catholic school teachers are members of a Catholic religious order (McDonald, 2007).

Students

Part of the decline in the Catholic school population is a result of a decline in the demand for a Catholic

education by Catholics. For Catholics born before 1950, at least half of them attended a Catholic school for at least 1 year. By 1991, only about one in five Catholic children of elementary school age attended a Catholic school (Youniss and Convey, 2000).

The decline in the demand for a Catholic education by Catholics has been partially offset by an increase in the demand for a Catholic education by non-Catholics. In 1970, only about 3% of Catholic school students were not Catholic. By 2007, the percentage of non-Catholics in Catholic schools increased to about 14%. Part of the increase in non-Catholics attending Catholic schools is a result of more non-Catholic African-Americans in big cities attending Catholic schools. For example, in Chicago about three out of four blacks in Catholic schools are not Catholic (McDonald, 2007; Sander, 2001).

Although most students in Catholic schools are non-Hispanic whites, the percentage of minorities in Catholic schools has increased over time to about one in four students in 2007. About 7% of Catholic school students are black, 6% are Hispanic, 3% are Asian, and 2% are multiracial (McDonald, 2007).

Location

Catholic schools are concentrated in urban areas and in the East and Midwest regions.

Over 40% of Catholic schools are located in big cities while about one in three are located in suburbs of cities. The rest are located in rural areas. Further, over 50% of Catholic schools are located in the East or Midwest regions where the Catholic population is more concentrated. The ten largest Catholic school systems are as follows: (1) New York, (2) Chicago, (3) Philadelphia, (4) Los Angeles, (5) Brooklyn, (6) Cleveland, (7) St. Louis, (8) Cincinnati, (9) Boston, and (10) Newark (McDonald, 2007).

Some metropolitan areas are served by more than one Catholic school system such as New York and Chicago. The reason for this is that the boundaries of the school system are defined by the Catholic archdioceses rather than census boundaries.

Tuition and Costs

The average tuition at Catholic schools in 2007 was US \$2607 at parish-based elementary schools and US\$6906 at secondary schools although the per-pupil cost was higher – US\$4268 at grade schools and US\$8743 at high schools. The difference between tuition and cost is a result of many factors such as parish subsidies and fund raising. This is below the average per-pupil expenditures at public schools. One of the reasons for relatively low costs at Catholic schools is the relatively low teacher salaries. Further, subsidies from parishes and elsewhere help keep tuition below costs. Recent data indicate that

the tuition at Catholic grades schools covers 61.7% of the actual cost per pupil while 80% of the cost per pupil is covered by tuition at Catholic high schools (Harris, 1996; McDonald, 2007).

Hoxby (1994) shows that higher Catholic-population densities have several important implications for tuition and per-pupil cost. First, the number of Catholic schools and Catholic school places per person increase as density goes up. Second, subsidies as a percentage of Catholic school income increase substantially as the Catholic share in the population grows. Third, tuition per pupil decreases as the Catholic share in the population increases.

Market Served

Although Catholic schools were established to serve all Catholics and did so for many decades, higher costs and tuition are resulting in Catholic schools serving fewer low-income students and more high-income students. Still, many Catholic school systems try to reach out to students who cannot afford them. For example, in Chicago many Catholic schools are designated as Big Shoulders schools – schools that mostly serve low-income minority students. The dropout rate in these schools is only 1%, while the high school graduation rate is 97%. The dropout rate for public schools in Chicago is markedly higher (Sander, 2001, 2006).

School Practices

It is possible that Catholic schools are more effective than public schools due to differences in school practices (Figlio and Ludwig, 2000). It has been reported that the proportion of students in Catholic schools who report that their school is excellent or good in effectiveness and of discipline is substantially higher than what is reported by public school students (72% vs. 42%). They report similar differences between Catholic and public schools in fairness and discipline (46% vs. 36%).

Vouchers

Vouchers that would enable more students to attend Catholic schools have been a controversial political issue in the United States. Several voucher programs are now ongoing in several states. In the New York voucher experiment, Howell and Peterson (2002) compare the achievement of voucher recipients relative to a similar control group, where the voucher amount was applied mainly to tuition at low-cost Catholic schools. They find that there are positive gains from using educational vouchers only for African-Americans. However, these gains are not consistent across the years of the trial. They have been challenged on methodological grounds by Krueger and Zhu (2004) who

find that the difference in test scores between the treatment group and the control group is not significant.

Catholic Schools in Other Countries

Catholic schools are also present in many other countries. In fact, the Catholic school system is the world's largest faith-based educational network with 120 000 schools and over 1000 colleges and universities (Grace and O'Keefe, 2007). In Australia, Catholic schools form the second largest sector after government schools (Wikipedia). As of the early 1990s, private schools accounted for about 25% of enrolment with approximately 75% attending Catholic schools (Vella, 1999). In Canada, seven of the 13 provinces and territories fund faith-based Catholic schools (Wikipedia).

In England and Wales, 2300 Catholic schools educate around 840 000 pupils each year. In Scotland, Catholic schools are all fully funded by the government. In Northern Ireland, about half of all students attend Catholic schools (Wikipedia).

In Italy, Catholic schools are relatively expensive and therefore tend to serve high-income families. In 1998, approximately 10.3% of high school graduates attended private schools in Italy. Of these, about one-third were Catholic (Di Pietro and Cutillo, 2006). In the Netherlands, about one in five primary schools are Catholic (Levin, 2002). In Chile, about one in ten grade school students is enrolled in a Catholic school (McEwan, 2001).

Demand

Many factors affect the probability that parents send their children to Catholic schools. The most recent study that estimates the relative importance of these factors finds that the probability of attending a Catholic school is higher for Catholics, especially more religious Catholics. Catholics who attend church at least weekly have about a 50% likelihood of sending their children to Catholic schools; Catholics who attend church once a month only have about a 25% likelihood of sending their children to Catholic schools; and Catholics who attend church less than once a month have an even lower probability of sending their children to Catholic schools. Non-Catholics have a very low probability of sending their children to Catholic schools regardless of their level of religiosity (Cohen-Zada and Sander, 2007).

Over time, Catholic religiosity as measured by church attendance has declined for Catholics aged less than 65 years. About 50% of Catholics 35–44 years attended church almost every week or more often during the 1970s. Regular church attendance declined for this age group to about 25% by the 1990s. If church attendance by adults is a determinant of the demand for a Catholic education,

declines in Catholic religiosity is a plausible reason for some of the decline in the demand for a Catholic education for children (Sander, 2005).

Other factors that have been found to affect the demand for Catholic schools include family income, parents' education, location, and race. Families who have very low incomes are less likely to send their children to Catholic schools. Parents with some college are more likely to send their children to Catholic schools relative to parents with a college degree and parents with a high school diploma. Parents with less than a high school education were the least likely to send their children to a Catholic school. Also, African-American has a positive effect on the demand for Catholic schools. Although blacks are disproportionately Protestant, a likely reason that they have a higher demand for Catholic schooling is that they are concentrated in big cities where the quality of public schooling is problematic (Cohen-Zada and Sander, 2007).

Another important factor that affects the demand for Catholic schooling is price. Large declines in the number of teachers in religious orders have forced Catholic schools to hire lay teachers who are more costly. Further, declines in subsidies from Catholic parishes have resulted in large increases in tuition. This is partly a result of declines in Catholic Church contributions over time. If one goes back to the 1960s, Catholics contributed over 2% of their income to the church. This declined to about 1% by the 1980s (Harris, 1996; Zech, 2000).

Further, the quality of public schools in a locality affects the demand for Catholic schools. In inner-city areas where the quality of public schooling is often perceived as low, the demand for a Catholic education is higher. For example, in Chicago about half of the children of non-Hispanic whites attend private schools. Most of these schools are Catholic. In the suburbs of Chicago, the demand for Catholic schools is much lower because the quality of public education is higher. Catholic parents are less willing to pay for both public schools and Catholic schools in such areas (Sander, 2006).

At the aggregate level, several factors affect the share of students in a county that attend Catholic schools (Cohen-Zada, 2006). The variable that has the most substantial effect is the Catholic share in the population. A one standard deviation increase in the Catholic share in the population increases the county Catholic-enrolment rate by more than 2 percentage points. This variable has a concave effect on the Catholic-enrolment rate. It has been shown that in places where Catholics are a lower share of the population, a higher percentage of them send their children to Catholic schools. One possible reason for this is that in these places where they are a minority, they have a stronger need to send their children to Catholic schools in order to preserve their religious identity. A higher Catholic-enrolment rate is also associated with a higher population density, higher mean income of the

population, higher share of African-Americans in the population, and a lower share living in a rural area. Finally, for a given Catholic share in the population, a higher share of Hispanics implies a lower-Catholic enrolment rate.

Effects

Academic Achievement and Educational Attainment

Students who attend Catholic high schools are more likely to graduate and go on to college relative to their public school counterparts. Recent data put the high school graduation rate in Catholic schools at 99.1%. The public high school graduation rate is only 71.0% if general educational development (GED) certificates are excluded. It is 86.5% if they are included. Further, students in Catholic schools have higher test scores on the average than students in public school. Data from the National Assessment of Education Progress (NAEP), the nation's report card, indicate that students in Catholic grade schools and high schools have higher test scores on the average than students in public schools (McDonald, 2007).

Higher graduation rates and test scores do not necessarily indicate that Catholic schools provide superior schooling. It could be the case that Catholic schools simply select better students. This so-called selection issue has received considerable attention by researchers.

There are a large number of studies on the effect of Catholic schools on various measures of educational attainment and academic achievement that try to control for selectivity bias. Important studies in the early 1980s by James Coleman and others at the University of Chicago indicated that Catholic high schools had positive effects on test scores and high school graduation rates (Coleman and Hoffer, 1987; Coleman *et al.*, 1982). The results in these studies were considered problematic by some because they did not control for selection into Catholic schools, especially on unobserved variables like unobserved aspects of family background.

A number of studies over the past two decades have tried to statistically control for the possibility of positive selection into Catholic schools (Neal, 1997; Perie and Goldstein, 2005; Sander, 2001). The idea is that if Catholic school attendance is correlated with any determinant of students' outcome that is missing in the estimation, one is likely to obtain biased estimates of Catholic school attendance on educational outcomes. The bias is a result of the estimated coefficient of Catholic school attendance capturing the effect of the missing variable on the outcome. For example, Cohen-Zada and Sander (2007) show that religiosity is positively correlated with Catholic school attendance and student outcomes. Thus, if religiosity is not taken into account, one tends to overestimate the effect of Catholic school attendance on educational outcomes.

Most studies try to control for selection into Catholic schools by using instrumental variables that causally affect Catholic school attendance, but do not have a direct effect on educational outcomes. Using this strategy, one estimates the effect of Catholic school attendance on outcomes using a two-stage approach. In the first stage, Catholic school attendance is regressed on the instruments and all of the other exogenous variables in the model. Assuming the instruments are exogenous, the predicted Catholic school attendance that one obtains from the first stage is also exogenous. This allows one to tease out the exogenous component of the variation in Catholic school attendance. In the second stage, the outcome equation is estimated by replacing Catholic school attendance with its exogenous approximation obtained from the first stage. This identification strategy is valid only if there is no unobserved determinant of the educational outcome that is correlated with the instrumental variable.

The results of many of the studies on the effect of Catholic schooling are somewhat problematic because the instruments that are used are not valid. That is, they have a direct effect on the outcome and are thus likely to be correlated with the error term. For example, Cohen-Zada and Sander (2007) show that Catholic religion and density of Catholic schools, which are often used as instruments for Catholic school attendance, are correlated with religiosity which is often missing in estimations of the treatment effect of Catholic schools. Altonji *et al.* (2005b) examined the validity of religious affiliation and the proximity to Catholic schools as instruments for Catholic school attendance and found that none of them were useful sources of identification of the Catholic school effect.

Perhaps the best study to date on Catholic high school effects finds that they have a positive effect on high school graduation rates and on attending college but no effect on test scores. This study acknowledges that none of the previously used instruments for Catholic school attendance is valid and thus develops a new estimation method for obtaining a lower bound for the causal effect of Catholic school attendance on outcomes based on the assumption that the amount of selection on the unobservables is not more than the amount of selection on the observables (Altonji *et al.*, 2005a). Recently, Cohen-Zada (2007) shows that the Catholic share in a county in 1890 is a valid instrument for private school competition and a potentially valid instrument for Catholic school attendance.

Another important study on Catholic high schools finds that the benefits of a Catholic education are particularly high for minorities in big cities where the quality of public schooling is low (Neal, 1997). Although most of the studies on Catholic schools have tended to focus on Catholic high schools, studies on Catholic grade schools indicate that the effects on academic achievement are modest at best (Jepsen, 2003; Sander, 2001).

Bad Behavior

A recent study uses a propensity score matching method to control for positive selection into Catholic schools and finds that Catholic school attendance reduces the propensity that female students use cocaine and have sex. However, it increases the propensity that male students use and sell drugs (Mocan and Tekin, 2006). Other studies provide evidence that Catholic schools are not more effective than public schools in reducing marijuana use, alcohol abuse, or smoking although Catholic school attendance may reduce some risky youth behaviors including sexual activity, criminal behavior, and the use of hard drugs (Figlio and Ludwig, 2000).

Civic Participation and Altruism

A number of studies have examined the effect of Catholic and other private schooling on civic participation and altruism. Some results from this literature are as follows. A study on the effect of vouchers on students' altruistic behavior finds that students attending private (mostly Catholic) schools in Ohio, after being randomly assigned to these schools through a lottery, gave more to charitable organizations but not more to their peers (other children attending the experiment) (Bettinger and Slonim, 2006). Another study using data from the National Household Education Survey of 1999 finds that Catholic school attendance is positively associated with community service participation, civic skills, political knowledge, and tolerance (Belfield, 2004). Greeley and Rossi (1966) found similar results regarding tolerance of civic liberties; on the other hand, they did not find that Catholic school attendance was related to community involvement. Other findings include Catholic schools increasing racial tolerance and voting (Dee, 2005; Greene, 1998).

Economic Effects

One of the few studies that considers the effects of Catholic schooling on economic outcomes finds that attending a Catholic high school increases earnings both directly and indirectly for young black and Hispanic men. Catholic schooling directly increases wages after controlling for educational attainment and indirectly increases wages by increasing the probability of graduating from high school and college. In this study, no effect is discerned for non-Hispanic white men (Neal, 1997).

Other Effects

Although studies on Catholic schools have focused on academic effects, other effects have been considered as well. One line of research focuses on the effect of Catholic

and other private schooling on the quality of public education. One of the issues of interest is whether competitive pressures from private schools could increase the quality of public schools. The findings from research on this topic are not conclusive (Hoxby, 1994).

Catholic schools exist in part to provide a religious value-based education. The data indicate that Catholics who attend Catholic schools are more religious Catholics. They tend to pray more, attend church more often, retain a Catholic identity as an adult, and have Catholic beliefs. Statistical analysis of the effects of Catholic schools on religiosity indicates that Catholic schools have a positive causal effect on all of these outcomes except church attendance (Sander, 2001).

The Effect of Catholic School Attendance in Other Countries

In the last decade, researchers have examined whether the substantial effect reported for attending Catholic schools in the United States, also exists for students in Catholic schools in other countries. A study on Catholic schooling in Australia indicates that attending a Catholic school increases the probability of completing high school, attending college, and being employed (Vella, 1999).

A recent study on Catholic schooling in Italy finds that attending a Catholic school increases the probability of attending a university, but it does not affect the probability of dropping out of college (Di Pietro and Cutillo, 2006).

A study on Catholic schooling in the Netherlands finds significantly higher achievement scores for fourth-, sixth-, and eighth-grade students in Catholic schools (Levin, 2002). The Dutch experience is of particular interest because Dutch law mandates equal public financing across all schools, regardless of their religious affiliation.

Conclusions

Catholic schools have made important contributions to education in the United States and elsewhere. However, the effects of Catholic schooling have been difficult to nail down conclusively. Further, little attention has been given to the changing nature of Catholic schooling by location and over time. Similarly, very little attention has been given to the effects of different types of Catholic schools such as parish-based schools or schools sponsored by religious orders. This is the grist for future research.

Glossary

Charter schools – Are schools that receive public funding under a contract, or charter, with a public entity (e.g., school district, state, and universities), and are given greater autonomy than other public schools over curriculum, instruction, and operations.

External validity – An estimate of an effect that is valid beyond the sample of observations included in the analysis.

Fixed effects – Econometric method of estimating time-invariant factors in panel data analysis.

Internal validity – An estimate of an effect that is valid only to the sample of observations included in the analysis.

Selection bias – Estimated effect of programs could be biased because participants have chosen to participate, which is not captured by the econometric model.

Introduction

Charter schools are an educational reform in the United States that provides more school alternatives to parents and more local autonomy for individual schools. Individual schools receive public funding under a contract, or charter, with a public entity (e.g., school district, state, and universities), and are given greater autonomy than other public schools over curriculum, instruction, and operations. In exchange for greater autonomy, charter schools are held accountable for results.

The first US charter school opened in 1992, and the scale of the charter movement has grown to 4000 schools and over a million students in 40 states plus the District of Columbia. Charter enrolments constitute about 2% of annual public school enrolments in the United States with enrolment shares as high as 18% and 25% for Arizona and the District of Columbia, respectively. About 20 communities with more than 10 000 public school students have charter enrolment shares of 13% or more.

Charter reform has been a contentious education and public policy issue. Proponents argue that traditional public schools are burdened by excessive centralized control and regulation and greater school autonomy under charter

reform allows schools to innovate and improve (Finn *et al.*, 2000). School choice is heralded as a key component of charter success – charters must compete for students with traditional public schools, and their survival is literally predicated on their ability to implement programs that attract students.

Critics see charters as drawing resources away from traditional public schools and distracting them from internal reforms and innovation. These opponents argue that charter schools are no more effective than traditional public schools, that they may exacerbate racial segregation, that they create fiscal strains for school districts, and that too many of them are unreliable operations (Wells *et al.*, 1998). Charter competition is seen as inconsequential in many cases or as counterproductive when traditional public schools placate parents with programs that do little to enhance student learning.

The emergence of charter schools in the United States has paralleled movements in other countries that enacted legislation to create foundation or independent schools that operate much like charter schools in the United States – that is, they receive substantial public funding and have independent authority over curriculum and governance (Brewer and Hentschke, 2008). A key difference between these independent schools and traditional public schools is that enrolment is generally tied to parental choice. As with charter schools, the choice aspect of these schools means that their existence is directly tied to their ability to serve parents and their children.

Policy Questions

In the past several years, research has examined the comprehensive effects of charter schools on the educational system in the United States. Most of the current literature has narrowly focused on how charter schools affect achievement for students who attend these schools. However, it is important to consider the possible impact charter schools are having more broadly, including their cost effectiveness, systemic effects (e.g., effects on students who choose not to attend traditional public schools), distributional effects, both by ability and race, and any operational differences between charter and traditional public schools, which may lead to broader educational innovations. Other outcomes may be important as well, including parental satisfaction, behavioral outcomes, school safety, educational attainment

(measured by graduation rates or post-secondary attendance), and labor-market outcomes. However, the last set of outcomes has either not been addressed, or is so difficult to assess that it is hard to know what to make of the results. Therefore, this article primarily focuses on four issues:

1. What are the demographic and academic profiles of students entering charter schools, and how do charter schools affect the mix of students in traditional public schools by race/ethnicity and academic ability?
2. Are charter and traditional schools receiving comparable funding? Do charters have the same public resources to educate students as traditional schools?
3. What is the effect of charter schools on the achievement and educational attainment of their students? Do these effects differ across race/ethnicity? Are there operational features associated with achievement gains?
4. Do charters promote improved achievement in traditional public schools by introducing competition, or do they harm the performance of traditional public schools?

When summarizing the literature across these questions, we first highlight why these questions are important. Next, we establish a criterion for analyzing the quality of the research. Finally, we synthesize the findings across the literature, bearing in mind the quality of the research.

What Types of Students Do Charter Schools Serve?

As charter schools are schools of choice, it is important to examine whether they are serving the full range of the student population and whether they are doing so in integrated settings. Charter-school critics argue that charter success might be illusory if charter schools are simply recruiting the best students from traditional public schools or if they further stratify an already ethnically or racially stratified system (Cobb and Glass, 1999; Wells *et al.*, 1998). In general, these critics fear that charter schools may not only have negative consequences for the charter students who attend these schools, but if charter schools skim off high-achieving students, they may also have social and academic effects for students who remain in traditional public schools. However, proponents of charter schools argue that charter schools will improve racial integration by letting families choose schools outside of neighborhoods where housing is racially segregated (Finn *et al.*, 2000; Nathan, 1998).

Several studies have examined the racial/ethnic makeup of charter schools relative to the average racial/ethnic makeup of their surrounding districts and states (Powell *et al.*, 1997; RPP International, 2000; Miron and Nelson, 2002; Frankenberg and Lee, 2003). While this research has provided some insights, it does have some weaknesses. First, it has exclusively examined race/ethnicity, ignoring

altogether the issue of stratification by ability. Second, it has used cross-sectional snapshots of schools' enrolments, which do not permit examination of the movement of students between schools. Understanding how charter schools affect the mix of students requires a dynamic model that uses longitudinal data to examine the characteristics of students who migrate from a traditional public school to a charter and compares the students' characteristics with the distribution of students at the old and new schools.

Two recent studies examine the migration patterns of students of different race/ethnicity between traditional and charter schools. Bifulco and Ladd (2007) found that black students in North Carolina were likely to switch to charter schools with higher concentrations of black students than the traditional public schools they left. This charter-school migration increased the racial isolation of black students. Booker *et al.* (2005) also found that in California and Texas, black students generally transferred to charter schools with higher concentrations of black students. In contrast, Hispanic students in both states are likely to transfer to charter schools with a lower concentration of Hispanics than in the traditional public schools they left.

Charters may also attract students from middle-class families who would otherwise have attended private schools. Charter schools may be an important release valve for families frustrated with traditional public-school options. Toma *et al.* (2006) show that about 20% of Michigan charter school enrolments are drawn from private schools. This reengagement of parents in the public school system may improve prospects for improving public-education funding and reform efforts.

Are Charter and Traditional Schools Receiving Comparable Funding?

Charter schools are nominally entitled to funding comparable with traditional schools, but some evidence suggests that charter-school funding is lagging behind in many states (Osberg, 2006; Schneider and Tice, 2007). Average funding per pupil is about 22% lower for charter students, and some charters receive 30% less per pupil than do traditional public schools. The extent of these funding gaps is largely a function of state policies, including whether the state provides funding for facilities (or requires districts to provide facilities), whether state funds are supplemented by local resources to pay for education, and whether the state paperwork limited charter access to a large array of categorical funds.

In many states, charter schools are expected to pay for facilities out of the operating revenue, which creates large funding gaps (Krop and Zimmer, 2005). In addition, when states rely heavily upon local tax revenue to pay for education, charter schools are less likely to gain a share of these revenues – again creating large funding gaps

(Osberg, 2006). Finally, California and other states require education agencies to complete complex forms to receive categorical funding. In school districts, the cost of completing forms is spread over a large enrolment, but autonomous charter schools must complete comparable paperwork to receive funding for small numbers of students. This diseconomy of scale for charters reduces their access to categorical programs compared with traditional public schools and contributes to the reduced funding level of charter schools (Zimmer *et al.*, 2003).

The challenges of these funding gaps are gradually being recognized by states and some new policies have been introduced to address these issues. However, some argue that since one of the objectives of charter schools is greater efficiency, charter schools should prove they can provide similar or better results with fewer resources.

How Do Charter Schools Affect the Performance of Charter Students?

Over the last decade, a series of papers has emerged that has examined student achievement in charter schools in a number of states, including Arizona, Connecticut, Delaware, Florida, Illinois, Michigan, New York, Ohio, North Carolina, Texas, and Pennsylvania. In addition, a few recent studies have examined student achievement in charter schools nationally (Nelson *et al.*, 2004; Hoxby, 2004; Carnoy *et al.*, 2005). Some of this research has relied upon school-level data (Miron *et al.*, 2002; Rogosa, 2003; Greene *et al.*, 2003; LOEO, 2003; Russo, 2005) or cross-sectional comparisons of achievement in charter schools and traditional public schools at a single point in time.

A key weakness of a school-level analysis is the high degree of aggregation, which masks changes over time in the school's population of students, and variation of performance across different subjects and grades. In essence, school-level data may not pick up the nuances of school characteristics and can only provide an incomplete picture of why outcomes vary across schools. Meanwhile, point-in-time data, even at the student level, cannot account for the amount of time spent in different schools and cannot factor out the various nonschool forces at work.

Both school-level and point-in-time studies are likely to provide misleading indications of charter effectiveness due to a selection bias in charter-school enrolment. Parents choose charter alternatives because the traditional schools are not meeting their learning objectives. This parent selection process means that charter students are not representative of the pool of traditional school students, so the average difference in the performance of charter and traditional school students is a misleading indication of the effectiveness of charter schools. For example, if a charter school focuses on low-achieving students that are struggling in traditional schools, then the charter's average test score is likely to reflect the weak

preparation of its incoming students. Alternatively, if a high school charter's curriculum is built around college preparation, then the average charter test score may reflect the stronger preparation of its incoming students than that of a nearby traditional high school serving a broader mix of students. The danger is that charter effectiveness measures are easily confounded by the mix of student background and nonschool factors that lead parents to choose charter schools for their students.

Reliable measures of charter performance must assess the additional gain or value added from charter enrolment and not the historical background of students choosing charter schools. Researchers have dealt with the selection bias in charter enrolment in two ways: randomized experiments and longitudinal analyses. Both methods allow researchers to account for the amount of time a student has spent in a particular school, and both methods address differences among student populations served. Randomized experiments are often considered the gold standard in research, because, by assigning subjects randomly to the treatment condition or control condition, they ensure that differences observed later are the result of treatment rather than the result of background differences between the subject groups.

A few studies are beginning to examine oversubscribed charter schools that randomly admit students through lotteries. For instance, Hoxby and Rockoff (2004) examined four charter schools in Chicago, which provided evidence that this set of charter schools is outperforming traditional public schools. Later, Hoxby and Murarka (2007) used a similar design to evaluate 47 charter schools in New York City and found a small positive achievement effect for students attending charter schools. In addition, Mathematica Policy Research is currently in the midst of evaluating a small set of charter middle schools across a number of states for a project funded by the US Department of Education with the findings set to be released in 2008.

These studies have strong internal validity – in other words, the results have strong implications for schools included in the evaluation. One drawback of a randomized-design approach is that while it produces valid and reliable results for the set of charter schools examined, it may have limited implications for charter schools that are not part of the analysis. In other words, these studies have weak external validity. In order to conduct a randomized experiment of charter schools, researchers have relied upon randomly assigning students for schools that are oversubscribed with substantial wait lists. Therefore, these studies may have limited implications for those schools that do not have wait lists. In fact, one would expect schools with wait lists to be the best schools and it would be surprising if they had the same results as other charter schools.

When randomized designs have not been possible, or when researchers wanted to be more inclusive in their analysis of charter schools, researchers have often used a

fixed-effect approach to deal with the selection bias, which requires longitudinal student-level data. Fixed-effect approaches minimize the problem of selection bias by examining the academic gains made by individual students over time, factoring out those students' baseline achievement levels. Moreover, they permit within-student comparisons of achievement gains, examining changes in the achievement trajectories of individual students who move from traditional public schools to charter schools, or vice versa.

To date, a handful of studies have used this approach across a select number of states. In Arizona, Solmon *et al.* (2001) used the fixed-effect approach and found that students initially had lower scores, but students who remained 2–3 years in charter schools outperformed traditional public school students in reading and performed at least as well as public school students in math and possibly better (depending upon the model). Three separate studies using similar approaches found mixed results in Texas. Gronberg and Jansen (2001) found that charter schools that focus on at-risk students provided slightly more value adds than traditional public schools while non-at-risk charters provided slightly less value-adds than traditional schools. Hanushek *et al.* (2002) found negative achievement effects for Texas charter schools that were in the first few years of their operation, however, and no significant effect in reading and small positive effect in math in the long run. In a more recent study, Booker *et al.* (2007) found that in the first year of attending charter schools, student test scores drop, but the students' performance was comparable to students in traditional public schools by the second and third year in reading and math, respectively. In Florida, Sass (2006) found that charter schools initially had lower performance than traditional public schools, but eventually produced similar educational gains over time and by the fifth year, these schools were generally producing small positive effects. Bifulco and Ladd (2006) found negative reading and math effects for charter schools in North Carolina. In California, Zimmer *et al.* (2003) examined student-level data from six large districts and found that charter schools were performing on par with traditional public schools. In addition, Betts *et al.* (2006) examined charter schools exclusively in San Diego and similarly found that charter schools were performing on par with traditional public schools. In Milwaukee, Witte *et al.* (2007) found small positive effects for charter schools in math. Finally, in an anonymous district, Imberman (2007) found mixed results for charter schools with a small positive effect in math and a small negative effect in reading.

While the fixed-effect approach can be a strong control for selection bias and the papers using this approach are drawing significant attention, there are drawbacks to the fixed-effect approach as well. The fixed-effect approach provides an estimate of student achievement only for students who switch from a traditional public school to a

charter school or vice versa (switchers). Students who remain in either charter or traditional public schools for the duration of the analysis do not contribute to the estimate because the analysis does not compare their results in both contexts (charter schools and traditional public schools).

Recent work by Ballou *et al.* (2007) shows how the reliance on switchers can create two problems. First, charter schools that have high turnover rates (which may be associated with poor performance) will disproportionately contribute to the fixed-effect estimate. Second, Ballou *et al.* (2007) note that switchers may differ from nonswitchers in important ways, possibly biasing results that rely exclusively on switchers. They explore these issues by examining charter schools in Idaho using both a longitudinal student fixed-effect model, which only uses switchers, and by estimating the impact by using all tested charter and noncharter students. Exploring both approaches, they find conflicting results. The authors argue that the bias from only examining switching students in a student fixed-effect model may be greater than the self-selection bias the model attempts to correct and may imply that researchers should not exclusively rely upon fixed-effect models. However, in an interesting counterexample, Julian Betts *et al.* (2007), using data from San Diego, found that a fixed-effect approach produces math results much closer to the result of a randomized-design approach than other nonexperimental designs. In reading, random-effects model produced the best results. Overall, this suggests that researchers need to be explicit about the types of students the model is examining and what possible bias is remaining when examining charter schools through cross-sectional or longitudinal analyses, including the use of randomization.

Overall, the best of the current research has found that charter schools produce student-achievement results fairly similar to traditional public schools, but these effects vary across states. It is interesting to note that much of this research has shown that charter schools do improve over time, which implies that we may have to wait longer to draw definitive conclusions about the performance of charter schools.

Is Charter School Competition Improving the Performance of Traditional Public Schools?

While much of the existing research on charter schools has focused on student achievement effects for students who choose to attend charter schools, we argue that this focus may be too narrow. Supporters hope that charter schools can exert healthy competitive pressure on the existing K-12 educational system by giving families alternatives to traditional public schools. In fact, given that charter schools will probably never educate a substantial portion of the nation's student population, charter advocates argue that these schools may have their greatest impact through

systemic effects – the competitive effects of charter schools could improve the performance of traditional public schools and enhance the performance of students who do not attend charter schools.

The challenge in evaluating possible competitive effects is in knowing when district or school personnel will perceive a competitive threat. Do charter schools create competitive pressure when they are located near a traditional public school or when they first appear in a district? Do charter schools only create competitive pressure when they start recruiting students away from a particular school, or do they exert pressure when they capture a certain portion of students within a marketplace? In addition, the local environment may influence the competitive pressure that charter schools create. For instance, some districts may have well-developed, preexisting choice programs, including magnet schools or open enrolment policies. Moreover, some districts may be experiencing significant growth or already have overcrowded schools, in which case charter schools may act more like a release valve than a source of competitive pressure.

Nevertheless, research is developing around this issue and has made critical assumptions about the competitive process, which could affect conclusions made about the competitive effects. For example, Hoxby (2002) defines competition as where there is minimum market penetration of charter schools within a district and finds substantial positive competitive effects in Arizona and Michigan. However, Bettinger (2005), using an instrumental variable strategy, also examines competitive effects in Michigan as measured by distance and finds no effects. Using school-level data in North Carolina, Holmes *et al.* (2003) also used distance as a proxy for competition and found substantial competitive effects. In contrast, Bifulco and Ladd (2006) use student-level data in North Carolina and map out the distances of students exiting public schools to enter charter schools. Using this mapping, they analyze the effect charter schools have on traditional public schools within concentric distances of charter schools. Their analysis finds no competitive effects. Sass (2006) and Booker *et al.* (2004) also use student-level data in Florida and Texas, respectively, to examine competitive effects. Similar to Bifulco and Ladd, Sass uses concentric circles around public schools and measures whether a charter school is within these concentric circles and what proportion of total students are enrolled in charter schools. Using these approaches, Sass (2006) finds small positive competitive effects in Florida. Booker *et al.* (2004) uses two approaches, which find consistent competitive effects. First, like Hoxby, the authors use market-penetration measure at the district level. Second, they also use a campus-level market-penetration measure, which is defined by the percentage of students at a particular campus that exits the school to go to a charter school. They find competitive effects across both measures.

In a recent paper, Buddin and Zimmer (2005b) examine the competitive effects of charter schools using both survey and longitudinal student-level data in California. Examining survey responses from traditional public school principals about the changes in school operations, the analysis by the authors suggests that charter schools have no measurable impact on the performance or operation of traditional public schools. The authors go on to examine the student-achievement data, in which they use metrics of distance to the nearest charter schools along with the number of charter schools and the share of students attending a charter school within 2.5 miles of a traditional public school, while controlling for the level of preexisting competition and also using various measures of competition. Again, the authors found no evidence that charter schools create a competitive effect.

Across these studies, the authors generally found limited evidence of a competitive effect from charter schools. However, that could be explained by the fact that charter schools generally represent a low share of students in districts or states or by the fact that charter schools, at least in growing districts, may act as a release valve rather than a competitive pressure. It is possible that a broader implementation of charters would exert pressure on traditional public schools to improve their performance.

Conclusions

The charter movement grew out of a hope that by providing greater autonomy to schools, charter schools would be able to cut through bureaucratic frustrations and offer innovative, efficient, and effective educational programs, provide new options to families, and promote healthy competition for traditional public schools. However, critics feared that charter schools would drain scarce resources from the existing public education system, create greater stratification both by ability and race/ethnicity, and provide no real academic advantages to students attending these schools.

The current research has not shown charter schools to be a panacea for challenges facing the educational system that advocates hoped for, but expanding charter numbers and enrolments indicate that these schools may be meeting some other needs of parents, such as a safer educational environment or a wider array of instruction. Therefore, charter schools may be an initiative that should be given more time to show results, especially given that these schools are using fewer public resources.

Glossary

Charter schools – The publicly funded but privately managed and operated schools in the United States. They are free from many of the rules and regulations that apply to other public schools in exchange for accountability, and the exact rules governing this are set forth in each school's charter.

Sorting/cream-skimming – The phenomenon whereby private schools attract the most wealthy, best, and brightest students from the public schools, thus skimming the public schools off their cream.

Utility function – In economics, utility measures the satisfaction from consumption of goods. A utility function summarizes preferences of a consumer in terms of how much utility he or she gets from consuming the goods in the utility function.

Utility maximization – A concept in economics that, when making a decision, a consumer attempts to get the greatest value possible from the amount of money that he/she wishes to expend. This exercise yields the demand of the consumer for different goods.

Vouchers – A school voucher is a certificate by which parents are given the ability to pay for the education of their children at a private school of their choice rather than the public school to which they were assigned. This allows families to select the public or private schools of their choice and have all or part of the tuition paid.

One of the most important decisions that parents make regarding their children is the choice of their schools. A good education is often the cornerstone of a person's future life, being the foundation for his or her career. Most parents take care to choose a suitable school for their children, expending considerable resources in terms of time and money in the process. This short article reviews the economic aspects of parental choice of schools. We analyze the basic economic theory underlying a family's choice of schools for its children and then examine various dimensions of it, particularly as it relates to the organization of schools and provision of education in the real world. We briefly review the extensive literature that has come

up in recent years, partly fueled by a significant increase in school-choice options for students, and highlight contributions that have significantly increased our understanding of this important issue.

The Basic Economics of Parental Choice

It is instructive to begin with a review of the basic tenets underlying the economic theory of parental choice. This approach is rooted in the traditional paradigm of utility maximization, where school quality is considered a good, on par with other goods and services that families demand and consume.

In this framework, families with school-age children decide how to allocate their resources (wealth or income) among alternative goods, one of which is school quality. Formally, the family's preferences can be thought of as being represented by a utility function, where the family gets utility from school quality and a numeraire good (or money). School quality can be thought to be represented by a composite of school-related characteristics such as: academic performance, school demographics, school location/proximity, and school atmosphere. The family tries to maximize its utility given the income at its disposal (budget constraint) and various school types (represented by the above characteristics) and corresponding prices available to it. (For private schools, prices can be thought of as tuition. For various public school qualities, prices can be thought of as the opportunity cost of forgoing the next best option.) Under fairly standard assumptions regarding the shape and properties of the family's utility function, we can solve the maximization problem which yields the family's demand for school. (These assumptions are necessary to solve the model mathematically; however, the assumptions are fairly intuitive and likely to hold in real life. Formally, these include constraints on the shape of the utility function (nonsatiation and concavity).)

Given the utility function or preferences of the family, the demand for schooling depends on several factors, just like demand for other goods and services. These factors include the price or cost of different types of schooling or school quality, the family's income (or more broadly, resources at its disposal), and the prices of other goods that the family consumes (or might want to consume). In other words, the demand for school quality will change

with changes in these factors, holding the preferences of the family constant. For example, a rise in the price of other essential items that the family consumes may force it to cut back on its investments in schooling. (This may take different forms – e.g., a family might be forced to transfer its child to a school with lower costs (in terms of property taxes and/or tuition), or transfer to a school closer to home to save on transportation costs, or cut back on other investments complementary to schooling (such as computers at home), etc.) Of course, inherent preferences of families toward school quality are also likely to be different, and families who are more strongly committed to school quality (or a component of school quality) are more likely to forgo other expenses (or other components of school quality) in order to acquire it. Some recent studies have argued that such preferences might be systematically related to socioeconomic and demographic characteristics of households – these characteristics include parental education and incomes, race/ethnicity – this literature is reviewed later.

Choice among Alternative Types of Schools

One of the most important choices facing parents is whether to send their child to a public school or to a private school. The main distinguishing feature, from an economic point of view, is that public schools are free while private schools charge tuition and, hence, are costly to attend. Therefore, families are likely to send their children to private schools only if they believe that the benefits of private schooling outweigh the price differential. These benefits might be related to academic proficiency, or other noncognitive or even nontangible factors (discipline, safety, focus on moral values, etc.) In the United States, in particular, a significant percentage of the private schools are run by Catholic organizations or other religious denominations, and religion often plays an important role in family's choice of religious private schools.

Epplé and Romano (1998, 2002), Hoyt and Lee (1998), and Chakrabarti (2006, 2008) model a family's choice of private schools vis-a-vis public. In these models (with the exception of Hoyt and Lee (1998) where students differ only by income), students differ both in terms of family income – which affects their capacity to pay tuition and attend a private school – and in terms of inherent ability. The common finding in these theoretical models is that higher-income families and those with more able children will send their kids to private schools, and vice versa. Thus this leads to sorting by income and ability – children with higher family incomes and higher ability attend private schools, while children with lower family incomes and lower ability attend public schools.

Empirical Evidence on What Parents Care about

There is by now a large body of literature that investigates the characteristics of schools that parents prefer. These studies can be broadly divided into two parts: studies which survey individual families and ask them about their preferences for different school and schooling-related characteristics, and studies that look at actual schooling choices of parents and students. The findings from both strands of literature are discussed below. While the findings from the survey literature are interesting and informative, these suffer from an important caveat – the evidence is based on self-reporting by families. As a result, survey responses may often be associated with intended or unintended misrepresentation or parents not being completely honest with their preferences. Therefore, it is useful to compare findings of the survey literature with that of the observed choice literature. As can be seen from the discussion below, the findings from the two strands of literatures differ in important respects.

School Demographics

One of the most consistent results of the parental choice literature is that when surveyed, parents do not exhibit much preference toward student demographics and often display indifference toward the demographic composition of schools (Schneider *et al.*, 1998; Howell, 2004; Elacqua *et al.*, 2006; Weiher and Tedin, 2002; Williams *et al.*, 1983).

In contrast, observed choice behavior reveals significant parent preferences toward school demographics (Henig, 1990; Saporito and Lareau, 1999; Lankford and Wyckoff, 1992; Glazerman, 1997; Glazerman, 1998; Lankford and Wyckoff, 2000; Schneider and Buckley, 2002; Weiher and Tedin, 2002; Saporito, 2003; Hastings *et al.*, 2006; Elacqua *et al.*, 2006).

This finding is surprisingly consistent in this strand of literature in spite of the fact that the studies are based on different regions and time periods and the methodologies used to elicit choice behavior are also different. Schneider and Buckley (2002) study the search behavior of parents as they browsed information on the website <http://www.DCSchoolSearch.com>. This website provides detailed information (such as demographics, test scores, location, and academic programs) on public schools (both traditional and charter) in Washington DC. Elacqua *et al.* (2006) investigate search behavior of parents in the Metropolitan Region of Santiago, Chile and also compare these revealed preferences of parents with their survey responses relating to what they want from schools. Weiher and Tedin (2002) investigate the choice behavior of charter school parents in Texas and also compare them with expressed preferences of these same households. Hastings *et al.* (2006) analyze school-choice data from the Charlotte-Mecklenburg School

District in North Carolina; Henig studies enrolment patterns in magnet schools in Montgomery county, Maryland; Lankford and Wyckoff (1992) as well as Lankford and Wyckoff (2000) study school-choice decisions of parents in New York; Glazerman (1998) uses data from a public school choice program in Minneapolis, Minnesota; Saporito and Lareau (1999) use data from a large northeastern urban school district in the United States; and Saporito (2003) analyzes magnet school application data from Philadelphia.

In several studies in the US, researchers find that whites have a strong tendency to avoid minorities when choosing schools (Lankford and Wyckoff, 1992; Lankford and Wyckoff, 2000; Saporito and Lareau, 1999; Saporito, 2003). Some studies find this kind of behavior to be specific to whites (Lankford and Wyckoff, 2000; Saporito and Lareau, 1999), while others find that minorities also have own-race preferences (Weiher and Tedin, 2002; Glazerman, 1998; Hastings *et al.*, 2006). Schneider and Buckley (2002) find that parents generally seek out schools with fewer black students, with the result being stronger for more-educated parents. Research also shows parent preferences for school demographics other than race: Elacqua *et al.* (2006) find that 87% of parents in their sample only consider schools with student demographics similar to their own, as measured by parent education and socioeconomic status; Saporito (2003) finds that nonpoor parents are much more sensitive to poverty levels than poor parents when choosing schools; and Lankford and Wyckoff (1992) find that parents are very sensitive to income levels when choosing schools.

Academic Performance

Several studies of survey responses find academics to be the single most important factor for parents choosing schools (Williams *et al.*, 1983; Kleitz *et al.*, 2000; Howell, 2004; Elacqua *et al.*, 2006; some of these survey papers use criteria that likely encompass academics such as education quality (Kleitz *et al.*, 2000), and quality of teaching (Howell, 2004), thus, this list may be somewhat generous), or of generally high importance (Weiher and Tedin, 2002; Vanourek *et al.*, 1998; Greene *et al.*, 1998). Conversely, while some studies of observed behavior affirm the importance of academics (Saporito, 2003; Schneider and Buckley, 2002; Hastings *et al.*, 2006; Lankford and Wyckoff, 1992), others do not (Elacqua *et al.*, 2006; Saporito and Lareau, 1999; Weiher and Tedin, 2002; Glazerman, 1998).

Another important finding of studies relying on revealed preferences of parents is that parents give more weight to demographics than academics. Saporito (2003) finds that parent choices are significantly motivated by academic concerns, but that such concerns do not account for white families seeking schools with fewer nonwhite students. Schneider and Buckley (2002) find that parent Internet search behavior does reveal preferences for

better-performing schools; however, such preferences are less important than student demographics, both for parents with and without some college education. Hastings *et al.* (2006) find percent black to be a better predictor of school choice than school test scores. Elacqua *et al.* (2006) find that public school, private voucher, and private non-voucher parents, all construct school-choice sets with widely varying test scores; however, most parents do not choose the highest-performing school in their choice set, but nearly all parents only consider schools with demographics similar to their own. Saporito and Lareau (1999) “could not find evidence of white families’ decisions being linked to a range of school characteristics other than race” (p. 426). Weiher and Tedin (2002) find that most students transfer to schools with worse test scores, and that stating test scores as most important had no positive impact on the likelihood of transferring to a better-performing school. Lankford and Wyckoff (1992) find that parents do choose private schools based on academic performance, but that race may be a stronger predictor. Glazerman (1998) finds that test scores “were only important when middle and high ability choosers had a school with many low achieving potential classmates in their choice set” (p. 17).

Although it is certainly important to consider aggregate parent preferences, another question of significant interest is how parent preferences for academics vary across demographic groups. Some survey research finds little or no differences in preferences for academics across demographic groups (Kleitz *et al.*, 2000; Howell, 2004; Elacqua *et al.*, 2006), while other such research finds considerable differences. Williams *et al.* (1983) find that academic standards constitute the most important concern for private school parents and public school parents that considered other schools; however, it is somewhat more important for private school parents. Weiher and Tedin (2002) find that test scores are ranked most important for whites, second most important for blacks, and fourth most important for Hispanics – this holds true for parents with children in both at-risk and non-at-risk schools. Schneider *et al.* (1998) find that black parents and those with high school but no college education value test scores considerably more than parents of other racial groups and those that have attended college. Results from modeled and observed parent choices also show considerable differences, although fewer of these studies address the question. Schneider and Buckley (2002) find that parents with any level of college education value test scores much higher than those with no college. Elacqua *et al.* (2006) find the opposite: the chances of parents choosing the highest-performing school in their choice set decreases with education. Hastings *et al.* (2006) find that preference for higher-performing schools is strongly associated with higher income – both for whites and nonwhites – but overall, blacks seem to value test scores somewhat more than whites. Studying the same

choice program, Hastings *et al.* (2007) find that students whose parents had strong preference toward academic performance experienced gains in test scores as a result of going to the choice school, while students whose parents gave lower weights to academic performance experienced losses.

Location

Survey responses regarding the importance of location are mixed. Some show location to be very important with little differences across demographic groups, while others find it to be relatively unimportant but with considerable differences across demographic groups. Bridge and Blackman (1978) find that location was the single most important deciding factor for the majority of parents in their sample for all 5 years of the Alum Rock voucher demonstration. However, its importance decreased over the years as parents became more familiar with their school options. Elacqua *et al.* (2006) find location to be quite important to parents in choosing schools, being ranked first, second, or third out of eight factors for parents of all education levels and school types. Conversely, Kleitz *et al.* (2000) and Howell (2004) find location ranked fairly low across various demographic groups. However, both papers find more disadvantaged groups to value location higher. Williams *et al.* (1983) find distance to be of high interest to public school parents that did not consider other schools, moderate interest to public school parents that did consider other schools, and of very little interest to private school parents. Weiher and Tedin (2002) find that importance of location is ranked fifth out of six for whites and Hispanics and fourth for blacks.

Results from most of the literature relying on revealed preference show moderate to strong preferences for location. Saporito and Lareau (1999) find that both whites and blacks tend to choose schools close to their homes, but that whites are often willing to travel further to attend schools with higher proportions of white students. Hastings *et al.* (2006) find that families value location highly, but those with strong preferences for academics are generally willing to tolerate larger distances. Schneider and Buckley (2002) find that in parent Internet search behavior, location was the second most sought-after information after school demographics. However, they note that parents who know their city neighborhoods well may be using location as a proxy for other school characteristics. In contrast to the above literature, Glazerman (1998) finds that only 26% of the parents in his sample chose the school closest to their home, indicating a fairly low importance for location.

School Atmosphere: Safety, Discipline, Values, Class Size, and Friends

School atmosphere (i.e., safety, discipline, values, class size, and number of friends) is another factor that parents

consider when choosing schools. Since many variables associated with school atmosphere are relatively hard to observe (with the exceptions of safety and class size), most of the evidence on this factor comes from the survey literature.

Howell (2004) finds that discipline, safety, and order are ranked the second most important factor out of nine after quality of teaching and this factor is rated equally high by parents with children in performing schools and those with children in underperforming schools. Kleitz *et al.* (2000) find that safety is ranked third by all racial and socioeconomic groups, but is valued quite differently. Blacks are much more concerned with safety than Anglos, and Hispanics much more than blacks. Further, low- and moderate-income parents value safety similarly but consider it much more important than do high-income parents. They argue that variance in preferences for safety reflects differences in past school environments experienced by ethnic and income groups.

Williams *et al.* (1983) find that discipline and values/religion are most important for private school parents, less important for public school parents that considered other schools, and even less so for public school parents who did not consider other schools. Schneider *et al.* (1998) find that minority and less-educated parents value discipline much more than white and higher-educated parents, while white parents and those with higher education consider values and diversity much more than others.

Howell (2004) finds friends at school is ranked lowest both by parents with children in underperforming schools and those with children in performing schools and given nearly identical ratings. Of the five factors they consider, Kleitz *et al.* (2000) also find friends ranked lowest for Anglos, blacks, Hispanics, as well as for low-, moderate-, and high-income parents. However, they find friends are much more important for Hispanics than for blacks and Anglos, and much less important as income rises.

Kleitz *et al.* (2000) find that class size is ranked second and is of similar importance for all racial/ethnic and income groups. Howell (2004) finds class size is ranked third by all groups of parents, although those from underperforming schools rate it somewhat higher.

Does Parental Choice Vary by Income and Ability of Parents? Or Is There Evidence of Sorting by Income and Ability?

Apart from the above literature, there is also a rich empirical literature that investigates whether parental choice behavior varies with the income and ability of parents. Hsieh and Urquiola (2006) study the nationwide voucher program in Chile that was introduced in 1981 and find that wealthier families and families with higher education were more likely to avail of vouchers. In other words, they find that vouchers led to sorting by income and ability in

Chile. In the context of a national, means-tested school voucher program in the United States, Campbell *et al.* (2005) show that the chances of both application and actual voucher takeup increased with mother's education and decreased with family income. They argue that the pattern for income may be a reflection of the program feature that vouchers awarded to higher-income families were smaller. They also find that religious motivations (e.g., whether or not attended church services) played an important role in choice decisions. Peterson *et al.* (1999) find that voucher students in Cleveland had higher mother's education than public school students. Eppler *et al.* (2002) also find evidence of both sorting by income and ability. Howell *et al.* (2006) and Howell (2004) find that higher-income families were more likely to take a voucher in New York City, while Howell *et al.* (2006) find that low-income families were more likely to do so in Dayton, with no difference observed in Washington, DC. In a survey of previous literature, Levin (1998) finds that choosers were more advantaged both educationally and economically than nonchoosers.

Hoxby (2003) finds no evidence of cream-skimming in the context of charter school competition in the United States. Witte and Thorn (1996) and Chakrabarti (2006) study the Milwaukee voucher program. The former study finds that voucher applicants had lower income and higher mother's education than their counterparts in the Milwaukee public schools. Chakrabarti (2006) finds no difference in income between voucher applicants and nonapplicants in Milwaukee, but finds that the applicants had higher mother's education and parental involvement in education. Chakrabarti (2006) argues that the findings reflect the importance of voucher design – voucher design matters as far as student sorting is concerned. She argues that the program feature that vouchers could not be topped up (vouchers were to be taken as full payment of tuition and hence voucher-availing parents did not have to make any tuition payments) coupled with the absence of private school selection (private schools were required to accept students randomly if oversubscribed) likely resulted in the absence of sorting by income. Studying public school choice in New Zealand, Fiske and Ladd (2000) find that families who took advantage of choice tended to opt for higher socioeconomic status schools and the choice program resulted in minorities getting concentrated in low socioeconomic status schools. For a comprehensive review of this sorting literature, see McEwan (2000, 2004) and Howell *et al.* (2006).

The Role of Information

While it is important to consider, as the previous discussion does, what parents care about in schools, it is also

important to consider whether they have sufficient information about schools and school characteristics. Even strong preferences do not guarantee correct and educated parental choices unless and until they have adequate information. Two questions are relevant here. First, do parents have adequate information about their schools? Second, does better information matter? That is, does it entail different choices and better outcomes for families?

Drawing from a telephone survey of public school parents in the state of Massachusetts, Howell (2004) assesses the information that parents have about the statuses of their schools under the federal No Child Left Behind (NCLB) law, as well as general characteristics of their schools. Adequate knowledge of the statuses of their children's schools under NCLB is absolutely essential for parents to make informed choices. For example, low-performing statuses of schools make their students eligible for public school choice and supplemental services (such as tutoring), but parents can avail of these only if they are aware of their school's status. Howell (2004) finds that although parents assert that they are familiar with NCLB, most parents in low-performing schools are not aware of their schools' statuses and, consequently, the fact that they qualify for additional services. He also finds that minority, disadvantaged, and less-educated parents systematically had less information than white, more-advantaged, and more-educated parents.

In relation to the second question, Hastings and Weinstein (2007) analyze the effect of providing transparent information to parents (on school-level academic achievement) on their school choices and their child's subsequent academic outcomes. They find that providing transparent information resulted in parents making substantially better choices in terms of choosing higher-performing schools and attending these schools also resulted in significant increases in the children's test scores.

In contrast, Mizala and Urquiola (2007) find in the context of Chile that information on school effectiveness does not make much dent on school markets. They find that being identified as high-performing schools, where this information is widely disseminated, does not have much effect on the schools' enrolment, socioeconomic composition, or tuition. The differences in results in the two studies discussed above may be because they relate to very different schooling markets and school systems. Mizala and Urquiola (2007) argue that while parents may care about school effectiveness they might care about other factors more such as peer composition, or this information may not be new to them in the sense they may have already deduced the effectiveness of the schools on their own.

Conclusions

In this brief article, we have surveyed the evidence on how parents choose schools for their children.

The literature focuses on different aspects of this choice, highlighting features of schools such as composition of its student population, its academic performance, location or proximity, and school atmosphere. Somewhat surprisingly, and despite their professed indifference about it, many parents are observed to pick up schools based on similarities in demographic characteristics. This is in contrast to the role played by academic performance, which is often found to be of secondary importance (although some studies find performance to be the main concern). Parents are also found to be sensitive about the location of schools, and prefer schools with positive atmosphere as reflected in school safety, discipline, and class size.

The literature also finds that there is interesting heterogeneity in preferences of parents across income and racial groups. Several studies have also documented that more-educated and higher-income families disproportionately avail of school-choice options, thereby increasing the possibility of segregation. However, the design of these particular choice programs plays a crucial role in this respect. It is also instructive that better and more transparent information has the potential to play a significant role in families' choices, at least under certain circumstances. These findings have important implications for school-choice policy and its design, and also calls for better transmission of information to parents, as this might, at least in some circumstances, lead to better choices by them.

Glossary

Growth model – A measure of aggregate student test performance based on year-to-year changes in the test scores of individual students.

Principal-agent problem – A circumstance in which one individual or group is entrusted to make decisions on behalf of other people who may not share the same objectives.

Status model – A measure of aggregate student test performance based on the average level of student test scores.

Test-based school accountability – The practice of identifying, rewarding, and sanctioning schools on the basis of aggregated student test performance.

Demands for more accountability and results-based incentive systems in K-12 education come from many directions and currently dominate much of the education policy discussion at both the state and federal levels in the United States (Ladd, 1996; Ladd and Hansen, 1999) and abroad (Burgess *et al.*, 2005). Accountability in education is a broad concept that could be addressed in many ways: using political processes to assure democratic accountability, introducing market-based reforms to increase accountability to parents and children, developing peer-based accountability systems to increase the professional accountability of teachers, or using administrative accountability systems designed to drive the system toward higher student achievement. This article focuses on this last approach and pays particular attention to programs that focus on the individual school as the primary unit of accountability.

The use of school accountability programs in other countries notwithstanding, this article focuses exclusively on evidence and policies from the United States. The accountability systems of interest here operate within the traditional public school system and rely heavily on student testing (Hanushek and Raymond, 2003). Most emblematic is the federal No Child Left Behind Act (NCLB), which became law in 2002. NCLB requires states to test students in reading and mathematics in grades 3–8, as well as in one high school grade. In addition, it requires states to assess schools on the basis of whether their students (both in the aggregate and by subgroup) are making adequate yearly progress (AYP)

toward the ultimate goal of 100% proficiency by 2014, and it imposes consequences on schools and districts that fail to make AYP. This law is the most recent incarnation of a bipartisan standards-based reform movement that emerged from a historic 1989 summit in Charlottesville, Virginia, between President George H. W. Bush and the state governors. The meeting generated a set of national education goals that were subsequently embedded in the Clinton administration's 1994 Goals 2000: Educate America Act. NCLB differs from that act by its far heavier emphasis on accountability and its significantly greater federal intrusion into the operations of individual schools and districts.

School-based accountability programs preceded NCLB in many states. As of 2001, 45 states published report cards on schools, and 27 of them rated schools or identified low-performing ones (*Education Week, Quality Counts, 2001*). Several states (e.g., North and South Carolina, Texas, Kentucky, and Florida) as well as districts such as Chicago, Dallas, and Charlotte-Mecklenburg, also had full school-based accountability programs in which they rated schools based on their students' performance, provided rewards either to schools or to teachers for improved performance, and provided some combination of sanctions and assistance to low-performing schools.

The Rationale for School-Based Accountability

The current school-based accountability efforts emerged from the broader standards-based reform movement that began in the 1980s. Standards-based reform involves the setting of clear, measurable, and ambitious performance standards in a set of core academic subjects for students at various ages, aligning curriculum to these standards, and establishing high expectations for students to meet them. Assessment of students is a key component of standards-based reform. These assessments are used to measure student progress toward mastery of the standards and also the effectiveness of the schools they attend. The goal is to provide incentives for schools to raise student achievement.

In the context of standards-based reform, accountability is only one part of a larger policy package. Accountability – whether for schools, students, teachers, or districts – can also be viewed as a stand-alone policy. One rationale for such a policy comes from comparisons to the private sector

where business firms focus attention on results and rely on benchmarking procedures to measure progress. Another rationale is provided by the economists' model of the principal-agent problem. In such a model, school administrators and teachers may underperform because the state policymakers do not have a good means of monitoring them. It follows that student achievement would improve if state policymakers could monitor the teachers and school administrators more effectively.

School accountability systems serve as a mechanism for counteracting this principal-agent problem. By assessing schools against a common metric, policymakers generate independent information about the performance of schools and school districts. This common yardstick then allows policymakers to compare each school's performance to that of another school or to an external standard. By measuring, reporting, and, in many cases, attaching positive consequences to strong school performance and negative consequences to weak performance, policymakers provide incentives for schools and school districts to focus attention on what is being measured and possibly to change the way in which they deliver education. Such information may also facilitate improved monitoring by another important set of stakeholders in the education system, namely parents. Whether by complaining about poor performance or by threatening to withdraw their child from the school, parents could potentially use the publicly provided information on school performance to induce their children's schools to improve.

Most administrative accountability systems measure only a very small fraction of the educational outcomes that parents and policymakers value. The outcomes in such systems typically include student achievement as measured by test scores in only the core subjects of math and reading, supplemented in some cases (as under NCLB) with some nontest-based measures such as student attendance or graduation rates. As documented by Rothstein and Jacobson (2008), educational stakeholders value a much broader range of academic outcomes as well as other outcomes such as citizenship. Some of these, according to Hanushek and Raymond (2003), are more highly related to student achievement than are others. However, the narrow focus of administrative accountability systems on test results in math and reading clearly privileges one narrow set of outcomes over others.

School accountability systems can also provide administrators with incentives to game the system. Some of these responses, which tend to increase the measured achievement of a school's students but not necessarily their true achievement, are described later in this article. A number of other factors may also keep an accountability system from generating better student outcomes. Outcomes might not improve, for example, if the extrinsic motivations imposed by the accountability system crowd out powerful intrinsic motivations for educating children

(Frey, 2000). Perhaps, most important is that educators may lack the necessary skills, knowledge, or resources to meet the expectations of an accountability system. Thus, it could be that one of the major assumptions underlying stand-alone accountability programs – namely that teachers are underperforming because of insufficient monitoring of their behavior – is incorrect. In any case, greater learning gains associated with school accountability are by no means assured.

Designing School Accountability Systems

How a school accountability system is designed can have a significant impact on the nature of and the strength of the incentives that schools face to raise student achievement in the tested subjects. Moreover, the design can affect which students are likely to receive the most additional attention.

Broadly speaking, two main approaches have been used to measure school performance – status measures in which schools are judged based on their levels of performance, typically measured by average test scores or by the fraction of students attaining certain proficiency levels, and growth or value-added measures in which schools are rated on how much they improve individual students' performance from one year to the next (Hanushek and Raymond, 2003). The simplest way to measure achievement growth, or value added, is to use gains in student test scores from one year to the next. In some cases, those gains, averaged across all students in the school, are then compared to the gains in test scores that are predicted for that school given the achievement level of its students in the prior year. More refined measures of value added can be based on regression models, with or without additional statistical controls for student characteristics (Ladd and Walsh, 2002). States and local school districts have used variations of both the status and the growth approach (Hanushek and Raymond, 2003). Although NCLB requires that schools be evaluated in terms of their AYP toward the ultimate goal of 100% proficiency, such progress is measured based on comparisons of aggregate levels of student performance from one year to the next. Thus, the current iteration of NCLB is essentially a status model not a growth model, although the US Department of Education has recently given a few states the authority to introduce some growth elements into the basic approach.

The two types of measures have somewhat different goals and generate somewhat different incentives. Status-based systems that focus on the percent of students who achieve at proficient levels seek to encourage schools to raise performance at least to that level. This approach is appealing to many policymakers because it sets the same target for all groups of students and because it encourages schools to focus attention on the set of low-performing

students who in the past may have received little attention. Status-based systems also have the advantage of being transparent.

The goal of the growth-model approach is to encourage schools to improve the performance of their students independently of the absolute level of that achievement. Such an approach is appealing to many people because of its perceived fairness. It explicitly takes into account the fact that where students end up is heavily dependent on where they start and the fact that the starting points tend to be highly correlated on average with family background. At the same time, the use of the growth-model approach may raise political concerns, both because the public may find the approach less transparent than the status approach and because some see it as a way of letting schools with low average performance off the hook.

Systems using status and growth models generate different incentives in part because they lead to different rankings of schools. Many schools deemed ineffective based on their aggregate performance levels may actually have quite high value added and vice versa (Kane and Staiger, 2002). Some accountability systems (e.g., Florida's and North Carolina's) encourage both high levels of performance and high test score growth, by focusing on both levels and gains (Ladd and Zelli, 2002; Rouse *et al.*, 2007).

In addition, the two approaches send different signals about which students deserve more attention. Under a status-based system designed to encourage schools to raise student performance to some threshold level, the position of the threshold matters. A challenging performance threshold – for example, one that would be consistent with the high aspirations of the standards-based reform movement – would provide incentives for schools to focus attention on a larger group of students than would be the case with a lower threshold. Evaluating schools on the basis of value added, by contrast, provides a stronger incentive for schools to expend effort on the entire student body. In such a system, however, schools may have an incentive to focus attention on the more-advantaged students because the test score gains of those students are likely to exceed those of the less-advantaged students (Ladd and Walsh, 2002).

Under either approach, random errors in the measurement of student performance can generate inconsistent rankings of schools over time – a factor that weakens incentives for improvement. That is especially true for small schools because the smaller the number of students in the school, the larger the school-wide average measurement error, and hence less consistent the school's ranking is likely to be from 1 year to the next. Schools deemed to be improving at one point in time are often found to be declining the next year due to measurement error (Kane and Staiger, 2002). The problem of measurement error is exacerbated when schools are rated based on the growth model because it requires test scores for more

than 1 year. The danger is that personnel in such schools may receive such inconsistent signals from 1 year to the next that they have little incentive to respond in a constructive way.

Measurement-error issues in accountability are particularly pronounced when an accountability system focuses attention on specific subgroups within a school, as is mandated by NCLB and some state accountability systems. A potential alternative to the subgroup requirement would be to focus special attention on the segment of the school's students that performed at a low level in the previous year and to track that group's growth. This segment would likely include a large fraction of the economically disadvantaged and racial minority students, and so might capture the spirit of the NCLB law without exacerbating the problem of measurement error.

Neither approach to measuring school performance captures what economists call school efficiency – the effectiveness with which schools use their resources to maximize student outcomes, given the students they serve. According to the economists' model of the education production function, student achievement is determined by the characteristics of the student and his or her classmates, the school's resources (including the quantity and qualifications of the teachers), and the efficiency with which those resources are used. Efficiency cannot be observed directly and therefore, it must be inferred from statistical analysis that controls both for the resources available to the school and the characteristics of the students being served (Stiefel *et al.*, 2005). If the goal of an accountability system is to induce schools to use the resources they have more effectively, then, in principle, schools should be rated on their efficiency, not simply on the level or growth of their students' achievement. The problem is that the data requirements for such efficiency measures are often daunting and the statistical techniques can be complex (Ladd and Walsh, 2002; and Stiefel *et al.*, 2005).

The Evidence on Student Achievement

Measuring the effects of test-based accountability systems on student achievement is not a simple task. When such systems are part of a larger standards-based reform effort, it is difficult to separate the effects of the accountability system from those of other components of the reform package. In addition, researchers face the challenge of finding appropriate control groups to determine what would have happened to student achievement in the absence of the accountability system. In practice, researchers have used a variety of empirical strategies to address these challenges.

Due to the short time since NCLB was introduced and the lack of a counterfactual, the most compelling studies of how accountability affects student achievement are

based on the state and local accountability systems that preceded NCLB. This research includes district- or state-specific studies as well as cross-state studies that measure achievement using the results from the National Assessment of Education Progress (NAEP). Researchers conducting district- and state-specific studies (e.g., Ladd, 1999; Jacob, 2005; Figlio and Rouse, 2006; West and Peterson, 2006; Rouse *et al.*, 2007; Neal and Schanzenbach, 2007; Krieg, 2007) have used a combination of state- or district-wide trends in achievement, along with trends or patterns in school and student-level achievement in other comparable districts or states, to sort out how the specific accountability system in that district or state affected student achievement. The main advantages of district and state studies are that the analysis is firmly focused on a specific, well-defined accountability system. Some of the studies, particularly those for particular states, are hampered by the difficulty of predicting what would have happened to student achievement in the absence of the state's accountability system. However, it is possible to exploit idiosyncratic differences in state policy effects (e.g., Figlio and Rouse, 2006) or changes in accountability rules (e.g., Rouse *et al.*, 2007) in order to make apples-to-apples comparisons within a state.

Cross-state studies (e.g., Carnoy and Loeb (2002) and Hanushek and Raymond (2005) make use of the variation across states in the nature or timing of accountability systems. Although the conclusions of cross-state studies are sensitive to how accountability policies are defined as well as to methodological considerations such as the determination of control groups, the findings of cross-state studies are likely to be less idiosyncratic and more generalizable than those that emerge from the analysis of a specific program.

Some researchers have found modest but meaningful gains in test scores associated with school accountability, though many studies find little or no effect. Although a few methodologically rigorous studies, including Jacob (2005), Rouse *et al.* (2007), and Neal and Schanzenbach (2007), find positive impacts on reading scores, positive achievement effects emerge far less frequently in reading than in math. Larger and more consistent effects for math are intuitively plausible and are consistent with findings from other policy interventions such as voucher programs and tax and expenditure limitations. Compared to reading skills, math skills are more likely to be learned in the classroom, the curriculum is well defined and sequenced, and there is less opportunity for parents to substitute for what goes on in the classroom (Cronin, 2005).

Some evidence from the district- or state-specific studies suggests that the schools at the bottom of the performance distributions exhibit the greatest gains under an accountability system. This conclusion emerges from both Chicago (Jacob, 2005) and Florida (Figlio and Rouse, 2006). Working in the other direction is the finding

from Cronin *et al.*'s (2005) national study that the effects of high stakes are greater for the higher-scoring students. As predicted theoretically, school accountability systems often lead schools to target attention to students at particular points in the ability distribution: Neal and Schanzenbach (2007) and Krieg (2007) show that the gains in achievement associated with a status-based system tend to be most concentrated in the bubble students near the margin of proficiency, and Rouse *et al.* (2007) find that when Florida moved away from a status-based system to one that incorporates gains in student test scores, the students at the ends of the distribution (away from the bubble) appear to have benefited the most.

Evidence on Unintended Consequences

In any monitoring situation, those being monitored face incentives to appear as effective as possible against the metric being assessed. Thus, the concern arises that teachers might teach so narrowly to high-stakes tests that little or no generalizable learning would take place (Koretz and Barron, 1998). Typically, however, as long as the high-stakes tests reflect material that policymakers and the public consider important, teaching to the test would still be expected to improve student learning in the tested areas, at least to some extent. In a few cases, however, reported gains may be completely bogus. Jacob and Levitt (2004), convincingly demonstrate, for example, that a small fraction of Chicago teachers responded to accountability pressures in that city by engaging in outright cheating in order to boost measured student test performance.

Regardless of whether teacher cheating takes place, substantial evidence supports the conclusion that schools tend to concentrate their attention on the subjects tested and on the grades that have high-stakes tests (see, e.g., Deere and Strayer, 2001; Ladd and Zelli, 2002). Other studies (e.g., Hamilton *et al.*, 2005; Stecher *et al.*, 2000) show that teachers and schools tend to narrow the curriculum and shift their instructional emphasis from nontested to tested subjects, while earlier work by Shepard and Dougherty (1991) and Romberg *et al.* (1989) suggest that teachers focus more on tested content areas within specific subjects. In related work, Chakrabarti (2005) presents evidence that schools may concentrate their energies on the most easily improved areas of instruction, rather than on subjects across the board.

A common way to examine whether student learning has increased is to measure achievement using a low-stakes test, that is, one with no specific consequences for schools. A natural test for that purpose is the NAEP, which has been administered to a nationally representative random sample of students since the early 1970s and to representative samples of students in grades 4 and 8 in

most states since the 1990s. The downside to measuring achievement using scores from a test with no consequences for students or teachers is that students may not take the test sufficiently seriously to do their best work. Unless student effort differs from one administration of the low-stakes test to the next, however, changes in performance on the low-stakes test should provide a reasonable estimate of gains in student learning. In some cases, tests offer low stakes for schools but high stakes for students (e.g., for track placement or school choice); here, the low-stakes tests could potentially provide at least lower-bound estimates of the effects of accountability on genuine learning. In general, smaller estimates of accountability effects emerge when the researcher focuses on tests with lower stakes, although in some cases the lower-stakes test results approach the magnitudes of the high-stakes test results.

Schools may also engage in strategies that artificially improve test scores by changing the group of students subject to the test. The most widely studied behavior of this type is the selective assignment of students to special education programs. Many studies, including Cullen and Reback (2006) and Jacob (2005), show that schools tend to classify low achievers as learning disabled in the context of accountability systems. Though there may be some debate about whether the greater rates of classification are undesirable in all cases, nonetheless, they highlight the possibility that schools are manipulating the testing pool specifically to inflate measured school performance. Figlio's (2006) finding that some Florida schools changed their discipline and suspension patterns around the time of the testing in ways consistent with the goal of improving test-takers' average scores reinforces this concern.

Evidence suggests that schools engage in other types of strategic behavior as well. For example, Figlio and Winicki (2005) demonstrate that schools change their meal programs at the time of the tests in an apparent attempt to raise performance on high-stakes examinations, while Anderson and Butcher (2006) find that schools subject to accountability pressure are more apt than other schools to sell soft drinks and snacks through vending machines.

Many of these behaviors are less likely to occur in growth-based accountability systems than in status-based systems. The reason is that in the growth approach, the manipulative behavior that increases student achievement in one year would make it more difficult for the school to attain accountability goals the following year. No such trade-off arises in status-based accountability systems.

New evidence shows that Florida schools subject to accountability pressures in a system that includes both status and growth measures changed their instructional policies and practices in productive ways. Using detailed survey data collected from a census of public schools in Florida, Rouse *et al.* (2007) find that changes in educator practices account for a significant proportion of the realized

test-score gains associated with the change in accountability systems. The results indicate that accountability systems not only provide educators with incentives to change their behavior but also that their design affects the mix of productive and unproductive responses.

In conclusion, school accountability systems have the potential to influence school behaviors in tangible ways. School accountability systems in the United States appear to have modestly increased measured student test performance, at least in mathematics, and have likely done so through a combination of substantive and artificial means. There remains much to learn on the subject, and the research on the mechanisms through which accountability influences student achievement – and the macro-consequences of these mechanisms – is still in its infancy. More work is needed to fully understand the relative benefits and costs of school accountability systems.

Glossary

Children Scholarship Fund – Scholarship program for students to attend private schools funded by the Walton Family Foundation.

Indirect effects – Effects on students not utilizing vouchers to attend private schools.

Means-tested – A criterion that uses the ability to pay as means of being eligible for a voucher.

PACES program – A Colombian program offered educational vouchers to over 144 000 low-income students throughout Colombia from 1992 to 1997.

Scholarships – While both vouchers and scholarships are entitlements to attend a private school, vouchers are publicly funded while scholarships are privately funded.

Sectarian schools – Schools affiliated with particular faith or religion.

Selection bias – Estimated effect of programs could be biased because participants have chosen to participate, which is not captured by the econometric model.

Self-selecting – Students choose to attend a private school.

Vouchers – A government-financed entitlement that students and their families could use to attend any school, including private schools.

Introduction

Advocates for vouchers argue that vouchers create incentives for schools to compete for students and that such competition can make all schools more effective and efficient. Milton Friedman originally proposed vouchers as a government-financed entitlement that students and their families could use to attend any school, including private schools (Friedman, 1955, 1962). Over time, support for voucher programs has come from diverse groups such as conservative pro-market advocates (including Friedman), Roman Catholic bishops hoping to reinvigorate parochial schools in urban cities, and minority advocacy groups.

Voucher opponents argue voucher programs cream skim the best students and that vouchers can increase

inequities if selection into voucher programs falls along racial or economic divides. They claim that by reducing public school enrolments, vouchers intensify the fiscal strains already felt by public schools.

Debates over vouchers have increased in the last decade or so with the advent of publicly funded voucher programs in Milwaukee, Cleveland, and Florida. Additionally, the increase in the number of foundations and philanthropists providing private money for students to attend private schools has also increased the public awareness of voucher programs. Outside of the United States, voucher-like programs have also increased in popularity; and while the motivation for these voucher programs differs from those in the US, debates over these programs rage worldwide. In this article, we examine many of the claims and counter-claims of the debate by surveying the research literature on both domestic and international programs.

In reviewing the existing voucher literature, we focus exclusively on empirical evidence on vouchers and do not include a review of other forms of school choice including charter schools, home schooling, or the effectiveness of private schools generally. While some research has extended beyond academic and behavioral outcomes or the distributional effects of voucher programs and examined the effects of voucher programs on residential housing markets (Nechyba, 2000), cost effectiveness of voucher programs (Levin, 2002), on subsequent public support for vouchers, or lack thereof (Brunner and Imazeki, 2006), and on who wins and loses under voucher programs (Epple and Romano, 1998, 2003), we only discuss these broader effects to the extent that the studies shed light on the specific voucher programs that we review.

This is not the first review of vouchers programs (e.g., Zimmer and Bettinger, 2007; Gill *et al.*, 2001; Levin, 2002; McEwan, 2000, 2004). These reviews include the conceptualization of, and rationale for, voucher programs as well as evidence on the efficacy of vouchers. This article builds on these reviews, but focuses on the achievement and behavioral effects of vouchers on students and the effect these programs have on access and integration.

Structure of Voucher Plans

Voucher programs differ greatly in their specific design. Much of this variation is related to the differences in the motivation for vouchers among the voucher advocates

* This review is an abbreviated version of our previous review (Zimmer and Bettinger, 2007).

(Levin, 2007 *Handbook*). For example, many conservatives believe that flat-rate, modest vouchers can increase efficiency through increased competition (e.g., Friedman, 1955, 1962). Other proponents argue that means-tested vouchers can promote equity by providing better educational opportunities to low-income families in inner-city schools. Programs also differ in their advocacy of subsidies for transportation, degree of information availability, regulation of admission policies, and accountability mechanisms (Jencks, 1970; Levin, 2002). In practice, voucher programs differ substantially in their level of support, the target population, and admission of sectarian schools.

The various programmatic details change with reference to who participates in the voucher program and are likely to influence the generalizability of individual programs and studies. For instance, programs that restrict participation to low-income students are likely to have different distributional effects than a universal voucher program. Programs that allow students to attend sectarian schools are also likely to attract a particular set of students—specifically students seeking religious instruction opportunities. Finally, the scale of the programs may affect whether these programs will generate general equilibrium effects that may be even larger than the localized effects of voucher programs (e.g., Nechyba, 2000; Epple and Romano, 1998, 2003).

As the programmatic design can affect outcomes this article, as in our previous review, highlights the details of each voucher program and the associated outcomes individually. We synthesize the results in the final section and provide a summary of the programs and outcomes in Table 1.

Domestic Voucher Programs

Domestic voucher programs have been funded either by public taxes or private donations, primarily through philanthropists or foundations. While the scale and regulation of public and privately programs may differ, they are similar in that they both provide a subsidy for students to attend private schools.

Publicly Funded Programs

The Milwaukee voucher program

The most visible domestic voucher program began in Milwaukee in 1990. The program focused on low-income students. The program started small being capped at 1% of the school district's population. In examining the program, Witte (2000) compared the performance of voucher students to that of all other students in the Milwaukee school system finding no differences in test scores. Greene *et al.* (1997, 1998), found increases in reading and math test scores when they compared outcomes for voucher recipients who had stayed in voucher schools for

multiple years to outcomes for a comparison group of students who had wanted to use the voucher but could not because of a lack of space. These divergent results led to an often heated debate over the results and methodologies (e.g., Mitgang and Connell, 2003; McEwan, 2000). Rouse (1998) attempted to resolve the controversy. Rouse took advantage of the fact that oversubscribed schools used randomization to assign vouchers. (McEwan (2007) discusses how randomization is the gold standard in evaluative research.) Rouse found slight positive, significant effects of the voucher program in math test scores, but none in reading.

Milwaukee's voucher experience also sheds light on the impact voucher programs can have on access and racial integration. African-Americans made up over 62% of the voucher population. Hispanics made up about 13% (WLAB, 2000). The program successfully targeted low-income families with the average family income for program participants being around US\$11 600 (Witte, 2000). Other studies showed that the voucher parents had slightly higher educational levels (Rouse, 1998; Witte, 1996; Witte and Thorn, 1996) than other parents in Milwaukee.

While the early Milwaukee program offered insights to policymakers, the small scale of the program limited the policy implications. In 1995, the state of Wisconsin greatly expanded the scholarship cap and the range of private schools that students could attend. These changes dramatically redefined the scope of the program. While only 341 students attended seven private schools in 1991, over 15 000 students attended dozens of sectarian and non-sectarian schools by the 2004–05 school year (Gill *et al.*, 2001). This expansion led some researchers to investigate whether Milwaukee's program resulted in changes in nearby public schools (e.g., Hoxby, 2005). Unfortunately, the expanded program did not require testing within the private schools, which resulted in no new studies of the program. A recently commissioned study (funded by the Bradley and Joyce Foundations among others) seeks to reevaluate the Milwaukee voucher program by having private schools voluntarily administer a standardized test.

The Cleveland voucher program

In 1995, the Cleveland Municipal School District began. The program was initially intended to allow vouchers to be used at sectarian schools; however, court decisions immediately blocked this provision. Not until many years later were students allowed to choose among both sectarian and nonsectarian schools. In 2007, Cleveland's program served over 6000 students.

Cleveland's voucher program has not yielded clear answers about the program's impact on academic achievement. As in the Milwaukee program, the problem with the evaluations was whether the researchers used an adequate comparison group. The most often cited evaluation of the program (Metcalf *et al.*, 2003) compared the

Table 1 Summary of international research on vouchers

<i>Voucher site</i>	<i>Authors</i>	<i>Measures effects on</i>	<i>Identification strategy</i>	<i>Key results</i>
Milwaukee WI	Witte (1990)	Voucher users	Regressions with controls	No substantial effect
	Greene, Peterson, Jiangtao (1997, 1998)	Voucher users	Quasi-experimental design	Significant effects in both reading and math
	Rouse (1998)	Voucher users	Quasi-experimental design with covariate controls	Significant effects in math only and the effects grew over time
Cleveland OH	Metcalfe (2003)	Voucher users	Observational with covariate controls	No effect
	Belfield (2006)	Voucher users	Quasi-experimental design with covariate controls	Little effect from the voucher program
Privately financed voucher programs (Children's Scholarship Fund)	Mayer <i>et al.</i> (2002), Howell and Peterson (2002)	Voucher users	Randomization of vouchers with baseline controls	Positive effects primarily among black students
	Kruger and Zhu (2004)	Voucher users	Randomization of Vouchers	No effect for any set of students, including black students
	Bettinger and Slonim (2006)	Voucher users	Randomization of vouchers	Little effects of the voucher program on student test scores; increased altruism among voucher recipients
Colombia	Angrist, Bettinger, Bloom, Kremer, and King (2002)	Voucher users	Randomization of vouchers	Positive effects on school years completed and tests
	Angrist, Bettinger, and Kremer (2006)	Voucher users	Randomization of vouchers	Positive effects on high school graduation
	Bettinger, Kremer, and Saavedra (2006)	Voucher users at vocational schools	Randomization of vouchers	Positive effects on high school graduation
Chile	Gallego (2005)	Overall system	Instrumental variable for voucher presence	System-wide increase in test scores
	Mizala and Romaguera (1998)	Voucher users	Regressions with controls	No effects on users
	Sappelli and Vial (2002)	Voucher users	Heckman selection model	Positive effects
	Rounds (1996)			
	Hsieh and Urquiola (2003)	Overall system	Regressions with controls; aggregation	No system-wide increase in test scores
	Bravo, Contreras, and Sanhueza (2000)	Voucher users	Regressions with controls	No effects on users; effects depend on controls
	McEwan (2001)	Voucher users	Regressions with controls	No effects at most voucher schools
	McEwan and Carnoy (2000)	Voucher users	Regressions with controls	Mixed effects but private schools more cost effective
	Tokman (2001)	Voucher users	Regressions with controls	Mixed effects depending on student background

academic achievement of voucher users to two groups of students: (1) students offered vouchers who did not use the vouchers, and (2) a matched set of students who were not offered vouchers. Other researchers, including Gill *et al.* (2001), argued that the study failed to create an adequate control for students self-selecting into the program. Belfield (2006) used a different comparison group focusing on applicants who were rejected in their application to private schools. Overall, he finds little effect on academic achievement.

Another key motivation for establishing the voucher programs was to improve students' access to better schools. Kim Metcalf (1999) found that the program successfully targeted minorities and students from low-income families. The mean income level of students utilizing the vouchers was US\$18 750 and these students were more likely to be African-American students than a random sample of Cleveland students. As in Milwaukee, parents of voucher applicants had slightly higher levels of education (Metcalf, 1999; Peterson *et al.*, 1999).

Other publicly funded voucher programs

Voucher programs are also in place in Vermont, Maine, Florida, and Washington, DC. Of these programs, only DC's Opportunity Scholarship program has any publicly released results, which are only the first-year impacts. The Institute of Education Sciences-funded evaluation of Washington's program is using a randomized design to evaluate the effectiveness of the program. To date, the results suggests that parents are more satisfied with the program, but students utilizing the vouchers do not report higher levels of satisfaction or feeling safer. In addition, test scores for these students are on par with nonvoucher students (Wolf *et al.*, 2007). However, caution is warranted in interpreting these results as they are noted only after the first year of implementing the voucher program.

Domestic, Privately Funded Programs

Roman Catholic dioceses have provided scholarships to students to attend their schools for years. The use of philanthropists and foundation money for private school scholarships was first popularized by J. Patrick Rooney, who formed the Educational Choice Charitable Trust in 1991. This trust allocated private scholarships to low-income students to use at private schools in Indianapolis. Other programs in Milwaukee, Atlanta, Denver, Detroit, Oklahoma City, and Washington, DC, soon followed.

Some of the programs were established and financed by conservatives who wanted to either open up sectarian school options to more students or to create competition between private and public schools. Other programs (e.g., Oklahoma City) were funded by liberal voucher proponents who wanted to provide additional schooling opportunities for inner-city students.

In 1994, the Walton Family Foundation helped create the Children's Educational Opportunity Foundation (CEO America) to support and create private scholarship programs. Shortly thereafter, the number of privately funded programs quickly expanded across the country. Of these programs, one of the most ambitious was a CEO America program in San Antonio funded at US\$5 million a year for at least 10 years. The program provided full scholarships to over 14 000 at-risk students making it the largest privately funded voucher program in existence at the time.

In 1998, the Walton Family Foundation helped create the Children's Scholarship Fund (CSF). CSF partnered with local funders to provide scholarships in cities across the nation. In April 1999, 1.25 million low-income students applied for 40 000 partial scholarships. Over the last decade, more and more of the programs developed, often receiving very little national attention, making it difficult to know exactly how many of the programs currently exist.

Of these programs, CSF has received the most national attention partially because of its relatively large scale and partially because CSF used randomization to assign scholarships. With randomization, researchers can compare students who participated in the lotteries to determine the effectiveness of these programs. (Zimmer and Bettinger (2007) discuss some of the challenges in these studies.) Other studies have been carried out in Charlotte, Dayton, New York, and Washington, DC among other locations. While Greene (2000) found a positive overall effect on test scores in Charlotte after 1 year, these studies have generally shown no effect. The one exception is among African-American students. Howell and Peterson (2002) and Myer *et al.* (2002) found that African-American students' test scores improved in New York's program. However, additional research by Krueger and Zhu (2002) showed that this research was sensitive to the definition of an African-American student. While the original analysis used the student's mother's identified race for the student's race, Krueger and Zhu define African-American students as those whose mother or father are identified as African-American. This more inclusive definition results in a scholarship effect size that is smaller than reported in the original study and is not statistically significant.

In a more recent study, Bettinger and Slonim (2006) focus on the effects of vouchers on nonacademic outcomes. Using surveys and new methods from experimental economics, they attempted to measure the effects of the vouchers on traditional outcomes such as test scores and on altruism. To test the effects of the voucher program on altruism, Bettinger and Slonim gave students US\$10 each and invited them to share some of their money with charities. In this context, they show that voucher recipients gave more to charities as a result of the voucher program.

Given that these programs were designed to target impoverished students, it is not surprising to find that

participants have relatively low income. Peterson (1998), for example, found that the average income level of families of students participating in the New York scholarship program was only US\$10 000. The parents' education level of the participants, however, was slightly higher than the average level of the eligible population. Similarly, Howell and Peterson (2000) and Wolf *et al.* (2000) found that the families of participating students were low income. In terms of race, 100% of students participating in the Washington, DC scholarship program were minorities, while 95% of the students in New York were minority, mostly Hispanic students. In Dayton, the percentage of minorities was lower but was still 66%.

Finally, these private voucher programs typically serve a low percentage of special education students. For example, in New York, 9% of participating students have disabilities compared to the district-wide average of 14% of special education students (Myers *et al.*, 2000). In Charlotte, 4% of participating students had disabilities, while the district-wide average of special education students was 11% (Greene, 2000).

International Voucher Programs

There are a number of educational voucher or voucher-like programs across the world, including programs in Chile, Colombia, Sweden, Netherlands, Belize, Japan, Canada, and Poland. These voucher programs often differ significantly from the US programs either in terms of the motivating factors or the policy context. For example, many of the non-US programs are motivated by the goal of increasing school attendance among girls or low-income students. The relationship between church-sponsored private schools and public schools is also less defined in other countries where, in many cases, religious groups operate public schools.

We focus our attention on two programs that have figured most prominently in debates on the efficacy of vouchers – Colombia's *Programa de Ampliación de Cobertura de la Educación Secundaria* (PACES) voucher program and Chile's national voucher program.

Colombia PACES Program

The PACES offered educational vouchers to over 144 000 low-income students throughout Colombia from 1992 to 1997. The voucher program awarded full private school tuition to secondary school students who wished to transfer from public to private school at the start of their secondary school. Over time, the voucher's value did not keep up with the cost of inflation.

In contrast to the US programs, the motivation for Colombia's voucher program was to expand the capacity of the public school system. In Colombia, most high

school buildings host multiple high school sessions per day. Since most private schools were not overcrowded, Colombia established the voucher program to take advantage of excess capacity in the private system.

In cities where PACES was oversubscribed, cities held lotteries to award the vouchers. Angrist *et al.* (2002) use this randomization to measure the effects of the program. They find that within 3 years, voucher students had completed about 0.1 years of schools more than their peers and had test scores about 0.2 standard deviations higher than those who did not receive vouchers. They also find that the incidence of child labor and teenage marriage was lower as a result of the educational voucher. Based on follow-up research on students' high school careers, Angrist *et al.* (2006) find that voucher lottery winners were 20% more likely to graduate from high school than voucher lottery losers.

In Colombia, the evidence on the impacts of stratification is less developed and conclusive than the effects on achievement. Colombia's educational vouchers targeted low-income families living in the poorest neighborhoods, and Ribero and Tenjo (1997) report that the vouchers were largely effective in reaching this population. Voucher applicants generally came from families with higher educational levels than other families in the same neighborhoods (Angrist *et al.*, 2002).

Chile

In 1980, Chile embarked on an ambitious series of educational reforms designed to decentralize and privatize education. At the urging of Milton Friedman, who along with other prominent economists advised the Pinochet government at the time (Rounds, 1996), Chile established perhaps the world's largest ongoing voucher program. The program offered tuition subsidies to private schools. Before the reform, the budgets of public schools were insensitive to enrolment; however, after the reform, local public schools lost money when students transferred to voucher schools.

Unlike Colombia, where vouchers targeted poor students, the Chilean system was available to all students. Additionally, unlike other programs that do not allow selective admission, voucher schools in Chile could admit the students they most preferred. As a result of these policies, Rounds (1996) found that the poorest families were less likely to attend voucher schools.

Research on the efficacy of Chile's voucher program has been much more difficult to interpret than the Colombian research because of the nature of this admission policy. Some of the early evidence suggested that voucher schools modestly outperformed public schools. This finding was common in many papers (e.g., Bravo *et al.*, 1999; McEwan and Carnoy, 2000) but was sensitive to the types of controls included in the empirical model,

the specific municipalities included in the sample, and the statistical methods used. McEwan (2001), for example, found that Catholic voucher schools tended to be more effective and productive than other schools, but only for certain specifications of the model. McEwan and Carnoy (2000) show that academic achievement is slightly lower in nonreligious voucher schools, particularly when located outside the capital. Given that these voucher schools have less funding, however, McEwan and Carnoy suggest that they could still be more cost effective than public schools.

As research on the Chilean system continued, many researchers took note of the fact that the voucher program altered the composition of both public and private schools. For example, Hsieh and Urquiola (2003) showed that more affluent families took advantage of the vouchers. Similar to McEwan and Carnoy (2000) and Carnoy (2000), Hsieh and Urquiola suggest that this shift in student populations could account for the finding that private schools appear to be more effective than public schools. In the early 1990s, many voucher schools began charging tuition in addition to the voucher, and the difference in parents' incomes and education levels between these tuition-charging voucher schools and the other voucher schools was significant (Anand *et al.*, 2006).

How this increased sorting across voucher and non-voucher schools affects student achievement depends on the nature of peer effects. If improvements in peer quality lead to better educational outcomes for voucher users, then the sorting associated with the voucher program could improve their outcomes. At the same time, given the exit of high-quality students from the public schools, the students left in those schools may have systematically worse outcomes because of the deterioration of their peers. The aggregate effect of the voucher depends on the strength of these two effects.

Hsieh and Urquiola (2003) argue that the only way to identify the overall effects of the voucher program is to focus on aggregate outcomes because it is difficult, if not impossible, to remove the selection bias inherent in comparisons of different schools. The change in aggregate test scores reflects both the direct achievement effects for voucher recipients and the indirect effects for students who remain in public schools. When the authors look at changes in aggregate test scores throughout Chile, they find no evidence that the voucher program increased overall test scores.

Gallego (2005) provides other evidence on the Chilean voucher program. Gallego uses an instrumental variable approach to estimate the effects of the program. His findings suggest positive effects of the voucher program on the academic outcomes of students throughout municipalities where the voucher program had more penetration. While the result may be indicative of competitive effects, it is driven in part by the effects of the program on

voucher recipients. It echoes earlier research (McEwan, 2001; McEwan and Carnoy, 2000) which suggested that voucher schools affiliated with Catholicism had better outcomes than other voucher schools, public or private. As McEwan and Carnoy (2000) show, Catholic schools produced better students at a lower cost than other, public or private, voucher schools.

Summary and Conclusion

Table 1 summarizes the achievement findings from both domestic and international voucher programs. The table highlights the location, program, methods used in the analysis, and their key findings.

Research on domestic voucher programs has produced inconsistent results. While advocates have often pointed to positive effects for African-American students in the CSF program as proof that vouchers can work, the strength of these findings has been questioned – leaving many skeptical about the purported benefits of vouchers. International studies have also found mixed results. The evidence from Colombia indicates that voucher users have better academic and nonacademic outcomes than they would have in the absence of the voucher. In Chile, the estimated effects differ across studies, and a number of confounding factors make it difficult to ascertain the true effects. The research generally shows that students who take advantage of vouchers are disadvantaged students, especially in voucher programs that are means tested and specifically target such students.

To date, most of the voucher studies focus on programs that are typically small in scale. Hence, it is not clear whether the results generalize to large-scale programs. For a program with massive movements of students, an important policy consideration is not only who is participating in these programs, but what happens to the racial/ethnic and ability distribution of students in public schools.

In sum, researchers have failed to come to consensus on the efficacy of vouchers as a reform effort. This murkiness may be clarified as new studies emerge, including studies of the current Milwaukee program and the federally funded Washington DC vouchers.

Future research needs to peer inside the black box and to examine the mechanism in which outcomes differ among schools. Voucher researchers should take the opportunity to look at private schools that may be doing things differently and how the variation in the operation affects outcomes. Additionally, future research can shed additional light on the effects of vouchers on other critical outcomes such as individual behaviors, educational attainment as measured by college attendance, and wages.

It is also interesting to consider the value of vouchers programs relative to other forms of choice. When the idea

of vouchers were first introduced, the only choices a family could make was sending their students to private schools without subsidies or choosing among various public schools based on residential location. However, over the last 50 years, a number of other alternatives have evolved including charter schools, magnet schools, and other inter- and intra-district choice programs. A relevant policy question has to do with the advantages and disadvantages of voucher programs relative to these other choice options, especially when many of these choice options are politically more feasible.

Tiebout Sorting and Competition

T J Nechyba, Duke University, Durham, NC, USA; National Bureau of Economic Research, Cambridge, MA, USA

Over 50 years ago, Charles Tiebout hypothesized that decentralized provision of public services (such as public schools) through local governments can result in efficient levels of such services (Tiebout, 1956). His key insight was that residential mobility of households might provide a disciplining force analogous to typical market forces under perfect competition in private goods markets. Local communities are viewed as analogous to competing shopping malls that offer different services – competing with one another while, at the same time, appealing to somewhat different clienteles. By considering the mix of local taxes and public services much as they consider the mix of services and goods at malls, households in effect vote with their feet, choosing communities (much like malls) that best meet their needs while making it difficult for local governments (much like mall owners) to engage in excessive rent-seeking.

Such Tiebout competition has three essential features. First, when households demand different mixes for public services, decentralization permits the emergence of different packages of such services (and taxes) across communities, providing opportunities for households to match to communities that are optimal from their perspective. Second, the resulting competition between communities for residents reduces the scope for local governments to focus on inefficient behavior that is not aimed directly at meeting the needs of their customers. It was hypothesized by Tiebout that this results in sorting of households across communities, with competition between communities providing a sufficient array of choices to satisfy different household needs in a productively efficient manner. At the same time, however, demand is determined in part by ability to pay – which implies a third feature of such Tiebout competition: sorting will occur at least in part on the basis of household income.

Over the past half century, it has become clear that Tiebout's insights have considerable empirical support. In the area of public education, however, it is far from clear that the results from Tiebout competition are as unambiguously desirable as might have been originally assumed. This is in large part due to the nature of education production that involves financial and non-financial scarce resources which are rationed through the same Tiebout forces that cause households to sort across communities. While such sorting indeed occurs along the lines suggested by Tiebout, much of it is related to household income and race – and this implies a public school system in which public school quality invariably becomes highly correlated

with these household characteristics even when higher-level governments equalize financial resources available to local public schools. The equity concerns that arise from residential Tiebout segregation (and the resulting sorting of nonfinancial inputs into schools) may then need to be balanced with any efficiency gains from sorting and from competitive pressures on school producers.

The following sections are discussed below. First, in the section titled 'Residential mobility, capitalization, and household preferences for education', we review the empirical literature that has validated important aspects of Tiebout's hypothesis while cautioning that this evidence implies that efficiency in education markets is not fully obtained through the type of competition envisioned by Tiebout. Second, in the section titled 'Tiebout sorting and the rationing of school inputs', we turn to the equity concerns that arise from the types of sorting that result from Tiebout competition. Third, we turn to a brief review of the portion of Tiebout's theory that relates to productive efficiency from residential competition (in the section titled 'Tiebout competition to enhance productive efficiency'). Finally, in the section titled 'A partial divorce between competition and Tiebout', we explore the various ways in which recent policy reforms introduce other forms of school competition alongside the type of competition envisioned by Tiebout.

Residential Mobility, Capitalization, and Household Preferences for Education

The earliest empirical tests of the Tiebout hypothesis (that decentralized provision results in efficiency) were, in many ways, only tests of the underlying Tiebout assumption of residential mobility. These tests, beginning with Oates (1969), took the form of tests for the extent to which inter-jurisdictional differences in local service and tax levels are captured in house prices. When higher service levels and lower taxes are accompanied by higher house prices – and when lower service levels and higher taxes are accompanied by lower house prices, economists refer to this as capitalization of service and tax levels. The only mechanism that would give rise to such capitalization is precisely the one that arises from Tiebout's assumption of residential mobility. If households indeed consider local service and tax levels as they determine their optimal residential location, it was argued, then identical houses in different jurisdictions will be priced differently depending on the differences in

these jurisdictional variables. At the same time, as was first pointed out by Edel and Sclar (1973) in a response to Oates, the presence of such capitalization can be interpreted as evidence against Tiebout's larger efficiency hypothesis. This is because capitalization of public service and tax levels suggests there is room in the market for additional communities to form – with increased supply of housing attached to such service/tax levels driving down capitalization as new communities emerge to meet demand. The presence of capitalization therefore suggests that there exist barriers to the emergence of such new communities – but a central feature assumed by Tiebout for his efficiency result was that such barriers do not play a significant role. A more careful theoretical exploration of capitalization under Tiebout competition, reviewed in more detail by Epple and Nechyba (2004), then clarified some of the initial confusion over the relationship between empirical findings of capitalization and the validity of the larger Tiebout hypothesis.

The empirical literature on capitalization of local services, and of school quality in particular, is substantial and has increased in sophistication since Oates' original publication. Black (1999) introduced a particularly useful innovation by considering housing price differences immediately around district boundaries rather than comparing housing across districts more generally – thus limiting the analysis to houses that arguably differ primarily in terms of the access they provide to local schools. This boundary discontinuity research design has since been generalized in more complete (or structural) models that attempt to directly estimate household tastes for school and neighborhood characteristics rather than merely identifying the magnitude of capitalization into housing prices (Bayer *et al.*, 2007). Although magnitudes differ, the qualitative finding of capitalization effects has been robust across all research designs. More importantly, however, the most recent literature directly confirms the importance of strong household tastes for both schools and neighbors, a result that has important implications for Tiebout sorting of households across communities when access to public schools is based on household residence.

Tiebout Sorting and the Rationing of School Inputs

Equity concerns that arise from Tiebout sorting are then closely linked to an understanding of the mechanism that gives rise to school quality. If financial inputs, such as per pupil spending, which, in turn, is closely linked to teacher–student ratios, fully characterized the education production process, such concerns could easily be addressed through higher-level government redistribution of financial resources. In many ways, this was precisely the focus of policy for a number of decades,

following a wave of state court decisions that found excessively decentralized public school funding mechanisms to violate the equal protection clauses in state constitutions. Beginning with the famous California Serrano decisions in California in the 1970s, states have responded with a variety of interventions ranging from mandating essentially equal per pupil spending across all districts to different state aid formulae that assist poorer districts in increasing per pupil spending levels. It is now well understood, however, that there is a limit to the extent to which such policies can address the inequities in a Tiebout-based system of public education. The reason for this is that financial inputs represent only one category of inputs essential for public school quality, with a number of different nonfinancial inputs playing a significantly more important role.

These nonfinancial inputs have often been modeled as peer effects. Researchers begin with the assumption that students have some innate ability level, and a given student's performance is dependent on the ability levels of students who attend the same school or class. When such ability levels are correlated with household income, the residential Tiebout sorting of households then implies a nonrandom sorting of ability levels into schools – with higher-income schools disproportionately benefiting from the nonfinancial input of good peer effects. This, in turn, implies that equalization of financial inputs cannot be expected to equalize educational quality so long as such nonfinancial inputs are sorted through Tiebout competition.

More generally, the same applies to other nonfinancial inputs that can be modeled in ways similar to such peer effects. For instance, teacher quality, long recognized as both an important input into school production and largely uncorrelated with measurable characteristics of teachers, is similarly allocated across schools in nonrandom ways – especially in systems that do not permit differential pricing of teacher salaries. In particular, when high-quality teachers cannot be adequately compensated through salary differentiation, they either leave the teaching profession or are compensated through assignments to more desirable schools in higher-income districts (Loeb and Page, 2001). This mechanism then gives rise to a differential sorting of teachers that is correlated with the residential sorting of higher-income households. It is similarly recognized that parents themselves are an important input into school production – both because of the home production of education (that results in different levels of child ability) and because of the role they play in monitoring schools. Both these features of parental inputs into education are similarly correlated with parental income – once again implying a differential allocation of nonfinancial inputs that arises from residential Tiebout sorting.

When incorporated explicitly into Tiebout models of residential location choices, this understanding of school production as emerging from both financial and

nonfinancial inputs has given rise to empirically grounded simulation models that can be used to investigate the potential for policy to address equity concerns from Tiebout sorting. Such models begin with a characterization of the underlying housing market within and across jurisdictional boundaries. (While early attempts modeled housing as differing primarily or solely between jurisdictions, it has been documented that housing quality varies both within and across districts – which, in turn, has led to different approaches for introducing within-jurisdiction differences in housing quality. In some such approaches, these differences emerge from the fact that households differ in terms of the relative weight they place on housing quality and school quality (Epple and Sieg, 1999). Alternatively, the distribution of housing quality can be modeled as historically determined within and across districts, with housing prices adjusting to equilibrate supply and demand at each location (Nechyba, 2000). These approaches are discussed in greater detail in Epple and Nechyba (2004) and Nechyba (2006).) School production is then introduced as a function of both financial and nonfinancial inputs, with the latter assumed to be correlated with aspects of the income distribution of the households whose children attend local public schools. Such Tiebout models that combine housing markets with realistic school production processes allow researchers to understand the emergence of school inputs from residential location choices that, in turn, are linked to housing markets. Nonfinancial inputs emerge from the residential sorting patterns that result from households voting with their feet, and financial inputs emerge both through a political process in which households vote in the more traditional sense and from the determination of local tax bases that is driven by supply and demand in housing markets.

The complexity of such theoretical models then precludes an analysis that is purely analytic – there are simply too many competing forces that depend on the underlying primitives in the models. These primitives include the characteristics of housing markets and the nature of jurisdictional boundaries, the relative weight that school production functions place on financial and nonfinancial inputs, the underlying income distribution and the parameters that characterize household tastes for consumption, schooling, and housing quality. It therefore becomes necessary to find ways of allowing data to inform these underlying primitives – in essence, to convert a rich theoretical model into one that is empirically grounded to the extent that it can replicate important features of local education and housing markets. Initial attempts relied heavily on the calibration of these primitives while more recent attempts rely on statistical and econometric estimation of underlying parameters of the models.

A series of papers emerging from Nechyba (2000), reviewed in greater detail by Epple and Nechyba (2004) and Nechyba (2006), relied solely on calibration techniques

to give rise to computational models that could replicate the salient features of local school and housing markets while providing a platform for simulating alternative policy regimes. Several insights have emerged from such simulations. First, while they suggest that the move toward less reliance on local sources of funding for public schools has resulted in a narrowing of education quality differences under Tiebout competition, they also provide evidence that substantial inequities persist precisely because of the rationing of nonfinancial resources that emerges from Tiebout sorting across housing markets. This sorting appears to be largely immune to state-level differences in school finance policy. Second, by introducing private school markets that do not explicitly rely on Tiebout sorting in admitting students, the simulations suggest that the decoupling of residential location from school choices has profound impacts on residential location patterns and that Tiebout sorting across public schools cannot be analyzed fully without taking the impact of private school markets into account. This becomes particularly important in the light of increasing efforts to decouple location from schooling within the public sector through nontraditional public schools (such as charter schools) and through explicit formulations of public school choice policies in many cities. Third, simulations of different types of private school competition – ranging from horizontal competition through targeted curricula to vertical competition through cream skimming of the best students from the public system – suggest that the systemic effect of new innovations on public school quality within a framework of residential Tiebout sorting differs widely depending on the precise nature of the competitive forces unleashed through such innovations.

Alongside this emergence of calibrated Tiebout models of education markets, recent attempts have focused on developing new methodologies for using econometric techniques to estimate (rather than calibrate) an increasingly rich set of underlying theoretical models. Three different strains have emerged in this new literature. First, Ferreyra (2007) builds an estimation framework directly on the Nechyba (2000) model while introducing explicit channels for horizontal differentiation of schools. Second, Epple and Sieg (1999) estimate an alternative framework based on the theoretical model of Epple and Platt (1998) that assumes the housing stock within and across jurisdictions adjusts more quickly to changing circumstances. Finally, Bayer and McMillan (2006) develop a more flexible and computationally tractable approach grounded in methodological innovations from industrial organization and focus more directly on the link between household income and race in Tiebout sorting.

Each of these empirical methodologies has provided independent evidence for the importance of Tiebout's insights that households indeed vote with their feet within local economies while uncovering ways in which this leads

to complex patterns of residential sorting which, in turn, forms the basis for admission to traditional public schools. Ferreyra's approach again highlights both the limits of traditional school finance policies as well as the potential role for policy to inhibit or foster horizontal competition through policy innovations that introduce non-residence-based competition. Bayer and McMillan have demonstrated that the inclusion of race into Tiebout models of residential and school choice adds an important and previously neglected level of complexity. Not only does ability to pay determine residential sorting patterns, but race also is independently important as members of different racial groups exhibit a desire to live in communities in which their racial group is represented. For middle-income black households, in particular, this results in a difficult set of trade-offs in many cities – with better public schools located in primarily non-black communities and large representations of black households primarily located in communities with poor public schools.

Tiebout Competition to Enhance Productive Efficiency

The literature highlighted previously has concentrated on sorting patterns that emerge from Tiebout competition linked to education markets. As such, it has focused heavily on the first of the two primary features of Tiebout competition – the sorting of households as households match with communities. At the same time, this literature has remained largely disconnected from the second primary feature of Tiebout competition – the potential for a disciplining market-like force that restrains rent-seeking and thus enhances efficiency. This force has been most notably highlighted by Hoxby (2000) who finds that increased public school competition (as represented by a higher concentration of local school districts within an education market) leads to lower costs and better educational outcomes. While the result has not been uncontroversial, it relates directly to one of the central arguments in favor of decentralized provision of public schooling envisioned by Tiebout.

The empirical question is whether allocating nonfinancial inputs that are linked to households is in essence a zero-sum game or whether more competitive mechanisms for achieving such an allocation result in more efficient production of school quality. Simulations emerging from the Nechyba (2000) model suggest that, if such competitive forces are sufficiently strong, the introduction of more competition through nontraditional school markets can in principle overcome equity concerns that emerge from increased vertical sorting across schools, but that – in the absence of sufficient efficiency gains, the reverse would hold as competition leads to lower nonfinancial inputs in some public schools. In other words, sufficiently strong disciplining forces through competition can give rise to

school reforms that result in a positive sum game, but whether they do depends ultimately on the nature of such reforms and the degree to which such forces are empirically important. Most recently, Bayer and McMillan (2005) provide evidence in favor of strong competitive effects among public schools within a framework that builds on the structural estimation techniques that have come to be prominent in the empirical Tiebout competition literature.

A Partial Divorce between Competition and Tiebout

When confined to the traditional Tiebout setting in which residential location patterns directly determine the allocation of students (and thus the distribution of nonfinancial inputs) into public schools, an inherent tension therefore emerges between the equity concerns from income- (and race)-based rationing of nonfinancial inputs and the potential for productive efficiency gains from decentralized competition. A major thrust in school finance policy over the past decade, however, introduces an added element that emerges from deliberate attempts on the part of policymakers to partially disconnect residential location choices from school assignments. Such policies, whether they take the form of non-residence-based public school competition or increased private school activity subsidized through some form of school voucher, essentially introduce new channels of competition that operate alongside the traditional Tiebout competition through housing markets. The challenge for researchers and policymakers alike lies in identifying potential channels through which such new forces can operate alongside traditional forces to address both efficiency and equity concerns that emerge under Tiebout competition.

The nature of the underlying issue can be put into focus by considering explicitly how different policies would ration access to the scarce resource of seats within good schools. In the traditional Tiebout mechanism, such rationing occurs solely through housing markets that indirectly price access to schools in the public sector. In traditional private schools, on the other hand, this rationing arises both from explicit tuition pricing and from admissions policies defined by them. As greater non-residence-based choice is introduced into the public sector, neither the implicit pricing through housing markets nor the explicit pricing through tuition levels is available as such public-choice schools explicitly reject residential location as a main determinant for admission while at the same time being constrained to offer seats for free to those who are admitted. This has resulted in some role for lotteries to determine allocations of students to public choice schools when such schools are oversubscribed. In charter schools, such lotteries are simply designed for each school independently, but an increasing number of cities and school districts have turned

toward a greater role for lotteries in their assignment mechanisms for all public schools – both those that emerge from the traditional Tiebout-based system and those that have formed more recently as charter schools.

Such districts typically do not rely solely on lotteries to determine where children are assigned. Rather, a Tiebout element is retained as walk-zones are defined around public schools – with households that reside within these zones given preference. Similarly, preference is typically given to siblings of children who are already enrolled in a particular school. Households provide school districts with rankings for schools to indicate their preferences, and assignments then proceed with both these rankings and the priority classes in mind. The resulting assignment mechanisms are therefore structured in tiers that define priority classes, with ties within classes broken through lotteries. Early incarnations of such mechanisms, however, had the unfortunate feature that they were not what economists call strategy proof in that they contained incentives for households to misrepresent their true preferences in attempts to alter the outcomes. For instance, households might not rank their most-preferred school if they viewed their chance of being assigned to that school as low, choosing instead to list less-preferred schools to which they were more likely to be assigned.

Economists have played an important role in refining these assignment mechanisms in large urban districts as such districts move toward increasing non-Tiebout choice within their public systems. In particular, strategy-proof mechanisms built on the same common priority classes have been developed and implemented, with such mechanisms designed to remove the incentives for households to strategically misrepresent their true preferences (Abdulkadiroglu and Sönmez, 2003). Such mechanisms can now be viewed as filling in the gap between the extremes of relying solely on Tiebout competition or relying solely on lotteries. They also provide potential opportunities for the public and private school systems to partially merge into a single system if public funding is extended to private schools to the extent to which private schools accept student assignments through the same mechanism (thereby foregoing the ability to explicitly cream skim students from public schools).

The challenge of such attempts to foster nontraditional channels of competition within an environment of Tiebout competition lies in finding ways of minimizing the undesirable features of competition from vertical sorting (or cream skimming) while maximizing the desirable features from horizontal sorting and from gains in productive efficiency. As the literature that we have reviewed illustrates, vertical sorting emerges naturally under Tiebout competition as ability to pay determines where households will locate in equilibrium and where the nonfinancial inputs that accompany households are located. Such vertical sorting plays a similar role in private schools that

rely on tuition pricing to ration access, with explicit attempts by private schools to cream-skin the best students from public schools reinforcing such sorting further. The introduction of nontraditional competition through mechanisms that reduce the role of residential location in school assignments reduces the vertical sorting that emerges in Tiebout-based school assignments, and, to the extent to which private schools are included in such assignment mechanisms in exchange for public funding, such vertical sorting into private schools is similarly ameliorated. At the same time, such new forms of competition open the door to more desirable channels of competition – that is, those that provide incentives for schools to compete by targeting students through pedagogical or curricula innovations and those that reward productive efficiency.

Conclusion

A rich literature on Tiebout competition in education markets has moved increasingly in the direction of developing empirical computational models that, in turn, have shed light on both the positive and negative aspects of a system that relies on residential location as the primary vehicle for assigning students to public schools. By incorporating nontraditional schools into the analysis, researchers have demonstrated alternative channels of school competition that can play a role within local economies in which Tiebout forces that are closely linked to household income and race play an important role. The challenge for researchers now emerges directly from new policy innovations that emphasize new channels through which competition operates. While the current literature offers hints as to how the resulting competitive forces might change the availability and distribution of educational opportunities, a new generation of models that explicitly analyzes different versions of such policies within the context of Tiebout competition will be needed for further progress to be made.

Supreme Court Decisions and Desegregation Methods

Beginning with the decision in *Brown*, states lost the power to separate blacks and whites into two entirely separate school systems, a power affirmed by the 1896 ruling in *Plessey v. Ferguson*. As Welch and Light (1987) and Lutz (2005) summarize, there have been a number of Supreme Court decisions following *Brown* that have shaped the rules governing the allocation of students into schools. The early post-*Brown* decisions expanded the powers of those seeking to desegregate the schools and substantially broadened the arrangements classified as illegal. However, the 1974 ruling in *Milliken v. Bradley* made it difficult to seek a remedy for segregation across districts, and the 1975 ruling in *Morgan v. Kerrigan* sanctioning magnet schools as a valid desegregation method weakened the ability of the courts to mandate the implementation of coercive desegregation plans. Finally, the 1991 and 1995 decisions that require districts merely to take all practical steps to end the legacy of segregation (*Board of Education of Oklahoma v. Dowell*) and not to hold districts responsible for low achievement (*Missouri v. Jenkins*) reveal a movement away from mandatory desegregation as a primary means to increase school quality, at least at the federal level.

The recent Connecticut State Supreme Court ruling *Sheff v. O'Neill* (1996) that requires Connecticut officials to desegregate the schools may signal a shift of the desegregation battle to state courts, similar to the legal battle

over school finance equity. If this comes to pass, the standards for desegregation will vary by state, just as do those for funding inequality.

Districts have used a number of techniques to desegregate schools depending upon the legal precedents in effect, severity of segregation, residential housing patterns, availability of alternative public schools, and the extent of community resistance. Circumstances sometimes necessitated the use of more than one technique, while in other cases, a simpler construct was adequate.

Desegregation techniques can be classified as voluntary or involuntary depending upon whether students are permitted to choose the school they will attend; the distinction does not reflect whether or not the courts required desegregation. Welch and Light (1987) divide plans into six categories, three voluntary and three nonvoluntary. The voluntary techniques include open enrolment, magnet, and other transfer programs, while the involuntary plans include neighborhood-attendance zones, rezoning, and pairing and clustering (combining two or more schools into a single-attendance zone in which all students attend early grades at one school and later grades at another).

Trends in School Enrolment Patterns: 1968–2000

This section uses office of civil rights public elementary and secondary school enrolment data to describe school-enrolment patterns for non-Hispanic blacks (see Rivkin

Table 1 Racial composition of public elementary and secondary schools, by region and the United States as a whole: 1968, 1980, 1988, and 2000 (percentages)

Region	Percent White				Percent Black				Percent other ^a			
	1968	1980	1988	2000	1968	1980	1988	2000	1968	1980	1988	2000
Northeast	84.4	78.3	75.8	67.5	11.5	13.6	12.4	15.3	4.1	8.1	11.8	17.2
North Central	87.9	83.8	83.6	76.6	10.6	12.5	11.4	14.7	1.5	3.7	5.0	8.7
South	70.1	65.9	63.7	56.3	25.3	25.4	25.3	26.4	4.6	8.7	11.0	17.3
West	78.2	67.1	62.6	50.2	6.3	6.7	5.7	6.5	15.5	26.2	31.7	43.3
National	79.9	73.3	70.7	61.4	14.8	16.1	15.2	17.1	5.3	10.6	14.1	21.5

^aResidual category including Hispanic, Asian, and Native American.

Table 2 Average percentage of blacks' schoolmates who are white by region: 1968–2000

Percent of schoolmates Who are white	Distribution of enrolment (percentage)			
	1968	1980	1988	2000
United States	22.3	36.2	36.2	31.1
Region				
Northeast	33.7	27.8	26.9	24.9
North Central	23.3	30.9	32.1	29.1
South	17.9	40.8	40.1	33.7
West	26.7	34.6	36.0	30.7

and Welch (2006) for a detailed description of these trends across the school proportion black distribution) and whites for the years 1968, 1980, 1988, and 2000 (see Welch and Light (1987) for a comprehensive description of the data). Three interrelated pieces of information characterize school enrolment patterns, and I document changes over time in all three: demographic composition, segregation, and interracial contact. Note that segregation refers to the extent to which students are mixed conditional on the overall demographic shares of the district, state or other geographic entity, and interracial contact refers to the share of schoolmates who are white. Notice that overall demographic composition and degree of segregation jointly determine the level of interracial contact. (The focus here is exclusively on the enrolment patterns of non-Hispanic blacks and whites because the nation's integration policies have focused on the segregation of blacks.).

Table 1 shows the demographic composition of public schools by region. Between 1968 and 1988 the decline in white enrolment nationally as a percentage of the total was roughly offset by increases for Hispanics and Asians, while between 1988 and 2000 the continued decline in the white enrolment share was offset by increases in both the black (15.2–17.1%) and the Hispanic and Asian (14.1–21.5%) enrolment shares.

There are regional differences and similarities in both the magnitude and timing of demographic change. The decline in the white enrolment share was smaller in the

north central region than in the rest of the country, particularly prior to 1988. On the other hand, all regions experienced their largest white enrolment share decline following 1988, driven in part by the very high rate of migration into the US from Asian, Latin American, and West Indian countries.

Although demographic changes tempered the effectiveness of desegregation efforts to raise black/white contact in the schools, **Table 2** documents the substantial increase following 1968 in the average percentage of blacks' schoolmates who are white (exposure index). The average percentage of blacks' schoolmates who are white, also known as the exposure index, equals $\sum_{i=1}^n B_i^* PW_i/B$, where B_i equals the number of blacks in school i , PW_i equals the proportion of white students in school i , and B equals the number of black students in the region or nation. Nationally, exposure to whites increased by more than 50% between 1968 and 1980, rising from 22.3% to 36.2%. Between 1980 and 1988, exposure remained relatively stable prior to declining by 5 percentage points between 1988 and 2000. For the nation as a whole, the decline in segregation between 1968 and 1988 swamped the loss of whites on a national level, while following 1988, the demographic changes reduced exposure to whites.

The subsequent rows reveal regional differences in the timing of school enrolment changes. The region with the highest average exposure to whites in 1968, the northeast, had already become the region with the lowest average exposure to whites by 1980, while the south went from being the region with the lowest exposure to the region with the highest exposure during this same period.

The contrast between changes in overall demographic composition and the average exposure to whites provides clear evidence of a decline in segregation, and the dissimilarity index is used to document changes in both school and district segregation. School segregation comes from race differences in both the distribution of students among districts and school attendance patterns, while aggregation of the data to the district level isolates race differences in the distribution of students among districts. This is a crude decomposition of overall school segregation into housing and school attendance policy

components, as private school enrolment and housing patterns within districts also affect segregation levels conditional on district enrolment policies. Yet, since the evidence suggests that private school enrolment changes have not had a substantial impact on segregation at the regional or national level, this decomposition does provide a sense of the importance of housing segregation in determining school enrolment patterns. (Rivkin and Welch (2006) provide information on private school enrolment.)

The school (district) index measures the degree to which the distribution of students among schools (districts) deviates from a distribution in which all schools (districts) have identical enrolment shares. The dissimilarity index varies from zero to one, with a value of one indicating complete segregation and a value of zero indicating complete integration. The magnitude of the index reflects the share of blacks (or whites) that would have to switch schools (districts) to achieve complete integration. (Formally, the dissimilarity index measuring school segregation between blacks and whites is defined as, $\sum t_s |p_s - p| / 2Tp(1 - p)$, where the subscript s indicates school, t_s is total enrolment in school s , p_s is the black share of enrolment in school s , p is the black enrolment share in the nation (or region), and T is total enrolment in the nation (or region).)

The left panel of the top row of **Table 3** shows that the school-level dissimilarity index for the US as a whole declined from 81.2 to 71.0 between 1968 and 1980, remained almost constant during the 1980s and declined to 66.7 between 1988 and 2000, but the remaining rows reveal substantial differences in the timing and magnitude of changes in segregation that match up with the observed differences in the changes in interracial contact. The south made by far the most headway against segregation during the 1970s but experienced little subsequent change throughout the distribution, while the desegregation gains in the north central region were smaller but steadier. The west also experienced a substantial segregation decline during the 1970s and additional gains during the 1980s and 1990s. Consistent with the decline in exposure to whites, the northeast experienced virtually no change in segregation through 1988 and a modest decline during the 1990s.

The right panel presents district segregation curves that show that the remaining segregation in 2000 resulted primarily from the allocation of students among districts. Even if all schools had achieved complete integration without changing the distribution of students among districts, the school-level dissimilarity index would have declined from only 76 to 74 in the northeast, 76.5 to 74.5 in the north central, 58.8 to 49.2 in the south, and 64.3 to 63.7 in the west. Clotfelter (1999) documents a similar degree of segregation using metropolitan area rather than district as the unit of analysis.

In each region, there was substantial segregation at the district level throughout the time period. Each experienced some degree of additional segregation by district during the active desegregation period of the 1970s, but they differ in the extent to which segregation lessened in the subsequent decades. The south in particular was notable for its lack of progress following 1980.

Desegregation and White Enrolment Decline

Table 4 describes major studies of enrolment shifts in response to school desegregation, beginning with Coleman *et al.* (1975). Although the exact methods varied, the predominant approach was to compare enrolment changes around the time of program implementation with those several years before and several years after, allowing for differential effects by a number of factors. The pattern of findings up to 1985 provides no consensus on the magnitude or persistence of white flight from school desegregation (see Rivkin and Welch (2006) for additional detail). Although most studies reported sizeable enrolment changes surrounding program implementation, these changes were often not related to program characteristics in the expected ways. Welch and Light (1987) set out to resolve these uncertainties through an analysis of 125 large districts. They compiled 16 years of data on enrolments and desegregation program status and examined in detail, the changes in white enrolment surrounding the implementation of 116 major plans during the period of study.

Table 3 School and district dissimilarity indexes by region: 1968–2000

	School				District			
	1968	1980	1988	2000	1968	1980	1988	2000
<i>School districts</i>								
Northeast	76.9	78.8	78.5	76.0	70.9	76.7	76.7	74.0
North Central	85.7	80.1	78.9	76.4	74.5	77.4	76.9	74.5
South	80.1	57.3	57.1	58.8	44.2	48.9	49.9	49.2
West	81.4	70.6	66.9	64.3	65.7	66.5	63.4	59.6
National	81.2	71.0	70.4	68.7	63.8	66.2	66.2	63.7

Table 4 Summary of selected research on white flight

Article	Findings
Coleman <i>et al.</i> (1975)	Plans reduced segregation but increased the white enrolment decline
Clotfelter (1976)	A higher nonwhite student population share increased growth of private school enrolment for whites
Taeuber and Wilson (1978)	No lasting desegregation effect on rate of white enrolment decline; schools not often cited as a primary reason for moving
Rossell (1978)	Significant implementation-year decline in white enrolment, but small or nonexistent longer term effects
Armor (1978)	Enrolment fell relative to its projection, dropping sharply following plan implementation and continuing to fall thereafter
Farley <i>et al.</i> (1980)	Confirmed findings of large contemporaneous white enrolment decline following plan implementation
Wilson (1985)	Enrolment response was short lived and did not depend upon the attributes of the desegregation program
Welch and Light (1987)	White enrolment dropped below trend when desegregation programs were introduced, and the effect appeared to persist; effect magnitudes varied with plan type and district characteristics
Rivkin (1994)	White enrolment declined substantially in virtually all large central city districts regardless of the scope of desegregation efforts
Reber (2003)	Desegregation plans had a significant effect on white enrolment, and the type of program and number of nearby school districts were important predictors of white response
Lutz (2005)	Dismissal of desegregation orders moderately reduced black exposure to whites and did not reverse white flight in the short term
Clotfelter <i>et al.</i> (2005)	Dismissal of desegregation orders increased segregation in southern districts with a lag

Welch and Light find that white enrolment also declined much more in the year of plan implementation, although in contrast to the change in segregation the average enrolment decline picked up the year prior to implementation and remained above the preplan level in the year following implementation. The higher enrolment losses in the years following implementation are consistent with national enrolment data showing that losses were greater during the late 1970s than in earlier periods. But the fact that enrolment losses are much greater during implementation provides strong evidence of the existence of an enrolment response to segregation, just as the timing of the changes in the dissimilarity index document desegregation's substantial effect on district attendance patterns.

Not surprisingly, the most comprehensive plans led to larger declines in segregation. Both before and after the Swann (1970) decision, stating that racially identifiable schools must cease to exist and sanctioning the use of district-wide busing plans that combined rezoning with pairing and clustering, produced the largest decline in the dissimilarity index. A second clear pattern emerging in the post-Swann period is that plans using pairing and clustering produced larger average changes in enrolment (prior to Swann there is no obvious pattern in enrolment changes, likely because this was a period of trend reversal in total white enrolment that varied geographically).

The finding that pairing and clustering leads to greater departures from trend than rezoning, magnets, and other voluntary plans reflects qualitative differences among the desegregation techniques. Not only is pairing and clustering mandatory, but it typically requires that students travel greater distances than under rezoning, the other mandatory program type. All in all, it is not surprising that the mandatory plan type that is most disruptive for

students produces the largest average changes in both segregation and white enrolment.

Welch and Light also investigate differences in the white enrolment response on the basis of region and district urban status in order to allow for different responses in the south and in countywide districts. Countywide districts are particularly interesting, because the districts typically include suburban areas where white students are concentrated. These geographically larger districts tend to raise both the cost of moving out of the district in terms of the additional commute time to work and average distance students must be bused to achieve a given amount of desegregation. Consequently, it is unclear *a priori* whether countywide districts should experience a larger white enrolment response to desegregation-plan implementation, though families in these districts do have an unambiguously greater incentive to switch to a private school if one is available. In fact, Welch and Light (1987) show that departures from trends in white enrolment tended to be smaller for the countywide districts than for the urban southern and nonsouthern districts despite the fact that the countywide districts experienced much larger average reductions in segregation.

The discontinuous nature of the white enrolment changes following the implementation of desegregation programs provides strong evidence of a causal link between desegregation and white enrolment declines. Nonetheless, the possibility remains that other factors could produce a similar pattern. As an alternative to the approach used by Welch *et al.* (1987), Reber (2003) uses differences in the timing of implementation for the same set of school districts to estimate white enrolment changes around the time of implementation. The panel data method essentially compares changes in school districts around the time of

implementation to the national average white enrolment changes over corresponding years. Her results confirm the findings in Welch *et al.* (1987). Moreover, she finds that white flight appeared to increase with the number of districts in a metropolitan area, supporting the notion that the higher relocation costs of geographically larger districts more than offset larger increases in school commute times in terms of the incentive to switch districts.

Importantly, desegregation-induced enrolment declines may appear quite large at the time of program implementation but may have very little impact over the long term given the widespread suburban migration. The evidence in Rivkin (1994) suggests that desegregation programs may not have been a primary contributor to white enrolment loss over the longer term. Between 1968 and 1988, the distribution of white enrolment loss in the 10 large urban districts that experienced the largest decline in segregation is quite similar to the distribution for the 10 large urban districts that experienced the smallest decline in segregation. This holds despite the fact that the 10 nonintegrating districts began with much lower white enrolment shares and thus lower potential losses. It appears that as the time horizon increased, the deviations from trend caused by the implementation of a desegregation plan diminished in importance, relative to persistent long-term influences.

The ubiquitous white enrolment decline in large urban districts across the country also imposes a severe limit on district efforts to expand interracial contact. Even if whites in the 2000s were to respond much more favorably to expanded desegregation programs than did whites in the 1970s, the low white enrolment share in virtually all large districts precludes sizable increases in exposure to whites. As the district and school-level segregation curves and measures highlighted in the previous section show, it is the sorting of families among communities rather than district attendance policies that limit the extent of interracial contact in the schools as long as the Milliken (1974) finding, that there can be no interdistrict relief without an interdistrict violation, remains the law of the land.

Moreover, given recent Supreme Court decisions lowering barriers to the dismissal of desegregation orders, a contraction of desegregation efforts is much more likely than an expansion. Lutz (2005) finds that the number of years since the dismissal of a court-ordered plan is positively related to the change in segregation, and this in turn has led to a modest reduction in black exposure to whites. Moreover, Lutz finds no immediate white enrolment response to the dismissal in the form of reverse white flight. The findings in Clotfelter *et al.* (2005) are consistent with those of Lutz, particularly in the sense that resegregation is not immediate but increases over time. In the context of overall changes during this period, this evidence suggests that the dismissal of desegregation orders offset other factors that were tending to reduce

segregation. It is important to recognize that longer term effects may differ and the responses in the affected districts may not be representative of all districts with court-ordered plans currently in place.

Desegregation Program Effects on Academic and Economic Outcomes

Despite the movement of large numbers of whites out of central city school districts, school desegregation succeeded in dramatically increasing black exposure to whites. Moreover, many programs reallocated students among schools, exposing blacks and whites to different teachers, facilities, and other factors thought to affect school quality. Supporters of desegregation expected these changes to improve the quality of education for blacks and reduce the racial gap in school quality and future economic and social outcomes. (See Rivkin and Welch (2006) for additional detail.)

There are also reasons to believe that student or school efforts to neutralize desegregation, longer commute distances, and other adverse side effects might limit or even eliminate the benefits of school desegregation. Clotfelter *et al.* (2003) find evidence of substantial within-school segregation in North Carolina junior high and high schools but not in elementary schools. Clotfelter (2002) also finds some racial differences in the distributions of blacks and whites across extracurricular activities, although these activities do provide a vehicle for interracial contact. Such resegregation within schools not only reduces interracial contact, it may also lessen the improvement in teacher and school quality actually experienced by blacks bused to a non-neighborhood school. (Rivkin (2000) finds that busing and other desegregation programs appear to weaken the link between the quality of education experienced by blacks and nonblacks in the same school.) Finally, evidence suggests that busing students out of their neighborhoods decreases parental participation (Edwards, 1993; Leake and Faltz, 1993).

Consequently, the question of whether desegregation benefited blacks must be answered empirically, and that answer likely depends on characteristics of both programs and students. This section describes existing research on racial composition and desegregation effects on achievement and other outcomes. It begins with a discussion of relevant methodological issues prior to summarizing the findings.

Methodological Issues

Families and various entities including local school districts and the courts combine to determine the allocation of students among schools and districts. This nonrandom grouping of students in districts and schools provides a formidable impediment to the identification of the

relationship between academic, social, and economic outcomes on the one hand and desegregation efforts and school racial composition on the other. Manski (1993), Moffitt (2002), and others consider these issues in the more general context of the estimation of peer effects; here the focus is on those specific methods used in the study of racial composition and desegregation.

Equation [1] models outcome O for student i in grade G in school s as a function of family, desegregation program status, and peer influences:

$$O_{iGs} = X_{iGs}\beta + D_{Gs}\gamma + \bar{P}_{(-i)Gs}\lambda + D_G\bar{P}\theta + e_{iGs} \quad [1]$$

where D is an indicator variable for desegregation program status (or a vector of indicators for program type), \bar{P} is peer quality measured by average characteristics of schoolmates (individual i is omitted from the calculation); X is a vector of family background variables; and e is the error term. Note that the effects of peer composition are permitted to vary by desegregation program status.

The identification of γ and λ is complicated by the nonrandom sorting of children into schools and classrooms and the cumulative nature of schooling. Any correlation between \bar{P} and D on the one hand and current or past unobserved factors that affect outcomes on the other leads to biased estimates of γ and λ . Failure to account for the dynamic character of the learning process can also introduce bias and complicate the interpretation of the estimated effects. (Rivkin (2005) examines the identifying assumptions regarding the depreciation of knowledge for a number of education-production function specifications.) A number

of different methods have been used to identify desegregation program and racial composition effects including random-assignment experiments, ordinary least squares regression, value-added models, and panel data techniques.

A separate issue from identification is the relevance of the results for education policy. Most desegregation programs were implemented around 1970, and much of the research on desegregation effects on achievement comes from that period. Not only have demographic changes and residential movements dramatically altered the composition of schools, but also school-finance reform, shifts in student and teacher attitudes regarding race, expansion of school accountability systems, charter schools, and other public school reforms almost certainly have affected the benefits of both expanded interracial contact and attendance at a non-neighborhood public school. The heterogeneity of both desegregation program types and the environments that form the context of racial interactions introduce additional variation into the likely effects of specific interventions. Nevertheless, the literature provides important information on the contribution of desegregation to black academic and economic progress, the likely benefits of program expansion, and the potential harm from the dismissal of desegregation orders.

Summary of Results

The studies summarized in **Table 5** provide mixed evidence on the effects of school desegregation programs and

Table 5 Selected research on effects of desegregation and racial composition on student outcomes

Article	Findings
Coleman <i>et al.</i> (1966)	Higher percentage of black school-mates lowered achievement
Crain (1970)	Exposure to whites raised income and occupational achievement by leading to greater interaction with whites
Cook (1984)	Desegregation had at most a small effect on academic achievement
Armor (1992)	School desegregation contributed little to the closing of the black/white achievement gap
Boozer <i>et al.</i> (1992)	A higher proportion of high-school schoolmates who were black was associated with fewer years of schooling, a less-integrated work environment and lower wages
Grogger (1996)	A higher proportion of high-school schoolmates who were black reduced wages, and the size of the effect increased between 1979 and 1986
Rivkin (2000)	Little or no effect of exposure to whites on achievement, school attainment, or earnings regardless of type of desegregation plan
Hoxby (2000)	Higher black enrolment share lowered achievement, and the effect was larger in schools with a mid-range proportion black
Hanushek <i>et al.</i> (2004)	Higher black enrolment share lowered achievement, and peer average achievement accounts for little of the proportion black effect
Guryan (2004)	Desegregation accounted for roughly one half of the decline in the black high-school dropout rate between 1970 and 1980
Angrist and Lang (2004)	Little or no evidence that urban, black, and Hispanic students bused to a suburban district adversely affected achievement of non-black or Hispanic suburban students
Lutz (2005)	Desegregation program dismissal raises high-school dropout rates in northern but not southern school districts
Card and Rothstein (forthcoming)	School desegregation has little effect on SAT scores, possibly because of resegregation within schools

school racial composition. On the one hand, the random-assignment experiments of the benefits of busing reveal little evidence that desegregation substantially increased black student achievement. On the other hand, observational studies generally support the hypothesis that desegregation and interracial contact are beneficial, particularly for longer term outcomes including school attainment and earnings.

In a comprehensive summary of random-assignment studies of school desegregation effects on reading and mathematics achievement in early grades, Cook (1984) concludes that meta-analyses of the results of a number of studies supports the view that the effects were quite small or even zero. There are a number of factors, however, that raise doubts about this interpretation of the evidence. First, the small sample sizes common in studies of single desegregation programs limit the power of the estimates, and this makes it very difficult to identify small but potentially important effects on test scores. Second, any heterogeneity in the effects of different types of desegregation programs implies that the estimates depend in part on the composition of programs included in the studies. Third, it may take a few years to work out the glitches of new programs.

Nevertheless, the contrast between the generally small estimated effects of desegregation on elementary school achievement in random-assignment studies and the generally much larger effects on achievement and longer term outcomes in observational studies is striking. Beginning with the landmark legislatively mandated report, *Equality of Economic Opportunity* (Coleman *et al.*, 1966), the bulk of observational research finds that desegregation and interracial contact raised achievement, schooling, and earnings, and in some cases the estimated effects are quite large.

A number of alternative explanations could separately or together reconcile these disparate results. First is the aforementioned concern that the random-assignment studies failed to uncover the true benefits of desegregation. Second is the possibility that desegregation raises academic attainment but not test scores. This is supported by Guryan (2004), Lutz (2005), and Card and Rothstein (2006) but not Rivkin (2000). Third is the possibility that desegregation program induced interracial contact is less beneficial than contact resulting from residential integration, which is consistent with the positive effects of exposure to whites found in Hanushek *et al.* (2004) and Hoxby (2000) but not consistent with Guryan (2004) who finds that expanded interracial contact contributes to the positive desegregation effect on schooling.

A final and certainly not mutually exclusive explanation is that the observational studies fail to account for confounding factors and other sources of bias despite the use of a variety of empirical methods. Nonrandom sample selection, inadequate controls for confounding factors, retrospective information on school racial composition

that may be influenced by one's own experience, and the use of cross-sectional information on school attendance such as the US census that cannot identify recent movers into the district and often lacks geographic detail so that the allocation of students to districts tends to include surrounding suburbs not part of desegregation efforts all raise concerns. Some studies depend on the identification of appropriate counterfactuals (Guryan, 2004; Lutz, 2005), others rely on observed controls (Grogger, 1996), others use patterns of cohort differences in racial composition (Hanushek *et al.* 2006; Hoxby, 2000), some use aggregate information on racial composition (Card and Rothstein, 2006; Rivkin, 2000) and the study by Boozar *et al.* (1992) uses state of birth by cohort dummies as instruments for school racial composition. A final concern is that some of these empirical approaches are not consistent with a cumulative model of knowledge acquisition such as that developed by Todd and Wolpin (2003). Regardless of the exact approach, each makes strong assumptions that must be satisfied to produce consistent estimates.

An important issue for policy concerns the underlying determinants of any relationship between desegregation or interracial contact on the one hand and outcomes on the other. Are effects driven by peer influences, teacher quality, school factors, or some combination of the three? Do effect magnitudes vary by black student characteristics such as initial academic achievement? Do the reduced form estimates often based on specific states or experience over 20 years ago provide valuable information on the likely effects of additional desegregation efforts or the dismissal of plans currently in place?

Education Production Functions: Concepts

D N Harris, University of Wisconsin–Madison, Madison, WI, USA

Glossary

Education production function – This constitutes all combinations of inputs that produce a given set of outputs. In education, outputs are typically measured by achievement scores and graduation rates. Inputs include both school and family factors that influence outcomes.

Value-added model – A method of estimating the impact of school programs and inputs that uses data on individual students linked over time so that each individual's achievement growth can be calculated. Value-added models can be used to estimate effects of programs and inputs (e.g., teacher experience) as well as the effects of individual teachers and schools. The concept of value-added is rooted in economics and refers to the difference in the economic value of outputs and inputs.

Introduction

The production function is one of the core concepts of microeconomics and its application to education has been one of the central research activities of quantitative education researchers, especially economists of education, for many decades. The education production function (EPF) is implicitly part of any research that attempts to establish a statistical relationship between education resources (e.g., class size) and measures of student outcomes (e.g., scores on standardized achievement tests). Results from these studies have had a significant impact on policy debates about how, and how much, public funding should be provided for education. The quasi-experimental research methods associated with EPFs have also become an increasingly common approach to education program evaluation, influencing a wide range of policies beyond education funding.

The importance of EPF research has also grown with the recent availability of rich data sources that include test scores for each student in each year and allow the scores of each student to be linked over time and to individual teachers, schools, and education programs. These data can be used to estimate value-added versions of EPFs that produce arguably more valid estimates of the (causal)

effects of programs and resources. In theory, value-added models can also be used to measure the effectiveness of individual teachers and schools, which can be used as the basis for accountability. In the next section, I describe the basic meaning, variations, and assumptions of the various types of EPFs, blending intuitive and technical explanations. This is followed by a discussion of the different uses of EPF estimates (e.g., program evaluation and accountability) and evidence of the validity of some of the assumptions that underlie production function research. Most of the research in this area, and therefore the examples given, relate to K-12 schools, although these ideas also extend to higher education.

Production Function Models and Assumptions

The EPF is the set of education outputs associated with all possible combinations of education inputs, under the assumption that inputs are utilized efficiently. As it is widely believed that schools, as well as many other organizations, use resources at less-than-optimum efficiency, this assumption is almost always violated and studies of the relationships between inputs and outputs are therefore not, strictly speaking, studies of EPFs (Hanushek, 1979). This is more than a semantic issue because the measured impact of any given input will depend on the efficiency of the input choice and use. For example, if different types of students were affected in different ways by the same inputs, then the measured effects of the inputs on student outcomes would depend on how well schools target particular inputs to the students who stand to gain the most from them. Nevertheless, the assumption about input efficiency does not invalidate the usefulness of EPF results and, for this reason, the issue is typically ignored and the EPF term, therefore, refers to any study of the quantitative relationship between education inputs and outputs.

Under certain assumptions, these input–output relationships can be plausibly interpreted as causal effects of inputs. The assumptions, which are necessary to draw causal inferences, and produce valid estimates for such inferences, are discussed throughout the remainder of this article. For a more detailed discussion of the issues associated with causal inference, see, for example, Shadish *et al.* (2002).

Basic Assumptions

The most basic assumptions have to do with the types of factors that influence student outcomes, which are informed by education theory and evidence. School inputs represent the first important category, commonly measured by funding levels, class size, teacher education, teacher experience, and availability of computers and textbooks. The second general category that affects education outcomes is family and other nonschool inputs. The importance of nonschool inputs initially became evident with the publication of the Coleman Report (1966) in the United States. Coleman found that the variation in education outcomes was explained primarily by the variation in family background rather than school inputs. While Coleman's methods were somewhat simplistic, the central importance of family background has been widely corroborated in more recent and sophisticated studies (see, e.g., Rothstein (2004) for a review).

The next step toward the specification of the EPF is to express this basic theory mathematically. Define education output for individual student i at time t as A_{it} which is a function $f(\cdot)$ of the school inputs S and family inputs F from current and all previous time periods, a fixed student contribution I_i and an error term, ε_{it} . This yields:

$$A_{it} = f(S_{it}, S_{it-1}, \dots, F_{it}, F_{it-1}, \dots, I_i, \varepsilon_{it}) \quad [1]$$

The fixed student contribution, I_i is often called innate ability by economists and is akin to what psychologists consider general intelligence, or g . The more general term, fixed student contribution, is used here because it is virtually impossible with education data sets to estimate anything like innate ability. No data sets include measures of student abilities at birth or, in their absence, sufficiently measure family and other environmental factors well enough to distinguish innate from environmental differences. Research by Lee and Burkham (2002), for example, suggests that there are wide differences in education achievement between different racial groups when students first enter kindergarten and these are partly explained by observed differences in the home environment.

As the home environment contributes substantially to student outcomes, but in ways difficult to observe and measure, researchers increasingly emphasize the importance of accounting for unobserved differences. Accounting for something that is unobserved may seem impossible, but it is possible when data are available on individual students over time so that each student can, in effect, serve as his or her own control group for the subsequent year. In other words, by observing changes in each student's entire growth trajectory over time, and being able to measure important school inputs, it is possible to isolate the school contribution from the student contribution.

Consider what would happen if the (unobserved) student contribution were not accounted for. Taking a simple

correlation between school inputs and achievement gains, one would be concerned that students with higher scores come from families with higher incomes who, not coincidentally, send their children to schools that have greater school inputs. In this case, how is one to determine to what degree the simple correlation between school inputs and achievement gains reflects a causal effect of school inputs or a causal effect of family background? In an experiment, these unobserved differences would be addressed by randomly assigning students to control and treatment groups. In secondary data analysis, and specifically in eqn [1], the unobserved differences are captured. This makes it reasonable to interpret the elements of φ as causal effects of school inputs in eqn [1] and, more generally, to call the EPF approach an example of quasi-experimental methods.

The fact that eqn [1] includes school inputs from previous periods ($t-1$ is shown and $t-2$, $t-3$, etc. are implied) is important and reflects the cumulative nature of education – that outcomes in each period are the result of the accumulation of all student experiences from birth up to the current time t . In the earliest generations of EPF research, the cumulative nature of education production was only occasionally mentioned and almost never really addressed because data were rarely available except at a single point in time. In effect, researchers were forced to make the questionable assumption that past inputs were irrelevant to current outputs.

The EPF also requires that there is a single education output, usually measured in terms of student standardized test scores. As Hanushek (1979) points out, the implications of this assumption depend on whether excluded outputs (e.g., students' socialization, civic-mindedness, and motivation) also influence student achievement. If they do not, then the exclusion of some outputs does not bias the estimates of the EPF for the included output measure (achievement). Student motivation and student achievement, for example, are almost certainly interconnected and this may bias estimates of the EPF estimates of the effects of inputs on achievement. While there are techniques for estimating models with multiple outputs, the data are rarely, if ever, available.

Additional Common Assumptions

By adding some additional assumptions, it is possible to make eqn [1] more concrete. Todd and Wolpin (2003) outline a now commonly used EPF in which they assume the following:

1. *Age independence.* The cumulative EPF does not vary with age so that, for example, the effect of an input applied in second-grade on third-grade student outcomes is the same as the effect of an input applied in third-grade on fourth-grade student outcomes.

2. *Additive separability.* The EPF is additively separable so that the effects of inputs do not interact with one another.
3. *Fixed family inputs.* All family inputs are fixed over time.

The last assumption implies further that the fixed family contribution can be combined with the fixed student contribution, so that the student contribution I_i becomes the student–family contribution γ_i . This assumption, like many others, is mainly one of convenience and reflects the lack of data available on students' families and home environments. These assumptions yield the following more concrete EPF:

$$A_{it} = \varphi_1 S_{it} + \varphi_2 S_{it-1} + \dots + \gamma_i + \varepsilon_{it} \quad [2]$$

where φ represents the set of contributions given by current and previous school inputs. Economists call these the marginal effects or marginal products of inputs, reflecting the change in output associated with a small (marginal) change in inputs. These are often, although sometimes misleadingly, referred to simply as effects. Whether this is a reasonable term depends on the potential violations of the assumptions and their influence on causal inference, although I adopt the term effect for simplicity.

Some additional simplification can be achieved by adding another assumption:

4. *Geometric decay.* Suppose the effects of all prior school inputs decline geometrically with the time between the application of the input and the measurement of achievement so that $\varphi_2 = \lambda\varphi_1$, etc., where λ is some constant.

Intuitively, this just formalizes the idea that the most recently received inputs have the greatest impact on current student achievement. For example, some estimates show that $\lambda = 0.8$, suggesting that a small increase in school inputs (class size, etc.) in the previous period ($t-1$) would only increase current achievement 80% as much as the same increase in inputs in the current period (t). If the geometric decay assumption is valid, then the achievement equation can be reduced to:

$$A_{it} = \varphi_1 S_{it} + \lambda A_{it-1} + \gamma_i + \eta_{it} \quad [3]$$

where $\eta_{it} = \varepsilon_{it} - \lambda\varepsilon_{it-1}$. This form of the error term has important implications for the computation of the value-added EPF, as discussed later. Equation [3] and similar models that account for unobserved differences across students and families are sometimes referred to as the value-added EPF specification. One reason for using this term is that accounting for unobserved student and family contributions makes it reasonably plausible that the estimated effects are causal. Moreover, unlike eqn [2], eqn [3] can be estimated with newly available administrative data sets.

Not surprisingly, estimating eqn [3] is difficult and involves a number of assumptions in addition to those mentioned above regarding the derivation of the equation:

1. *Interval-scaled tests.* The student achievement test scores are interval-scaled so that a one-unit change in score means the same thing on all parts of the scale.
2. *Uniform input effectiveness.* Each school input is equally effective for all types of students.
3. *Student assignment based on fixed characteristics.* Students are assigned to school (and nonschool) inputs in each period based on their fixed characteristics, not time-varying characteristics such as previous period achievement gains.

There are also two additional assumptions that relate to the computation of eqn [3] and to the properties of the data. First, recall that the error term in eqn [3] was defined as $\eta_{it} = \varepsilon_{it} - \lambda\varepsilon_{it-1}$. The usual estimates of eqn [3] (using ordinary least squares) are biased in this case because the error term contains a lagged value of achievement error and because lagged achievement is one of the inputs. It is possible that the lagged error will be correlated with lagged achievement and therefore biases the estimates. One way to address this is to assume that $\lambda = 1$ and lagged achievement can be subtracted from both sides and the dependent variable becomes $A_{it} - A_{it-1}$. This avoids the problem of the possible correlation between the lagged error and lagged achievement, but, as noted by Boardman and Murnane (1979) and Todd and Wolpin (2003), also imposes the false assumption that the effects of past school inputs are the same as the effects of current school inputs. This means, for example, that the quality of a child's kindergarten must have the same impact on their achievement at the end of age 5 as it does on their achievement at age 18. In contrast, recall that the earliest generation of EPFs assumed, perhaps even more unrealistically, that past inputs did not matter at all in producing current outcomes (i.e., $\lambda = 0$). Thus, it is necessary to make one of the following assumptions:

- h1. The lagged error is uncorrelated with lagged achievement.
- h2. No decay in school input effects.

In summary, this section discusses some general assumptions of EPF (e.g., regarding the school and nonschool influences on student outcomes) as well as three assumptions necessary to derive a general cumulative EPF (age independence, additive separability, and fixed family inputs), and assumptions required to obtain the value-added specification and to allow for causal interpretation of school input effects (geometric decay, interval-scaled tests, equal teacher effectiveness, and students assigned based on fixed characteristics). Many of these same assumptions are required in other forms of experimental and quasi-experimental methods. As discussed below, the implications of violations of the assumptions can be significant, depending on the nature of the conclusions the researcher is trying to draw.

EPFs and Accountability

The examples given so far have focused on the effects of school inputs, such as class size. Another possible application of eqn [3], however, is to estimate the contributions to student learning made by individual teachers and schools, which could be used to hold educators accountable for their performance. Harris (2008) describes this as the distinction between value-added for program evaluation (VAM-P) and value-added for accountability (VAM-A).

Estimating school effects is, in principle, simply a matter of adding to eqn [3] an indicator (dummy) variable for each school. This yields an estimated school effect that can be interpreted as the school's contribution to student learning (controlling, once again, for the student's contribution). This effect is identified from the movement of students across schools, including perhaps structural moves from lower-grade-level schools (e.g., elementary schools in the US) to high-grade-level schools (e.g., US middle schools). These school moves allow the researcher to observe and compare each student's learning trajectory in multiple school settings.

When including school effects, there is also a choice to be made regarding which measured school inputs (e.g., class size) should continue to be included in eqn [3]. If the objective of accountability is to hold schools responsible for aspects of school performance that they can control, then the general rule here should be to include those inputs that are outside the control of schools. What this means in practice depends on the larger policy context. In the United States, schools have very little control over the inputs they receive and, in these cases, the best approach is to include a wide variety of measurable school input measures.

The same logic applies when trying to estimate the effects of individual teachers. This can be accomplished by adding an indicator variable for each teacher. The teacher effects in this case are estimated from the movement of students across teachers, both across time and, in secondary schools, across classes within years. The shift from the school to the teacher level also raises issues about matching the specific education output being measured (e.g., math or reading) with the specific teacher who is responsible for that specific output. This is less of an issue at the school level because the school as a whole is considered responsible for all outputs.

The resulting teacher or school effects compare the contributions to student learning of each teacher/school relative to every other. That is, estimated teacher effects measure the value-added of each teacher compared with the other teachers in the sample, and likewise for schools. This is important because it highlights the fact that there is no absolute scale on which value-added measures can be compared – there is no way to determine whether any teacher or school is as efficient as possible, or above some objective standard.

Some researchers (e.g., Harris and Sass, 2005) have estimated multilevel models with student, teacher, and school effects together. This is not only computationally challenging, due to the very large number of variables (one per student, teacher, and/or school), but also changes the interpretations of the estimated effects. When school effects are excluded, teacher effects reflect each teacher's value-added compared with the average teacher in the database. When school effects are included, teacher effects reflect each teacher's value-added compared with the average teacher within the school. The interpretation of the school effects also changes depending on whether teacher effects are included. Without teacher effects, the school effects reflect the overall contribution of the school, including the teachers. When teacher effects are included, the school effect reflects only the effect of nonteacher factors, for example, some of the effect of school leadership.

An argument can also be made for including teacher and/or school individual effects even when the main purpose is to estimate the effects of inputs such as class size, an example VAM-P. Harris and Sass (2007) argue, for example, that including teacher effects helps to account for the nonrandom selection of teachers to teacher education, which is the focus of their study. There are also legitimate questions, however, about whether teacher and school effects should generally be included in VAM-P studies and whether VAM-A studies are really useful. Every combination of teacher and school effects changes the basis of comparison and it is not always clear which comparison is most useful, nor do researchers always make it clear what comparisons they are making. The inclusion of teacher and school effects also substantially reduces the degrees of freedom in the analysis and, consequently, the precision of the estimates. For this reason, there is considerably more agreement among researchers about the use of student effects than the use of teacher and school effects. More research is needed to confirm that teacher and/or school effects generally reduce bias and therefore whether the reduction in precision is offset by an even more important reduction in bias.

Evidence on the Assumptions of the EPF

There is relatively little research testing the validity of the assumptions discussed earlier, although interest in this is growing. In some cases, the assumptions are tested directly using standard tests of statistical significance. In other cases, where it is difficult to test the assumptions directly, researchers have focused on the sensitivity of the results of the various possible assumptions.

Harris and Sass (2005) test a variety of assumptions using an unusually rich database including nearly all students in grades 3–10 in the US state of Florida. First, they find that using lagged achievement, in conjunction

with the geometric decay assumption, is sufficient to capture the role past schooling inputs. They test this assumption by estimating an EPF that includes both actual previous period inputs (e.g., lagged class size) and previous achievement; in this case, previous inputs (jointly) have no statistically significant influence on current achievement, suggesting that these inputs can be dropped as in eqn [3].

Second, Harris and Sass (2005) find that the specific assumption about the degree of geometric decay has little effect on the estimated teacher effects, for realistic values. They find that conclusions about the effects of teacher experience and professional development are almost completely unaffected by the assumption about λ , except for very low values (0–0.2) that appear unrealistic. This suggests that the assumptions about geometric decay are fairly unimportant, which further implies that it is reasonable to assume $\lambda = 1$, move lagged achievement into the dependent variable, and thereby avoid the potential correlation between lagged achievement in the error term which produces biased estimates in ordinary least squares (OLS). McCaffrey *et al.* (2004) also test this assumption, comparing the teacher effects models in which $\lambda = 1$ with a model that leaves achievement on the right-hand side and leaves λ unrestricted. They, as well as Harris and Sass (2005), find a high correlation between the teacher effects using these different assumptions.

Harris and Sass (2005, 2007) find that the way in which family and home environment are accounted for matter significantly. They compare EPFs with student unobserved effects versus measured student characteristics such as student race and family income. This yields dramatically different estimates of the effects of teacher experience, for example. Given the apparent importance of family and home environments, this is perhaps not surprising, but the implications are significant: this means that the earlier generations of studies, which relied on student race and family-income-related measures generally produced biased estimates of school effects.

Some of the assumptions are addressed through more *ad hoc* adjustments to eqn [3] and associated statistical tests. For example, a modest number of studies have considered the possibility of nonadditive separability of a specific school input – teacher experience. In these cases, researchers include experience and experience squared as dependent variables. If the coefficient on the squared term is negative, it implies diminishing marginal returns in school inputs. This is the typical assumption made in economic models of production and an example of the more general possibility of interaction effects among inputs.

At least two studies have apparently focused on the general presence of additive separability. Figlio (1999) finds, using US data, that the class-size effect does not depend on starting teacher salary, but does depend on the number of school instructional hours. Harris (2007), using

international data, also finds evidence of interactions among a wide range of school and nonschool inputs, although these include a complex mix of diminishing and increasing returns. While the EPF models used in these studies are not based on a formally derived model, such as eqs [1]–[3], they do provide evidence against additive separability.

While this review is not comprehensive, it is reflective of the general lack of evidence available about the validity of the various EPF assumptions and, therefore, about the conclusions being drawn from EPF analyses. Because of the growing availability of student-level, longitudinally linked data, a large number of studies are currently in progress to address these issues. Access to these data will also undoubtedly add much to our knowledge of the relationship between education inputs and outputs, building on the insights of earlier generations of EPF research.

Education Production Functions: Developed Country Evidence

E A Hanushek, Stanford University, Stanford, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Educational production function – A function that relates various inputs to education including those of families, peers, and schools to the maximum level of student achievement that can be obtained.

Fixed effects – A form of statistical analysis that removes the average effects of a factor (such as individual schools) from the analysis; in the case of teachers, the fixed effect in models of achievement growth is often interpreted as a measure of teacher quality.

Value added – In the context of education production functions, the value added of an input would be the separate contribution of learning after allowing for other inputs and the base level of knowledge of the students.

Overview

Much of the analysis in the economics of education flows from a simple model of production. The common inputs are things like school resources, teacher quality, and family attributes; and the outcome is some measure of student achievement – frequently but not always student test scores. Knowledge of the production function for schools can be used to assess policy alternatives and to judge the effectiveness and efficiency of public provided services. This area of research is, however, distinguished from many others because the results of analyses enter quite directly into the policy process.

Historically, the most frequently employed measure of schooling has been attainment, or simply years of schooling completed. The value of school attainment as a rough measure of individual skill has been verified by a wide variety of studies of labor-market outcomes (e.g., Mincer (1970) and Psacharopoulos and Patrinos (2004)). However, the difficulty with this common measure of outcomes is that it simply counts the time spent in schools without judging what happens in schools – thus, it does not provide a complete or accurate picture of outcomes. It assumes a year of schooling produces the same amount of student achievement, or skills, over time and in every country.

Recent direct investigations of cognitive achievement find significant labor-market returns to individual differences in cognitive achievement (e.g., Lazear (2003), Mulligan (1999), and Murnane *et al.* (2000)). Similarly, society appears to gain in terms of productivity; Hanushek and Kimko (2000) demonstrate that quality differences in schools have a dramatic impact on productivity and national growth rates. (A parallel line of research has employed school inputs to measure quality but has not been as successful. Specifically, school input measures have not proved to be good predictors of wages or growth.) The economic implications of differences in cognitive achievement appear to be very large (Hanushek, 2005).

As outcomes cannot be changed by fiat, much attention has been directed at inputs – particularly those perceived to be relevant for policy such as school resources or aspects of teachers.

Analysis of the role of school resources in determining achievement begins with the Coleman Report, the US government's monumental study on educational opportunity released in 1966 (Coleman *et al.*, 1966). While controversial, the study's greatest contribution was directing attention to the distribution of student performance – the outputs as opposed to various school inputs such as spending per pupil or characteristics of teachers (Bowles and Levin, 1968; Hanushek and Kain, 1972).

The underlying model that has evolved as a result of this research is very straightforward. The output of the educational process – the achievement of individual students – is directly related to both inputs – ones that are directly controlled by policymakers (e.g., the characteristics of schools, teachers, and curricula) and others that are not so controlled (such as families and friends and the innate endowments or learning capacities of the students). Further, while achievement may be measured at discrete points in time, the educational process is cumulative; inputs applied sometime in the past affect students' current levels of achievement.

Family background is usually characterized by socio-demographic characteristics such as parental education, income, and family size. Peer inputs, when included, are typically aggregates of student-sociodemographic characteristics or achievement for a school or classroom. School inputs typically include teacher background (education level, experience, sex, race, and so forth), school organization (class sizes, facilities, administrative expenditures, and so forth), and district or community factors (e.g., average expenditure levels). Except for the original Coleman

Report, most empirical work has relied on data constructed for other purposes, such as a school's standard administrative records. Statistical analysis (typically some form of regression analysis) is employed to infer what specifically determines achievement and what is the importance of the various inputs into student performance.

Measured School Inputs

The state of knowledge about the impacts of resources is best summarized by reviewing available empirical studies. Most analyses of education production functions have directed their attention at a relatively small set of resource measures, and this makes it easy to summarize the results (Hanushek, 2003). The 90 individual publications that appeared before 1995 contain 377 separate production-function estimates. For classroom resources, only 9% of estimates for teacher education and 14% for teacher-pupil ratios yielded a positive and statistically significant relationship between these factors and student performance. Moreover, these studies were offset by another set of studies that found a similarly negative correlation between those inputs and student achievement. Twenty-nine percent of the studies found a positive correlation between teacher experience and student performance; however, 71% still provided no support for increasing teacher experience (being either negative or statistically insignificant). Studies on the effect of financial resources provide a similar picture. These indicate that there is very weak support for the notion that simply providing higher teacher salaries or greater overall spending will lead to improved student performance. Per-pupil expenditure has received the most attention, but only 27% of studies showed a positive and significant effect. In fact, 7% even suggested that adding resources would harm student achievement. It is also important to note that studies involving pupil spending have tended to be the lowest quality studies as defined below, and thus there is substantial reason to believe that even the 27% figure overstates the true effect of added expenditure. More recent studies do not change this picture about how resources relate to student outcomes.

These studies make a clear case that resource usage in schools is subject to considerable inefficiency, because schools systematically pay for inputs that are not consistently related to outputs.

Study Quality

The previous discussions do not distinguish among studies on the basis of any quality differences. The available estimates can be categorized by a few objective components of quality. First, while education is cumulative, frequently only current input measures are available,

which results in analytical errors. Second, schools operate within a policy environment set almost always at higher levels of government. In the United States, state governments establish curricula, provide sources of funding, govern labor laws, determine rules for the certification and hiring of teachers, and the like. If these attributes are important – as much policy debate would suggest – they must be incorporated into any analysis of performance. The adequacy of dealing with these problems can thus be used as a simple index of study quality.

The details of these quality issues and approaches for dealing with them are discussed in detail elsewhere (Hanushek, 2003) and only summarized here. The first problem is ameliorated if one uses the value added versus level form in estimation. That is, if the achievement relationship holds across grades, it is possible to concentrate on the growth in achievement and on exactly what happens educationally between those points when outcomes are measured. This approach ameliorates problems of omitting prior inputs of schools and families, because they will be incorporated in the initial achievement levels that are measured (Hanushek, 1979). The latter problem of imprecise measurement of the policy environment can frequently be ameliorated by studying performance of schools operating within a consistent set of policies – for example, within individual states in the US. As all schools within a state operate within the same basic-policy environment, comparisons of their performance are not strongly affected by unmeasured policies (Hanushek *et al.*, 1996).

If the available studies are classified by whether or not they deal with these major quality issues, the prior conclusions about research usage are unchanged (Hanushek, 2003). The best quality studies indicate no consistent relationship between resources and student outcomes. The studies finding strong resource effects, particularly for expenditure per pupil, are heavily concentrated in the group of lowest quality studies.

An additional issue, which is particularly important for policy purposes, concerns whether this analytical approach accurately assesses the causal relationship between resources and performance. If, for example, school decision makers provide more resources to those they judge as most needy, higher resources could simply signal students known for having lower achievement. Ways of dealing with this include various regression-discontinuity or panel-data approaches. When done in the case of class sizes, the evidence has been mixed (Angrist and Lavy, 1999; Hoxby, 2000; Rivkin *et al.*, 2005).

The most significant innovation of recent years is the use of large administrative databases. These databases employ state or local records on individual student's performance and are most notable for tracking students across grades. Student performance is then related to those programs and personnel that each student is exposed to over time. These large-scale databases, often following all students

in a state over time, permit controlling for a wide range of influences on achievement through the introduction of fixed effects for schools, individuals, and time (see, e.g., Rivkin *et al.* (2005) or Boyd *et al.* (2006)). These fixed effects hold constant any systematic differences that are constant among the category (such as constant differences among the sampled schools in terms of the selection of schools by families and teachers) and obtain estimates of various inputs from their variation within each of the schools. By eliminating systematic selection and sorting of students and school personnel, they can concentrate on specific causal factors that determine individual student outcomes.

A final alternative involves the use of random-assignment experimentation rather than statistical analysis to break the influence of sample selection and other possible omitted factors. With one major exception, this approach nonetheless has not been applied to understand the impact of schools on student performance. The exception is the logislated Student/Teacher Achievement Ratio progs (or Project STAR), an experimental reduction in class sizes that was conducted in the US state of Tennessee in the mid-1980s (Word *et al.*, 1990). To date, the use of randomized experiments has not had much impact on research or our state of knowledge about the impacts of resources. While Project STAR has entered into a number of policy debates, the interpretation of the results remains controversial because of concerns about the quality of the experiment (Krueger, 1999; Hanushek, 1999). The results of this experiment suggested a significant but small impact of lower class size but that all of the impact was concentrated in the first year of schooling (kindergarten or grade one). Smaller class sizes in later years had no additional impact on student outcomes.

Benefits and Costs

Throughout most consideration of the impact of school resources, attention has focused almost exclusively on whether a factor has an effect on outcomes that is statistically different from zero. Of course, any policy consideration would also consider both the magnitude of the impacts and the costs of change. For magnitude of impact, even the most refined estimates of, say, class-size impacts do not give very clear guidance. The experimental effects from Project STAR indicate that average achievement from a reduction of eight students in a classroom would increase by about 0.2 standard deviations, but only in the first grade of attendance in smaller classes (kindergarten or first grade) (see Word *et al.* (1990) and Krueger (1999)). Hoxby (2000) in her regression-discontinuity estimation for Connecticut schools finds no systematic effect of class size. Rivkin *et al.* (2005), with their fixed-effects estimation, find effects half of Project STAR in grade 4 and declining to insignificance by grade 7.

From a policy perspective, the magnitude of alternative estimates is at best small. In order to be relevant for policy, it is necessary to compare the outcomes of any change with its costs. Most educational research ignores such comparisons and neglects any consideration of costs.

It is easy to see the importance of cost considerations when put in the context of the debates over class-size reduction. In economic terms, the potential impacts of class-size reduction are very small when contrasted with the costs of such large class-size reductions, which typically involve some of the most expensive policy changes currently contemplated (see the range of cost estimates in Brewer *et al.* (1999)). The relevant alternative policy would be to compare the gains from spending on class-size reduction with the potential gains from improving the quality of teachers, the subject of the next section.

Do Teachers and Schools Matter?

Due to the Coleman Report and subsequent studies discussed above, many have argued that schools do not matter and that only families and peers affect performance. Unfortunately, these interpretations have confused measurability with true effects.

Extensive research since the Coleman Report has made it clear that teachers do indeed matter when assessed in terms of student performance instead of the more typical input measures based on characteristics of the teacher and school. The alternative approach to the examination of teacher quality concentrates on pure outcome-based measures of teacher effectiveness. The general idea is to investigate total teacher effects by looking at differences in growth rates of student achievement across teachers. A good teacher would be one who consistently obtained high learning growth from students, while a poor teacher would be one who consistently produced low learning growth.

The general research design is to estimate models of the growth in individual student achievement that can be attributed to various measured school and family factors and to mean differences in learning across the students with different teachers. The differences in student-achievement growth across classrooms, which can be taken as a measure of teacher quality, appear to be very large. Hanushek (1992) estimates that the variation in student outcomes from a good to a bad teacher can be as much as a full year of knowledge per academic year; in other words, while a poor teacher gets gains of 0.5 grade-level equivalents during a school year, a good teacher gets gains of 1.5 grade-level equivalents. Clearly, with a string of good or bad teachers, the implications for student performance could be very large.

More modern research into state administrative databases have helped refine the understanding of the importance of differences in teacher quality. For example,

Rivkin *et al.* (2005) and Hanushek *et al.* (2005) are able to provide rough bounds on the variation in teacher quality as seen within Texas (the source of their administrative database). By these studies, one standard deviation in teacher quality implies around a 0.15 standard deviation in the growth of student achievement. By this, having a series of good teachers (teachers at the 84 percentile of the quality distribution) instead of average teachers would lead to substantially different learning after just a few years. For example, 4–5 years of a good teacher could close the average achievement gap between low-income and high-income students.

These results can also be reconciled with the prior ones. These differences among teachers are simply not closely correlated with commonly measured teacher characteristics (Hanushek, 1992; Rivkin *et al.*, 2005). Moreover, teacher credentials and teacher training do not make a consistent difference when assessed against student-achievement gains (Boyd *et al.*, 2006; Kane *et al.*, 2006). Finally, teacher quality does not appear to be closely related to salaries or to market decisions. In particular, teachers exiting for other schools or for jobs outside of teaching do not appear to be of higher quality than those who stay (Hanushek *et al.*, 2005).

Some Conclusions and Implications

The existing research suggests inefficiency in the provision of schooling. It does not indicate that schools do not matter. Nor does it indicate that money and resources never impact achievement. The accumulated research surrounding estimation of education production functions simply says there currently is no clear, systematic relationship between resources and student outcomes. At the same time, more modern research into the determinants of student achievement strongly indicates that teacher-quality differences are the most significant part of differences across schools.

Glossary

Education production function – The process by which by cognitive and noncognitive skills are learned by students, which includes influences from both inside and outside of the schools they attend. Factors that influence the development of these schools can be thought of as inputs into the production of those skills.

Endogenous program placement bias – When using regression analysis to estimate the causal impact of factors that affect the variable of interest (in this case, cognitive or noncognitive skills), estimates of the impact of a variable that indicates which schools participated in some type of program may be biased if that program is deliberately targeted to schools where students are performing particularly well or particularly poorly.

Measurement error bias – When using regression analysis to estimate the causal impact of factors that affect the variable of interest (in this case, cognitive or noncognitive skills), the estimated impacts of explanatory variables that have errors in their measurements will be biased, often in the direction of underestimation of the causal effects.

Omitted variable bias – When using regression analysis to estimate the causal impact of factors that affect the variable of interest (in this case, cognitive or noncognitive skills), exclusion of one or more causal factors from the regression may lead to biased estimates of the impacts of the remaining variables in the regression.

Selection and attrition bias – When using regression analysis to estimate the causal impact of factors that affect the variable of interest (in this case, cognitive or noncognitive skills), the impact of a variable that also influences which observations (students) are in the data used for the regression may lead to biased estimates. For example, a school characteristic that leads to increased learning may also attract new students to a school. If the academic performance of those new students is higher (lower) than the students that were already in the school, the estimated impact of that school characteristic will be overestimated (underestimated).

Introduction

Economists and other social scientists have accumulated convincing evidence that education makes individuals more productive and thus increases their incomes. Education also provides nonpecuniary benefits, such as improved health and social integration. Much of the gap in living standards between developed and developing countries may be due to wide gaps in education. Thus, efforts to raise enrolment rates and to increase student learning could greatly improve living standards in developing countries.

This article addresses a central issue in education research: What education policies are most effective at raising enrolment and increasing learning in developing countries? While much research has been conducted, many estimated policy impacts may be biased, or may not apply to other countries. This article assesses what has been learned and, equally important, what remains unclear and thus merits further research. The article begins by introducing the education production function, a concept used by economists, and several other relevant relationships. The next section reviews estimation issues. The subsequent section summarizes research on enrolment and learning in developing countries, and the final section concludes the article.

The Education Production Function

Formal education increases individuals' well-being primarily through their acquisition of skills, both cognitive (e.g., literacy and numeracy) and noncognitive (e.g., social and organizational skills). Thus, an understanding of the process by which formal education produces those skills is crucial for crafting effective education policies. Economists characterize this process as the education production function.

Economists have studied factories, farms, and other productive organizations for two centuries. They have gradually developed a comprehensive, yet flexible, framework for thinking about production processes. At first, depicting education as production may seem strange, but upon further reflection this approach is useful because it provides a comprehensive framework for thinking about how formal education generates those skills. Most importantly, this framework provides crucial guidance on how to use

education data to estimate the impact of education policies (and other causal factors) on students' acquisition of skills.

The process by which both cognitive and noncognitive skills are learned is determined by many different factors. Production functions simply depict this process as a mathematical relationship. These relationships can be very flexible, allowing for almost any learning process. In this sense, an education production function always exists, although one must realize that its existence does not guarantee that one can estimate it.

Factors that determine learning, henceforth referred to as variables or inputs in the production process, can be divided into school, child, and household variables. A simple, yet flexible, learning production function is:

$$A = a(S, \mathbf{Q}, C, H, I) \quad [1]$$

where A is skills learned (achievement), S is years of schooling, \mathbf{Q} is the set of all school and teacher characteristics (quality) that affect learning, C is all child characteristics (including ability) and H is all household characteristics that affect learning, and I is educational inputs that households contribute, such as children's daily attendance and purchases of textbooks and other school supplies. While years of schooling (S) and educational inputs (I) can be grouped with child or household variables, eqn [1] separates them from C and H because they are (in part) under parents' control.

Equation [1] shows how each variable affects learning, holding other variables constant. This qualification is important. Consider an improvement in one school quality variable, call it Q_j , such as reducing class size. Equation [1] shows how changing Q_j affects learning for given values of the other variables. However, changing Q_j (or any school quality variable) could change household behavior, that is change S or one or more I variables. For example, parents may keep children in school longer (increase S) or reduce educational inputs (reduce I variables) in response to improved school quality. Thus, the full impact of changing Q_j on skills (A) is not captured by that variable's impact as depicted in eqn [1].

To obtain the full impact of changing school quality, one must know how changes in both the \mathbf{Q} variables and in other variables affect S and I in eqn [1]. These relationships can be expressed as:

$$S = f(\mathbf{Q}, C, H, \mathbf{P}) \quad [2]$$

$$I = g(\mathbf{Q}, C, H, \mathbf{P}) \quad [3]$$

where \mathbf{P} depicts the prices relevant for these household decisions, such as tuition, school supply prices, and even child wages (the price of children's time spent in school).

Inserting [2] and [3] into [1] gives another expression for A :

$$A = b(\mathbf{Q}, C, H, \mathbf{P}) \quad [4]$$

which economists call a reduced form relationship. It shows the full causal impact of school quality variables (and other variables) on learning. Equation [4] is not a production function because it depends on households' preferences (which guide households' decisions) and because it includes prices. While the production function in [1] shows the direct impacts of all variables that influence learning, when analyzing policy impacts one must estimate the full impact, which includes indirect impacts that work by changing variables that households control. Equation [4] shows this full relationship.

Should education policymakers focus on eqn [1] or eqn [4]? Equation [4] is useful because it shows actual changes in A after the \mathbf{Q} and \mathbf{P} variables change, and government policies primarily affect these two sets of variables. Yet, the impacts of \mathbf{Q} on A in eqn [1] are also important because they better capture overall welfare effects. Intuitively, if increases in Q_j induce parents to reduce educational inputs (I), household welfare increases because savings from these reduced purchases can be spent on other goods. Equation [4] shows the drop in A from reducing I , but not the increased household welfare from purchasing other goods. In contrast, the structural impact measured in [1] ignores both effects. Since they have opposing impacts on household welfare, they largely cancel out each other. Thus, overall welfare effects are better approximated by changes in A measured in [1]; see Glewwe *et al.* (2004) for details. Overall, estimates of both [1] and [4] are useful for policymakers.

Of course, some government policies cannot be described as changes in school quality (\mathbf{Q}) or schooling prices (\mathbf{P}). Examples are policies that decentralize decision-making processes or change teachers' contracts. Such policies affect schooling outcomes by changing what happens in classrooms, or changing prices for education goods and services. Glewwe and Kremer (2006) explain that one can depict \mathbf{Q} and \mathbf{P} as determined by (functions of) education policies, and perhaps by community characteristics. Ultimately, both skills (A) and years of schooling (S) are determined by child and household characteristics, education policies, and community characteristics. Knowledge of these ultimate relationships directly links education policies to these education outcomes.

Estimation of Production Functions

While knowledge of skills production functions and other education relationships is crucial for effective education policies, these relationships are very difficult to estimate. This section explains the methods used, potential problems, and possible solutions.

Consider estimating the production function in eqn [1]. (These estimation issues also apply to other education relationships, such as the determinants of years of

schooling, eqn [2].) This can be estimated using linear regression methods. Assuming linearity is not restrictive if one adds squared and interaction terms to the variables in [1]. A simple linear specification of [1] is:

$$A = \beta_0 + \beta_1 S + \beta_{Q1} Q_1 + \beta_{Q2} Q_2 + \dots + \beta_{C1} C_1 + \beta_{C2} C_2 + \dots \\ + \beta_{H1} H_1 + \beta_{H2} H_2 + \dots + \beta_{I1} I_1 + \beta_{I2} I_2 + \dots + u_A [1']$$

where each variable in Q , C , H , and I is shown explicitly. An error term, u_A , is added, for several reasons. First, data never exist for all variables in Q , C , H , and I , so u_A accounts for all variables in [1] that are not in the data. Second, u_A indicates that [1'] is only a linear approximation of [1]. Third, observed test scores (A) may measure actual skills with error, so u_A includes the difference between observed A and the true A . Finally, the right-hand-side variables in [1'] may also have measurement errors, so differences between their true and measured values are also in u_A .

While u_A may seem unimportant because it is unobserved, the causal impacts of the observed variables in [1'] on learning, the β coefficients, can be consistently estimated by ordinary least squares (OLS) only if u_A is uncorrelated with all the observed explanatory variables. Unfortunately, u_A is very likely to be correlated with those variables. The following subsections offer four reasons.

Omitted Variable Bias

The explanatory variables in eqn [1'] could be correlated with u_A because of omitted variable bias: no data set contains all variables in each set of variables (Q , C , H , and I), and many unobserved variables (which end up in u_A) may well be correlated with some observed variables. Difficult-to-observe variables include: teachers' motivation (a Q variable), school principals' management skills (Q), children's ability (C) and motivation (C), and parents' willingness (H) and capacity (H) to help, and the time they spend helping (I), their children with schoolwork. OLS estimates of the β 's in eqn [1'] may be biased because these variables, if unobserved, are probably correlated with some observed variables in [1']. For example, high-quality schools are usually better in many dimensions, both observed and unobserved. This produces positive correlation between u_A and observed school and teacher quality variables, leading to overestimation of the impacts of those variables. Similarly, parental tastes for children's education are rarely observed and probably positively correlated with parental education, causing overestimation of the latter's impact. Omitted variable bias can also induce underestimation of observed variables' impacts. For example, high school quality may lead parents to reduce time spent helping their children, generating negative correlation between school quality and u_A (assuming some parental efforts are unobserved, which is likely, and thus are in u_A). (When unobserved variables correlated with u_A are endogenous in the sense that

households choose them, researchers sometimes call the resulting bias endogeneity bias.) Omitted variable bias affects the estimated β terms not only for observed variables that are correlated with u_A but also for those uncorrelated with u_A .

Selection and Attrition Bias

Sometimes changes in school and teacher characteristics (Q) affect which children attend school. Improved school or teacher quality should increase enrolment, but new students may differ from original students in unobserved ways. New students' parents may care more about education and take (unobserved) actions to help their children beyond enrolling them in better schools. Alternatively, improved schools could attract students who would otherwise drop out (students with lower academic ability or less parental support). The former effect overestimates impacts of school quality variables on learning; the latter leads to underestimation. Bias due to changes in enrolment is called selection bias. A related phenomenon is attrition bias: current students are less likely to drop out if school quality improves. If weaker students would otherwise have left, the β 's on many school quality variables would be underestimated (due to their negative correlation with u_A).

Endogenous Program Placement Bias

School quality could also be correlated with u_A if governments improve schools with unobserved education problems (Pitt *et al.*, 1993). Governments may also raise school quality in areas with good education outcomes, if those areas have political influence (World Bank, 2001). The former causes underestimation of school-quality variables' impacts on learning, while the latter causes overestimation.

Measurement Error Bias

Anyone who has seen household or school survey data collection in developing countries understands that even the best data contain many errors. Data on school characteristics (including tuition fees) may be inaccurate or out of date. Child, household, and school input variables are prone to errors. Because measurement error is the difference between the true and observed values of a variable, it causes u_A to be correlated with the observed variable. Random measurement error typically causes underestimation of true impacts, while nonrandom errors could cause underestimation or overestimation.

Whatever the cause, the key point is: anything that induces correlation between u_A and the observed variables in [1'] will lead to biased estimates.

Methods to Reduce or Remove Bias

The above estimation problems are difficult to solve. When estimating the impacts of policy variables (P or Q) on learning, all difficulties arise because students facing different policy variables probably differ in unobserved ways. One approach to address omitted variable, measurement error, and endogenous program placement biases is instrumental variables, which uses other variables (that must be uncorrelated with u_A) to predict the variable(s) correlated with u_A . Unfortunately, it is difficult to find plausible instruments. Glewwe and Kremer (2006) provide further discussion. Another approach uses panel data to estimate the impact of changes (over time) in observed variables on changes in test scores; if the unobserved variables correlated with observed variables do not change, they are differenced out of the equation (their change over time is zero). However, many unobserved variables could change, and such differencing may exacerbate measurement error bias.

The ideal solution to these estimation problems is randomized trials: randomly divide the population into two groups, one is treated but not the other. Random assignment ensures that unobserved characteristics do not differ across groups, so they are uncorrelated with the policy treatment. Comparison of outcomes for these groups provides unbiased estimates of that policy's impact. Unfortunately, this approach might be costly or infeasible for other reasons (including ethical reasons). Yet, several studies discussed in the next section use this approach, which should raise one's confidence in their results.

Evidence from Developing Countries

This section presents basic facts concerning education in developing countries and then reviews the evidence from

those countries on the impact of various education policies on school attainment and learning. For detailed reviews, see Glewwe and Kremer (2006) and Glewwe and Miguel (2008).

Education in Developing Countries

Despite dramatic increases in school enrolment in most developing countries, they still lag behind developed countries. One widely available indicator is the gross enrolment rate, the number of children enrolled in a particular education level, regardless of age, divided by the population in the age group associated with that level. In 1960, primary school gross enrolment rates were 65% in low-income countries, 83% in middle-income countries, and over 100% in high-income countries (**Table 1**). By 2000, enrolment rates reached or exceeded 100% in low- and middle-income countries, and in all regions except sub-Saharan Africa (sub-Saharan Africa's gross enrolment rate increased to almost 100% by 2005). Secondary enrolment rates increased dramatically since 1960 (**Table 2**).

Gross enrolment rates above 100% do not imply that all children are enrolled. Grade repetition can cause gross rates to exceed 100% even when some children never enroll. Another measure of education progress is net enrolment rates, the number of children enrolled in a particular schooling level of the age associated with that level, divided by all children of that age. Net enrolment rates cannot exceed 100%; they remove the upward bias in gross rates caused by enrolment of overage children (due to repetition or delayed enrolment). **Table 1** shows that primary net enrolment rates are much lower than gross rates. Sub-Saharan Africa's net enrolment rates are particularly low, only 70% in 2005 (although this represents progress since 2000, when it was 56%). The educational outcomes in sub-Saharan Africa are low even

compared to low-income non-African countries; its primary and secondary rates are well below those of South Asia, which is as poor as Africa. These averages hide some gender disparities, which are largest in South Asia (Table 3).

In 2004, the adult literacy rate in developing countries reached 77%, but was only 54% in least-developed

countries (UNESCO, 2006). Illiteracy arises because many adults never attend school and because attending school may not develop literacy. Sub-Saharan Africa exemplifies the latter. Figure 1 shows that the probability of being literate after 6 years of schooling in Africa is about 70%, while the same probability is attained after only 3 years in non-African low-income countries.

Problems in attaining literacy likely reflect low school quality in many developing countries; children learn much less per year of schooling than children in developed countries. This may reflect the rapid expansion of education in developing countries in recent decades (see Tables 1 and 2), which strained financial and human resources. Education quality comparisons across countries require internationally comparable data on academic performance. Two sources of such data are the Third International Mathematics and Science Study (TIMSS) and Progress in International Reading Literacy Study (PIRLS), administered by the International Association for the Evaluation of Educational Achievement.

The first two columns of Table 4 show the 1999 TIMSS mathematics test scores of grade 7 and 8 students. The two developed countries' scores were 579 (Japan) and 502 (US). Korean students scored even higher (587), and Malaysians also performed well (519). Other developing countries had much lower scores, ranging from 275 (South Africa) to 467 (Thailand).

The TIMSS data include few sub-Saharan African countries, but three comparable data sets exist for African countries: UNESCO Monitoring Learning Achievement (MLA) program, which covers 72 (African and non-African) countries; Programme d'Analyse des Systèmes Educatifs de la CONFEMEN (PASEC) program, which monitors 15 French-speaking African countries, and Southern African Consortium for Monitoring Educational Quality

From IAEEA (2000, 2003).

(SACMEQ), which conducted surveys in 15 southern and eastern African countries. These programs indicate that school quality varies widely across Africa. For example, in terms of correct answers on the PASEC test, the highest scoring country (Côte d'Ivoire) had an average score

2.5 times higher than the lowest (Mauritania). **Table 5** shows African countries' performance on these tests. Note that South Africa, the worst performer in the TIMSS, is about average for African countries.

These assessments imply that raising learning in developing countries requires not just increased enrolment but also more learning per year enrolled. Policy interventions that increase enrolment and/or learning can be classified into those that increase the demand for education and those that improve the supply of education services. The following subsections review both types. **Table 6** summarizes the findings. The discussion is limited to policy impacts on enrolment and learning; see Damon and Glewwe (2007) for comparisons of the costs and benefits of specific policies, focusing on Latin America.

Demand Interventions

Policies that raise demand for education increase learning by increasing time in school. This is done by increasing available household income and/or reducing education costs. (Raising school quality can also increase demand, but for convenience we treat school provision as a supply side intervention; see the next subsection.) Income transfers directly raise parental income. Unconditional transfers may increase households' education spending, but such effects may be small. Yet, two recent studies, based on pension reforms, find sizable (unconditional) income effects. Edmonds (2006) showed that, in South Africa, receiving a generous pension (about 125% of black households'

median income) increased enrolment among children living with pensioners. For example, male pension eligibility increased rural boys' school attendance by 18 percentage points. Carvalho (2000) finds similar effects from

Brazil's new pension scheme. For a benefit increase of R \$100 (about half the minimum wage), girls' enrolment increased by 4.5 percentage points. Boys' enrolment increases were much smaller.

Table 6 Summary of empirical results

			Impact on enrolment	Impact on learning
<i>Demand-side policies</i>				
Unconditional transfers (pensions)	Edmonds (2006)	South African pension scheme	Yes	Not estimated
	Carvalho (2000)	Brazilian rural pension scheme	Yes	Not estimated
Conditional cash transfers	Schultz (2004)	Progresa, Mexico	Yes	Not estimated
	Maluccio and Flores (2005)	Nicaragua	Yes	Not estimated
Conditional transfers in kind	Glewwe, Olinto and de Souza (2004)	PRAF, Honduras	Yes	Not estimated
	Ravallion and Wodon (2000)	FFE, Bangladesh	Yes	Not estimated
	Vermeersch and Kremer (2005)	Kenya, school breakfast	Yes	Yes
	Kremer <i>et al.</i> (2003)	Kenya, school uniforms	Yes	No
Abolition of school fees	School Fees Abolition Initiative (2006)	Kenya	Yes	Not estimated
Vouchers	Angrist <i>et al.</i> (2001)	Colombia	Yes	Yes
	Hsieh and Urquiola (2006)	Chile	No	No
Health: deworming	Miguel and Kremer (2004)	Kenya	Yes	No
<i>Supply-side policies</i>				
School construction	Duflo (2001)	Indonesia	Yes	Not estimated
Contractual teachers	PASEC (2004)	Mali	Yes	No
	Sy (2007)	Mali	Not estimated	No
Class size	Angrist and Lavy (1999)	Israel	Not estimated	Yes
	Urquiola (2001)	Bolivia	Not estimated	Yes
Teachers incentives	Glewwe, Ilias and Kremer (2003).	Kenya	No	No
Remedial education	Banerjee <i>et al.</i> (2005)	India	Not estimated	Yes
Traditional inputs (textbooks, etc.)	Glewwe <i>et al.</i> (2007)	Kenya	No	No
Computer-assisted education	Banerjee, Duflo and Linden (2003)	India	Not estimated	Yes

These findings imply that higher household income increases enrolment, which should increase learning. Thus, any economic policy that increases household incomes should increase enrolment and learning. For a detailed theoretical discussion, see Glewwe and Jacoby (2004).

To ensure that income transfers increase enrolment, one could condition them on education choices. Conditional cash transfer (CCT) programs provide transfers to households only if their children are enrolled in, and regularly attending, school. The best-known CCT program is Mexico's *Programa de Educación, Salud y Alimentación* (PROGRESA) program (now called *Oportunidades*). Schultz (2004), exploiting the randomized implementation of PROGRESA, estimates that after 3 years it raised children's years of schooling by 0.66 years. Honduras and Nicaragua also implemented CCT programs, and also randomized their implementation, which facilitates assessment of their impacts on schooling. Maluccio and Flores (2005) estimate that Nicaragua's program, which assisted poor children in grades 1–4, increased school enrolment rates by 13 percentage points, and increased attendance, conditional on enrolment, by 20 points. Glewwe *et al.* (2004) estimate that Honduras's CCT program raised children's completed years of schooling from 4.2 to 4.9. Bourguignon, Ferreira and Leite, using microsimulation techniques, show

that Brazil's CCT program, *Bolsa Escola*, induced 60% of poor, out-of-school 10- to 15-year-olds to enrol. They also simulated the impact of the transfer without conditionality, and found no impact on children's schooling.

While CCT programs appear to increase demand by raising incomes, they really work through prices: CCT programs decrease the price of education. Indeed, the price becomes negative; parents are paid for enrolling their children. Policies that directly reduce education prices have similar effects. Several African countries, including Ethiopia, Ghana, Kenya, Malawi, Mozambique, Tanzania, and Uganda, recently abolished school fees (School Fees Abolition Initiative, 2006). For example, Kenya did this in 2003, and nearly 1 million new pupils enrolled. Primary enrolment increased by 16%, overwhelming schools and ill-prepared teachers (World Bank, 2004).

Several Latin American countries have implemented vouchers, which provide poor households funds to enrol their children in private schools. Two programs have been rigorously evaluated. Colombia's *Programa de Ampliación de Cobertura de la Educación Secundaria* (PACES) awarded vouchers to over 125 000 poor urban students from 1992 to 1997. In most communities, demand for vouchers exceeded the supply, so eligibility was determined by lottery, creating a natural experiment. Angrist *et al.*

(2002) estimate that poor urban students given vouchers completed 0.12 additional years of schooling. The benefits may be even higher: voucher recipients' test scores were 0.2 standard deviations higher, equivalent to 1 year of schooling. In contrast, Hsieh and Urquiola (2006) found no effect of vouchers on Chilean students' test scores, repetition rates, or years of schooling.

Another policy that changes education prices is transfers in kind. Bangladesh's Food for Education program provides an in-kind subsidy equivalent to 5–10% of household income. Ravallion and Wodon (2000) estimate that this increased enrolment from 74% to nearly 100%. In Kenya, provision of school meals and uniforms were evaluated using randomized trials. Vermeersch and Kremer (2004) found that free breakfasts at preschools increased school participation (which combines enrolment with daily attendance) by 30%. Test scores also increased. Such programs reduce schooling costs and also improve children's nutritional status. Several studies show that better nutrition in the first years of life helps children stay in school and learn more per year of schooling (see Glewwe and Miguel, 2008). Providing uniforms also increased enrolment; Kremer *et al.* (2003) estimate that free uniforms increased pupils' participation by 15%.

Finally, some interventions to improve school-age children's health have strong impacts. Miguel and Kremer (2004) implemented a randomized trial in an area of western Kenya with very high helminth infection rates. The program, which provided students deworming medicine, increased school enrolment and attendance at very little cost. Surprisingly, no effect was found on learning.

In summary, evidence from many countries indicates that higher household incomes and especially lower schooling costs greatly increase school enrolment. This should increase children's acquisition of skills.

Supply Policies

Many government education policies operate not through increasing education demand but instead by improving the supply. Most supply-side policies take two forms: (1) increasing the quantity of schooling services offered and (2) increasing the quality of schooling services. The former involves building more schools and/or increasing the capacity of existing schools.

Building new schools reduces households' distance to the nearest school. Long distances reduce enrolment. Some regard distance as particularly harmful to girls' schooling (Foster and Rosenzweig, 2004; Bommier and Lambert, 2000). Filmer (2004) argues that decreasing distance to schools increases enrolment, but not by much. Duflo (2001), using a natural experiment, showed that building new schools increased years of schooling in Indonesia by about 0.15 years.

Another quantity policy is hiring more teachers to increase existing schools' capacity. In French-speaking West Africa, several countries have recently hired additional teachers, but on different terms. Contract teachers have short-term renewable contracts, receive little training, and are paid much less than permanent, civil service teachers. Senegal, Mali, and Niger have hired thousands of such teachers, permitting large enrolment increases. For example, Mali hired 11 400 contract teachers between 1992 and 2004; between 1998 and 2002 they constituted 86% of newly hired primary and secondary teachers. PASEC (2004) estimates that this allowed 100 000 additional pupils to be enrolled, a 5% increase.

The impact of contract teachers on education outcomes is widely debated, but few reliable evaluations exist. Results using PASEC data suggest that contract teachers raise student learning as much as regular teachers do (Sy, 2007). Theoretically, the impact is ambiguous. Lower wages could reduce incentives, but worries of losing one's job due to underperformance may offset this. Yet, designing performance-based teacher contracts is difficult. Glewwe *et al.* (2003) implemented a randomized trial in Kenya to assess the impact of awarding teachers prizes based on student learning. They found little impact of incentives on learning.

Consider next policies to increase education quality (increasing learning per year enrolled). Additional teachers may raise school quality as well as quantity. Banerjee *et al.* (2007) conducted a randomized evaluation of a program that hired young educated women from the community to teach basic literacy and numeracy skills to children falling behind in India's government schools. The program was very effective, increasing test scores by 0.14 standard deviations after 1 year, and 0.28 after 2 years. Similar results were found in Chile by Chay *et al.* (2005).

Increased enrolment from reduced tuition or other policies increases class size, which may reduce learning. Angrist and Lavy (1999) exploited an Israeli natural experiment arising from strict application of a rule that class size should not exceed 40 (which is low by sub-Saharan Africa's standards) to investigate how class size affects learning. They found that smaller classes improve learning; having ten fewer students increased reading scores by 2.5 points (the average score was 72, with a standard deviation of 8). Urquiola (2006) finds similar results for Bolivia.

Another way to improve education quality is to provide material inputs. Two randomized trials, one that provided textbooks and another that supplied flipcharts, were conducted in Kenya. Surprisingly, neither textbooks nor flipcharts increased learning, except that textbooks raised learning among the best students (Glewwe *et al.*, 2004, 2007). In India, Banerjee *et al.* (2005) conducted a randomized evaluation of computer-assisted education. Fourth graders were given 2 h of computer time per week to play games that reinforced mathematics skills.

The program increased math scores by 0.47 standard deviations after 2 years. These results persisted for at least 1 year after students finished the program.

Conclusions and Suggestions for Future Research

Developing countries have made great strides to ensure that all children complete primary school and most enrol in secondary school. Researchers have demonstrated that several policies do raise enrolment (see **Table 6**). Yet, school enrolment does not ensure that students learn fundamental cognitive (and noncognitive) skills. While hundreds of policies have been advocated to increase learning, few have been rigorously evaluated, and even fewer appear to be effective. Randomized evaluations of proposals to increase learning deserve the highest priority for future research.

In our opinion, six specific phenomena require further study. First, grade repetition is high in many countries (on average, 13% in sub-Saharan Africa and 12% in Latin America; see Glewwe and Kremer, 2006). Repetition is an inefficient policy for helping students who fall behind. The real issue is: How should schools accommodate students with very different backgrounds and abilities? Some advocate tracking (grouping students by academic performance). Others argue that tracking is inherently unequal. In any case, the impact of repetition on education outcomes and alternatives to that policy merit further research.

Second, to pass entrance exams to secondary or post-secondary education, many public school students in developing countries attend private tutoring classes (see Dang, 2007; Dang and Rogers, 2008). Tutors are often teachers from the students' own school, which may tempt teachers to reduce effort during the school day to generate demand for tutoring services. One policy that may avoid this is to forbid teachers from tutoring their own students. More research is needed on both possible problems and effective remedies.

A third issue, discussed above, is the costs and benefits of contract teachers. A fourth is the timing of education services: hours per school day, days per year, and vacation times. In some countries, schools operate during periods of high demand for agricultural labor.

Fifth, little is known about peer effects in developing countries. Peer effects may magnify the impacts of many policy interventions. For example, a primary school intervention that increases students' learning may increase learning among children those students are grouped with in secondary school.

A final question concerns language. In most sub-Saharan African countries, children in school face, even in first grade, a language (usually English or French) they do not know. Teaching in local languages, at least

during the first years, facilitates initial learning but may inhibit mastering the academic language used in higher education. Thus, teaching in local languages deserves further study.

Acknowledgment

We would like to thank Dominic Brewer and Patrick McEwan for comments on an earlier version of this article, and Meng Zhao for helping to prepare the tables. Some of the material in this article draws from Glewwe and Kremer (2006).

Family Environment in the Production of Schooling

R Rothstein, Economic Policy Institute, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

The association between social class and student achievement (measured by standardized test scores of basic skills) is well known. In 1966, James Coleman and colleagues concluded that “schools bring little influence to bear on a child’s achievement that is independent of his background and general social context” (Coleman *et al.*, 1966: 325). Shortly afterwards, Jencks *et al.* (1972) confirmed this finding. Researchers have replicated this relationship many times since. In 1998, social scientists, using more elaborate data, concluded that family environment accounted for more than half of the black–white achievement gap at the beginning of schooling, and if environmental measures could be more elaborate still, “environmental differences between blacks and whites may explain the entire test score gap” (Phillips *et al.*, 1998: 104).

Nonetheless, dispute persists regarding whether this association stems from disadvantaged children’s less adequate instruction in less adequately resourced schools; from background characteristics (such as family, community, social, and economic) that influence achievement after controlling for instructional quality; or from both school quality and background characteristics in concert.

The current (2001–2008) United States policy assumes that if school quality is not fully responsible for academic failure, schools can overcome negative influences of student background. Federal law requires schools to bring students from low-income and from racial and ethnic minority families to proficiency at challenging levels, without any prior narrowing of socioeconomic inequality. The law, however, has been ineffective, and claims that excellent schools can close (as opposed to narrow) the achievement gap between disadvantaged and middle-class students have not withstood careful scrutiny (Rothstein, 2004; Carnoy *et al.*, 2005).

Nonetheless, anecdotal accounts are plausible that high-quality schools get relatively better achievement from disadvantaged children, even if they do not fully close the gap. This article describes pathways by which family, community, as well as social and economic conditions also cause academic failure. Modest improvements in these would also yield better achievement.

There has been little experimentation with socioeconomic improvements to raise achievement. One experiment was ‘Moving to opportunity’, sponsored by the US Department of Housing and Urban Development in the 1990s. It found less impact than expected of offering lower class families housing in less distressed neighborhoods. However, families tended to choose

new neighborhoods not significantly less distressed than their home neighborhoods, making conclusions from the experiment difficult to draw (Sanbonmatsu *et al.*, 2006). A few experiments in the 1970s found improved achievement from a negative income tax for poor families (Maynard and Murnane, 1979). Other experiments (such as placing health clinics in schools) would be easy to implement, but have not been undertaken, although nonexperimental evidence of positive impact is abundant (Geierstanger *et al.*, 2004).

Without more experimentation, we cannot conclude whether reducing social and economic inequality would be more powerful ways to raise achievement than school improvement. Most plausible is that both are required.

This article describes specific pathways by which socioeconomic disadvantage plausibly causes lower achievement. As racial minority status overlaps with lower class status in the United States (33% of black children are from poor households, compared to 14% of all children (NCES, 2007, table 21)), and because data on black children are sometimes more available than on disadvantaged children generally, this article uses black, disadvantaged, and lower class as interchangeable terms. This does not imply that black children would more likely be lower class, in the absence of the specific racial inequalities of American society.

In all cases, lower class characteristics have average effects. Some disadvantaged children have higher achievement than typical middle-class children, and some middle-class children have lower achievement than typical lower class children. For any characteristic, outcome distributions are broad; social-class distributions overlap. Children’s varied school and socioeconomic experiences, and innate variability, interact to produce a range of outcomes. The fact that some lower class children have better outcomes is not evidence that socioeconomic factors are not powerful, or that superior school quality is the cause.

Social-Class-Based Child-Rearing Practices

Parents of different social classes raise children differently, on average. More-educated parents read to young children more consistently, and encourage them to read more for themselves when older (Bianchi and Robinson, 1997; Hofferth and Sandberg, 2001). Most children whose parents have college degrees are read to daily before

beginning kindergarten; children whose parents have less education benefit less from daily reading. Young children of more-educated parents are surrounded by books at home, while children of less-educated parents see fewer books (Denton and Germino-Hauskens, 2000, tables 19 and 20).

A child who enters school recognizing some words, used to turning pages of stories, will be easier to teach than one who has rarely held a book. The second child can be taught, but with equally effective teaching, the first will more likely have higher test scores.

Schools' inability to overcome disadvantages of less literate homes characterizes nations generally. The number of books in homes consistently predicts scores within almost every country (Lemke *et al.*, 2002, figure 17). Turkish immigrant students suffer from an achievement gap in Germany, as do Algerians in France, as do Caribbean, African, Pakistani, and Bangladeshi pupils in Great Britain, and so do Okinawans and low-caste Burakamin in Japan (Begag, 1990; Garner, 2004; Neuman and Peer, 2002; OFSTED, 1999; Ogbu, 1992; Sciolino, 2004; Ermisch *et al.*, 2001).

An international reading survey of 15-year-olds found strong relationships between socioeconomic status and student literacy in most countries. The literacy gap between children of highest status workers (e.g., doctors, professors, and lawyers) and lowest status workers (e.g., waitpersons, taxi drivers, and mechanics) was greatest in Germany and the United Kingdom, still great in France and the United States, somewhat lower in the Scandinavian countries and in Korea (OECD, 2001).

More-educated parents, often with professional occupations, read more themselves. When parents read to solve problems or for entertainment, they stimulate children's motivation to read. If parents do not read for themselves, they signal the unimportance of literacy (Snow and Tabors, 1996; Lareau, 1989).

How parents read to children matters; more-educated parents read aloud differently. Working-class parents reading aloud more likely tell children to pay attention without interruptions, sound-out words, or name letters. Parents' questions are more likely to be factual, asking for names of objects or recall of events. More-literate parents more likely ask creative, interpretive, or connective questions, such as "What do you think will happen next?" Middle-class parents are more likely to read aloud to have fun or to start conversations. Their children are then more motivated to read in school (Mikulecky, 1996).

When more-educated parents converse in children's presence, they use larger vocabularies and more complex sentences. Although middle-class preschoolers do not use such language themselves, they have an advantage when they hear college-educated teachers speak or when these words and constructions are encountered in books (Mikulecky, 1996; Snow and Tabors, 1996). Educated parents are more likely to give indirect instruction ("You

don't want to make so much noise, do you?"), inviting children to think through the reasoning. Children entering school with a background of indirect instruction have practiced what educators call critical thinking, upon which academic success relies.

Twenty years ago, University of Kansas researchers recorded home conversations of families from different social classes. On average, middle-class parents spoke over 2000 words per hour in the presence of very young children, working-class parents about 1300, and welfare mothers about 600. By age 4, children of professionals had vocabularies nearly 50% greater than those of working-class children and twice as large as those of welfare children.

The Kansas researchers also tracked how often parents verbally encouraged or reprimanded behavior. Toddlers of professionals got an average of six encouragements per reprimand. Working-class children had two. For welfare children, there was an average of one encouragement for two prohibitions (Hart and Risley, 1995). When these children later go to school, teachers cannot fully offset these differences. Children whose initiative was encouraged from early ages are more likely, on average, to take responsibility for their own learning.

These differences mirror those of adult roles. Parents whose professional occupations entail authority and responsibility believe more strongly that they can affect their environments and solve problems. At work, they explore alternatives and negotiate compromises. They naturally express these personality traits when giving their children indirect instruction or designing problem-solving activities. Middle-class parents are more likely to explain why rules are reasonable.

However, parents whose jobs entail following orders or doing routine tasks express a lesser sense of efficacy. Lower class parents are more likely to instruct children without extended discussion because following orders, after all, is how they themselves behave at work. Their children are more likely to be fatalistic about obstacles, in and out of school.

Middle-class children's self-assurance is enhanced in after-school activities that sometimes require large fees for enrolment and almost always require parents to have enough free time and resources to provide transportation. Organized sports, music, drama, and dance programs build self-confidence and discipline in middle-class children. Lower class parents find fees for such activities more daunting, and transportation less accessible – organized athletic and artistic activities are not available in many lower class neighborhoods. Therefore, lower class children's sports are more informal and less confidence building, with less opportunity to learn teamwork and self-discipline (Hofferth and Sandberg, 2001; Lareau, 2003).

Differences in role modeling also contribute to social-class achievement gaps. Where adults perform jobs requiring little academic skill, children's own academic

ambitions are influenced. As always, beware of deterministic simplification: some lower class children, despite few educated role models, succeed in school, perhaps as the first in their families to attend college. But on average, these children must struggle harder to motivate themselves to achieve than children who assume that, like their parents' social circle, appropriate roles are professional.

One survey found that 93% of middle-class parents had a friend or relative who was a teacher, compared to 43% of working-class parents and 36% of poor parents. Medical doctors were identified as friends by 70% of middle-class parents, 14% of working-class parents, and 18% of poor parents (Lareau, 2002). These adult friendships reinforce how children imagine future roles, and what they strive to achieve.

More affluent parents are more likely to seek to influence school policy (preferring their children assigned to a different teacher's classroom, wanting children admitted to a gifted program, or seeking special services for children having difficulties) and more confident about challenging administrators (Horvat *et al.*, 2003; Jacob and Lefgren, 2007). This adds to the academic achievement gap.

Educators attempt to overcome lower class parents' alienation from schools, because parents more involved in schooling may raise their children's comfort with academic ambition. Therefore, educators try to enlist lower class parents in classroom observation, helping teachers, ushering field trips, or raising supplementary funds (Rothstein *et al.*, 1999). However, parental involvement styles are also class-based. Parents whose own jobs are routine, expected to follow well-defined roles, assume schools should operate similarly. With less education themselves, they have neither qualifications nor confidence to question how teachers design instruction. Middle-class parents, in contrast, more easily assume a right to collaborate with teachers because these parents have comparable educations and their own professional roles often place a premium on collaboration.

In the United States, education policy has for two decades stressed raising disadvantaged children's achievement. From 1990 to 2007, mathematics proficiency of black children increased substantially. For fourth graders, average black student math achievement is now higher than white student achievement in 1991 (NCES, online). If white students' performance had been stagnant, there would now no longer be a fourth-grade mathematics achievement gap and only a small eighth-grade gap.

Black students have had no comparable reading gains, yet instructional improvement efforts have been as intense in reading as in math. It seems likely, and worthy of further investigation, that literacy is more dependent on the class-based family factors described in this section, while mathematics proficiency is more responsive to improved instruction in schools alone.

Health Influences on Achievement

Overall, lower class children are in poorer health.

Those with vision problems have difficulty reading. In the United States, 50% of poor children have vision impairment that interferes with academic work, twice the normal rate (Egbonu and Starfield, 1982; Starfield, 1982).

Some require corrective lenses but many also need eye-exercise therapy to correct focusing, converging, and tracking problems. Where therapy or lenses were provided to randomly selected fourth graders from low-income families, those receiving optometric services gained in reading achievement, while children without such services fell farther behind (Orfield, 2007; Harris, 2002).

Lower class children may be more likely to have vision problems because of less adequate prenatal development than middle-class children whose pregnant mothers had better medical care and nutrition. Visual deficits also arise from disadvantaged children being placed in inexpensive low-quality child-care settings where they watch too much television, activity that does not develop hand-eye coordination and depth perception – 42% of black fourth graders watch 6 h or more of television a day, compared to 13% of whites (NCES, 2003, table 117). Middle-class children more likely have manipulative toys that develop such coordination.

A longitudinal study of entering kindergarteners reveals that fine-motor-skill development at age 5 is a stronger predictor of later mathematics and reading performance than is kindergartners' preliteracy knowledge (of the alphabet, of numbers, and of phonemes) (Grissmer and Eiseman, 2008).

Lower class children also have more hearing difficulties, possibly because of untreated ear infections that occur in children whose overall health is less robust. Ear infections are easily treatable for children with access to regular pediatric care. But lower class children with less access to such treatment are less attentive, on average, in school (Egbonu and Starfield, 1982).

Children without dental care have more toothaches; untreated cavities are 2–3 times as prevalent among poor as among middle-class children (GAO, 2000, figure 1; GAO, 2008). Although only some cavities produce toothaches, children with toothaches pay less attention in class and are more distracted during tests, on average.

Children who live in older buildings have more lead dust exposure that harms cognitive functioning and behavior (Egbonu and Starfield, 1982; GAO, 1999; Neisser *et al.*, 1996; Neisser, 1997). High lead levels also contribute to hearing loss (Brooks-Gunn and Duncan, 1997). Low-income children have dangerously high blood lead levels at 5 times the rate of middle-class children (GAO, 1999).

Indeed, lead poisoning now exacerbates the achievement gap more than it once did. For middle-class children, leaded fumes from auto exhaust were once the chief

source of lead exposure. With automotive gasoline now unleaded, lead poisoning afflicts mostly low-income children who continue to suffer from lead in house paint to which they are exposed. They are also more likely to live in areas where leaded paint peels from fire escapes or steel beams of elevated trains (Johnson, 2003). Although lead-based paint was banned from residential construction in 1978, low-income children more likely live in buildings constructed prior to that date and in buildings not frequently repainted to prevent older layers from peeling. Urban children are also more likely to attend older schools, where drinking fountains draw water through pipes containing lead (Barton, 2003; Blum, 2004).

Lower class children, particularly those who live in densely populated city neighborhoods, are also more likely to contract asthma – the asthma rate is substantially higher for urban children, for those whose families are on welfare, and for those from single-parent or poor families (Forrest *et al.*, 1997). A New York City survey found that one of every four children in Harlem suffers from asthma, a rate 6 times as great as that for all children (Perez-Pena, 2003). A Chicago survey found a nearly identical rate for black children and a rate of one in three for Puerto Ricans (Ritter, 2004). Asthma is provoked partly from breathing fumes from low-grade heating oil, diesel trucks, and buses (school buses idling at schools are a serious problem); excessive dust and allergic reactions to mold, cockroaches, and secondhand smoke also contribute (Halfon and Newacheck, 1993). In the Chicago neighborhoods with high asthma rates, nearly 50% of the children suffering from the disease live in homes where adults smoke.

Asthma keeps children awake at night. If attending school, asthmatics are more likely to be drowsy and inattentive, more irritable and with more behavioral problems, and more likely to refrain from exercise and thus be less physically fit. Middle-class children typically get treatment for symptoms, while low-income children get treatment less often. Asthma has become the biggest cause of chronic school absence, with sufferers from low-income families more likely to miss school than those from middle-class families (Forrest *et al.*, 1997; Halfon and Newacheck, 1993).

Children without regular medical care are also more likely to contract other illnesses that keep them from school. Despite federal programs to make medical insurance available to low-income families, there remain gaps in access and utilization. Many eligible families are not enrolled because of ignorance, fear, or lack of conviction about medical care's importance.

Thus, 20% of poor children are without consistent health insurance, compared to 12% of all children; 13% of black children are without insurance, compared to 8% of white children (Mills and Bhandari, 2003, figure 4; DeNavas-Walt *et al.*, 2004). Yet, even with health insurance, parents' low-wage work interferes with medical-care

utilization. Parents who are paid hourly wages lose income when they take children to doctors. Parents with blue-collar jobs risk discharge for excessive absence, so are likely to skip well-baby and routine pediatric care, seeing doctors only in emergencies. Salaried middle-class parents have more flexibility to schedule doctor visits, for themselves and for their children, without loss of job or income.

Lower class families with health insurance also confront disparities in medical facilities. A survey of one low-income minority Los Angeles neighborhood found one primary care physician for every 13,000 residents. A nearby high-income neighborhood had one for every 200 residents (Brown *et al.*, 2003). Low-income families, with or without insurance, are more likely to use emergency rooms and less likely to use primary care doctors, even for routine care.

As a result, black preschoolers are one-third less likely than whites to get standard vaccinations for diphtheria, measles, and influenza (Hoffman *et al.*, 2003). Ongoing differences in regular pediatric care result in poor children losing many more days from school than the nonpoor, on average. School attendance differences, attributable to disparities in health-care access alone, cause differences between black and white children's average achievement. Good teaching cannot do much for children who are not in school.

Youngsters whose mothers consumed alcohol during pregnancy have more difficulty with academic subjects, are less able to focus attention, have poorer memory skills, less ability to reason, lower intelligence quotients (IQs), less social competence, and more aggression in the classroom (Astley, 2003; Simmons *et al.*, 2002). In adolescence, these children continue to have difficulty learning (Richardson *et al.*, 2002; Streissguth *et al.*, 1994).

Fetal alcohol syndrome, a collection of the most severe cognitive, physical, and behavioral difficulties experienced by children of prenatal drinkers, is 10 times more frequent for low-income black than for middle-class white children (Abel, 1995). Data are not available for disparities by social class for less severe symptoms of prenatal alcohol consumption; however, it can be presumed that the consequences are greater for the more disadvantaged. Although affluent women consume more alcohol than lower class women, the latter tend to drink in binges that apparently do more harm to developing fetuses (CDC, 2002a; Abel and Hannigan, 1995).

Smoking in pregnancy also contributes to lower achievement. Children of mothers who smoked prenatally do more poorly on cognitive tests, their language develops more poorly, and they have more serious behavioral problems, more hyperactivity, and more juvenile crime (Astley, 2003).

Thirty percent of poor women smoke, compared to 22% of nonpoor women. During pregnancy, 25% of high-school dropouts smoke, 50% more than the rate for high-school graduates, and 13 times more than that for college graduates (CDC, 2001).

Partly from prenatal smoking, low-income children are more likely to be born prematurely or with low birth weight and to suffer from cognitive problems; low-birth-weight babies, on average, have lower IQ scores and are more likely to have mild learning disabilities and attention disorders (Hack *et al.*, 1995). Thirteen percent of black children are born with low birth weight, double the rate for whites (Hoffman *et al.*, 2003). Even if all children benefited from equally high-quality instruction, this difference alone would ensure lower average achievement for blacks.

Low birth weight is only partly caused by inadequate prenatal care, exposure to urban pollutants, diet, smoking and drinking. The interaction of poor health habits with other stresses exacerbates children's adverse outcomes. Maternal stress has hormonal consequences that interfere with nutrient absorption on which healthy fetuses depend (Rich-Edwards *et al.*, 2001; Wadhwa *et al.*, 2001; Lu and Halfon, 2003). Thus, low birth weight, alcohol consumption, and smoking all have greater negative effects on poor children than on middle-class children who were exposed to similar risks. Poor women, with greater stress and less adequate nutrition, can tolerate less smoke and alcohol and still deliver healthy babies than women whose better overall health conditions protect their fetuses from the effects of alcohol or smoking (Abel and Hannigan, 1995). Middle-class children more easily overcome earlier health shocks, rebounding when they later experience healthier environments after exposure to risk (Egbonu and Starfield, 1982).

Poor nutrition also contributes to achievement gaps between lower and middle-class children. Even moderate undernutrition affects academic performance, particularly if sustained. Iron-deficiency anemia affects cognitive ability: 8% of all US children, but 20% of black children, are iron deficient (CDC, 2002b). Anemia also makes it more probable that children will absorb lead to which they are exposed (Brown and Sherman, 1995). Iron is but one example – compared to middle-class children, the poor also lack other vitamins and minerals (Koch, 2002). In experiments where pupils got inexpensive vitamin and mineral supplements, test scores rose from that treatment alone (Neisser *et al.*, 1996).

Cumulatively, differences in the health of children from different social classes explain a significant portion of the achievement gap. According to one recent calculation, a few measurable differences in children's health and in the health of their mothers (particularly, the frequency of depression) accounts for approximately 25% of the black-white achievement gap (Currie, 2005).

Housing and Student Mobility

Housing instability also contributes to poor academic achievement. In the US, urban rents have been rising faster than working-class incomes. Even low-income families with stable employment are more likely to move

when they miss rent payments. Family breakup and bouts of unemployment also cause mobility. In some schools in low-income neighborhoods, mobility rates are over 100% (for every seat, two children were enrolled at sometime during the year) (Kerbow, 1996; Bruno and Isken, 1996).

A 1994 survey found that 30% of the poorest children had attended at least three different schools by third grade, while only 10% of middle-class children did so. Black children were more than twice as likely as whites to change schools this much (GAO, 1994). High-mobility schools are frequently disrupted by classroom reconstitution, to avoid placing all newcomers together or because classes get too large or too small from arrivals and departures. Teachers with mobile students use more discrete instructional units, are less able to integrate instruction over time, more likely to review old than introduce new material, and less able to adjust instruction to unfamiliar students' individual needs (Bruno and Isken, 1996).

High mobility depresses achievement not only for movers, but also for stable children in schools whose classes are reconstituted.

Middle-class children usually have a quiet place at home, perhaps their own bedrooms, to read or do homework. Children in more crowded housing can less often escape television, conversation, or siblings.

Based on Texas student data, a recent analysis concluded that about 14% of the black-white achievement gap, and 8% of the gap between children from low-income families and others, could be explained by differences in the housing mobility rates of otherwise similar families (Hanushek *et al.*, 2004).

Income and Wealth Differences that Influence Achievement

When parents lose employment, children's achievement tends to suffer. Parents under economic stress are more likely to discipline children arbitrarily, causing more misbehavior. When parents lose work, adolescents are more likely to be delinquent, use drugs, lose faith in the future, and suffer from depression (McLoyd, 1990; McLoyd *et al.*, 1994; Flanagan and Eccles, 1993). Recovery is slow from these effects. Workers with lower incomes when employed (e.g., blacks and workers with only a high-school education or less) are more likely to experience periodic unemployment (Mishel *et al.*, 2009, tables 4.2 and 4.4). Between black and white families whose current incomes are similar, black workers are more likely to have suffered recent job loss than whites, even if now reemployed. This contributes to average achievement differences of their children.

Family assets, as well as income, influence achievement. Families with similar incomes may have different social-class positions because of differences in wealth. Median family income for blacks is about 60% of

whites', but family net worth for blacks is only 10% of whites' (Mishel *et al.*, 2009, tables 1.3 and 5.5). Thus, among middle-class families whose incomes are similar, whites are more likely than blacks to have spacious housing, not only because whites suffer no housing market discrimination but also because white parents are more likely to have received capital contributions from their own parents for a first home down payment. Black middle-class parents are more likely to be the first generation in their families to have middle-class status with their own parents less likely able to help in this way.

Asset differences also influence how much families of all races save for children's college educations. Once enrolled in college, family home equity predicts whether students graduate (Brown *et al.*, 2003). Secondary school students' awareness that their families have resources for college can influence the confidence with which those students assume that college attendance is within their grasp.

Conclusion

Considered separately, each of these social-class differences (in childrearing and literacy practices; health characteristics; housing stability; and in economic security) as well as others not discussed here, such as neighborhood crime and peer influences, may have very small influence on the test-score gap. But together, they sum up to cumulative disadvantage for lower class children, which depresses average performance, even with high-quality instruction.

None of the many background characteristics influencing achievement operates separately. Each interacts with others, and with children's unique genetic endowments. For any characteristic or group of characteristics predicting low achievement, some children possessing them will achieve at higher levels than those characteristics alone might predict.

But on average, with equally high-quality instruction, children from disadvantaged families will achieve at lower levels than those from families without these disadvantages. Strategies to improve lower class children's performance will be more effective if they combine school improvement with policies to narrow social and economic inequalities.

Neighborhoods and Peers in the Production of Schooling

J Vigdor, Duke University, Durham, NC, USA

This article considers the role of peers and neighborhoods on educational outcomes. It begins by reviewing social scientific hypotheses linking peer and neighborhood characteristics to the amount of learning accomplished by youth in a given interval. It then summarizes recent empirical work testing these hypotheses, drawing upon earlier reviews to integrate earlier studies on the subject. While the issue of neighborhood or school segregation by social class or race/ethnic groups is of concern around the world, including in Europe, the former Soviet bloc, and South Africa, our article focuses primarily on empirical evidence drawn from the United States given the availability of high-quality longitudinal data sources and substantial changes over time in levels of segregation. In summary, recent experimental or quasi-experimental evidence suggests that neighborhood poverty, and associated characteristics have at most only modest impacts on educational outcomes at least over the medium run. Recent studies have more consistently found significant associations between school or classroom composition and student achievement. The effects are often small in magnitude, and in other cases they do not conclusively demonstrate that using policy to alter the assignment of students to schools or classrooms would necessarily lead to overall improvements in educational outcomes.

Why Peers and Neighborhoods Might Matter

Figure 1 presents a basic conceptual framework outlining the potential causal mechanisms linking schoolmates, classmates, and neighborhoods to academic outcomes (see also Jencks and Mayer, 1990 for an excellent discussion). Neighborhood factors could affect these outcomes directly or indirectly through the traditionally strong tendency for schools to serve particular neighborhoods or sets thereof. The strength of the link between neighborhood characteristics and schoolmate or classmate characteristics can be influenced by school attendance policies, including explicit desegregation or integration plans implemented by school districts (the use of which seems likely to decline in the wake of two 2007 Supreme Court decisions striking down school desegregation plans in Louisville and Seattle), or the use of school choice plans.

Even when there is no correlation between neighborhood and schoolmate or classmate characteristics,

neighborhood characteristics might still impact academic outcomes. Most directly, public schools often rely on local-source revenues to fund capital and operating expenses. Residence in a poor jurisdiction might therefore expose a student to inferior resources. School finance equalization policies enacted in virtually all states over the past three decades have undoubtedly ameliorated this concern to some extent. Nonetheless, evidence indicates that equalized spending across jurisdictions will not necessarily lead to an equalization of the quality of all relevant school inputs, since teachers exhibit clear preferences for working in lower-poverty environments.

Beyond this fiscal mechanism, the neighborhood social environment could shape youth expectations regarding appropriate forms of behavior and the return to schooling. Students in poor neighborhoods may perceive the return to schooling to be lower for several reasons. They may encounter few highly educated, successful neighbors, or may encounter a higher proportion of less educated yet relatively successful neighbors. Students may also perceive life expectancy to be shorter either because the incidence of chronic disease is higher in their neighborhood, or because they are exposed to a higher rate of violence.

The characteristics of schoolmates and classmates might associate with individual student achievement for any of several reasons. Given the importance of local financing for schools mentioned above, exposure to wealthier classmates might imply superior resources. In such a scenario, controlling for resource quality directly would reduce the magnitude of estimated schoolmate effects. However, education input quality is often difficult to measure. For example, it is widely acknowledged that teacher quality, defined as the ability to produce year-over-year increases in standardized test scores, varies substantially and is an important determinant of academic outcomes, but teacher quality correlates only modestly with commonly observed teacher characteristics and qualifications.

Schoolmates and classmates may contribute to the formation of students' expectations regarding the return to investments in human capital, but the relationship is not inherently clear. On the one hand, exposure to high-achieving peers may provide lower-achieving students with motivation to increase their effort. On the other hand, such exposure may do little more than convince lower-achieving peers that their ultimate schooling attainment is predetermined and that their own effort will have little impact on later outcomes. This sort of

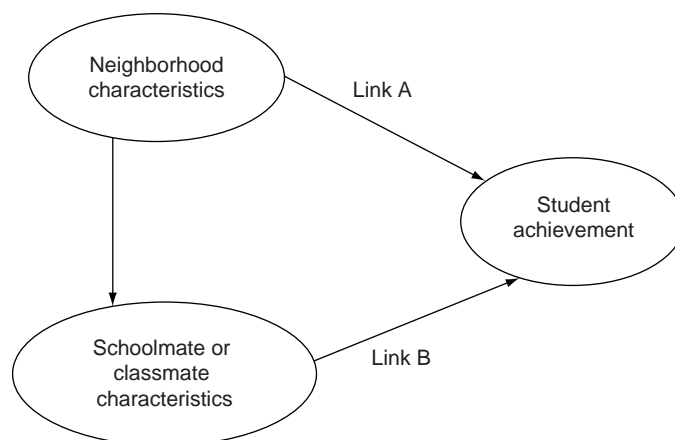

Figure 1 Link A mechanisms: community resources, student-expectation formation, violence or other disruptions to student learning; Link B mechanisms: parental resources, student-expectation formation, classroom disruptions, teacher expectations, and peer-to-peer education.

effect may be particularly acute in classrooms where achievement correlates with race, gender, or other easily observed characteristics associated with stereotypes. Exposure to lower-achieving peers has similarly ambiguous effects on the effort of higher-achieving students.

Even if schoolmates and classmates do not influence students' own expectations, they may influence the expectations of teachers, leading them to alter curricular choices in ways that may be beneficial or detrimental to any individual student. Teachers may tailor the overall difficulty level to the modal or median student, to the detriment of students who deviate strongly from that central tendency. Teachers may also be incentivized to improve the performance of small subgroups of students, to the detriment of others.

Peers, particularly classroom peers, may directly contribute to an individual's education, or detract from it. In the best-case scenario, students may learn through discussing topics with their classmates, or by directly asking their classmates with assistance in solving complex problems. In the worst-case scenario, classmates may interfere with the process of learning, by disrupting the entire classroom and preventing any instruction from occurring, or by disrupting individuals with off-topic conversation or other distractions. With these mechanisms, schoolmates and classmates may alter the actual return to investments in human capital, rather than the perceived return. Reading a book to prepare for a class discussion will generate higher rewards if other students also prepare; the return to paying attention in class may be diminished if the teacher cannot return that attention.

Understanding the distinct mechanisms that underlie peer and neighborhood effects is important for policy because policies like public or private school choice have the potential to change school but not neighborhood social compositions for children, while some housing-mobility interventions like the widely cited moving-to-opportunity

(MTO) experiment discussed below seem to generate larger changes in neighborhood than school characteristics. To the extent that peers or neighborhoods matter because they alter student perceptions, one could imagine interventions that directly target these perceptions, for example, by providing students more accurate information regarding the future returns to human capital investments. If peer and neighborhood effects simply reflect the impact of unmeasured inputs into education production, such as teacher quality, purely fiscal interventions might have a strong impact on the outcomes of disadvantaged students.

Evidence on Neighborhoods

Whether or how neighborhood context affects students' long-term life chances independently of school context remains somewhat unclear. The best evidence currently available suggests that moving from a poor or racially segregated neighborhood into a more socioeconomically or racially integrated one has at the most, very modest effects on children's test scores or other schooling outcomes, at least through the first 5 years or so following the neighborhood change.

Decades of research throughout the social sciences have documented substantial variation across neighborhoods in adult or child outcomes, even after conditioning on observable individual or family attributes (see e.g., Duncan *et al.*, 1997; Sampson *et al.*, 2002). Yet these studies, by and large, fail to provide convincing evidence in favor of any of these pathways, because they cannot separate the effects of neighborhoods *per se* from those of unmeasured individual attributes associated with residential selection.

The most compelling evidence for neighborhood effects on youth outcomes has come from quasi-experimental studies that exploit neighborhood changes induced by

housing programs. One of the best known of these quasi-experiments is Chicago's Gautreaux residential mobility program, which resulted from a 1976 Supreme Court decree finding that the Chicago Housing Authority and Housing and Urban Development (HUD) had engaged in systematic and illegal segregation. Follow-up interviews with Gautreaux families suggested improved outcomes for those who moved to the suburbs rather than other parts of Chicago, particularly for youth (Rubinowitz and Rosenbaum, 2001). For example, only 5% of suburban movers dropped out of high school compared to 20% of city movers, with an impressively large suburban advantage in college attendance as well (54% vs. 21%). However, more recent studies of Gautreaux show smaller impacts (Keels *et al.*, 2004). Moreover, Gautreaux has important limitations: the degree to which the program breaks the link between family preferences and mobility outcomes is unclear, since convincing documentation of the voucher offer and acceptance process remains difficult to reconstruct. In addition, Gautreaux studies cannot compare outcomes for program movers versus nonmovers or nonparticipants.

Motivated by the encouraging findings from Gautreaux, the US Department of HUD launched the MTO randomized housing-mobility intervention to identify the causal effects of residential-mobility interventions on families (Kling *et al.*, 2007). MTO has been in operation since 1994 in five cities (Baltimore, Boston, Chicago, Los Angeles, and New York). Eligibility for the voluntary MTO program was limited to low-income families with children living in public housing or Section 8 project-based housing located within designated high-poverty census tracts in these cities, with poverty rates of 40% or more.

By random lottery, some families were assigned to a Section 8 group that was offered unrestricted Section 8 subsidies (vouchers) that they could use to move to a new private-market apartment of their choice. (The Section 8 program provides housing assistance through rental certificates or vouchers. Income eligibility is usually set to 50% of local median income, with subsidies equal to the difference between 30% of tenant income and an area-wide threshold established by HUD. Since MTO started, the voucher program has been renamed the housing choice voucher (HCV) program, although we will use the terminology in effect at the start of MTO.) Other families were assigned to an experimental group that was offered housing-search assistance and Section 8 subsidies that could only be used to relocate to a low-poverty census tract (with a 1990 poverty rate below 10%). A third control group received no special assistance from MTO but remained eligible for public or project-based housing and other social programs.

The explicit goal of MTO was to help move families into less economically distressed communities, and as shown in **Table 1**, by this measure MTO was successful.

One year after random assignment families in the two MTO treatment groups live in census tracts with average poverty rates 11–13 percentage points (25–30%) below those of the control group. (Parentheses in **Table 1** show standard errors for the group means, which provides some sense for the statistical uncertainty surrounding our estimate.) The gap declines somewhat over time in part because of subsequent mobility among all groups. But even 6 years after, the treatment-control differences in tract poverty equal 7–8 percentage points (20% of the control mean), while the differences in cumulative exposure to neighborhood poverty (duration weighted averages) are 9–10 percentage points (20–25%). However, MTO treatment assignment had much more modest impacts on the neighborhood racial composition of participating families. Evidence also suggests that the treatment-control differences in the characteristics of public schools attended were also very modest. Thus, evidence of treatment-control differences in youth outcomes from a study such as MTO would point more clearly to causal pathways that did not involve school characteristics.

Table 2 summarizes results for MTO youth, drawn from analyses conducted 4–7 years after random assignment. **Table 2** presents mean outcomes for the control group together with the difference in average outcomes between those assigned to the MTO experimental group versus those assigned to the MTO control group (known in the program evaluation literature as the intent-to-treat effect, or ITT, which will understate the effects of actually relocating through the program because not all families assigned to the experimental group actually relocate). These data yield no evidence for statistically significant differences across MTO-assigned groups in reading or math-achievement scores measured using the Woodcock–Johnson revised tests (Sanbonmatsu *et al.*, 2006). While a growing body of research in developmental psychology, neuroscience, and economics suggest that children may be more sensitive to environmental changes early in life, there is no statistically significant evidence to date from MTO that treatment-control differences in test scores vary by age at random assignment, at least within the range of ages found among those MTO children who were administered tests. Those MTO participants who were very young children at baseline were not tested as part of the interim study, and so it remains possible that MTO effects on their achievement may be more pronounced.

There is a hint in the MTO data that female youth assigned to the experimental group may be somewhat more likely to graduate from high school than those assigned to the control group, although the point estimate is not statistically significant and the estimated experimental-treatment effect on graduation for male youth is negative (and also not statistically significant). More generally, the interim MTO evaluation finds that treatment-group assignment improves a variety of behavioral outcomes for female

^bAverage post RA neighborhood attributes calculated using address duration as weights (or duration-weighted postrandomization neighborhood averages).

youth but on balance has detrimental effects on behavior for male youth (Kling *et al.*, 2005, 2007).

One way to reconcile the MTO and Gautreaux findings is that the latter engendered more neighborhood racial segregation than the former, and so perhaps it is the racial rather than social class composition of a community that matters for youth schooling outcomes. This possibility can be tested by exploiting variation across MTO sites in treatment effects on mobility outcomes to use site-treatment group interactions as instruments for specific neighborhood characteristics. Census tract minority composition is a stronger predictor of youth violent criminal behavior than is either the tract poverty rate or local-area crime rate (Ludwig and Kling, 2007). However, in unpublished results, MTO researchers have found no evidence for an association between tract minority composition and children's achievement test scores.

Evidence, in some measure, of a small role for neighborhood socioeconomic characteristics from the MTO study is corroborated by recent quasi-experimental studies of families randomly assigned to public housing units in Toronto (Oreopoulos, 2003) and families displaced by public housing demolition in Chicago (Jacob, 2004). Studies using sibling comparisons or propensity score-matching methods (which are similar in spirit to methods that use statistical regression to control for observable differences across children) do report significant associations between neighborhood characteristics and youth outcomes. Studies have also documented a tendency for black-white disparities in educational outcomes to be more severe in more residentially segregated cities. But each of these methodologies is subject to criticism, and none can exclude the possibility that schools are the main causal pathway between neighborhood characteristics and outcomes. The next section focuses more specifically on arguments that racial disparities in school characteristics, made possible by school segregation, influence the magnitude of the black-white test-score gap.

Evidence on Schoolmates and Classmates

The methodological equivalent of conducting an MTO-style experiment to assess the importance of schoolmate or classmate characteristics would involve randomly assigning students to classes of varying composition, for potentially varying periods of time. To our knowledge, no such experiment has taken place at any point in history. There has been one noteworthy attempt to use a randomized trial, initially intended to study the impact of class size, to study the impact of assignment to peers of varying ability levels. By randomly assigning students to classes of different sizes, the Tennessee student teacher achievement ratio (STAR) experiment effectively assigned some students to higher

across-classroom variance in peer ability. If mean classmate ability is a predictor of achievement, then the wider variance in mean ability observed in smaller classes should produce a greater degree of variance in the ultimate outcome among students assigned to small classes. This exact pattern appears in the experimental data, indicating that students perform better when assigned to classes with higher mean ability (Graham, 2008).

Nonexperimental studies face the challenge of separating the influence of peers from the impact of unmeasured determinants of achievement that may correlate with peer characteristics. A common strategy for addressing this issue is the use of within-school variation in peer characteristics, across year-of-birth cohorts or classrooms within schools. This addresses the concern that individuals with strong unobservable characteristics sort into schools with observably more-able peers. The school fixed-effect strategy also eliminates at least one hypothesized mechanism linking peer ability to student outcomes – the tendency for more affluent parents to invest more resources in their children's school. Estimates derived from school fixed effects might therefore understate the benefit to some children from attending a school with more-able classmates, if these benefits accrue to the school at large and not to the specific classroom or cohort to which they belong.

Bearing this caveat in mind, several prominent studies that control for school fixed effects report patterns entirely consistent with experimental estimates. These studies use large administrative databases covering the population of students in Texas, North Carolina, or Florida. While not universally supportive of a positive association between peer ability and individual test scores, most of these studies report such a finding in at least some specifications.

Ability, as measured by prior year test scores, is not necessarily a sufficient statistic for all the potential peer characteristics that could influence student achievement. Researchers have also devoted considerable attention to the relationship between classroom racial or gender composition, or average socioeconomic status, and standardized test scores.

Some quasi-experimental studies have attempted to infer the impact of racial composition on outcomes by exploiting variation in the timing of school desegregation orders in the 1960s and 1970s, as well as unitary status declarations in a later time period. These studies rest on the assumption that variation in the timing of such court orders is idiosyncratic from the perspective of the individual student. Court-ordered school desegregation plans appear to have reduced black dropout rates by 2–3 percentage points, with no detectable effect on whites (Guryan, 2004). Qualitatively similar – but reversed – effects have been associated with the termination of many of these desegregation plans during the 1990s (Lutz, 2005). These court-ordered desegregation plans may also reduce violent crime-victimization rates among black and white youth, and

offending rates by blacks and perhaps whites as well (Weiner *et al.*, 2007).

Among studies examining school-level variation, which are subject to concerns regarding nonrandom sorting across schools, the Coleman report of 1966 is perhaps the best known (Coleman *et al.*, 1966). This study found that a school's socioeconomic class composition was among the more important predictors of individual student-achievement levels, certainly much more important than school racial composition. Recent studies that use cross-sectional variation in school segregation often generate similar findings – school racial composition seems to be weakly if at all related to student outcomes, while socioeconomic status (SES) of the school's student body may have a stronger association with student achievement (Rivkin, 2000; Cook and Evans, 2000; Card and Rothstein, 2006).

One study that used administrative data from Texas and controlled for school fixed effects reported that a 10% reduction in percentage of black in school would increase test scores for blacks by around 0.025 standard deviations and increase test scores for whites by around 0.01 standard deviations (the latter estimate is not statistically significant) (Hanushek *et al.*, 2004). These effects are about twice as large for black students at the top of the achievement distribution compared to those at the bottom of the distribution. Importantly, their finding holds even after controlling for either the average achievement level or social class composition of other students in the school. These authors control for a variety of potential confounding factors, including student-specific rates of change in achievement test scores and hard-to-measure factors that vary at the level of the school-by-grade or even the attendance zone-by-year.

A separate study of Texas data used plausibly random variation across cohorts in student demographic composition in Texas and found that a 10% increase in the share of one's classmates that are black reduces achievement test scores for blacks by around 0.1 standard deviations in reading and around 0.06 standard deviations in math (Hoxby, 2000). The effects of changes in segregation appear to be strongest in schools that are composed of at least one-third black students already. The effect of changes in racial segregation in the school on white students is of the same sign as for black students but only around one-quarter as large in magnitude. These effects may understate the impact of segregation because they exclude school-level causal mechanisms, or may overstate them if the restriction to cross-cohort variation in peer group composition fails to eliminate all potential sources of omitted variable bias.

However, more recent research using administrative data on North Carolina public schools to examine the relationship between peer composition and test scores at both the school and classroom levels fail to show any negative association between peer percent black and the

relative performance of black students (Vigdor and Nechyba, 2007). Relative to the Texas administrative data, the North Carolina data include more detailed family-background information and permit the matching of students to classrooms and teachers in elementary grades. The authors also analyze variation in peer composition associated with the opening of new schools in rapidly growing districts, by examining how achievement scores change for students that have a substantial change in peer-group composition (without moving schools themselves). The absence of peer effects could be attributed to differences in methodology, including the focus on elementary rather than middle-school grades.

Discussion

Overall, the most reliable evidence suggests that students learn more when they are placed in a school environment with more able peers, or more socioeconomically advantaged peers. Changing a student's neighborhood environment, without altering the school environment, appears to have at most only a modest impact on educational outcomes at least over the medium run. The frequently voiced concern that nonexperimental estimates of the relationship between neighborhood or schoolmate characteristics are contaminated by omitted-variable bias receives substantial support in the form of markedly attenuated effect estimates in more recent experimental or quasi-experimental literature.

The significant relationships estimated between classmate characteristics, most notably ability as measured by standardized test scores, and individual student achievement implies that the distribution of peers across classrooms has significant equity implications. The segregation of schools by factors that correlate with ability, or the stratification of classrooms by ability (commonly known as tracking) confers advantages on already-advantaged students and disadvantages on already-disadvantaged students. Integrating schools or classrooms by ability would amount to a progressive redistribution of resources across households.

While the equity implications of peer effects are clear, the implications for overall student learning (i.e., efficiency) are less clear. Would it be possible to rearrange students in a school, district, or metropolitan area in a manner that produced education gains that exceeded education losses? Would it be possible to rearrange pupils in a way that created gains without any losses whatsoever? For several reasons, existing literature has not provided details sufficient to answer these questions. While literature has provided fairly clear evidence that peer ability matters, it is much less clear whether the impacts of peer ability on individual students is nonlinear. Only in the presence of nonlinearities in peer effects, or in the presence

of some groups being completely immune to peer effects, would reallocation of students across settings improve the overall average level of learning for all students.

A second reason why existing literature is insufficient to address efficiency concerns is that standardized test scores, the most common outcome variable in the peer effects literature, have no obvious mapping into the ultimate goals that society holds for the development and well-being of children. A test-score gain for a student at the bottom end of the ability distribution may be much more socially valuable than a comparable gain to a student at the top end. The reverse might also be true. Ultimately, society's valuation of education improvements for individuals of differing inherent ability is a subjective matter; seen from this light, even the strongest evidence on the operation of nonlinear peer effects would be unlikely to settle debates regarding the most appropriate method of assigning students to classrooms within and across schools.

Teacher Quality in Education Production

What is a good teacher? Do good teachers make a difference in improving student achievement? While these are simple questions, the answers are more complex. Policy-makers and educators are searching for strategies to improve student outcomes. In the US, the 2001 the No Child Left Behind Act (NCLB) requires that all classroom teachers be highly qualified. The assumption is that highly qualified teachers will produce higher measured student achievement. NCLB has set certain criteria for determining the credentials that such teachers must have, but does little to define the characteristics and skills a teacher must possess in order to be considered high quality. In fact, the research evidence on what observable teacher characteristics impact student achievement provides little guidance. In this article, we discuss empirical evidence on teacher quality in education production. Several comprehensive reviews of the literature have been conducted (see the sections titled ‘Bibliography’ and ‘Further reading’), so our focus here is on more recent studies.

The Education Production Function

The education production function is an economic formulation of an input–output model: measured input variables, such as teacher quality, are mapped to a certain measured output, usually student achievement test scores or test score gains. Although a few experimental studies exist (e.g., Glazerman *et al.*, 2006), the empirical estimation of education productions is typically via multivariate regression models in quasi-experimental or nonexperimental settings. Hence, the vast bulk of the research evidence is able to detect correlational relationships between various characteristics and student achievement, with no or weak inferences about causal effects. Further, early studies of education production were typically conducted at an aggregate level – for example, examining mean years of teaching experience or the percentage of teachers with certification, in a school or district. More recent research has been able to take advantage of student-level longitudinal data in which it is possible to identify the characteristics of the specific teacher that taught a particular student.

The landmark study by Coleman *et al.* (1966), *Equality of Educational Opportunity* (also known as the Coleman report), which was commissioned by the US federal government, is among one of the most widely known education production studies. Coleman found that measured

school resources explained a small portion of the variance in student achievement. This finding was (mis)interpreted to mean schools do not matter. However, the main issue is whether there exist systemic differences in the ability of schools and teachers to raise student achievement (Hanushek *et al.*, 2005). Many researchers have demonstrated that schools matter a great deal (Clotfelter *et al.*, 2006; Rivkin *et al.*, 2005) and that teacher quality is the single most important factor among all school-related components (Hanushek, 2002; Rivkin *et al.*, 1998; Sanders and Rivers, 1996). Not only can teachers positively impact their students (Goldhaber, 2007; Clotfelter *et al.*, 2006), a series of high-quality teachers can potentially mitigate socioeconomic inequalities for individual students. Hanushek (2002) notes that “schools have the ability to compensate for educational differences arising from family backgrounds [where a long] string of above average teachers can entirely close the achievement gap, by income level” (p. 27). However, there are large differences in teacher impact on student achievement and identifying the high-quality teachers is problematic.

What Is Teacher Quality?

The majority of production function research assumes that observable characteristics of teachers are important determinants of student achievement. Teacher quality is a combination of observable and unobservable characteristics (Goldhaber and Anthony, 2007; Rivkin *et al.*, 2005; Hanushek *et al.*, 2005). For example, two easily observable teacher characteristics are years of experience and degree level (Boyd *et al.*, 2006; Clotfelter *et al.*, 2006; Glazerman *et al.*, 2006; Hanushek *et al.*, 2005; Rivkin *et al.*, 2005; Rockoff, 2004). These two variables are typically the basis for paying teachers in the US and hence commonly collected information. More refined measures may also be utilized including the degree major or coursework, in an attempt to determine the importance of subject-matter knowledge or pedagogical training. Other characteristics include proxies for ability such as the quality of the college or university (indicated by the selectivity of the institution) attended by the teacher (Murnane and Phillips, 1981; Ehrenberg and Brewer, 1994; Clotfelter *et al.*, 2006; Glazerman *et al.*, 2006), or tests of teacher ability such as scores on the National Teacher Exam, Scholastic Aptitude Test (SAT) or American College Testing (ACT) scores, or

specially designed tests (Ehrenberg and Brewer, 1994, 1995; Summer and Wolfe, 1977, 1975; Ferguson and Ladd, 1996). Similarly, various studies have examined the relationship between teacher certification and student achievement (Goldhaber and Brewer, 2000; Goldhaber, 2007; Goldhaber and Anthony, 2007).

Unobservable characteristics refer to characteristics not easily measured. Some examples may include pedagogy used by the teacher, classroom management skills, philosophy of teaching, and interpersonal or social skills (Goldhaber and Anthony, 2007; Glazerman *et al.*, 2006; Rockoff, 2004). Goldhaber *et al.* (1999) estimate that as much as 97% of teacher effects are attributable to unobservable characteristics. Data are typically not available for most of these factors, and it is difficult to separate them out conceptually or design policy interventions that can affect them with much certainty. In the next section, we focus, therefore, on the variables most commonly studied: teacher experience, certification, subject-matter preparation, advanced degrees held, and ability.

Teacher Experience

Many education production studies have examined whether or not teacher experience matters. Given data limitations, research is typically able to simply count a teacher's number of years of experience, treating all years as identical; hence, there is usually no information on the quality of any given year of experience. While hundreds of education production studies have been conducted since the Coleman report, they have not necessarily reached similar conclusions. Hanushek (1986), one of the most widely cited reviews of education production literature, concluded that there was no strong evidence that a teacher's years of experience positively effects student achievement; for example, in his 1989 update on school expenditures and performance, he found that only 29% of the 140 studies that included teacher experience as an input had statistically positive coefficients (Hanushek, 1989). However, Greenwald *et al.* (1996), in their own review of similar studies found experience was related to student achievement. These divergent conclusions are explained largely by differences in weighting of the studies and methodologies used to aggregate the results (Eide *et al.*, 2004).

The consensus view is that the experience gained in the first few years of teacher's career are the most important. In other words, a teacher's learning curve is steep (Murnane, 1975; Boyd *et al.*, 2006; Clotfelter *et al.*, 2006; Hanushek *et al.*, 2005; Rivkin *et al.*, 2005; Rockoff, 2004). The issue is whether some years of experience matter more than others, and if so, which ones. Although there is disagreement about the number of years that makes a difference, studies show that most improvement occurs in the earlier years. Rivkin *et al.* (2001) find that students'

learning gains are small after their teacher's first few years of experience. Rockoff (2004) measures the impact of individual teachers on student achievement by using panel data that matches student test scores to teacher assignment, and finds that teaching experience significantly improves student outcomes, but only in the first few years. After teachers reach the cutoff point of about 10 years, teaching experience offers only marginal returns (Rockoff, 2004). According to Rockoff (2004), reading scores in particular differ by approximately 0.17 standard deviations on average between beginning teachers and teachers with 10 or more years of experience.

Similarly, Rivkin *et al.* (2005) suggest that beginning teachers perform worse than more experienced teachers and find important gains in teacher quality after the first year of experience. They suggest that teachers early in their careers engage in learning by doing, finding little evidence that improvement continues after the first 3 years of teaching (Rivkin *et al.*, 2005). Furthermore, they suggest that the effects of nonrandom selection – where lower-quality teachers stay in the profession and more talented teachers exit the profession – affect the average quality of the teaching pool (Goldhaber, 1997; Hanushek *et al.*, 2005). They also suggest that teachers “may vary [their] efforts systematically with experience in response to tenure decisions or other institutional and contractual issues,” and this could also affect student achievement (p. 17). Consistent with other studies, Clotfelter *et al.* (2006) examine teacher experience and find student achievement peaking in classrooms with teachers that have between 13 and 26 years of experience. The purpose of their study is to examine teacher effectiveness given that the matching of teacher and student is nonrandom (Clotfelter *et al.*, 2006). Taken together, these studies provide strong evidence that the early years of teaching matter a great deal, and observable effects of over 10 years of experience are quite small or negligible (Clotfelter *et al.*, 2006; Hanushek *et al.*, 2005; Rockoff, 2004).

Teacher Certification

The minimum requirement for teaching in most states in the US is some form of certification. Discussions of teacher certification and preparation programs are inherently complex because of the wide variation in requirements (Darling-Hammond and Youngs, 2002). Earlier studies looking at teacher education do not necessarily separate teacher certification from subject-matter preparation and degree (Hanushek, 1994, 1989, 1986). Although teacher certification is required, there is little evidence from which to determine whether or not teacher certification itself has a significant impact on student achievement (Boyd *et al.*, 2007).

Studies on teacher certification find conflicting evidence. Goldhaber and Brewer (2000) find that students of teachers with standard certification in mathematics had higher achievement than students of teachers who are not credentialed in their subject area. Yet, the authors also find that mathematics and science students with emergency credentialed teachers do no worse than students of teachers with standard credentials, suggesting that simply having a standard credential does not make for a high-quality teacher, rather, having teachers credentialed in their subject area is what makes a difference. Unfortunately, studies of certification are hampered by the lack of good data that actually describe the content, sequencing, and quality of certification programs, which differ widely across states and from program to program within a state. Data often do not even permit clear distinctions among emergency, noncredentialed, standard, or alternative certification or credentials, making it difficult to interpret findings in a way that can improve the outcomes of the credentialing process.

In recent years, various alternative teacher certification programs, including district-sponsored programs as well as national efforts such as Teach for America (TFA), have become more widespread. According to Glazerman *et al.* (2006), TFA novice teachers are as effective in producing student achievement as other (traditional or other alternative program) novice teachers and experienced teachers alike in producing gains in math. The effect size on math scores was about 15% of a standard deviation. They also find TFA teachers are no worse than other novice and experienced teachers with respect to student achievement gains in reading (Glazerman *et al.*, 2006). This study is important because it randomly assigned teachers to students within a school district. Boyd *et al.* (2006) find small differences in gains, typically about 2–5% of a standard deviation, among students who had TFA or New York City Teaching Fellows teachers and teachers from traditional college-based teacher-preparation programs and alternative programs; however, these small differences disappear within 3 years as the teachers mature. These findings are consistent with the findings on teacher experience, and suggest the effects of teacher characteristics interact with each other in ways that are not always separable.

Degree Level and Subject-Matter Preparation

Many teachers in the United States earn advanced degrees, a plausible indicator of teacher quality. However, the consensus view is that a teacher education *per se* does not significantly impact student achievement (Hanushek, 1994, 1989, 1986; Murnane, 1975; Murnane and Phillips,

1981; Summer and Wolfe, 1975, 1977). Hanushek (1994) found that 100 of the 113 studies, including teacher education as an input, have statistically insignificant results and of the remaining 13, the positive and negative results are divided. More recently, Hanushek *et al.* (2005) and Rivkin *et al.* (2005) suggest that while advanced degrees are important for teacher compensation, they are not important for student achievement, which is consistent with earlier studies.

However, there is some evidence that advanced degrees in the subject being taught do make a difference, at least in math and science. For example, Goldhaber and Brewer (2000, 1997b) find that teachers with advanced degrees in mathematics produced greater high school student achievement in math. Similarly, Monk and Rice (1994) studied eighth-grade students and found that teachers who took several math courses in college had a positive impact on student achievement, but only when these teachers were assigned to teach more advanced math courses.

Teacher Ability

Teacher ability is another indicator of teacher quality. According to Eide *et al.* (2004), teacher ability is a stronger predictor of student achievement than years of experience or advanced degrees held. In a reanalysis of the data from the Coleman report, Ehrenberg and Brewer (1994) find a positive relationship between teacher performance on a short verbal ability test and student achievement gains. Rowan *et al.* (1997) reach a similar conclusion using one question on the National Educational Longitudinal Study (NELS) of 1998 teacher survey: those who accurately answered a math quiz item show a 0.018 effect size on student achievement in math at schools with average-ability students (Rowan *et al.*, 1997). Ferguson (1991) finds a link between student achievement and teacher's language score on the Texas Examination of Current Administrators and Teachers (TECAT). In an earlier study, Strauss and Sawyer (1986) find that a 1% increase in teacher quality, as measured by teacher test scores, results in a 5% decline in student failure rate on high school competency exams. Ehrenberg and Brewer (1994) find that students learn more from teachers who attended more selective undergraduate institutions. While Greenwald *et al.* (1996) found that teaching experience and degree levels were statistically significant and positively related to student achievement in 15% and 29% of education production function studies, respectively, they report teacher academic proficiency was positive in 50% of the studies. Although not a complete measure of teacher quality, teacher ability is clearly a quantifiable predictor of teacher effectiveness in the classroom.

Conclusion

One common theme from studies of teacher quality in education production has been a growing interest in how teacher labor markets work. If teacher quality is important in affecting student achievement, then questions pertaining to teacher attrition, retention, and recruitment become critical (Glazerman *et al.*, 2006; Boyd *et al.*, 2006; Rockoff, 2004). Similarly, how teachers are distributed across students is important. Does the sorting of teachers evolve into patterns of teacher–student matching that affect student achievement? How does this occur? The empirical evidence suggests that teacher sorting and teacher–student matching is not random (Clotfelter *et al.*, 2006; Rivkin *et al.*, 2005; Lankford *et al.*, 2002). Generally, schools in urban and low-performing districts tend to have difficulties attracting and retaining teachers (Hanushek *et al.*, 2004). In a descriptive study of teacher sorting of New York city schools, Lankford *et al.* (2002) find that these schools lose teachers to schools with more appealing environments. Some school districts find tempered relief from alternative teacher-preparation programs such as TFA and New York City Teaching Fellows, which place teachers exclusively in hard-to-staff schools with the hope to improve the educational opportunities of less-advantaged students (Glazerman *et al.*, 2006; Boyd *et al.*, 2006). More experienced and highly qualified teachers tend to be in schools that are more high performing, affluent, white, and suburban; inexperienced, less-qualified teachers work in schools that are low performing, poor, minority, and urban (Clotfelter *et al.*, 2006; Lankford *et al.*, 2002; Jacob, 2007).

Teacher sorting also occurs within schools. For example, it may be the case that tenured teachers are more able to leverage their seniority to influence teaching assignments in their favor, leaving more difficult positions to teachers with less seniority. Clotfelter *et al.* (2006) suggest that experienced teachers are better able to resist being assigned to less-able students. Yet, low-performing students are in greatest need of more experienced and effective teachers (Rivkin *et al.*, 2005). These placements in turn contribute to high teacher attrition rates among new teachers (Murnane and Steele, 2007). Unfortunately, to respond to the large numbers of vacancies, many schools place inexperienced, noncredentialed substitute teachers in classrooms. While teacher assignment policies allow this sorting practice, the distribution of teachers will continue to be uneven, favoring more-advantaged students over less-advantaged students. These distributional effects make measuring the effects of particular teacher characteristics on student achievement difficult to estimate.

The empirical estimation of education production functions has been an active research endeavor for more than 30 years. From this work, we have some important

results: teaching experience in the first few years of teaching matters but not much thereafter; teacher ability (as measured by test scores or selectivity of educational institutions attended) makes a difference; advanced degrees, *per se*, are not significant but subject-matter preparation, at least in technical subjects such as math and science is probably important; and teacher certification is not likely critical at least as it currently operates in the US. Although still largely reliant on quasi- and non-experimental designs, improvements in data quality and econometric techniques have made recent results more convincing. Despite this, much remains unknown. Little progress has been made toward breaking down the largely unobserved aspects of teacher quality into more finely grained measurable characteristics, or observable behaviors that can be convincingly linked to student achievement and which can be reliably measured or even taught. Future research aiming for descriptive analysis from which more nuanced instruments of measurement could be developed and tested would further our understanding of teacher quality.

The Economics of Class Size

D W Schanzenbach, University of Chicago, Chicago, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Class-size reduction is a politically popular but relatively expensive education reform. Understanding the causal relationship between class size and student achievement is critical for determining whether class-size reduction can be recommended as a policy to improve student outcomes. We begin with a review of the theory of why class size might matter, followed by a discussion of the empirical strategies for identifying the causal impact of class size on student achievement. Next, the empirical literature on class-size reduction is reviewed, focusing on studies using experimental and quasi-experimental techniques because these rely on the most credible strategies for identifying the true causal relationship between class size and student achievement.

Why Class Size Might Matter

For most readers, class size and academic outcomes are probably intuitively linked. Nonetheless, it may be helpful to formalize the idea somewhat. Lazear (2001) puts forth a useful theory of educational production. In it, reducing class size decreases the amount of time that the classroom is disrupted, increasing time devoted to productive tasks. A simple summary of the model is as follows: a child is behaving in class at a given moment with probability p , and misbehaving with probability $(1 - p)$. In the model, misbehavior is broadly defined, ranging from talking or fighting, to behaviors such as asking questions that slow down the class or monopolizing the teacher's time. When there are n children in the classroom, p^n is the probability that the entire class is behaving and learning is taking place (assuming that p is independent across children). Assuming a constant disruption rate, having fewer students in the class means that learning is taking place in a larger fraction of time.

In the model, the impact of reducing class size depends not only on the size of the class, but also on the behavior of the students in it. As a result, the Lazear theory predicts that class-size effects should be larger for classes with more poorly behaved students. For example, on average p may decrease with age, so the impact of class-size reduction might be smaller for high school students than elementary school students. The impact of class-size reduction – all else equal – is predicted to be larger for groups with lower propensities to behave.

Empirical Approaches to Studying the Impact of Class Size

Economists typically model the relationship between student achievement and class size for student i in school j as

$$Y_{ij} = aS_{ij} + bF_{ij} + \varepsilon_{ij} \quad [1]$$

where Y represents a measure of student achievement. S contains information on school-level inputs that impact achievement, such as class size, F contains family inputs, such as parental education, and ε is an error term. Both S and F measure inputs over the child's entire lifetime, and may contain inputs that are not observable to the econometrician. A negative coefficient on class size would suggest that student achievement declines as class size increases.

The problem with estimating eqn [1] (and similar versions of it) is that class size may be endogenous such that $E(\varepsilon | S, F) \neq 0$. For example, if students are assigned to small classes or better teachers in a compensatory manner – perhaps, because of low baseline test scores, or low levels of family inputs – but that information is not available to the researcher, the estimated impact of school resources will be biased. The most obvious such example is remedial or special-education courses, which tend to be small in size. Similarly, bias will result if parents who are more involved in their children's education are more likely to push for a smaller class or better teachers, and parental involvement is not measured in the dataset.

Due to these confounding factors, researchers have relied on strategies that use (plausibly) exogenous variation in class size in order to identify the causal impact of class size on student achievement. In other words, to identify the effect of class size, the variation in class size must come from factors that are more or less out of the control of decision makers such as parents and educators. The easiest example of this is where students are randomly assigned to classes of different size. The benefit of using a randomized experiment is that the treatment assignment is unrelated to any omitted characteristics. Such a design allows researchers to isolate the impact of the policy they are trying to test, without confounding factors such as parental pressure or compensating assignments. Thus, an experimental study typically offers more compelling evidence than a nonexperimental study, which simply observes the relationship between Y and S in the real world.

With a well-designed experimental assignment, a straightforward comparison of means by class type will

provide an unbiased estimate of the impact of class size on achievement. In the case of (an idealized version of) a class-size experiment in which students are randomized within schools, the equation to be estimated might be as follows:

$$Y_{ics} = \beta_0 + \beta_1 SMALL_{cs} + X_{ics}\gamma + \alpha_s + v_{ics} \quad [2]$$

where *SMALL* is an indicator variable for randomly assigned small-class treatment, and *c* indexes class *c* in school *s*. *X* is a vector of student-level characteristics. When treatments are randomized, student-level covariates are not related to class assignment and their inclusion should not change the estimated effect on class size, but should just contribute to the overall explanatory power of the model. A school-level fixed effect, α , is included, so that identification of small-class effects are identified off of within-school comparisons. Finally, the error term *v* contains class-level and individual-level components, reflecting random differences in teacher and student quality.

Nonexperimental Research

There have been volumes of research looking at the relationship between class size and student performance in nonexperimental settings. These are well summarized in a pair of influential meta-analyses by Hanushek (1986, 1997). In them, he argues that the lion's share of the economics of education literature finds no consistent relationship between class size and student performance. In the 277 estimates from 59 published studies included in the 1997 paper, only 15% showed a positive, statistically significant impact of class size on student outcomes. A re-analysis by Krueger (2003) raised questions about the validity of the meta-analysis, and argued that the literature largely supports a positive impact of reduced class size. Interested readers are encouraged to refer to Krueger (2001) and Hanushek (2003) for an overview of the debate.

The usefulness of the Hanushek meta-analyses is limited by the underlying quality of the studies included in them. Most – but certainly not all – of the underlying studies relied only on observational variation and did not have a research design that would allow the estimation of the causal impact of class size on student achievement. This is problematic for several reasons. For one, within-school variation in class size (in the absence of a true experiment) is seldom random. If, for example, there is compensatory assignment to smaller classes, then the coefficient on class size will not only pick up the true effect of being in a smaller class but also any correlated omitted variables such as special-education status or poor prior achievement as discussed above (see also Boozer and

Rouse, 2001). In addition, if there are only small differences in class size within school – for example, one classroom with 22 students and the other with 23 students – then one would need a large amount of data to precisely estimate the effect of such a small difference in class size. In general, it is inappropriate to base public policy on research that does not have a compelling identification strategy. As a result, much more weight should be placed on the experimental and quasi-experimental evidence outlined below.

Experimental Research

The most influential studies of class-size reduction are based on data from Project STAR, a large-scale randomized trial in the US state of Tennessee to test the impact of reducing class sizes in grades K-3. Mosteller (1995) described Project Steps to Achieving Resilience (STAR) as “one of the most important educational investigations ever carried out and illustrates the kind and magnitude of research needed in the field of education to strengthen schools.” In the experiment, students were randomly assigned within school to one of three treatment types: a small-size class (target of 13–17 students), a regular-size class (target of 22–25 students), or a regular-size class with a full-time teacher's aide. Importantly, teachers were also randomly assigned to class types. The experiment took place in 79 public schools across a variety of geographic locations (inner-city, suburban, and rural; predominantly low income, and middle class) for a single cohort of students in kindergarten through third grade in the years 1985–89. An eventual 11 600 students and 1330 teachers took part in the experiment. It is worth noting that the experiment made some students better off than they would have been, but of course did not otherwise increase class sizes beyond their normal range in the state at the time. Thus, no students were made worse off by being assigned to abnormally large classes.

In the ideal implementation of this experiment, students were to remain with the same randomly assigned class type from kindergarten through the end of third grade. In practice, though, there were several major sources of deviation from this model. Students who entered a participating school while the cohort was in first, second, or third grades were added to the experiment and randomly assigned to a class type. There were a substantial number of new entrants – 45% of eventual participants entered after kindergarten. A relatively large fraction of students also exited Project STAR schools (45% of overall participants), due to school moves, grade retention, or grade skipping, which also caused deviations from the original plan (see Krueger (1999) and Hanushek (1999) for further discussion). Fortunately, many of these exiting students are recaptured in the

follow-up analysis described below, which includes all students in Tennessee in grades 4–8, and a nationwide match of college-entrance-exam takers when the cohort is around twelfth grade. In addition, in response to parental concerns about fairness to students, all students in regular and regular-aide classes were re-randomized across the two treatment groups in first grade. This deviation is less problematic for evaluation of the program, because it involved new randomization. In general, studies have found no difference in performance between regular and regular-aide classes, so these two groups are sometimes combined as the control group.

Finally, a smaller number of students (about 10% of participants) were moved from one class type to another in a nonrandom manner. It has been reported that most of these moves were due to student misbehavior, and were not typically the result of parental requests for moves to small classes (Krueger, 1999). Of all transitions, 25% were into small (more desirable) classes. This weakness of the experiment can be addressed through use of an intent-to-treat setup – that is, to use the variation caused by initial randomly assigned class type instead of the actual (possibly nonrandom) class type attended.

In practice, the nonrandom transitions and new entrants described above complicate the approach somewhat. Due to nonrandom transitions after initial assignment, it would be inappropriate to use current-year class type; instead, initial class-type assignment (the intent-to-treat measure) is typically used in studies using Project STAR data. That is, all impacts are measured with regard to the class that students were assigned to, and not the class that they actually attended. The intent-to-treat measure used in this case likely understates the impact of small classes by up to 15% (Krueger, 1999). Nonetheless, the conservative intent-to-treat measure based on random assignment is typically considered preferable to models which measure the impact of actual class type attended in cases in which there is nonrandom movement between classes. A simple example may help illustrate this: if a child were moved from a regular class to a small class because his parents insisted on the move, it is also reasonable to assume that the parents are especially active in other aspects of the student's education. For example, they may monitor homework closely or provide other education-enhancing opportunities. Researchers cannot control for these characteristics because they do not have perfect measures of the home environment. In the ideal case in which class type is randomly assigned, these home-environment measures are uncorrelated with class type and their impacts are absorbed in the error term in eqn [2]. When the effect of actual (nonrandom) class attended is measured instead, some of the impacts of the active home environment also may be picked up because actual attendance may be correlated with this home-environment component of the error

term. Using the experimentally induced variation in this case means that not all students actually attend their assigned class type, and some students' test scores will count toward the regular-size class they were assigned to, even though they actually attended small classes. This approach circumvents the causation problem, but provides an understatement of the true impact. Krueger (1999) provides a more detailed discussion of this matter.

As described above, new entrants into the program were randomly assigned to class types. So, even though new entrants in first, second, and third grades on average are more disadvantaged than the kindergarten entrants, randomization allows us to compare new entrants in each grade to other new entrants in the same school across class types. In practice, then, the school-level fixed effect in eqn [2] is replaced with a fixed effect that combines school with a student's grade of entry (K, 1, 2, or 3) to the experiment, as this is the pool within which random assignment was determined (K representing kindergarten). In general, work on Project STAR has employed the following approach:

$$Y_{igs} = \beta_{0g} + \beta_{1g}SMALL_{is} + \beta_{2g}AIDE_{is} + \beta_{3g}X_{is} + \alpha_{rw} + \varepsilon_{igs} \quad [3]$$

Here g indexes the grade of the outcome measure. Both the *SMALL* and *AIDE* variables are measured as initial assignment, and not actual class attendance. The fixed effect varies by the randomization pool – school interacted with entry wave w . The coefficient on the control for classes with a teacher aide is sometimes omitted, as there appears to be no difference in outcomes between regular and regular-aide classes. As a result, the coefficient of interest measuring the small-class effect is similar whether or not aide classes are separately controlled. For precision, other student-level covariates such as gender, race, and free-lunch status are included in the vector X of control variables, but because of random assignment, including these controls does not change the magnitude of the small-class effect. The dependent variable is an outcome such as the mean math and reading score on the Stanford Achievement Test (SAT) for each grade, or whether a student took a college entrance exam.

Checks for Randomization

Due to the experimental design, impacts of reduced class size are straightforward to measure as the within-school (and entry wave) difference between class types, provided the randomization was done correctly. A compelling check of randomization is to examine a pretest to ensure that there are no measurable differences in the dependent variable between class types before the program begins. Unfortunately, no baseline test measure was collected in Project STAR. Another

way to investigate whether randomization was done properly is to compare student characteristics that are related to student achievement but cannot be manipulated in response to treatment, such as student race, gender, and age. If there are no systematic differences in observable characteristics across class types, this provides support that the randomization was done properly. A similar check should be done on observable teacher characteristics.

Table 1 presents estimates of differences in nonmutable characteristics across initial treatment assignment. This is similar to tables presented in Krueger (1999) and Krueger and Whitmore (2001). The estimating equation is similar to eqn [3] above, with student or teacher characteristic on the left-hand side and indicators for small-class assignment and school-by-entry-wave fixed effects. Standard errors are clustered at the school level. Each table entry represents a separate regression, and only the coefficient and standard error on small-class assignment are reported. Since none of the coefficients are large or statistically significant, this is evidence that the randomization was done correctly, at least with regard to observable characteristics. The single exception is that the teacher having a master's degree or higher is marginally significant ($p = 0.06$). This means that teachers with more education were slightly less likely to be assigned to small classes. The results below are virtually unchanged

if direct controls for teacher characteristics are included. Now that the randomization is validated, it is straightforward to turn to results of the experiment.

Achievement Results

Table 2 reports the impact of initial assignment to a small class on student test scores in grades K–3. Equation [3] is estimated, and each table entry reflects a separate regression. Test scores are normalized into z -scores based on the regular and regular-aide population. Average math and reading scores are reported in most cases, though if a student was missing a test score for one test but not both, the score for the non-missing test is used. The coefficient on the indicator variable for small class can be interpreted as the standard-deviation impact of the treatment. As many researchers have found (Word *et al.*, 1990; Krueger, 1999; Krueger and Whitmore, 2001), the table indicates that overall, students benefit about 0.15 standard deviations from assignment to a small class. When the results are disaggregated by race, it appears that black students benefited more from being assigned to a small class than the overall population, suggesting that reducing class size might be an effective strategy to reduce the black–white achievement gap. Krueger and Whitmore (2002) find that this result is largely driven by a larger treatment effect for all students regardless of race

Table 1 Testing whether covariates appear randomly assigned^a

	(1)	(2)	(3)	(4)
Panel A: Overall	Kindergarten 0.187 (0.039)	Grade 1 0.189 (0.035)	Grade 2 0.141 (0.034)	Grade 3 0.152 (0.030)
Panel B: Black students only	Kindergarten 0.214 (0.074)	Grade 1 0.249 (0.063)	Grade 2 0.207 (0.054)	Grade 3 0.242 (0.060)
Panel C: Free-lunch students only	Kindergarten 0.188 (0.046)	Grade 1 0.195 (0.042)	Grade 2 0.174 (0.041)	Grade 3 0.174 (0.039)

^aEach entry represents a separate regression. Only coefficients on initial assignment to small class are reported. Standard errors are in parentheses, clustered by randomization pool. Other covariates include randomization-pool fixed effects and student demographic characteristics.

in predominantly black schools, suggesting that benefits from additional resources are higher in such schools. Benefits are also larger for students from low socioeconomic status families, measured by whether they receive free or reduced-price lunch.

In fourth grade, the class-size reduction experiment concluded and all students were returned to regular-sized classes. At the same time, the assessment test was changed from the SAT to the Comprehensive Test of Basic Skills (CTBS). Both tests are multiple-choice standardized tests that measure reading and math achievement, and are taken by students at the end of the school year. The CTBS results are scaled in the same manner as the SAT, in terms of standard deviation units. One important difference in the data is that all students in public schools statewide who had ever participated in Project STAR are included in the follow-up study, even if they had been retained a grade. It is estimated that 20% of students had been retained a grade by eighth grade, but this did not vary with initial class assignment. As a result, some students took the fourth-grade test in 1990, while others took it in later years or even took it more than once. In the analysis reported here, all scores from grade g – no matter what year a student was in that grade – are compared. In the event of multiple attempts at grade g 's test, the first available score is used. As in **Table 2**, all estimates are conditional on school-by-entry wave fixed effects and only the coefficient on small class is reported.

Results for grades 4–8 are reported in **Table 3**. Overall, there is a persistent positive impact of small-class assignment that is statistically significant (or borderline significant) through eighth grade, as has been found in previous studies (e.g., Krueger and Whitmore, 2001). The magnitude of the gain is one-third to one-half the size that was observed while the students were in the experimental classes. When the results are disaggregated, though, the impact appears to remain stronger with black and free-lunch students than with more advantaged students. There is also some evidence that nonacademic outcomes such as the rates of criminal behavior and teen pregnancy are improved (Krueger and Whitmore, 2002).

Another potential measure of student achievement is whether these students take the SAT or the American College Test (ACT) college-entrance exam, which can be used as an early proxy for college attendance. In order to measure this, Project STAR student data were matched to the national databases of college-entry test records, as described in Krueger and Whitmore (2001, 2002). To examine whether assignment to a small class influences the college-entrance exam test-taking rate, a binary variable indicating that a college-entrance exam was taken is the dependent variable in eqn [3]. The impact of small-class assignment on college test taking is included as the final column in **Table 3**. Overall, test-taking rates increase by about 2 percentage points. Black students were 5 percentage points more likely to take the SAT or ACT if they were assigned to a small rather than regular-size class. On average, 38% of black students assigned to small classes took at least one of the college-entrance exams, compared with 33% in regular classes. Such a striking difference in test-taking rates between the small and regular class students could occur by chance less than one in 10 000 tries. Krueger and Whitmore (2002) interpret the magnitude of these effects by reference to the resulting reduction in the black–white test-taking gap. In regular classes, the black–white gap in taking a college entrance exam was 12.9 percentage points, compared to 5.1 percentage points for students in small classes. Thus, assigning all students to a small class is estimated to reduce the black–white gap in the test-taking rate by an impressive 60%. After controlling for increased selection into the test among small-class students, the impact on test scores for blacks is 0.15 standard deviations – about the same as the test-score impact in third grade.

Additional Caveats

An important limitation to the experiment was nonrandom movement across class-type assignment, as well as sample attrition during the treatment phase. As discussed briefly above (and at much greater length in the referenced works, especially Krueger, 1999), nonrandom

Table 3 Small-class effects on long-term test scores^a

	Grade 4 (z-score) (1)	Grade 5 (z-score) (2)	Grade 6 (z-score) (3)	Grade 7 (z-score) (4)	Grade 8 (z-score) (5)	Took college entrance test (1 = yes) (6)
Panel A: Overall	0.035 (0.025)	0.048 (0.024)	0.060 (0.025)	0.040 (0.025)	0.036 (0.025)	0.024 (0.010)
Panel B: Black students only	0.078 (0.048)	0.080 (0.043)	0.105 (0.045)	0.066 (0.042)	0.063 (0.046)	0.050 (0.018)
Panel C: Free-lunch students only	0.029 (0.036)	0.058 (0.031)	0.080 (0.034)	0.067 (0.031)	0.064 (0.034)	0.031 (0.014)

^aEach entry represents a separate regression. Only coefficients on initial assignment to small class are reported. Standard errors are in parentheses, clustered by randomization pool. Other covariates include randomization pool-fixed effects and student demographic characteristics.

movement can be addressed through using initial class-type assignment and not the actual (nonrandom) class-type attended. The attrition problem is significantly addressed through the statewide and nationwide matches used for the follow-up analyses.

Another concern often raised about the results of randomized experiments generally is that the measured effect may be driven by Hawthorne effects and might not be generalized to nonexperimental settings. That is, people participating in the experiment might act differently than they normally do because they know they are being studied. Although one cannot directly test for Hawthorne effects, Krueger (1999) attempts to shed light on the issue by investigating differences in achievement using the variation across only regular-sized classes, as there is little reason to think that Hawthorne effects would cause some classes in the treatment group to behave differently relative to other treatment-group classes. Class size in regular-sized classes ranged from 16 to 30 students, but the bulk of the distribution was between 20 and 26 students. Whether or not school effects are controlled for, students in a regular class with slightly fewer members out-scored larger regular classes. The estimated magnitude of a one-student reduction in class size was consistent with the magnitude of the experimental results (which estimates the impact of a seven-student reduction).

Finally, another concern is whether the findings of this experiment may be generalized to other settings. Along many measures, Tennessee in the mid-1980s looks reasonably similar to other places that might be interested in implementing a class-size reduction policy, so it would be reasonable to expect similar effects as those in the experiment. On the other hand, the Tennessee sample has lower levels of education inputs than the United States overall at the time, as measured by spending per student and education level of teachers. If adding resources has a greater impact when the baseline levels are already low, this might mean that schools with higher levels of spending could experience a smaller impact of class-size reduction. In addition, in order to be eligible for the experiment, schools were required to have a large enough enrolment to support three classrooms per grade. As a result, Project STAR schools were about 30% larger than average schools in Tennessee or across the United States. If larger schools are somehow differently effective with additional resources, then the findings in Project STAR may not be generalizable to smaller school settings (see Schanzenbach (2007) for further discussion of these points).

Quasi-Experimental Research

As true randomized experiments are rare, researchers must also look for quasi-experimental approaches that allow isolation of the causal impact of class-size reduction.

One of the strengths of quasi-experimental approaches is that the participants are unaware that they are being studied, so Hawthorne effects are unlikely.

The most famous quasi-experimental approach to studying class-size reduction comes from Angrist and Lavy's (1999) use of a strict maximum class-size rule in Israel and a regression discontinuity (RD) approach. In Israel, maximum class size is dictated by Maimonides' rule, which specifies that no more than 40 students shall be in one class. As a result, if the school's total enrolment in a grade is 40 students or fewer, there will only be one classroom with a class size equal to the total enrolment. If the enrolment increases from 40 to 41 students, though, a second class must be added, and the average class size declines precipitously from 40 students to 20.5 students. Similarly, if enrolment increases from 80 to 81 students, a school must move from two to three classes and the average class size falls from 40 students to 27 students.

Using the local variation around the enrolment sizes that are multiples of 40 students, Angrist and Lavy isolate the causal impact of class-size reduction. They find strong improvements overall in both math and reading scores, of a magnitude that is consistent with Project STAR's experimental results. Like in Project STAR, they also find larger improvements among disadvantaged students.

Urquiola (2006) uses a similar RD approach in Bolivia and finds that a one standard-deviation reduction in class size (about eight students in his data) improves test-score performance by 0.2 to 0.3 standard deviations. Browning and Heinesen (2007) also find similar results on data from Denmark, even though average class size is much smaller in their study (20 pupils per classroom, compared to 31 students in Angrist and Lavy's Israeli data). Urquiola and Verhoogen (2008) provide a cautionary tale about possible endogenous responses of schools to class-size caps, and show that in Chilean data, these endogenous responses of schools lead to violations of the assumptions of the RD design. In addition, caveats about the external validity of these studies are required as was the case with Project STAR.

Another quasi-experimental approach comes from Hoxby's (2000) study of class size in the US state of Connecticut. In the study, Hoxby isolates the variation in enrolment that comes from random fluctuations in cohort sizes across adjacent years. That is, taking away any pre-existing trends in enrolment that might signify that a school district is waning or booming, the effect of class size is identified by variation in cohort size that reflects a temporary random shock in population size that may have been caused by an unusually small (or large) birth rate in a given year. Using this approach, Hoxby finds no positive effect of reduced class size, but has the statistical precision to rule out an effect as large as about one-fifth the size found in Project STAR. The discrepancy between these results and those of other well-identified experimental and quasi-experimental studies remains a puzzle.

Policy-Induced Variation

Another potentially promising approach to studying the effects of class-size reduction comes from sharp changes in policies regarding class size. The most famous recent example comes from the US state of California, where in 1996 a law was passed to give strong monetary incentives to schools to reduce class size in grades K–3 to 20 or fewer students. Unfortunately, from a research-design perspective, the take-up of the policy was nearly universal within a short period of time, so there was very little variation to exploit and evaluate its impact. In addition, test scores are only available starting in grade 4, so any evaluation of the policy was forced to use later test scores (instead of scores during the year that the reduced class size was experienced) as the outcome measure. Not surprisingly, the best evaluation of the policy found inconclusive results (Bohrnstedt and Stecher, 2002). It is unfortunate that this policy intervention, costing more than \$1 billion per year, did not yield useful information about the impact of class-size reduction on student outcomes.

Discussion

The bulk of the research using credible identification of the impacts of class-size reduction suggests that reducing class size will significantly improve test scores. In addition, the benefits appear to be larger for disadvantaged groups such as African American students and children from families with low socioeconomic status. The long-term follow-up of the Project STAR class-size experiment finds that the gains appear to persist even after students are returned to regular-sized classes. The prior research has been less able to credibly isolate potential nonlinear effects of class size, which is an important consideration for policymakers considering a potential class-size reduction.

An important question that policymakers must ask prior to embarking on class-size reduction is whether the projected benefits outweigh the costs. A cost-benefit study of Project STAR found that the overall benefits outweighed the costs (Krueger and Whitmore, 2001). The answer in other cases will depend on the school's situation. What is the current level of educational inputs? Are there many disadvantaged students? Do we want to put extra weight on questions of equity – for example, the potential for small classes to reduce the black–white achievement gap? Is there a ready supply of qualified individuals available to meet the increased demand for classroom teachers? And, of course, what is the next best use of the available funds?

The Economics of Early Childhood Interventions

M Nores, NIEER, Rutgers University, New Brunswick, NJ, USA

© 2010 Elsevier Ltd. All rights reserved.

The growing adoption of early childhood interventions derives from an increasing perception of the developmental importance of the early years for later educational, social, and economic outcomes and, more recently, the labor-market pressures on women. Early childhood education has not developed as fast as primary education did 50 years ago. Global pre-primary gross enrolment ratios are currently 37%. Enrolments in pre-primary education are under 20% in sub-Saharan Africa and the Arab States, between 20% and 40% in Asia, around 60% in Central and East Europe and Latin America, 72% in the Pacific, 78% in North America and West Europe, and 101% in the Caribbean (UNESCO, 2006). Although coverage has tripled in the last three decades, it remains extremely low in the developing world. While most growth has occurred in the public sector, child care continues to be provided mostly by private institutions. This is more the case in North America than in West Europe, consistent with their corresponding social spending traditions. Aid for early childhood policies has promoted early education interventions in many countries, but amounts to only 0.1–16% of aid to primary education.

The Economic Rationale

Why do governments provide early childhood education and child care? Why is early childhood education slightly increasing in the developing and first world country policy and aid agendas? From an economic perspective, there are two fundamental rationales for early childhood education and child care interventions (and education interventions in general): (1) market failures and (2) equity and redistribution (Gruber, 2007; Blau and Currie, 2005).

Market Failures

Market failures in education include (1) positive externalities (substantial positive effects associated with its consumption not directly observed by the consumer, and therefore not taken into account by him/her in the decision to consume); and (2) credit market failures (Gruber, 2007).

Externalities are benefits accrued to society (social benefits) when an individual chooses to consume a good or service, beyond those accrued to the individual (private benefits). Some private benefits, in particular earnings, are commonly known as private returns to education. Interventions that increase earnings produce private benefits.

Additional examples are our own health. On the other hand, social benefits are benefits that increase social welfare. Examples of social benefits are increased productivity of the labor force (contributing to economic growth and development), less welfare use of individuals with higher earnings, reduced crime, increased tax collection, and increased female productivity (by shifting women to the labor market). There are also a series of intangible social benefits that are harder to measure and relate to having a more educated society and less inequity (active participation and the quality of the democratic process).

Families do not take into account externalities when deciding about education (they are not willing to pay for them and these are not included in the price of schooling); therefore, they consume less than what is socially desirable (the social optimum). For example, a family knows that by investing in education his/her child will benefit through increased productivity and therefore earn higher wages as an adult. Therefore, they are willing to pay for education so long as the cost of educating their child is at least as much as the extra earnings the child will accrue in the future. However, society also benefits from an educated child and the family is not taking these benefits into account (only the additional earnings), therefore underinvesting in education.

Credit market failures relate to the inability of families to borrow to finance education (especially early childhood or basic education). When families cannot provide collateral (assets owned by the family that the bank can claim if the loan is not paid back), and because banks cannot ascertain whether individuals will earn enough in the future to pay for the loan (parents later on in their careers or the child when he/she grows up), they are not willing to supply the loan. This type of market failure can be addressed through loans to finance education which are absent for early childhood, unlike for higher education. Governments have chosen to provide early childhood services directly (e.g., preschool) or providing funds for it (e.g., vouchers and subsidized daycare).

Equity and Redistribution

The consumption of education, like the consumption of most goods, is dependent on the financial ability to pay for the service (i.e., the capacity of families to pay for education and the indirect costs of education, e.g., school uniforms, books, remedial classes, transportation, and parent association fees). Since higher family income renders

higher spending capacities, inequalities in income have the potential to translate into inequalities in educational attainment (and in the quality of education), and consequently, into differences in lifelong earning streams. Without government intervention, education has the potential to reproduce income inequalities. Through equality in access and educational opportunities, governments in democratic and nondemocratic societies have seen education as a way of redistributing income across generations. Public support for education based on distributional concerns is based on a belief that a children's access to education (and lifelong chances) should not be based on their parent's financial capital.

Similarly, whether or not most parents might be altruistic and prioritize expenditure on their children's education, the distributional argument also covers children whose parents might prioritize their consumption over their children's consumption (what is known as egotistic utility functions). Public provision of education and child care, as an alternative to money for child care or loans, ensures that all children are provided the same opportunities regardless of their parents' preferences.

Types of Early Childhood Interventions

Early childhood interventions have developed much later and at a lower speed than primary and secondary education, predominantly because governments and donor agencies have given a relatively lower priority to pre-primary education policies and expenditures. In the presence of market failures and a concern with redistribution, governments have three alternatives for intervention: regulation, funding, and provision. Although the reasons for government intervention described require a combination of regulation and funding, provision of early childhood education and child-care alternatives has prevailed in many countries.

Across countries, providers of early childhood education and care differ significantly. They support different aspects of childhood, from children's growth, development and learning (childhood education programs and preschool programs) to health, nutrition, hygiene, cognitive, social, physical, and emotional development. They take place in formal, informal, and nonformal settings, in arrangements ranging from center-based, to formal preschool education, to parent/community-based arrangements (UNESCO, 2006). In some countries, child care is provided at a parent's house serving children from the community and government subsidized (e.g., *Hogares Comunitarios* in Colombia); in these cases, the governments have chosen to increase access to early childhood care through increased funding and regulation predominantly.

In the last two decades, early childhood education has gained strength as a cost-effective way of reducing

disparities in educational outcomes and increasing schools' effectiveness. Because early environments (and disadvantages) define later outcomes, early childhood education has been promoted as a way of increasing educational attainment of the individual (productivity), as well as reducing social inefficiencies in the provision of education later on (reduce repetition, and the need for remedial or dropout prevention programs) (Carneiro and Heckman, 2003; Heckman and Masterov, 2007). Moreover, studies on cost effectiveness (measuring the cost of providing high-quality preschool education vs. the benefits produced by it in the form of higher productivity of the labor force, reduced welfare, reduced crime, and higher tax collection) have increased support for early childhood interventions.

In the international arena, as part of the millennium development goal of achieving universal primary education for all by 2015, early childhood education has been advocated to reduce disparities in primary educational attainment and increase attainment of the very poor. The overall argument on early childhood has moved from providing it as a basic human right to providing it because it is an effective way of reducing disparities in educational attainment that are the consequence of income inequalities. Because it leads to higher educational attainment, it increases individual welfare and reduces the probability of poverty in adulthood (the equity argument), while in parallel increasing efficiencies in the education system, reducing social costs, and increasing social welfare (the externality argument).

US and international evidence has shown that good-quality early childhood interventions have direct effects on cognitive and noncognitive development (Barnett, 2000; Blau and Currie, 2005; Boocock, 1995; Camilli, in press; Engle *et al.*, 2007; Heckman and Masterov, 2007). Important effects across different developmental dimensions have been present in several small controlled interventions, including random assignments, focused on disadvantaged populations. Among these are the Carolina Abecedarian Full-Day School Program, the Early Training Project, the Elmira Prenatal/Early Infancy Project, the Infant Health and Development Program, the Mauritius Preschool Study, the Milwaukee New Hope Project, and the Perry Preschool Project.

These studies are particularly valuable because randomization increases internal validity; namely, inferring causality between the program and the observed cognitive and noncognitive outcomes. On the other hand, as long as interventions remain small, external validity, or the degree to which conclusions can be generalized, remains small; that is, it is not clear whether the size of the results would remain the same when interventions are extended to a large-scale (i.e., national) level. This makes larger-scale interventions (e.g., evaluations of the Head Start program in the US, the Chicago Child-Parent Centers,

the Michigan School Readiness Program, the South Carolina Pre-K, the New York Pre-K, and the Effective Provision of Pre-School Education Project of the University of London, among others) substantiating the benefits of early childhood education, of fundamental importance (Blau and Currie, 2005; Heckman and Masterov, 2007).

Among the programs mentioned, the Perry Preschool Program is among the most-studied early childhood interventions, following a sample of 128 low-income children through age 40 (Barnett, 2000; Schweinhart, 2005). Children were randomly assigned to treatment and control groups, and the treatment group received half-day high-quality preschooling and weekly home visits for 2 years. The Abecedarian program consisted of a study following 111 children until the age of 21. Randomization was done at birth with the treatment group receiving center-based child care with an emphasis on language development, 8 h a day through the age of 5 (Heckman and Masterov, 2007). Similarly, the Chicago Child-Parent Center consisted on matching treatment individuals with similar children (of the same age, which would also be eligible for the program and of similar education and economic family background) rather than on random assignment of individuals. The program provided health and social services, free meals, and center-based half-day preschooling for 3- and 4-year-olds during the school year (Heckman and Masterov, 2007).

The different types of benefits observed from these interventions, as well as from international studies, are summarized below. These have been differentiated as cognitive (school progress and performance outcomes), noncognitive (social, behavioral, and labor-market outcomes), and indirect benefits to society.

Cognitive and Academic Outcomes

In the short and medium term, early childhood interventions, particularly those that focus on the developmental and cognitive aspects of childhood, are expected to impact participants' cognitive development, their school progress, and their educational attainment. These three types of indicators have been used as the basis for evaluating the success of most early childhood educational interventions.

Indicators, such as achievement tests and intelligence quotients (IQs), usually measure cognitive development. Several studies evidence positive effects of high-quality center-based care on children's cognitive growth. That is, children come into these programs extremely disadvantaged, and end up performing better than similar peers that were not granted access to the program. While in some cases IQ outcomes have been large, they have been short termed, sustained until school entry, and fading out through the first years of schooling except for the Abecedarian and Milwaukee programs. Not all types of

interventions have impacts on cognitive development as measured through IQ. Quality matters in early childhood (well-designed, intensive programs that include involvement with children and families). Moreover, children from impoverished homes benefit more from child care than children whose home environments are already supportive and stimulating (Engle *et al.*, 2007). The evidence from developing countries substantiates these findings (Boocock, 1995; Engle *et al.*, 2007; Schady, 2006).

Early childhood programs have also shown that they can have important medium- and long-term effects on school progress, that is, achievement, reducing repetition, reducing placement in remedial or special education, and increasing school outcomes (educational attainment). From random assignment studies, there is evidence of positive and lasting impacts of early child education on achievement (e.g., Milwaukee, Florida, Abecedarian, and Perry) (Barnett, 2000; Blau and Currie, 2005). Among the international research, there is evidence of increased achievement from various programs and evaluations; for example, carefully designed studies in Sweden (Boocock, 1995), a large program to construct preschool facilities in Argentina, a nutritional and early stimulation program in Jamaica (Schady, 2006), the Colombian *Hogares Comunitarios* program (Engle *et al.*, 2007), and the Cali Study (Boocock, 1995), integrating nutritional and child-care components.

Increased school readiness, achievement, and social development set the stage for improvements in school progress and educational attainment. That is, it reduces the chances that a child will repeat grades, need remedial education, be a special-needs child, and dropout. The evidence shows reduced grade retention, with the estimates for dropout rates across the Abecedarian, Chicago, and Perry interventions being quite similar (around 20–30%). There is also evidence of reduced special education rates or the number of years of special education (e.g., Abecedarian, Perry, Chicago, and Early Training Project). Center-based experiences in Nepal, Argentina, Burma, Mexico, and Colombia evidence improvements in enrolments, age of entry, retention, and performance (Engle *et al.*, 2007; Myers, 1992; Schady, 2006).

For the same reasons, since children come into school more prepared for it and progress through it more smoothly, they are also more likely to succeed in attaining a secondary education degree (and in consequence, more likely to transition into post-secondary education). In developing countries, transitioning into secondary education is an important concern. Only some few studies in the US and none in the international arena have followed children through high school and beyond. Abecedarian, Perry and Chicago, and the Florida studies, as well as evaluations on Head Start, have indicated effects on graduation rates of participants (Barnett, 2000; Blau and Currie, 2005).

Noncognitive Outcomes

Focusing on cognitive development indicators ignores the full array of social and economic noncognitive responses motivated by schools, families, and institutions. Short-term evidence on IQ or scores does not measure relevant nutritional, social, emotional, and overall developmental dimensions. Some examples of potential developmental outcomes of early childhood interventions are: improvements in the health and nutritional indicators of the child (whether because meal and nutrition programs are integrated into the intervention, or because of work being done with parents), effects on socialization (aggression and behavior indicators), which in the long term relate to delinquency and crime outcomes, and effects on motivation, self-discipline, and attentiveness that relate to long-term educational attainment.

Moreover, it is argued (Carneiro and Heckman, 2003) that while IQs might not be successfully affected by a variety of interventions, social and emotional skills are, leading to increased educational success, reduced criminal activity, integration of disadvantaged population into mainstream society, etc. A lifetime approach has addressed path dependency of circumstances and behaviors resulting from early education. Growing attention is being paid to how early cognitive development defines later attainments, life behaviors, opportunities, and experiences (Heckman and Masterov, 2007). When preschool programs deter children from transgressions, they may dissuade them from a life of crime. A similar argument goes for health-related behavior. While many programs are critically evaluated on cognitive development indicators, medium- and long-run behavioral effects translate into socioeconomic savings through life-long behavioral changes.

In the developing world, in the context of high child mortality rates, stunting, and serious child illnesses and hunger, health and nutrition take on added importance for child development (Barnett, 2000; Engle *et al.*, 2007). Health, nutritional, and developmental improvements have been evidenced across interventions in developing countries (e.g., Chile, Colombia, Egypt, Guinea, Jamaica, Kenya, Mexico, Mauritius, and Vietnam; Engle *et al.*, 2007; Myers, 1992; Raine *et al.*, 2003) and the US (Elmira Prenatal/Early Infancy Project), with improvements varying from improvements in iodine and iron deficiencies, to improvements in height/weight measures.

Substantial lifetime (long-term) effects are mediated through higher educational attainment. The effects of educational attainment on earnings are well established and long lasting. Higher educational attainment reflects cognitive advantages and enhanced noncognitive attributes, for example, self-discipline or diligence. Overall, higher attainment is associated with higher economic well-being over the long term, in particular, higher earnings and

employment status. The Perry Preschool Program followed children up to age 40, observing their earnings well into adulthood. Program males and females showed considerable higher earnings than the control group (Nores *et al.*, 2005). While increased earnings are a private benefit, these directly translate into higher amounts of tax payments (income taxes, through increased annual earnings, and sales taxes through increased consumption).

Reduced crime is another indication of social and emotional effects of early childhood. The Perry Preschool Project evidenced substantial lower rates of criminal activity for the treatment group. The Chicago Child-Parent Center (and an expansion program later on) showed reduced delinquency and crime. Evaluations of the Florida and Colorado Head Start (for females only), the Panel Study of Income Dynamics (PSID) Head Start study (comparing Head Start to non-Head Start participants between the ages of 18 and 31) and the Mauritius Preschool Study, support the findings from the Perry and Chicago random studies. Many of the benefits from reduced crime can be summarized into victims (some of these, such as pain, being intangible), policing, criminal justice system, and incarceration costs; all of which are different types of social benefits. Private benefits from reduced crime may vary from increased quality of life, to intergenerational benefits (discussed below), and a series of intangible benefits (such as freedom).

As individuals attain higher levels of education, subsequent increased earnings, and evidence reduced criminal behavior, the aggregation of such behavioral and economic changes are expected to reduce welfare use. The Perry Preschool Program indicates lower welfare reliance of the treatment group (the PSID Head Start evaluation also looked at welfare but found no difference across groups).

Other indicators of social and behavioral changes relate to improvements in the quality of life, health-related behavioral changes, and teenage pregnancy. Teenage pregnancy effects might be the consequences of postponing childbirth through increased educational attainment or through health-related behavioral changes. For youth and adults, the Abecedarian and Perry studies provided indication of health-related behavior in terms of drug usage and tobacco. These two programs also generated increases in the age when the participants had their first child (Schweinhart *et al.*, 2005; Blau and Currie, 2005).

Indirect Effects

Besides benefits reaped directly from the child's increased educational attainment and lifetime behavioral responses, early childhood interventions impact a child's family in two additional, important, yet indirect, ways: (1) by

freeing up women's time and (2) through the intergenerational links across earnings and across education.

Female Labor Supply

As an increasing number of mothers have entered the labor market, especially with global trends in urbanization and industrialization, the question has arisen on how to take care of their children. Even though child protection and the enhancement of child development and school readiness has been at the center of government interventions, increased female labor participation has increased awareness on the issues of early child care and education. Although female employment in developing countries is also increasing, females in these settings tend to concentrate on self-employment and unpaid family work.

Early childhood interventions may offer opportunities for maternal participation in the labor market as well as increased school participation of older siblings (usually females) freed from child-care responsibilities. Child care and labor-market choices are competing uses of the time of the mother and child-care prices affect labor-market choices, in particular, for married women who evidence a higher elasticity (option to decide depending on the price) in their labor supply with respect to child-care prices than single women who have no choice but to work, depend on welfare, or a relative. Mothers in non-wage jobs (e.g., agricultural work in their household) tend to combine work and family responsibilities more often than women in wage jobs (urban areas and developed countries). Moreover, in developing countries young daughters frequently act as providers of free child care, releasing mothers for free child care.

Evidence from the expansion of child-care policies and subsidies in the US and developing countries show a substantial relation between women's decision to work, in particular, single and low-earning mothers and child-care prices (e.g., see Gelbach (2002) and Bainbridge *et al.* (2003) for the US; Berlinski and Galiani (2007) for Argentina, and Lokshin *et al.* (2000) for Kenya). This decision to work is accompanied with increases in household earnings and reductions in welfare dependency.

Intergenerational Effects

Estimation of the intergenerational benefits of early childhood interventions has been done for the Abecedarian and Perry studies (Barnett and Belfield, 2006). However, these tend to be projections based on: (1) studies on the intergenerational links across earnings and across education, and (2) the literature on the determinants of educational attainment. Studies on the intergenerational links across earnings and education have estimated these links to be strong, although far from the unit (Bowles *et al.*, 2005). The literature on the determinants of educational attainment

has emphatically shown that parental education, earnings, and employment status (socioeconomic status) are the strongest determinant of a child's cognitive development and success. The combination of these two sets of literature leads to project at least educational and earning effects on subsequent generations. On the other hand, the effect of reduced crime and welfare behavior benefits across generations has proved harder to establish, although there is some evidence that health-related and social behaviors from children relate to parental behavior.

Conclusions

The economic rationale for early childhood interventions is similar to that of providing primary and secondary education. Early childhood interventions are argued based on the existence of externalities, family credit constraints, and equity. Expected benefits from good-quality early childhood interventions, on the basis of the evidence, vary from short-term impacts on cognitive measures such as IQ, to higher achievement, school progress, reduced repetition, reduced special education placement, higher educational attainment, higher earnings, more taxes paid, reduced crime, reduced welfare reliance, reduced teenage pregnancy, and improved health-related behavior. Moreover, early childhood interventions also free mothers (and in some contexts, older female siblings) for labor-market opportunities, thereby increasing female productivity.

Because many of the externalities of early childhood education have been quantified, it has gained support as a policy alternative to interventions later on. Early childhood education has gained strength as a cost-effective way of reducing disparities in educational outcomes and increasing schools' effectiveness. In parallel, while developed and developing contexts vary in terms of impact and needs (e.g., nutrition), the equity argument has gained strength as an outcome of early childhood provision over time. Early childhood interventions increase educational progress and attainment, increasing individual welfare and reducing the probability of disadvantages in adulthood.

An Overview of Teacher Labor Markets

H Lankford, University at Albany, Albany, NY, USA

J Wyckoff, University of Virginia, Charlottesville, VA, USA

The market for K-12 teachers is important both for its sheer size and because teachers can have large impacts on the life outcomes of students. The 3.6 million elementary and secondary school teachers in the United States make up 9.2% of all college-educated workers 25–64 years old (National Center for Education Statistics (2006); Digest of Education Statistics, (2006); US Census Bureau Educational Attainment in the United States (2005)). Research confirms the conventional wisdom that teachers can substantially contribute to improved student achievement (Sanders and Rivers, 1996; Aaronson *et al.*, 2003; Rockoff, 2004; Rivkin *et al.*, 2005; Kane *et al.*, in press). Yet, achievement levels often fall short of that expected by the public and policymakers. Despite improvements over the last 20 years, it remains common that US schools with largely poor, nonwhite students have fewer than half their students reach basic performance and fewer than 20% reach proficiency (e.g., on the 2007 National Assessment of Educational Progress (NAEP) eighth-grade mathematics achievement tests, 53% of all African Americans performed below the basic level and only 11% reached the proficient level), with subsequent high school graduation rates also below 50%. (Many states do not yet employ cohort-based graduation rates and thus estimates are notably inaccurate. New York State did employ a cohort-based approach to estimate that in 2002, fewer than half of all African Americans in ninth grade graduated from high school by 2006.) Thus, it is natural for policymakers and researchers to look to improvements in teaching as an important component in addressing long-standing

concerns about student-achievement gaps by socioeconomic status as well as the increasingly poor performance of US students in comparison to international peers.

The qualifications of college graduates who enter teaching in the US have declined over the last 40 years (Bacolod, 2007; Corcoran *et al.*, 2004) and the least qualified of those entering teaching typically teach poor, nonwhite, and low-performing students – the very students whose educational success is most dependent upon their teachers (Betts *et al.*, 2000; Lankford *et al.*, 2002; Peske and Haycock 2006; Clotfelter *et al.*, 2007c).

This is an extraordinarily exciting period for research exploring teacher labor markets. Policymakers appear intent on improving the quality of classroom instruction and are experimenting with a range of policies intended to improve teacher recruitment, preparation, retention, support, and evaluation – all in an effort to improve student outcomes. (As is increasingly common in the literature, we differentiate between teacher qualifications and teacher quality. Teacher qualifications are the measures of ability, knowledge, and skills of teachers such as test scores, certification status, and education level. Teacher quality is a measure of a teacher's ability to improve outcomes for students, such as value-added scores or principal evaluations.) In response, researchers interested in informing policy are employing a variety of methods and data in efforts to identify how policies can be leveraged to improve the educational achievement of students. An increasing number of states and districts have longitudinal data on teachers and students that provide a rich

understanding of the individuals who enter teaching, the nature of their preparation, their career choices, and the performance of their students on achievement tests. Designs that exploit natural experiments, regression discontinuities, or instrumental variables are increasingly commonplace. Finally, randomized control trials that evaluate treatments that isolate specific aspects of teacher labor markets have become more common as a result of research programs at the US Department of Education Institute of Educational Sciences (Angrist, 2004). While much work remains to be done, the methodological ante for applied research on teacher labor markets has risen, thereby providing policy-makers increasingly useful causal evidence.

The field is now better positioned to build a knowledge base that identifies what policies work in improving student outcomes. We highlight three important, unresolved research questions relating to teacher labor markets. We focus on these questions because addressing them will inform the most pressing educational-policy questions; these questions incorporate many more specific teacher-labor-market issues. (Many teacher-labor-market research questions fall under these three broad areas. To name but two: What is the role that teacher-retirement benefits play in defining teacher labor demand and supply? How have the No Child Left Behind Act (NCLB) and state accountability policies affected teacher demand and supply?) Besides, they illustrate some important conceptual and empirical issues:

1. Recruitment: What are the most efficient ways to attract individuals, who will be effective teachers, to the profession?
2. Preparation: Of those who enter teaching, what teacher preparation and professional-development policies best increase teachers' capacity to improve student outcomes?
3. Retention: Given the substantial concern over teacher retention, what policies ensure that effective teachers are retained, while ineffective teachers are encouraged to pursue other alternatives?

To answer these questions, researchers must develop causal understandings of a number of more traditional empirical questions pertaining to teacher labor markets, such as: how to define and measure teacher quality; how teacher quality varies with observable attributes of teachers; the elasticity of teacher quality with respect to wages and other working conditions; how transfer and quit decisions by teachers respond to changes in wages and other working conditions; and the relative marginal productivity of differing teacher-human-capital investments. The answers to these and other questions likely are context specific – the causal relationships differ across, and even within, teacher labor markets. For example, recruitment, preparation, and retention strategies to improve student outcomes may well differ between

schools having predominately low- and high-performing students and between schools in urban and rural settings. Ignoring such heterogeneity can result in misguided policy recommendations.

Much has been written on issues related to teacher demand and supply, with several recent papers providing excellent summaries of various aspects of this literature (e.g., Hanushek and Rivkin, 2006; Dolton, 2006; Murnane and Steele, 2007; Goldhaber, 2008). In addition, the articles following this overview provide excellent summaries of specific features of teacher labor markets. Our intent in this article is to provide a conceptual and empirical framework within which to situate the research questions outlined above. We begin by describing some features of teacher labor markets that both differ from many other labor markets and create challenges when analyzing the factors that contribute to poor student performance.

Teacher Labor Markets

Teachers are important to the education process because of their ability to contribute to student learning, both directly and indirectly. Equation [1] is a stylized version of the education-production function model that underlies most research linking teachers to student outcomes.

$$A_{it}=f(C_{it}, F_{it}, T_{it}, P_{it}, S_{it}) \quad [1]$$

A_{it} reflects educational outcomes for student i at time t , and C_{it} , F_{it} , T_{it} , P_{it} , and S_{it} represent all current and prior values of relevant attributes of the student (C) and his or her family (F), teachers (T), classroom, school, and neighborhood peers (P) and other inputs available in the school (S). (For a detailed discussion of models of student achievement and their estimation see Todd and Wolpin (2003)). Research estimating variants of eqn [1] finds that differences in teacher quality have substantial effects on student achievement. For example, Sanders and Rivers (1996) estimate that differences in teacher quality can result in a 50 percentile improvement in measures of student achievement and that these improvements are additive and cumulative over subsequent teachers. Aaronson *et al.*, (2003) find that a two-standard-deviation increase in teacher quality improves student achievement by 25–45% of a grade equivalent. Kane *et al.*, in press) estimate that the difference in effectiveness between the top and bottom quartile of teachers results in a third of a standard deviation difference in student test-score gains. However, teacher effects are estimated with substantial uncertainty, implying true values may differ from these estimates (McCaffrey *et al.*, 2003).

What determines the teacher quality a particular student receives? The allocation of teacher quality can be

viewed as a function of demand, supply, and market-specific institutional constraints.

$$T^d = g(A^*, w, r, C, X) \quad [2]$$

$$T^s = b(w, C, Y, Z) \quad [3]$$

Demand for teacher quality, T^d , is a function of the desired outcomes for students (A^*), teacher wages (w), prices of other inputs (r), the exogenous attributes of students (C), and restrictions placed on employers regarding the hiring of teachers (X), for example, regulations and a single-salary schedule. Teacher supply, T^s , is also a function of the wage (w), the characteristics of students (C), other working conditions (Y), and requirements associated with eligibility to teach (Z), for example, certification requirements.

Differences in teacher quality reflect the decisions of prospective teachers and school officials that determine initial job matches and subsequent decisions that affect job quits, transfers, and terminations. Most research on teacher labor markets has used models developed for the private sector. However, markets for public-school teachers typically differ in three ways from assumptions usually made in modeling private-sector labor markets – sorting of employees (teachers) with respect to clients (students), wage contracts determined almost entirely by experience and education, and, like other public-sector-hiring authorities, have limited incentives to operate efficiently. In addition, as in private professions, public-school teachers in the US typically are subject to rather stringent credentialing requirements. These aspects of the labor market for teachers likely have important implications for deciding who enters teaching, where they teach, and their career paths, all of which affect the overall quality of teaching and its distribution.

The allocation of poorly qualified teachers to schools with concentrations of poor, low-income, and low-achieving students ultimately reflects teacher preferences and the incentives they face. Policies have the potential of creating incentives to encourage more able individuals to become teachers and to allocate more effective teachers to low-performing schools. Unfortunately, many common policies and practices fail to account for basic realities of teacher supply and inefficiently allocate resources as a result.

The common practice of allocating students to schools by neighborhood-attendance zones, combined with residential sorting of families by socioeconomic status, race, and preferences for education, often leads to schools segregated by income, race, and achievement of students (Clotfelter, 2004; Lankford and Wyckoff, 2006). Research suggests that teachers prefer working in particular types of school environments as proxied by student-body attributes (Ingersoll, 2001; Lankford *et al.*, 2002; Scafidi *et al.*, 2003; Hanushek *et al.*, 2004; Boyd *et al.*, 2005) and other

Figure 1 The demand and supply of highly qualified teachers.

working conditions (Johnson *et al.*, 2004; Luekens *et al.*, 2004; Buckley *et al.*, 2004; Carroll *et al.*, 2004; Loeb *et al.*, 2005), as well as salary (Baugh and Stone, 1982; Brewer, 1996; Clotfelter *et al.*, 2006a; Dolton, 1990; Dolton and van der Klaaw, 1999; Dolton and Makepeace, 1993; Hanushek and Pace, 1995; Manski, 1987; Mont and Rees, 1996; Murnane *et al.*, 1989; Stinebrickner, 1999, 2001a, 2001b; Theobald, 1990; Theobald and Gritz, 1996). Not surprisingly, teachers seek out preferable working conditions – both the attributes of students and other school working conditions that often are correlated with student composition.

However, the single-salary contract, typical in most school districts, rewards teachers primarily for education and school-district teaching experience, regardless of the particular school in the district where one teaches. Thus, differential salaries within districts rarely are used to provide compensating differentials for factors related to the attributes of students affecting teacher supply to specific schools (although several districts are experimenting with various forms of incentive compensation, including performance incentives and differential pay for difficult-to-staff subjects and schools). This results in some schools and subjects having chronic staffing problems and low-performing students being disproportionately taught by the least-qualified teachers.

This outcome is easily depicted in a simple teacher-labor-market diagram (Figure 1). Assume that based on constant enrolments and norms about class size, the demand for high-quality teachers is perfectly inelastic at Q^d . Due to accountability or other external forces, assume the demand for high-quality teachers is the same for schools within a district regardless of their student composition; schools with disproportionately low-achieving students have the same demand for teacher quality as schools with mostly high-achieving students. In addition, assume that schools prefer to hire high-quality teachers

but hire low-quality teachers if insufficient numbers of high-quality teachers are available at the prevailing wage. Finally, assume that at any given wage, rate high-quality teachers prefer to work with higher- rather than lower-achieving students. S^l and S^h in **Figure 1** represent the supply of high-quality teachers in schools having lower- and higher-scoring students, respectively. If teacher salaries could freely adjust to take into account this difference in supply, schools with low-achieving students could attract sufficient numbers of high-quality teachers by paying the salary W^l , which is higher than the salary W^h needed to attract sufficient numbers of high-quality teachers in schools with high-achieving students. Note that teachers view the schools as being equally attractive even though salaries differ between the schools. ($W^l - W^h$ is the compensating wage differential that results in high-quality teachers being indifferent between teaching in the two school types. A compensating differential for teaching low-achieving students also could be made with combinations of other endogenous school variables, such as better leadership or better facilities, rather than salaries. In fact, adjusting other working conditions may be a more cost-efficient means to induce sufficient supply of high-quality teachers to schools with low-achieving students.) Such an outcome is precluded by the single-salary schedule being the same across schools within districts. The typical case is depicted by a district-wide wage W^* , where there is excess supply of high-quality teachers in schools with high-achieving students ($Q^h - Q^d$) and a shortage of high-quality teachers in schools with low-achieving students ($Q^d - Q^l$). The shortage of high-quality teachers is especially apparent in schools with low-achieving students in subject areas such as math, science, or special education, where teacher supply is more limited.

The differential qualifications of teachers across schools and subjects that result from the interaction of wage inflexibility and teacher preferences for working conditions is made worse by four other practices found in some districts: late hiring that results in a diminished pool of highly qualified applicants (Levin and Quinn, 2003), hiring decisions that do not effectively distinguish the qualifications of applicants (Ballou, 1996; Ballou and Podgursky, 1997), seniority-based transfer policies (Levin and Quinn, 2003), and personnel allocations between schools based on full-time equivalent (FTE) lines rather than monetary budgets (Roza and Hill, 2004).

In sum, the analysis of teacher labor markets makes clear that some policies and practices of school districts systematically lead to low-achieving students disproportionately being taught by the least-qualified teachers. At one level, policies to address these issues may seem apparent – if wage inflexibility with respect to working conditions leads to differential qualifications across schools, alter compensation policies to allow between-school salary differences to compensate for differences in working

conditions. This, of course, begs the question as to the size of the appropriate compensating salary (or other working condition) differential needed to offset such differences. Going beyond issues of teacher compensation, what other policies are effective in improving the quality of teachers, either through their selection or preparation, broadly defined? Much of the research on teacher labor markets is focused on various aspects of these questions. Before discussing this effort, we briefly explore some of the methodological issues that researchers must confront when attempting to empirically estimate these relationships.

Methodological Issues

Researchers are interested in identifying how a wide variety of demand and supply factors affect the composition and distribution of the teacher workforce as well as how teachers, teacher attributes, and various teacher-workforce policies affect student outcomes, as generically described in eqn [1]. Identifying such causal effects requires researchers to adequately address a number of conceptual and methodological issues. We highlight a few of the more important ones.

As discussed above, who teaches and where they teach depend upon a wide range of decisions: individuals deciding whether to attain teacher certification; teacher candidates deciding whether and where to seek employment; hiring authorities deciding whom among their applicants to hire; those employed deciding whether to change employment, either by leaving the profession or transferring within or between districts; and school officials deciding whether to terminate or council out untenured teachers. Researchers attempting to sort out how various factors affect such choices and, in turn, the matching of teachers to jobs, face methodological and statistical challenges that result from the types of data that are available. Even with good longitudinal data, researchers typically only know who teaches, where, and for how long, not, for example, who applied for which jobs, which of the sets of all applicants received offers, or any information about job offers that were turned down. Thus, when a person teaches in one school rather than some other, we typically do not know whether the teacher preferred the first alternative or actually preferred the second school but was not competitive for job openings there. Thus, inferring the attributes of teachers and jobs that are valued is made more difficult. Very modest progress has been made in developing an empirical approach for using matched employer–employee (e.g., school–teacher) data to isolate demand and supply factors (Boyd *et al.*, 2007b). However, findings from the vast majority of empirical studies exploring how various factors affect the selection of individuals into teaching, the sorting of teachers to jobs, as

well as teacher transfers and quits must be interpreted as reduced-form results reflecting various combinations of demand and supply factors.

Isolating the causal effects of teacher attributes on student outcomes also places considerable demands on data and empirical estimation. Detailed theories do not exist as to how the knowledge, skills, and other attributes of teachers influence student achievement within the context of a classroom where students interact with each other and a school environment that reflects a variety of other school inputs and constraints, all interacting in complex ways. As a result, we have only an *ad hoc* understanding of what variables to include and how to specify empirical models. In general, the number and nature of the variables required to fully specify eqn [1] is staggering.

Identification of the causal effects of educational interventions relies on having a counterfactual that credibly controls for all other factors that could influence the outcome, while varying the treatment (Barrow and Rouse, 2005; Angrist, 2004). In education research on teachers, several factors complicate establishing a believable counterfactual. Among the most important is the selection or sorting of teachers and students to schools, as described above. For example, suppose policymakers want to know whether gains in math achievement will be higher if students are taught by teachers certified to teach math rather than certified in another area. If students taught by teachers certified in math have relatively higher math scores, compared to students whose teachers are not math certified, one might be tempted to conclude that being certified to teach math contributes to the higher student achievement. The causal relationship, however, may operate in the opposite direction; the more qualified teachers may be in schools where students perform well in math because they prefer to teach motivated students, who are higher performing, other things equal, and are able to do so because employers want to staff their courses with in-field certified teachers. Without research strategies that preclude or account for such selection, empirical results will overstate the contributions of being math certified. Selection could be taken into account if all the attributes of teachers and students that are both associated with the selection and the outcome of interest were observed. Unfortunately, there are a variety of variables typically not observed (e.g., teacher and student motivation) that are likely associated with the matching of teachers to students, teacher retention, and student achievement. Similar selection issues complicate many other aspects of teacher labor markets.

Research relating to teacher labor markets has made remarkable progress in addressing selection issues over the last 10 years, due in large part to the increasing availability of panel data and research designs that attempt to negate the influence of selection. When well designed and

implemented correctly, randomized control trials (RCTs) with teachers randomly assigned to students avoid the selection issue altogether. There is now a lively discussion concerning the circumstances under which RCTs can yield useful policy insights regarding teacher-workforce issues (see, e.g., Cook, 2007; Murnane and Nelson, 2007; Raudenbush, 2008). To date, there have been few RCTs focused on issues relevant to teacher labor markets. A notable exception is an RCT examining the effectiveness of Teach for America teachers relative to teachers entering teaching through other routes (Glazerman *et al.*, 2006). Several RCTs now are underway exploring various aspects of teacher labor markets, including a pay-for-performance experiment in Nashville public schools.

However, the vast majority of research analyzing teacher labor markets employs observational data where issues of selection are common. Researchers have drawn upon a variety of circumstances and methods in their efforts to identify credible counterfactuals. Panel data estimation, propensity-score matching, regression discontinuity, and instrumental variable designs all employ quantitative methods to attempt to identify the effects of labor-market treatments while controlling for selection.

In recent years, there has been a dramatic increase in the use of panel data methods, largely resulting from the availability of state and district data that link individual teachers and students over multiple years. Researchers employing such data and methods have examined several aspects of the research questions outlined above. A partial list includes:

1. Supply and quality of teachers (Hanushek *et al.*, 2005a, 2005b; Clotfelter *et al.*, 2006b; Boyd *et al.*, 2007b);
2. Teacher preparation and professional development (Boyd *et al.*, 2006, 2008; Darling Hammond *et al.*, 2005; Harris and Sass, 2007a; Kane *et al.*, in press);
3. Qualifications and credentialing of teachers (Boyd *et al.*, forthcoming; Clotfelter *et al.*, 2007a, 2007b; Goldhaber and Brewer, 1997, 2000; Goldhaber and Anthony, forthcoming; Goldhaber, 2007; Harris and Sass, 2007b; Kane *et al.*, in press); and
4. Teacher retention (Hanushek *et al.*, 2004; Hanushek *et al.*, 2005b; Boyd *et al.*, 2005; Boyd *et al.*, 2007a; Goldhaber *et al.*, 2007; Feng, 2008).

Others have employed regression-discontinuity designs (Jacob and Lefgren, 2004; Lavy, 2004), instrumental-variable estimation (Ehrenberg and Brewer, 1996; Dee, 2004), and propensity-score matching (Lavy, 2004) to examine various aspects of teacher labor markets.

In addition to complications associated with selection, data quality issues limit empirical research analyzing teacher labor markets and student outcomes. Three points are particularly relevant. First, rarely are outcome measures other than student test scores available, and increasingly the tests employed are the high-stakes tests states

have implemented to comply with the requirements of NCLB. There are well-documented limitations and perverse incentives associated with these tests that raise questions about their use as instruments for research on teacher policies (Koretz, 2002; Koretz and Hamilton, 2006; Jacob and Levitt, 2003). Nonetheless, they are useful measures precisely because they have been identified as policy outcomes, are widely available, and, when employed in value-added models, have been shown to distinguish effectiveness between the bottom and top quartiles in ways that are consistent with principals' perceptions of teachers' value added (Jacob and Lefgren, 2005; Harris and Sass, 2008). Additionally, although information is limited, it appears that the high-stakes assessments in some states rate well on validity and reliability (Ferrara and DeMauro, 2006). At the same time, reasonable questions have been raised about the technical adequacy (i.e., psychometric properties) of assessments in many states for value-added modeling (Ballou, 2008; Briggs *et al.*, 2008).

Second, administrative databases, designed by school administrators, almost always fail to include some of the variables of conceptual and empirical interest to researchers. For example, databases at best contain only weak measures reflecting teachers' skills and knowledge, even though these attributes are believed to be important in differentiating good and bad teaching. Weak measures of the underlying variables of interest significantly limit identification strategies.

Third, identifying the effects of various teacher attributes is difficult when the available data have relatively little variation in the relevant variables. For example, if schools are able to attract a given quality teacher because of the wage and nonwage benefits offered, then one would expect that the teachers in that school would be of similar quality. Teachers within a school who lack one attribute may have others that compensate. This realization should encourage caution when researchers conclude that attributes of teachers are unimportant when they employ observational data. Note also that the range of knowledge and skills of teachers observed is substantially reduced by a variety of factors, including state certification. For example, most states require that teachers of core subjects have a subject-matter major in those areas or otherwise demonstrate sufficient content knowledge. If this requirement is effective, we may not observe a sizable effect of content knowledge not because content knowledge is unimportant, but because the range of observed content knowledge is restricted to be above the point where its variation makes a difference. Thus, there is a premium on measuring the differential quality of knowledge and skills that the teacher brings to the classroom as opposed to some cruder measure of content knowledge such as whether she has taken courses in the field.

Looking Ahead

Over the last 10 years, research on teacher labor markets has dramatically increased in quantity and quality. Much of this growth is explained by the increased focus on teachers and teaching brought about by various accountability efforts and the availability of much better data that has been spawned by these efforts. Despite these advances, research on teacher labor markets has resulted in limited insights for policy to date. The pressing policy questions we identified above have received only partial answers:

1. Some research suggests that both selection and preparation of teachers can make a difference, but there is good evidence that the variation within any groups characterized by a preparation pathway or teachers having particular attributes substantially exceeds the differences between groups. Thus, there is little guidance regarding whether or how to structure entry requirements. Similarly, we know that prospective teachers value compensation and other working conditions, but know relatively little about how to structure policies to most effectively attract high-quality teachers to all schools.
2. Even though most believe that knowledge and skills can improve teacher effectiveness, there is only limited empirical evidence on which to base the design of preservice or in-service preparation or how this should vary across the range of teaching environments that teachers encounter.
3. Teacher retention policies suffer from similar ambiguities. Many good teachers leave the profession early in their careers, as do many weak teachers. Research has provided limited guidance to school administrators regarding how to structure performance evaluation and retention policies to insure a high-quality workforce across all schools.
4. We are only beginning to understand the effects that dramatic increases in accountability are having on who enters teaching, what preparation they receive, how long they persist, and most importantly how teachers may change the nature of their work in relation to student outcomes.

That said, the field is vibrant and in the midst of rapid change, with interesting debate regarding many of these issues. Some of the questions are methodological: Do the available measures of student achievement capture the actual contributions of teachers? Do the value-added models employed sufficiently account for the interactions between the attributes of teachers and students so as to capture the important contributions of teachers? Do these models provide a credible identification strategy in the face of formidable issues of teacher and student sorting? Also, how robust are results across alternative model specification and alternative estimation strategies? Other

questions revolve around data – developing variables, not typically collected in administrative data that have detail sufficient to help guide policy, for example, which working conditions are most influential in retaining effective teachers. Finally, some questions go beyond teacher-labor-market research *per se*, and involve the nexus of research and policy. Much remains to be learned about how researchers, educators, and policymakers can work together to improve educational outcomes for children.

Compensating Differentials in Teacher Labor Markets

J Chambers, American Institutes for Research, Palo Alto, CA, USA

Glossary

Cost factors (uncontrollable factors) – The factors outside of local control that reflect variations in the local cost of living.

Comparable wage index (CWI) – An index that is intended to capture regional compensating differences in the wages for workers in comparable occupations or industries.

Compensating differential – A wage difference that compensates for the relative advantage or disadvantage of a job or location in the eyes of the worker.

Controllable factors – The factors that are within the power of district decision makers to influence or change.

Geographic cost of education index – An index that takes into account geographical differences in the salaries necessary to attract and retain a comparable workforce of instructional staff across local school districts.

Hedonic wage model – A model based on the theory that salaries will reflect not only compensation paid for specific human capital characteristics (e.g., the specific skills and training an individual brings to the job), but also other characteristics of the job that influence the attractiveness of living and working in a particular geographic locale.

Price of living index – An index that compares the prices of a market basket of consumer goods over time or across geographic locations.

there was any employment evidently either more or less advantageous than the rest, so many people would crowd into it in the one case, and so many would desert it in the other, that its advantages would soon return to the level of other employments. (Smith, 1976: 111)

The advantages to which Smith refers are the combinations of compensation and working conditions associated with any given job or location. In other words, employers and employees would make adjustments in their employment decisions to reflect the relative advantages and disadvantages of different occupations or locations. These resulting adjustments would move the market toward wage levels that would equate the relative desirability of different occupations or locations, and this would be accomplished through what we refer to in the literature as compensating differentials. A compensating differential is, in effect, a wage difference that compensates for the relative advantage or disadvantage in the eyes of the worker.

Early Efforts

An early attempt to estimate compensating differentials in teacher markets by Antos and Rosen (1975) used econometric models to assess discrimination in the market for teachers. The purpose of this early paper was to estimate the compensating differentials associated with, for example, general neighborhood hazard indicators such as student mobility, nonwhite history, and student poverty. In other words, how much does it cost to recruit and employ comparable teachers to work in more challenging school environments? The assumption is that schools with a more challenging environment would be associated with a positive wage differential to compensate for these greater challenges. Antos and Rosen present econometric results which show that white males and black females accept lower wages to teach in schools with lower poverty levels.

With the movement to improve equity and access to school funding that arose out of the war on poverty of the 1960s, other additional work by economists was directed at a broader perspective on compensating differentials in teacher labor markets (Brazer, 1974; Grubb and Hyman, 1975; Chambers, 1978a; Kenny *et al.*, 1975; Wendling, 1979). The goal of this new generation of work on compensating differentials focused on developing indices that could be used to adjust state aid to local school districts to

Background

Over the past 30 years, the need for understanding and estimating the compensating differentials within teacher labor markets has generated numerous empirical and theoretical studies. The concept of compensating differentials dates back to Adam Smith's well-known volume *An Inquiry into the Nature and Causes of the Wealth of Nations*. Smith states the following:

The whole of the advantages and disadvantages of the different employments of labour and stock must, in the same neighborhood, be either perfectly equal or continually tending to equality. If in the same neighborhood,

equalize the purchasing power of the educational dollar. In the 1960s and early 1970s, few, if any, states made any attempt to adjust state aid for geographic variations in the costs of schooling inputs.

The state of Florida implemented the Florida Price Level Index (FPLI) in 1973 as one approach to develop a geographic cost adjustment (Wood *et al.*, 2001). The FPLI is essentially a price of living index that compares the prices of a market basket of consumer goods across the 63 counties in Florida. The FPLI was applied on the assumption that geographic differences in the price of living drive education cost differences.

Purchasing Power of the Educational Dollar and Hedonic Wage Model

The new generation of studies of teacher labor markets brought the recognition that while geographic differences in the price of living and cost of education are related, the geographic cost of education index, even if narrowed to focus on teacher labor markets, extends well beyond accounting for price of living differences. These studies focused on teachers because they are the largest single category of schooling inputs into educational production. Teachers' salaries and benefits account for about half of total school district budgets. (See table 161 in the 'Digest of education statistics' which shows that instruction expenditures account for about 50–60% of total current spending in the US. Far and away the majority of these direct instructional expenditures are accounted for by teachers' salaries and benefits, the remainder going to paraprofessionals, books, and supplies and materials.) Moreover, the same factors that affect teacher labor markets were also found to affect labor markets for other professional or paraprofessional school personnel.

These studies of teacher labor markets focused on answering the following question: How much more or less does it cost to recruit and employ comparable teachers in different geographic jurisdictions (e.g., school districts) across a state?

The authors of these studies of teacher labor markets began by identifying all (or as many as possible) of the factors that affect variations in wages and then attempted to run simulations to answer the question set out above.

These studies employed the hedonic wage model as the conceptual framework to support the empirical work on teacher labor markets. Goldhaber *et al.* (2007) describe this model as follows:

The theory behind the hedonic model is that salaries will reflect not only compensation paid for specific human capital characteristics (e.g., the specific skills and training an individual brings to the job), but also other characteristics of the job that influence the attractiveness of living

and working in a particular geographic locale. For instance, it should be more expensive to hire personnel into less-desirable jobs than it would be to hire personnel of comparable quality into jobs that are more attractive, all else equal. There are, of course, many different factors besides salary and benefits that influence the relative attractiveness of a job. For example, teachers are likely to favor jobs in areas that have a low cost of living and greater amenities and in well-led schools with students who arrive at school ready to learn. (pp. 4, 5)

As Chambers (1981a) outlined the cost simulation model, factors affecting wage variations included two categories of variables: those within local control and those outside of local control. Within local control in this context means within the control of school district decision makers: that is, all of those factors over which decision makers can exert choice. Using the analyses of all factors affecting wages, these studies of teacher labor markets simulated how much of the variations in wages were due to factors outside local control (e.g., the locational attributes of the district and generally the characteristics of the students they served). These factors outside local control were also commonly referred to as the cost factors.

Table 1 shows a list of the types of variables included in each of these two categories. The controllable factors include teacher experience, college degree level, certification level, the quality of college attended for undergraduate study, test scores, and class sizes. These factors are considered controllable because the district decision maker can, within some limits, exert choice in the long run over the characteristics of the teaching staff as well as the class sizes in the jobs to which they are assigned.

The uncontrollable or cost factors included proxy measures that were intended to reflect variations in the local cost of living such as housing costs, crime rates of the city or locale within which the district is located, distance from the central city, and population or population density of the county within which the district was located. Some of these county-level factors tend to be proxies for access to shopping and medical facilities, climatic conditions, traffic congestion, and access to certain cultural amenities.

Other cost factors included attempts to capture the climate of the school or district and the challenges of the student population being taught. These included factors such as race-ethnic composition of the students, the percent of students living in poverty or eligible for the free or reduced-price lunch program, the percent of students who are English learners, and factors reflecting the type of district – e.g., urban, suburban, or rural – or district size.

Although some of the early studies (e.g., Brazer, 1974; Grubb and Hyman, 1975; Kenny *et al.*, 1975) were done with district-level compensation and teacher characteristics

Table 1 List of independent variables used in hedonic wage analyses*Discretionary factors:**Personal characteristics of the individual teacher (T):*

Sex;
 Racial-ethnic background;
 Marital status;
 Membership in professional teacher or educational organization;
 Age,
 Total years since first began teaching (general experience),
 Total years in the present school (school-specific experience),
 and Number of breaks in service;
 Highest degree level;
 Undergraduate major.

Job assignment or classroom characteristics of the individual teacher (C):

Percentage of full time;
 Nature of assignment (itinerate or substitute teacher);
 Index of relative class size for teachers in similar subjects;
 Whether the teacher is a mentor;
 Percentage of time teaching out of field;
 Nonschool time spent on school-related activities;
 Whether the teacher assigned homework in the most recent week;
 Percentage of time teaching high- or low-achieving students.

Characteristics of the school in which the teacher is employed (S):

Indices of student behavior and problems;
 Indices of teachers' sense of support, control, influence, and overall satisfaction with their work environment;
 Racial-ethnic composition of the students at the school;
 Percentage students absent on a recent day;
 School type (i.e., elementary, secondary, special education, vocational, and alternative);
 an index of admission requirements.

*Cost factors:**Characteristics of the district in which the teacher is employed (D):*

Racial-ethnic composition of the students in the district;
 District size as measured by enrolment;
 Percentage growth in enrolment.

Characteristics of the region in which the teacher is employed (R):

Percentage of total county enrolment accounted for by the largest district in the county;
 Measures of the distances from the closest central city;
 Percentage change in county population over the past decade;
 Value per acre of farm land;
 Population and density of the county and metropolitan area;
 County unemployment rate;
 Measures of climatic conditions (mean temperatures and snowfall);
 County-level crime rates;
 Number of banks per 100 000 population.

data, most of the studies done in the late 1970s and later (e.g., Chambers, 1978b, 1995b, 1997a; Wendling, 1979) had access to individual data on teachers and other school personnel. Such data sets on individual school personnel are commonly available in some form or another from state departments of education and include compensation along with personal and job assignment characteristics (i.e., the controllable factors).

Data on the uncontrollable or cost factors are generally obtained from school data sets, the Census Bureau, National Center for Education Statistics (NCES), National Weather Bureau, or other government agencies (e.g., the Uniform Crime Statistics of the Federal Bureau of Investigation).

For most of these studies, standard econometric techniques (multivariate ordinary least squares regression) were applied for estimating the parameters of what economists refer to as hedonic wage models to carry out the analyses of wage variations and cost index simulations.

Empirical Estimates of Compensating Differentials across the US

Variations in the costs of comparable teachers vary significantly across the nation and the states. The two national studies conducted by Chambers (1995b, 1997) using national data gathered by the NCES through the Schools and Staffing Survey for teachers and principals and the Current Population Survey (CPS) data for classified (noncertified) staff shows an overall range of variation of about 3.4 to 1 across all districts with the highest versus lowest average cost of comparable teachers. The full range of variation across individual districts was from 55 to 187, with 100 representing the index value for the district attended by the average student. The map in **Figure 1** shows the patterns of the average variation in the overall costs of education, most of which is accounted for by school personnel, including teachers, principals, and classified personnel, across the US estimated by Chambers (1997) using the national data sources.

Correlations over Time

Based on the national study of geographic cost differences done by Chambers for NCES, the data show that the indices are highly correlated over time: that is, the factors that affect geographic differences do not change very much from one year to the next. Over the 6-year period, the correlations were 0.96. This high correlation results from a consistent set of cost factors (independent variables used to capture the compensating differentials) being used with little change in the parameter estimates of the hedonic wage equation used to combine them into a single index.

Analysis of Differences between Public and Private Schools

In two other reports by Chambers (1985, 1995a), hedonic wage models were used to analyze the differences in

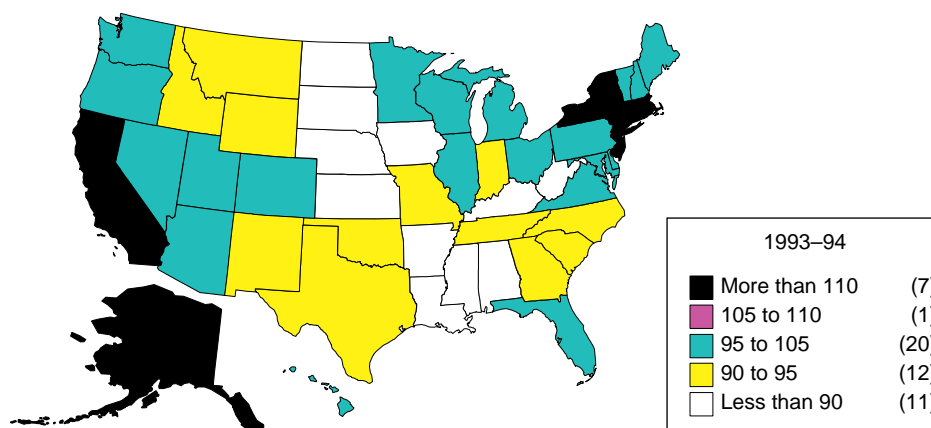

Figure 1 Geographic cost-of-education index by state, 1993–94. The geographic cost-of-education indexes are based on statistical analyses of the patterns of differences in the wages and prices of school inputs. Data sources include the following: (1) Bureau of the Census: Current Population Surveys, 1987–1994; 1990 Census of Governments, Survey of Local Government Finances; County level census files; (2) Bureau of Labor Statistics: Producer Price Indexes-1985–1994 data; Consumer Price Indexes. 1985–1994 data; (3) California Department of Education and Ohio Department of Education, databases on expenditures by object codes; (4) Geographic Names Information Systems (GNIS) CD-ROM (latitudes and longitudes for most U.S. cities, towns, and geographic locations); (5) Higher education Research Institute at the Graduate School of Education, electronic database on Scholastic Aptitude Test (SAT) scores for entering freshman, 1972, 1977, 1982 in approximately 2300 colleges in the United States; (6) National Climatic Data Center and the National Center for Atmospheric Research, The World Wealth Disc: Climate Data for the Planet Earth, CD-ROM; (7) US Department of Education, National Center for Education Statistics, Common Core of Data; Schools and Staffing Survey; 1990 Census School District Special Tabulation (summary file set I); and (8) US Federal Bureau of Investigation. (1995). The Uniform Crime Report (UCR), Return A, for the US Washington, DC.: US Department of Justice.

compensation between public and private schools. The notion here is that in the US, private schools tend to pay substantially less, on average, than public schools. In the 1996 study, Chambers reported that based on the Schools and Staffing Survey, which is a large random sample of more than 45 000 public and more than 8000 private school teachers, “public school teachers earn between about 25 to 119 percent more than private school teachers earn, depending upon the private subsector.” (p. 54). Private Catholic and nonsectarian private schools tend to be the highest paying, while Conservative Christian, Catholic parochial, and other religious-unaffiliated schools are the lowest-paying schools.

In his analysis, Chambers found that it was not possible to fully account for the differences in pay rates between public and private schools based on compensating differentials:

Between about 2 and 50 percent of this public–private difference can be accounted for by differences in teacher characteristics depending upon the private subsector. Controlling for differences in teacher and school characteristics between the public and private sectors, one observes a residual difference in the salaries of teachers that is simply associated with the sector in which the teacher is employed. (p. 54)

Basically, the model was not able to fully explain the differences in public–private teacher wage differences. One common perception is that the private school sector is a more desirable place to work or that there are unobservable

differences in teacher qualifications. To some degree, the differences may be a result of the lack of a free flow of teachers between the two sectors due to certification requirements in the public sector that do not exist in the private sector.

Problems with the Hedonic Wage Model

Most of the variations in geographic costs that have been measured in these studies represent broad regional or labor market differences rather than district-by-district differences. These are the factors that reflect the true cost of living as well as regional amenities that make one place more desirable to live than another. It has been difficult with the hedonic wage model to tease out the compensating differentials associated with unique district-level characteristics such as student poverty, English learner status, or other such variables that reflect the challenges associated with teaching.

Regional Factors and the Comparable Wage Index

Taylor (2006) has used various census and occupational-level data sources to estimate a comparable wage index (CWI) that is intended to capture these types of regional compensating differences. The notion here is that more or less the same factors that affect the wages paid to nurses,

business managers, lawyers, and other occupations requiring a college degree also affect teacher wages. Taylor includes only noneducation personnel in the analysis, and the advantage of using these data is that the index is independent of the actual levels of compensation being paid in local school districts. Rather, it captures the general context of the labor market within which local school districts must employ teachers or other school personnel.

The downside of the CWI is that it does not capture the tastes and preferences of teachers for these regional characteristics which may differ from those of individuals in other occupations. Perhaps more importantly, it does not capture any district unique factors (e.g., the challenges associated with the particular student population within a given district) that might make one district more desirable than another.

Measuring Teacher Quality

A more general problem that has been recognized with the hedonic wage models and the attempt to estimate compensating wage differentials results from the difficulty of obtaining adequate and comprehensive measures of teacher quality. This has been a problem acknowledged in the general literature on compensating differences (e.g., see Duncan and Holmlund, 1983) as well as the specific literature focused on teachers (e.g., see Goldhaber *et al.*, 2007; Boyd *et al.*, 2006). As Duncan and Holmlund state it:

If important but typically unmeasured characteristics such as “motivation” and “intelligence” lead to both higher pay and better working conditions, then the omission of measures of these characteristics may well bias the estimated relationship between wages and working conditions. (p. 367)

Goldhaber *et al.* (2007) point out that teacher quality is difficult to quantify because of the weak links between the commonly available teacher attributes such as experience, education, and certification and student outcomes (see Goldhaber and Brewer, 2000; Rivkin *et al.*, 2000). Other variables such as teacher intelligence, motivation, verbal ability, ability to relate to children, and classroom management skills are generally not easily accessible or measurable, and there is likely a correlation between these attributes and the working conditions to which teachers are subjected. The bottom line is that it may be difficult to obtain unbiased estimates of the cost factors to the extent that there is a correlation between unmeasured components of teacher quality and the included cost factors.

For example, consider the impact of student poverty on teacher wages. Wage differentials associated with student poverty may have many interpretations. Teachers may perceive a school with high percentages of students living in poverty as a challenging educational environment: that is,

higher poverty would require a compensating differential – i.e., high wages for teachers – all else equal. At the same time, poverty could be a proxy for the wealth of the community which one would anticipate to be associated with a greater ability to pay for and demand high-quality teachers: that is, lower poverty would be associated with higher wages reflecting the demand for unmeasured teacher quality.

Interpretation of Cost Factors

Another complicating issue with a variable like poverty is that it may be merely a proxy measure for something else that is difficult to measure. That is, what are the characteristics of the students that teachers would require a compensating differential? Is it poverty status, minority status, or status as an English learner *per se*, or is it the behaviors of students or the communities that may be correlated with these characteristics? For example, each of these characteristics could be associated with greater educational challenges or discrimination on the part of teachers of a different race-ethnic background. High-poverty communities may also tend to be associated with higher crime rates in the neighborhood or school and be regarded as threatening to someone considering the school or district as a place to teach. This is further complicated by the fact that the student behavior itself can be affected by district and school programs (for further discussion see Chambers (1981b)). Thus, it is difficult to measure and determine the impact of the job and assignment characteristics on wage differences.

Teacher Quality and Fixed-Effects Models

Chambers *et al.* (2006) used a teacher fixed-effects model to try and address the difficulty in measuring teacher quality. The fixed-effects model uniquely identifies each teacher in the estimation process using dichotomous variables and requires multiple years of data to capture these effects. The notion is that each teacher represents a bundle of qualifications which are essentially controlled for in the estimation technique. The difficulty with this approach is that the parameters used to estimate the regional- or district-level compensating differentials rely entirely on those teachers that move between schools and districts. With limited amounts of such movement across districts, it is difficult to estimate the parameters of this relationship.

Flexible Wages and the Nature of the Labor Market

Another flaw in the use of the hedonic wage models is that they essentially assume a competitive labor market similar to that observed in the private sector. That is, in such a labor market, wages are flexible and adjust to equate the

supply and demand for various employee and employer characteristics. While in most states there are generally many school districts competing for teacher services, there are some significant factors (e.g., lockstep salary scales, collective bargaining agreements, and state certification regulations) that create rigidity and reduce the applicability of the hedonic wage model. As Goldhaber *et al.* (2007) express it:

If teacher salaries are in fact ‘sticky’ in the sense that they don’t rapidly adjust to reflect preferences, then a key assumption of the hedonic model is violated and the distribution of teachers across schools does not convey the same information that it would in the context of a fully competitive labor market. In effect, there is likely to be an asymmetry in the information that we observe. If a salary offer for a particular teaching position does not meet the reservation wage of a teacher with a particular set of credentials, information is provided in that we will not see that teacher in that teaching position, and from this we can infer that a particular salary is not high enough to attract that teacher.

They go on to say:

Under a hedonic model it is assumed that there is no excess payment, so any excess leads to bias in the estimates of the factors influencing a teacher’s earnings. For example, if wealthier districts with low free/reduced-price lunch (FRL) student populations tend to pay teachers in excess of what is required to induce them to accept positions in schools, then the estimate of the amount that is required to pay teachers to teach in schools with few students on FRL would be biased upward, and conversely, the model would understate how much is required to induce teachers to teach in schools with large disadvantaged student populations. (pp. 6, 7)

Taylor *et al.* (2004) have used an alternative hedonic wage model to help account for this rigidity in wages that incorporates turnover behavior. This model requires multiple years of data to allow adjustment of the estimates to reflect the fact that certain wage payments to a teacher represent censored observations. For example, the wage of a teacher who moves in a subsequent year is effectively lower than the teacher reservation wage for the position and the turnover behavior in the following year is a flag that this wage value is a censored value and not a market clearing value. By accounting for this turnover in the econometric techniques, the procedure is intended to account for this lack of flexibility in wage levels.

Location as a Factor

Moreover, Boyd *et al.* (2006) indicate that one significant factor that teachers take into account in employment decisions appears to be the distance from where they

grew up. They also demonstrate that taking this factor into account and using an alternative econometric technique (a game theoretic approach to modeling the match between employers and employees in the labor market) can lead to very different parameter estimates on particular schooling attributes than the hedonic wage model. As Goldhaber *et al.* (2007) expressed it:

Unfortunately, the statistical methodology employed by Boyd *et al.* is quite novel (as far as we are aware it has not been used before in the context of estimating compensating differentials in teaching), complex and extremely computer resource intensive. Thus, at least for the time being, it is unlikely to be a practical approach for most states and localities. (pp. 6, 7)

Nevertheless, despite this practical consideration, Boyd *et al.* (2006) do identify what appear to be intuitive results regarding compensating differentials for teachers:

We find that employers demonstrate preferences for teachers with stronger academic achievement and for non-white teachers, while teachers show preferences for schools that are closer geographically, offer higher salaries, are suburban, and have a smaller proportion of students in poverty and of a different race. As predictable as these results are, they differ from wage-equation estimates that are often used to suggest, for example, that employers do not value teacher skills and that teachers do not value salary. (p. 3)

Concluding Remarks

Since the late 1960s with the movements to improve the equity of school funding, researchers and policymakers have explored various ways of measuring compensating differentials for teachers and other school personnel for the purpose of equalizing the purchasing power of the educational dollar distributed from states to local districts. It has even crept into the discussions of the rationale for adjusting federal Title I program allocations to states for differences in the statewide average per pupil expenditure.

The hedonic wage models have become a commonly used model for measuring compensating differentials and for developing geographic cost adjustments. While these models have been used since the 1970s in numerous studies, few states have adopted cost adjustments based on these types of studies.

Research monographs and published studies conducted since 2000 have raised a number of questions about the ability of the hedonic model to estimate unbiased parameter values for these compensating differentials. The problems with the hedonic wage model that have been cited include the rigidities that exist in the teacher labor market, the difficulties of measuring teacher quality, the measurement problems with the amenities,

and the tremendous complexity of modeling the labor market transaction between employers and employees.

The various econometric models that have been used in studies of teacher labor markets for the purpose of estimating compensating differentials represent black boxes to the typical policymaker and require a significant leap of faith. Ultimately, the value of these various methodologies that have been put forth must lie in the intuition of the estimates they generate. When policymakers, who are considering these models, look at the estimates, do they make intuitive sense? Do the variables and associated coefficients that reflect the challenges of teaching in certain districts or the factors that cause one district to be more or less attractive as a place to live and work jive with their perception of reality? Sometimes they do and sometimes they do not. When they do, the black box is a little easier to accept, but when they do not, it is impossible to accept.

One practical value of the concept of compensating differentials, whether they can be explicitly measured or not, is the recognition that there do exist factors that cause one job or job assignment to be more appealing than another and that teachers do and will respond to these differences (see Hanushek *et al.*, 1999). Despite the rigidities in the labor market and the commonly used salary scales for teachers, district decision makers can take advantage of recognizing these facts and use this knowledge to influence teacher decisions regarding employment. They can choose to provide additional incentives for teachers to take on job assignments in more challenging schools or classrooms. They can do this by providing additional compensation or better working conditions such as greater access to supplies and materials, smaller class sizes or caseloads, increased participation in school-level decision making, and improved opportunities for professional development.

Economic Approaches to Teacher Recruitment and Retention

S Loeb and J Myung, Stanford University, Stanford, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The quality of teaching in a school results from a range of factors, including available resources, curriculum, and instructional leadership, but it is also driven by the individuals who teach in each classroom. The staffing of teachers in schools, in turn, is a product of both recruitment and retention practices. This article describes how the choices of teachers and the actions of schools and districts influence who enters the profession and who stays. It then identifies common policy approaches for advancing recruitment and retention goals and summarizes the current research, discussing the effectiveness of these policies. The article focuses on teacher labor markets in the United States (for information on teacher labor markets outside of the US, see Ladd (2007) and Vegas (2007)).

The supply and demand model provides a simple framework for considering recruitment and retention. Wages and nonpecuniary job attributes combine to determine the supply of individuals interested in teaching in a given school, district, or state. A large body of research suggests that, like other workers, potential and current teachers respond to wage changes, although research on the degree of this response is not conclusive. Nonpecuniary components of teaching that influence the supply of teachers include working conditions, school location, and ease of entry into the occupation and the school. Feelings of success in the classroom also appear to be important for the retention of teachers already in the workforce.

The demand for teachers and the institutional constraints within which these demands are expressed also affect the teacher workforce. The number and characteristics of teachers demanded constitute a function of many factors, including student enrolment, teacher turnover, and the ability and willingness to pay for teachers. Institutional constraints, such as the skill and efficiency of hiring authorities, available information on the quality of individual teachers, budget timing, certification and licensure policies, tenure policies, and teacher contract provisions, can all affect the ability of districts to recruit and retain teachers.

In what follows, we address supply- and demand-side factors affecting this workforce in more detail, and conclude with a discussion of policies aimed at improving recruitment and retention.

The Supply of Teachers

The decisions of eligible individuals willing to teach aggregate to determine the teacher labor supply. Multiple factors affect the choices individual teachers make. Research has enumerated a few of these factors, including relative wages, working conditions, job location, and ease of entry into the occupation and into each job. Teacher self-efficacy also factors into teachers' decision of whether to remain in teaching.

Wages

A large body of literature suggests that individuals are more likely to choose to teach when starting teacher wages are high relative to wages in other occupations. Drawing upon multiple data sources, Bacolod (2007) found that highly qualified teachers are especially sensitive to changes in relative wages. Over the long run, trends in relative teacher pay have correlated with trends in teacher quality (Corcoran *et al.*, 2004). Wages may also affect retention. Murnane and Olsen (1990) found that teachers who are paid more stay longer in teaching, but that wages influence retention less for teachers with high test scores than for teachers with lower scores. Approximately 15% of public school teachers who decided to move to another school in 2004–2005 reported having done so for better wage or benefits (Marvel *et al.*, 2007). Wages are clearly associated with the retention decisions of teachers, although the causal analysis of this is less clear since high teacher wages in schools are often associated with a variety of other reasons for which teachers may choose to stay, such as better working conditions or higher student achievement.

While teachers respond to wages, much of the variation in teacher wages is between districts, reflecting differences in alternative wages, not within labor markets. Thus, the differences that we see across schools in the supply of teachers are likely driven by nonpecuniary characteristics of the jobs (Loeb and Page, 2000).

Working Conditions

Nonpecuniary job characteristics strongly affect the dynamics of the teacher labor market. While in some occupations additional wages compensate for adverse working conditions, in teaching, the single wage schedule

at the district level in the United States, and in many countries at the national level, can lead to great variation in the appeal of teaching in different schools, driven by variation in nonwage characteristics of the job.

Multiple studies have documented a relationship between teachers' career choices and the school's student population: teachers, on average, prefer schools with high-achieving, high-income, and white students. Whether these preferences are driven by direct preferences for particular types of students or by differences in working conditions in the schools these students attend is less clear. As an example, Georgia elementary teachers move from schools with higher proportions of minority students and from low-performing schools, but the latter appears to be explained by teacher preferences for fewer minority students (Scafidi *et al.*, 2003). Texas and New York data, on the other hand, found that teachers prefer higher achieving students even after controlling for student racial composition. Teachers, especially highly qualified teachers, are more likely to transfer or quit when teaching lower achieving students (Boyd *et al.*, 2005b; Hanushek *et al.*, 2004). As further evidence of the weight some teachers put on student-body characteristics, when class size reduction in California increased the demand for teachers across the state, many teachers in schools with low-achieving students switched to schools with higher achieving students (Betts *et al.*, 2000).

Student characteristics are not the only working condition that affects teachers' choices, in particular, school leadership also affect teachers' decisions. Approximately 37% of teachers move from their school due to dissatisfaction with their administrators (Marvel *et al.*, 2007). Weiss (1999) found perceived school leadership to be among the strongest variables associated with first-year teachers' feeling that it is worthwhile to exert their best effort, commitment to career path, and intentions to stay in teaching. An effective principal may have the ability to create a positive working environment for teachers, in spite of attributes of schools typically associated with high turnover. Other school factors are also important. A study of California teachers found that among the strongest predictors of turnover in a school are teachers' ratings of their tangible school conditions, such as physical facilities and availability of textbooks and technology, as well as the quality of professional development, involvement of parents, and quality and appropriateness of tests teachers are required to administer (Loeb *et al.*, 2005). Buckley *et al.* (2005) also found that facility quality is an important predictor of the decision of teachers to leave their current position, even after controlling for other contributing factors.

Psychic Benefits and Costs

Tangible working conditions are part of a job's appeal but teachers also respond to less-concrete job attributes.

Johnson and Birkeland (2003) found that new teachers who find that they cannot achieve a sense of success with students are less likely to find teaching a rewarding work and to remain in the classroom. Teachers who feel successful with students and whose schools were organized to support them in their teaching – providing collegial interaction, opportunities for growth, appropriate assignments, adequate resources, and school-wide structures supporting student learning – were less likely to leave their school than teachers in schools who were not organized to support them.

Farkas *et al.* (2000) similarly found the primary source of satisfaction among new teachers who planned to continue teaching was their confidence that they were making a difference in the lives of their students. In teachers' decisions to stay, leave, or transfer schools after the first year of teaching, more than anything else, teachers weighed whether they could be effective with their students. Difficult working conditions can affect a teacher's opportunity to teach well which, thus, affects his/her ability to succeed with students; however, it is this success that may ultimately determine whether or not the teacher chooses to stay.

School Location

School location has a strong influence on the distribution of teachers. Of all public school teachers who chose to move from one school to another between 2003–2004 and 2004–2005, 26% cited proximity to home as a very or extremely important factor in their decision to move; and of those who left teaching, 11% cited changing residence as very or extremely important (Marvel *et al.*, 2007). Most teachers prefer to teach close to where they grew up or in districts that are similar to the districts they attended as high-school students. Sixty-one percent of teachers who entered public school teaching in New York State between 1999 and 2002 started teaching in a school district located within 15 miles of the district where they went to high school, and 85% of teachers started in teaching in schools within 40 miles of their high school (Boyd *et al.*, 2005). Reininger (2006) found that these results are consistent nationwide in the US; in comparison to college graduates in nearly 40 other occupations, teachers were significantly more likely to reside in their hometown 8 years after high-school graduation.

Teachers' preferences to teach close to home or in similar settings pose serious concerns for urban districts, since urban areas produce a lower proportion of college graduates, and thus potential teachers, than do suburban areas. Rural areas also often have a smaller pool of college-educated workers from which to recruit teachers. Schools with large minority enrolments and large percentages of students receiving free and reduced-price lunch have significantly lower percentages of students earning bachelor's

degrees – a prerequisite for teaching. As a result, schools in these regions depend on hiring teachers from other regions. If they are unable to find qualified candidates, then they are forced to hire from a less-qualified pool of applicants or increase compensation.

Barriers to Entry

Traditionally, teaching in public schools in the United States required at least a bachelor's degree and certification, which in turn specifies coursework requirements, student teaching experiences, and a passing score on at least one standardized certification test. In theory, these requirements improve teaching by ensuring a minimum standard of quality on all teachers. However, these requirements also impose costs on qualified prospective teachers, which may deter them from entering the profession, effectively reducing the supply of teachers.

Until recently, while in theory teachers were required to be certified, in practice, many large urban areas employed a substantial number of uncertified teachers. Potentially, as a response to the Highly Qualified Teacher provision of the No Child Left Behind Act of 2001, schools and particularly schools serving a high proportion of students in poverty hire far fewer uncertified teachers. This tightened adherence to certification was accompanied by the creation of a number of alternative certification programs that reduced the entry requirements for teaching. Many states rely heavily on alternative routes for teachers. New Jersey, Texas, and California, for instance, obtain more than one-third of their new teachers from alternative routes. The reduced entry requirements in combination with substantial recruitment effort have substantially expanded the pool of individuals interested in becoming teachers. Furthermore, these new candidates often have stronger academic backgrounds than teachers entering from more traditional routes (Boyd *et al.*, 2006).

The Demand for Teachers

The supply of teachers determines the number of individuals willing to enter the profession and to teach in a given school, but the number of teachers actually hired and the characteristics of those teachers also depend on the demand. Important among demand factors are student enrolments, teacher retirement rates, class sizes, district hiring practices, and institutional constraints, which are described below.

Student Enrolment and Teacher Retirement

Due to the post-World War II baby boom, student enrolment increased in the United States in the 1950s and 1960s. Student enrolments declined by approximately

5 million between 1970 and 1990, but have since been steadily increasing. The baby boom era triggered a dramatic increase in the demand for teachers. Since the baby-boom generation moved through school, student enrolment changes have not driven as substantial an increased demand for teachers. However, currently, the teachers hired in the baby-boom era are reaching retirement age. Approximately 31% of public school teachers were aged 50 years or more in 2004–2005 (Marvel *et al.*, 2007). This segment of the teaching force is likely to retire over the next 10–15 years, which increases the demand for new teachers.

Reduction in Student-to-Teacher Ratios

Student-to-teacher ratios, which also affect the demand for teachers, have declined substantially during the past half century. In 1955, the ratio was 26.9; by the fall of 1985, it was 17.9, and in 2005, the average student/teacher ratio was 16.2 across all regular public schools (Marvel *et al.*, 2007). Federal policy has contributed to the decline of student–teacher ratios and the related increased demand in teachers since the 1970s. The Individuals with Disabilities Education Act (IDEA), implemented in 1975 and reauthorized in 2004, requires schools to provide accommodations for students with learning disabilities. Many schools have hired additional teachers to support students to comply with the act.

In a review of the research on class size effects, Hanushek (1998) attributed approximately a third of the decline in student–teacher ratios to special education accommodation. More recently, state policies such as the California Class Size Reduction Initiative of 1996, which paid schools to cap class sizes at 20 in grades K–3, have contributed to an increasing demand for teachers.

Hiring Processes

School and district hiring processes also affect demand and the resulting teacher workforce. In a study documenting district hiring practices across New York State, Balter and Duncombe (2008) found that most districts advertise openings in local newspapers and on the Internet; work with local colleges by supervising student teachers, posting job notices on campus, and contacting college faculty; attend at least one job fair; and use compensation for extracurricular activities and for outside teaching experience as recruitment incentives. Almost 90% of districts also use strategies to increase the local supply of teachers, such as recruiting substitute, alternatively certified, or retired teachers; or by providing assistance for paraprofessionals to become teachers. In spite of the efforts of districts in recruitment and hiring, however, it is difficult to tell who will be a good teacher. Jacob and Lefgren (2006) show that while principals are able to identify the

best and the worst teachers in their schools, they are not able to identify where the rest fall in the ability distribution. It is clearly even more difficult to tell who will be a good teacher during the hiring process. In a study of teacher hiring practices in New York State School Districts, districts most often chose candidates for interview on the basis of certification in the subject to be taught, major in the subject to be taught, and references or recommendations. A much smaller proportion of schools considered measures of a candidate's academic success such as his/her certification exam score, caliber of certifying institution, grade point average (GPA), and quality of teacher portfolio (Balter and Duncombe, 2008).

Institutional Constraints

The problem of suboptimal staffing is also driven by institutional constraints, outside the immediate control of schools and the district human resources department. In a study of district hiring patterns, the New Teacher Project uncovered three district-level policies contributing to the delays leading to suboptimal staffing patterns: lenient vacancy notification requirements, teachers' union transfer requirements, and late budget timetables (Levin *et al.*, 2005).

Lenient vacancy notification requirements do not require resigning or retiring teachers to provide notification of their intention to leave until late in the summer before the next school year. Such late notification deadlines make it very difficult for administrators to know which posts will be available when the school year starts, typically in September. By the time some districts extend offers, many of the applicants have already accepted other offers and have withdrawn their outstanding applications. Applicants who withdraw from the process early to accept other positions tend to be significantly better qualified than new hires in terms of undergraduate GPAs, a degree in their teaching field and completion of educational coursework.

Union contract provisions leave room for experienced teachers to request last-minute transfers, which excesses less senior incumbent teachers. In response, many principals delay advertising vacancies for fear of being required to hire a transferring teacher they do not want. Finally, as a result of late state budget deadlines, administrators are unaware of which positions will be funded in their schools. In 46 states, the fiscal deadline is not until 30th June, and even then, states can get extensions. Although stringent union contracts can decrease hiring effectiveness, in a study of the legal and policy structures designed to place high-quality teachers in high-minority schools, Koski and Horng (2007) did not find persuasive evidence that the seniority preference rules associated with union contracts independently affect the distribution of teachers across schools or exacerbate the negative relationship

between higher minority schools and noncredentialed and low-experience teachers.

Recruitment and Retention Policies to Date

Districts that face difficulty in hiring or retaining the teachers that they want aim to increase the supply of teachers and/or to remove institutional constraints to facilitate more effective hiring. This section looks at the following policies addressing recruitment and retention of teachers in the United States: partnerships between districts and local colleges, monetary incentives, changes in entry requirements, teacher induction and mentoring, performance-based pay, career differentiation, improving hiring practices, and modifying teacher due-process procedures. A review of extant literature reveals a lack of research that convincingly identifies the effects of most of these policy approaches.

Partnerships Between Districts and Local Colleges

To recruit potential teachers into the teaching pipeline, some districts have created partnerships with local colleges to encourage students to enter teaching. In New York State, for example, the most common college recruitment strategies used by districts are supervision of student teachers, posting of job notices at the colleges, and contacting college faculty in local colleges (Balter and Duncombe, 2008).

As a second example, the Urban Teacher Academy Program (UTAP) in Broward County Public Schools in Florida prepares high-school students for careers in urban education. This grow-your-own model provides successful program graduates with a scholarship at one of the district's higher education partners. While in college, these students major in education with opportunities for field experience in local schools. After finishing college, graduates are guaranteed a teaching job in the district. As of yet, no rigorous analyses of the effectiveness of such programs on teacher recruitment and retention have been conducted.

Monetary Incentives

In recent years, a number of states have experimented with various ways to offer higher compensation to prospective teachers to aid in recruitment and retention. Signing bonuses or crediting teachers for their years of experience teaching in other districts are examples of monetary incentive bonuses for recruitment. Some bonuses are paid in increments over time to promote retention.

Research on the effectiveness of monetary incentive programs for recruitment and retention is not conclusive. One such program, the Signing Bonus Program, implemented in Massachusetts in 1998 combined heavy recruiting, and a 7-week fast-track certification program, and a \$20,000 bonus paid in increments to all participants who continued to teach for 4 years in the state. The program did not succeed in retaining its participants – 20% of the first cohort of bonus recipients left teaching after 1 year, and attrition was particularly high in state-designated, high-need districts. Furthermore, over 50% of its second cohort ended up teaching in schools outside of the state-designated, high-need school districts for which the program was intended (Fowler, 2003).

Conversely, Clotfelter *et al.* (2006) found positive effects of North Carolina's program that provided yearly \$1,800 bonuses to teachers of math, science, and special education in middle and high schools serving low-income or low-performing students. The authors estimate that this program reduced teacher attrition by approximately 14%, though, perhaps because school eligibility for the bonus for a given academic year was not usually announced until the year had started, the program was not an effective recruitment tool.

Changes in Entry Requirements

Many states, in an attempt to increase the supply of teachers without the high cost of monetary incentives, are expanding the pool of potential teachers by reducing the cost of entry for academically competent individuals. Forty-seven states and the District of Columbia have some form of alternative-route program to recruit, train, and certify teachers. Many of these states rely heavily on alternative routes for teachers. Although alternative certification programs vary in size, scope, and competitiveness, the offer of alternative certification appears to be an effective recruitment strategy. Nearly 50% of those entering teaching through alternate routes say they would not have become a teacher if an alternate route to certification had not been available. Approximately one-third of entrants into teaching through alternate routes are nonwhite compared to 11% of the current teaching force. In terms of retention, nearly two-thirds of the survey respondents entering teaching through alternate routes expect to be teaching K-12 about 5 years from now. States with the highest percentage of alternatively certified teachers report that 87% of them are still teaching after 5 years. (Feistritzer, 2005).

Teacher Induction and Mentoring

Beginning teacher induction and mentoring have grown in prominence in school districts as methods to support new teachers' transition into the profession and to increase teacher retention. Induction programs typically involve

meetings, informal classes for new teachers, and the formation of new-teacher peer-support groups. The duration, intensity, and content of mentoring interactions can greatly vary across programs. Mentoring programs typically pair new teachers with experienced ones.

Studies of mentoring programs to date suggest that this may be a promising approach for increasing the retention of early career teachers. However, they are based on nonexperimental data and it is possible that districts or schools that implement high-quality mentoring differ from other districts, perhaps by being well run in other dimensions, and it is the other differences that drive the relationships that we see. In a synthesis of 10 empirical studies, Ingersoll and Kralik (2004) found empirical support for the claim that mentoring programs have a positive impact on teachers and their retention. Similarly, Smith and Ingersoll (2004) found that the turnover rates among new teachers decrease as the number of induction components in addition to mentoring increased – such as planning time with other teachers in the same subject, regularly scheduled collaboration with other teachers, and being part of an external network of teachers. In addition, schools that provided teachers with more autonomy and administrative support had lower levels of teacher attrition and migration. These studies suggest that mentoring may be a useful tool for retaining early career teachers. In one of the more convincing studies, Reed *et al.* (2006) found that in California, Beginning Teacher Support and Assessment (BTSA) programs in the early 1990s reduced the probability of transfer and exit among new teachers.

Performance-Based Pay

Some policymakers believe that the traditional single-wage schedule based on teacher's years of experience and number of university units provides no incentive for teachers to increase academic performance of students, and thus discourages particularly effective teachers from entering the classroom. Performance-based pay is a form of flexible compensation in which a portion of teachers' compensation is based on estimates of their effectiveness at raising student achievement. The unit of analysis can be individual teachers, groups of teachers, or schools, and payment can be based on student test performance or principal or peer evaluation.

Proponents of performance-based pay structures posit that rewarding teachers on the basis of an established set of goals would improve the motivation of teachers and assist in the recruitment and retention of high-quality staff. Critics of performance-based pay structures believe that teachers' output is too varied and difficult to observe. In addition, they worry that performance-based pay could distort incentives which could lead to suboptimal practices for long-term learning, such as teaching to the test. In addition, competition for merit awards could

result in competitive behavior among faculty at the same school and even reduce the appeal of teaching, particularly for individuals who are averse to risk.

There is little research on the effect of performance-pay on recruitment and retention, although the empirical research on the programs implemented to date has not found consistently positive effects from these reforms on student learning. Kelley (1999) examined the ways in which school-based performance award programs motivated teachers to modify or improve teaching practice in Kentucky, North Carolina, Colorado, and Maryland and concluded that such programs motivated teachers largely by creating conditions that increased intrinsic rewards and focused teacher efforts. Ballou and Podgursky (1993) found that teachers in districts that used performance-based pay did not seem demoralized by the system or hostile toward it, and that teachers of disadvantaged and low-achieving students were generally supportive of the system.

Career Differentiation Through Ladders

While the retention patterns of teachers are similar to that of other professions, such as nursing, social work, and accounting (Harris and Adams, 2007), some posit that teacher retention could be reduced by differentiating the profession, allowing paths for teacher promotion. Such promotions could provide the psychic benefits needed to improve retention. As an example, some career ladders divide the teaching career into stages by increasing responsibility and leadership, or by rewarding outstanding teaching practice. Career ladders have the potential to increase the job satisfaction of experienced teachers by diversifying their workday and skill set, thus increasing their likelihood of staying at the school, particularly because 20% of teachers leaving high-poverty urban schools report that more opportunities for advancement might induce them to stay (Ingersoll, 2004). Career ladders also have the built-in potential to increase retention among less-experienced teachers by presenting a challenging and rewarding future career prospect attainable without leaving the school. Brewer (1996) found evidence which suggests that later career opportunities affect quit decisions among teachers by examining the relationship between teaching and school administration. A study by Booker and Glazerman (2009) found that teachers in schools participating in the Missouri Career Ladder Program were less likely to leave the district as well as to leave teaching, as compared to those teachers in districts without career ladder programs, all else equal. However, the Missouri Career Ladder Program included bonuses with advancement, thus it is difficult to disentangle the impact of the monetary incentives on teacher retention from the impact of career differentiation itself.

Evidence of the effects of differentiation on teacher retention is mixed. Variations in the design and

implementation of career ladders influence teacher experiences with career ladders. Rosenblatt (2001) found that conditional on holding leadership roles that are well matched to individuals' skills and offer skill variety, career ladder programs can decrease the likelihood of burnout and increase teachers' intention to stay in their schools. However, career ladder programs that do not successfully match teachers skills to the position or offer variety can induce additional anxiety and stress for some teachers due to extra responsibilities (Henson and Hall, 1993). Without reasonable teacher assignment or without quality administrator support, the implementation of a career ladder policy is unlikely to have any positive effect on teacher satisfaction or retention. As with most retention and recruitment policies, there is little convincing causal evidence on either the advantages or disadvantages of career differentiation.

Improving Hiring Practices

Hiring practices have received attention from researchers, but relatively little attention from school leaders and policymakers. Given the contractual constraints placed on principals during the hiring process, principals are often forced to hire teachers late, by which time many higher qualified teachers may have already taken positions. Consequently, many teachers are hired late – more than one-third of new teachers in California and Florida were hired after the school year has already started (Liu and Johnson, 2006). Loosening institutional constraints on administrators and district personnel may increase efficiency in the hiring process. Jacob (2007) recommends that urban districts should streamline the administrative procedures associated with hiring so that they can make job offers more quickly; improve their ability to identify effective teachers from the pool of candidates; and implement a more decentralized process would likely result in better matches between teachers and schools. Furthermore, in their study of teacher hiring processes, the New Teacher Project formulated the following recommendations to facilitate more effective teacher hiring: ensure that transfer and excess placements are based on the mutual consent of teacher and receiving school, permit the timely hiring of new teachers, and better protect novice teachers who are contributing to their school.

Reform of Due Process

Teacher tenure policies were initially implemented to protect teachers who have successfully completed a probationary period from arbitrary dismissal. The job security tenure offers may attract prospective teachers in the teaching force and keep teachers already in the classroom. While little research has been conducted on the effect of teacher tenure on recruitment and retention, a study by

Brunner and Imazeki (2007) explored variation in probationary periods across districts and its relationship to variation in wage. The authors found evidence that districts compensate for longer probationary periods by offering higher wages. Wages for both beginning and experienced teachers are measurably higher in districts in states with longer probationary periods, which suggest that the offer of tenure may serve as a recruitment device, as teachers appear to value the prospect of an early tenure in their decision of where to teach. Clearly, tenure is a factor in a teacher's decision to remain teaching. After the probationary period, tenure creates a high level of job security and stability in the teaching profession, which could serve as an incentive for teachers to stay in the field, although no empirical work has been done to study the relationship between tenure with teacher recruitment or retention to date. Of course, tenure has the potentially negative effect of making it more difficult to dismiss less effective teachers and serves as a reminder that all teacher attrition may not be detrimental.

Conclusion

A growing body of research confirms the importance of teacher quality on student learning gains. These findings emerge at a time when policymakers and school leaders face growing concern about their ability to keep teachers currently in classrooms and how to replace teachers who leave. The teacher labor market is not all that different than other labor markets on average but the pool of available teachers is strikingly different across schools. Some schools, usually those with high proportions on non-white and low-achieving students, face a far more difficulty recruiting and retaining high-quality teachers. This article described how teachers' choices and their related preferences affect the supply of teachers and how the actions of schools and districts affect the demand for teachers and how supply and demand come together to create the workforce that we see. The article also summarized policy approaches to advancing recruitment and retention and the current research estimating the effectiveness of these policies. What stands out, as stands out in much of education policy research, is how little we know about the effectiveness of different policy approaches. Teachers respond to wage incentives, but nonwage aspects of jobs are at least as important in their decision to stay. Leadership plays a critical role both in working conditions and in the hiring process but, the market for school leadership faces similar issues of recruitment and retention and is an area in which we know even less.

Teacher Incentives

Teacher Incentives

Recent evidence suggests that teachers matter for student learning (OECD, 2005). Consequently, education systems around the world strive to recruit and retain high-quality teachers. To ensure qualified teachers get to the classroom (and remain there), salaries must be set accordingly. Because education is a labor-intensive endeavor, in many countries teacher salaries account for 60–95% of educational spending. The traditional way of paying teachers, however, using education- and seniority-based salary schedules is not designed to reward or encourage superior performance (Murnane and Cohen, 1985; Lavy, 2007; Hanushek, 1996). To tackle this problem, the use of targeted incentives or pay-for-performance has often been proposed.

The rationale behind using incentives to promote changes in individual behavior was first explored in the economics and business literature. Salary-incentive programs are designed to solve the employer's problem of motivating workers to perform well when individual effort and ability is not readily measured or observed (Asch, 2005). In other words, incentives are useful when a principal and an agent (i.e., an individual performing work for an employer) have differing objectives in a context of asymmetric information, when the employer cannot or does not want to dictate a particular procedure for attaining the outcome.

The school presents employers with a similar kind of principal-agent problem. School administrators, parents, and policymakers all want teachers to achieve certain outcomes (e.g., improve learning, develop well-adjusted adults, and build citizenship), but cannot monitor teachers' daily activities. To address this situation in a way that improves educational outcomes, incentive programs in education are being increasingly favored.

This article presents an overview of teacher incentive programs implemented in various countries. It begins with a brief background section on the kinds of incentive programs that have been put in practice. Second, it discusses the advantages of incentive programs and some of the positive results reported in the literature. These results are divided into individual and group incentives. Within these categories, the discussion is organized by type of outcome: efficiency and productivity, and the recruitment and retention of qualified teachers. Third, it explores some of the main disadvantages and criticisms of incentive programs as well as some of their unintended or adverse consequences. The last section concludes.

Background on Incentive Programs

Teacher incentive programs come in different flavors. They can be targeted to the individual or be designed to reward the group as a whole (a group of teachers, a school, or a school district). Incentives can be structured as rewards only, or as a system of rewards and sanctions. It can be a one-time event or an ongoing reward. They can be based on a relative criterion (value-added) or an absolute one (Lavy, 2007).

Most incentive programs reward teachers with salary bonuses, but some offer nonmonetary rewards. Incentives can be offered to teachers in the form of improved working conditions, in-kind contributions (e.g., educational materials), job stability, pensions, and the like (Vegas and Umansky, 2005). Other common examples of nonmonetary incentives are promotion-based (where promotions to higher grades in a career schedule are based on performance assessed over several time periods) and seniority-based incentives (when employers offer a reward later in an employee's career contingent on current levels of effort) (Asch, 2005). Both of these can be effective in improving worker productivity, but they are of limited use in educational systems. (Obviously, the first kind of incentives only works in an organization with a vertical hierarchy (e.g., workers promoted to managers). The second approach suffers from the problem of workers not wanting to retire when they are senior employees because they are being paid more than their productivity (Lazear, 1979, 1983). In addition, this approach is in some ways reflected by current salary schedules that are based on seniority. Research has found that more senior teachers are not necessarily more competent than junior teachers who have been teaching for at least 2–3 years (Hanushek, 1997). However, senior teachers receive higher salaries than novices do on all salary schedules.)

Murnane and Cohen (1985) discussed merit pay and concluded that most plans fail because the microeconomic framework under which most plans are based is not entirely appropriate for compensating teachers' work. For example, school administrators were rarely in a position to accurately explain why some teachers received merit pay and others did not, and what the latter group could do to receive merit pay in the future.

However, most recent incentive programs are merit-pay style programs focusing on student test scores as the main measure of teacher performance. Focusing on test scores is an attractive choice because they provide

observable measures of student learning. In addition, there is evidence to suggest that they are correlated with other longer-term outcomes such as lifelong earnings (Klerman, 2005). Next we discuss the main advantages of incentive programs. To illustrate these, a brief discussion of recent experiences is included. By design, most of the positive effects are on standardized student test scores. Whenever appropriate, however, we discuss effects on other outcomes of interest such as teacher attendance.

Advantages of Incentive Programs

This section discusses positive results reported by incentive programs implemented in various countries. It is organized in two main categories: incentives targeted to the individual teacher and group incentives. Within these two categories, the discussion is divided into efficiency and productivity results, and effects on recruitment and retention of qualified teachers.

Individual Incentives

Efficiency and productivity

In theory, the main advantage of incentive programs is that basing some part of a teacher's compensation (or offering incremental payments) on a common objective (learning, test scores, and graduation rates) enables the alignment of incentives directed to teachers or schools with those directed to students (Lavy, 2007). This could generate efficiency gains because teachers focus their efforts on those objectives that are valued most by parents and policymakers. Individual merit-pay schemes of this type help correct potential distortions in a teachers' effort that might result from gaps between her (work) preferences and those of her students (Lavy, 2007). In other words, incentives could produce better educational outcomes at lower or equal cost than traditional across-the-board salary raises.

There are some recent experiences that suggest the alignment of teacher and student objectives through incentives produces positive results. In India, Duflo *et al.* (2007) evaluated an intervention to reduce teacher absenteeism in rural areas through the use of teacher monitoring and incentives. An experiment of 57 randomly selected treatment schools (out of 113 schools) was conducted to explore if financial incentives would motivate teachers to have fewer absences (the baseline data suggested an absence rate of 42%). Teachers in the treatment schools were given a tamper-proof date and time camera to record their attendance at the beginning and end of the school day. Teacher salaries were calculated on the basis of valid school days. Tying salary to teacher attendance not only resulted in a drastic decline in teacher absence (to 21% in treatment schools over a period of two years) (the proper

evaluation phase lasted only 10 months; therefore, the positive effects on attendance lasted well beyond the experiment), but it also positively improved student achievement levels. A year after the program began, student test scores in treatment schools were higher (0.17 standard deviations) than test scores in comparison schools (Duflo *et al.*, 2007).

Other countries have experimented with incentives to improve teacher attendance in rural areas with less encouraging results. In Bolivia, teacher incentives were used to attract teachers to rural areas. The size of the incentive was small (between 0.3% and 1.1% of monthly salary) and was not successful in attracting teachers to these hard-to-staff areas. Furthermore, because of urbanization and demographic growth, some areas classified as rural were in fact borderline urban. The authors found that the test scores and other educational outcomes of students of urban- and rural-classified teachers with the same background and characteristics were not significantly different (Urquiola and Vegas, 2005).

In Mexico as part of the Programa para Abatir el Rezago Educativo (PARE) (this program was implemented in Mexico from 1992 to 1996 as part of a World Bank initiative to provide additional resources to very disadvantaged students, primarily those in rural areas and indigenous communities), teachers were offered monetary bonuses if they demonstrated they attended school regularly. A novel feature of PARE was that it was the parent associations who were in charge of teacher attendance records and monitoring. A qualitative evaluation of PARE, conducted in nine schools in two Mexican states, found incentives effectively reduced teacher absenteeism only in schools that had strong school principals and parent associations or had lower levels of teacher absenteeism (comparatively) before PARE was implemented (Ezpeleta and Weiss, 1996).

In Mexico, an evaluation of the national teacher incentive program *Carrera Magisterial* (teachers' career) showed slight positive effects of the monetary incentives on a small group of secondary school teachers, but virtually no effect on primary teachers (McEwan and Santibañez, 2005; Santibañez *et al.*, 2007). This program, unique in the world for its size and scope (implemented in 1992, the program is national in scope; hundreds of thousands of teachers and millions of students are tested every year as part of its yearly evaluations), awards bonuses beginning at 25% of base salary, up to 200% to teachers who consent to an evaluation of several factors including teacher knowledge (measured using a standardized teacher test) and student achievement (using a standardized student test). To evaluate the program and try to circumvent the fact that no natural comparison group exists, the authors used regression discontinuity design which compared teachers with strong incentives to those with weaker incentives during the evaluation year. (To obtain the bonus (get incorporated into the program) teachers must

obtain a minimum of 70 out of a total 100 points in the yearly evaluation. Up to 80 points of the total can be thought of as exogenous, because they either increase automatically every year or remain the same (the case of points given for seniority and highest degree earned, respectively), have virtually no variation (the case of the peer review component), or are within the control of the teacher (points given for obtaining professional development or the teacher test). Teachers with exogenous point scores below 50 or above 70 are in the weak incentive group. Teachers with exogenous point scores between 50 and 70 have a high incentive to improve student achievement, which is worth 20 points and could get them above the minimum cutoff for incorporation (McEwan and Santibanez, 2005). Results suggest that students of teachers in the strong incentive group who were competing for the bonus did exhibit slightly higher test results than teachers in the weak incentive group. This effect, however, was only observed for a very small group of secondary school teachers and not for primary teachers (McEwan and Santibañez, 2005; Santibañez *et al.*, 2007).

Using various data sources including the National Education Longitudinal Survey (NELS), Figlio and Kenny (2006) found that a strong positive association between the presence of merit pay in teacher compensation and student test scores in the United States. The authors were not able to conclude whether this positive association was the result of the incentives *per se* or of some unobserved measure of school quality not captured by the model.

Dee and Keys (2004) analyze the Career Ladder Evaluation System. This program was implemented in the state of Tennessee to improve student achievement through a blend of salary rewards with nonmonetary benefits such as more teacher autonomy and released time from teaching.

Using results from the Tennessee STAR class-size experiment, the authors found that the Career Ladder Evaluation System program had only mixed success in targeting rewards to the more meritorious teachers. They concluded that assignment to a career ladder teacher significantly increased mathematics scores by roughly three percentile points. However, most career-ladder teachers were not significantly more effective at promoting reading achievement. Furthermore, assignment to a teacher who had advanced further up the career ladder was not uniformly associated with significantly higher achievement (Dee and Keys, 2004). The authors acknowledge that one important caveat to their analysis stems from the fact that it uses an assessment system that was specifically designed to evaluate class size and not the effects of the incentive program.

Incentive programs could also encourage teachers to improve their practice or engage in professional development activities. One such study is the evaluation of the National Board Certification Pilot Project in Iowa. This project offers teachers' monetary incentives in exchange for obtaining advanced teacher certification. The evaluation

found that teachers involved in the certification process with the monetary incentives engaged in more professional development activities than teachers not targeted by the incentives (Dethlefs *et al.*, 2001). In Mexico, Ornelas (2002), in his study of CM, concluded that one of the major successes of the program's monetary incentives was to emphasize professional development. (However, it is not difficult to make the case that professional development should not be a goal in and of itself, but should be an intermediate objective to improving student learning. While it is important for teachers to receive continuous training, it is more important that training results in improvements in teaching that have ultimate beneficial consequences in the classroom.) A caveat to these programs is that teacher professional development or certification might not be an objective in and of itself. This is particularly true if these activities do not lead to better student learning. In this case, the incentive program could not lead to improvement in the bottom line goal of higher education quality.

Recruitment and retention of qualified teachers

If incentive programs correctly identify teacher productivity they will help recruit and retain more productive teachers. In theory, if the incentive program is well designed, it will tend to discourage teachers who are not as productive from remaining in the system and will tend to encourage more productive teachers to do so.

On the issue of how incentives affect teacher recruitment and retention, there is considerable US-based evidence suggesting that increasing teacher salaries affects who chooses to enter and remain in teaching. In the United States numerous studies suggest a link between higher teacher salaries and higher retention (Podgursky *et al.*, 2004; Stockard and Lehman, 2004; Kirby *et al.*, 1999; Gritz and Theobald, 1996; Brewer, 1996). Incentives used to attract teachers to less desirable schools may not work as well, however.

Group Incentives

Efficiency and productivity

Some of the gains in productivity discussed above are not only derived from individual incentive programs. Incentive programs designed to target a group of teachers or the school as a whole can help foster collaboration among teachers by getting them to work for a unified goal. This could have the dual positive effect of producing higher learning and overcome some of the potential negative effects of targeting individual teachers (Murnane and Cohen, 1986; Dee and Keys, 2004).

Glewwe *et al.* (2003) examine a teacher incentive program in Kenya which provided teachers with bonuses based on student performance and attendance. Teachers in 50 rural schools were randomly selected (out of 100)

for the incentive program based on the average test score of students already enrolled in school at the start of the program. Each year the program provided prizes valued at up to 43% of typical monthly salary to grade 4–8 teachers. The incentives were given to all teachers in the winning schools (regardless of their own individual performance), based on the performance of the school (relative to other schools) on the Kenyan government's districtwide exams.

The authors found that during the life of the program, students in treatment schools were more likely to score higher, at least on some exams, than students in the comparison group. This effect, however, tended to be short-lived. In addition, a closer examination of the channels through which this effect took place, suggested that teachers might have been teaching to the test. The authors did not find strong evidence to support that the program had induced greater teacher effort or that it would be able to reach longer term outcomes: student dropout rates did not fall, teacher attendance did not improve, the amount of homework assigned did not increase, and pedagogy did not change. There is, however, evidence that teachers' increased efforts to increase the number of pupils taking tests and to raise short-run test scores (by focusing instruction on the test). In addition, the authors found evidence that teachers adjusted to the program over time by offering more test preparation sessions (Glewwe *et al.*, 2003).

Lavy (2002) examined a small-scale program in Israel that provided incentives to teachers in 62 nonrandomly selected schools. He used a regression discontinuity approach to compare student outcomes in these schools with those of schools that just missed treatment because of eligibility rules. The program offered combined incentives to schools in the form of performance awards. These awards included merit pay for teachers and improvements in working conditions. Awards were based on student test scores and reduced dropout rates. This type of incentive program is of the rankorder type, which awards prizes based on the rank order of the winners.

An interesting feature of the Lavy (2002) paper is that it compares an incentive intervention with what he calls a resource intervention. That was a separate program awarding additional (and identical) resources, such as teacher training, to schools showing improvements. A comparison group of schools not admitted into the resource program serves as the basis for identification of programmatic effects. Lavy evaluates the effect of this parallel program and compares its effectiveness and cost to the teachers' incentives intervention.

Lavy's results suggest that monetary incentives had some effect in the first year of implementation in some schools and caused significant gains in many dimensions of students' outcomes in the second year in all schools. The program led to an increase in average test scores and a higher proportion of students who gained the high

school matriculation certificate (especially among those from a disadvantaged background). It also appears to have contributed to a decrease in the dropout rate in the transition from middle to high school. The results regarding the resource program suggest that it also led to significant improvements in student performance. However, the comparison of the programs based on cost equivalency suggests that the teachers' incentive intervention is more cost-effective (Lavy, 2002).

In Chile, the *Sistema Nacional de Evaluación del Desempeño de los Establecimientos Educacionales* (SNED) or National System of School Performance Assessment, offers monetary bonuses to schools that show high student-achievement marks. This program was implemented in 1990 and preliminary evidence shows a cumulative positive effect on student achievement for schools which had a relatively high probability of winning the award (Mizala and Romaguera, 2003).

Summary of Key Findings

Table 1 provides a summary of key findings from more recent studies, divided by type of intervention (individual or group incentives).

As the table suggests, most of the teacher incentive interventions that showed positive results on student achievement and other outcomes, were carefully designed, small-scale interventions with sizeable benefits for teachers and schools.

Disadvantages and Criticisms

The theory behind incentive programs is appealing in its simplicity. It is intuitive that individuals will tend to work harder if they know they will be rewarded for their efforts. As the evidence from the business field shows, this logic often tends to work. In practice, however, many incentive programs in education often fail to reach their intended goals. Most authors attribute these failures to both design and implementation factors.

First, incentive program design assumes that there is a clear and known definition of performance (Klerman, 2005). This implies a common agreement about outputs. In most examples from the economics and business literature, the output is well defined and has a readily available measure for performance. For example, papers in the business literature have shown incentives improved the productivity of workers installing car windshields (Lazear, 2000) and planting trees (Paarsch and Shearer, 2000).

Working toward achieving or producing a well-defined output is not usually the case in education. Teachers and schools have multiple and complex objectives which include, but are not limited, to student learning. Self-esteem, citizenship building, development of core values,

Table 1 Summary of key findings from recent studies, by type of intervention

<i>Study</i>	<i>Country</i>	<i>Scale</i>	<i>Description</i>	<i>Intervention design</i>	<i>Results</i>
<i>Individual incentives</i>					
Santibañez <i>et al.</i> (2007)	Mexico	National scale	Provides monthly salary bonus (beginning at 25% of base salary) to teachers who pass a national evaluation including tests of their knowledge and their students' knowledge	Nonrandomized intervention, voluntary participation. Most teachers in the country enrolled in program. Evaluation used regression discontinuity to identify a strong incentive group	Students of teachers in strong incentive group had slightly higher results in secondary schools. No significant results in primary schools.
Duflo and Hanna (2007)	India	Small pilot program	Provide financial incentives to teachers who could demonstrate regular attendance through the use of tamper-proof cameras	Experiment randomly selected 120 treatment schools and 60 comparison schools	Tying salary to attendance and using rigorous monitoring (cameras) significantly and drastically decreased teacher absence and improved student achievement
Urquiola and Vegas (2005)	Bolivia	National	Offered salary bonuses to teachers who taught at less desirable (i.e., rural) schools	Nonrandomized intervention, used regression discontinuity to identify effect of bonus	Rural pay differential was not successful in attracting more effective teachers to rural areas. The bonus had no effect on student test scores.
<i>Group incentives</i>					
Glewwe <i>et al.</i> (2003)	Kenya	Small pilot program	Provide teachers with bonuses (prized at 43% monthly salary) based on student performance and attendance. All teachers in winning school get the incentive.	100 rural schools, teachers in 50 randomly selected schools get treatment	Students in treatment schools scored higher in exams, only during life of the program
Lavy (2002)	Israel	Small-scale	Offered schools combined awards (salary bonuses for teachers and improvements in school working conditions) for improvements in student test scores and reduced dropout rates	Used regression discontinuity approach to evaluate results in 62 nonrandomly selected schools	The program had positive and significant effects on student test scores and dropout rates during its 2-year duration
Mizala and Romaguera (2003)	Chile	National scale	Offers monetary bonuses to schools that show high student-achievement marks	Nonrandom selection of schools. Descriptive and qualitative analysis.	Preliminary evidence shows cumulative positive results on student achievement for schools with high probability of winning the award

and social skills are all outputs valued to varying degrees by teachers, parents, and policymakers. Even when all of us could agree that student learning is the top priority, it is not clear that a standardized test can capture learning in a way that satisfies a common definition. In addition, the

objectives of teachers and their employers (principals, school boards, and education authorities) could compete with one another and even be mutually exclusive. For example, government agents might be interested in ensuring an equitable education for all its citizens, while

teachers or school administrators might want to keep difficult or at-risk students out of the classroom (Vegas and Umansky, 2005).

Second, incentive schemes assume workers know the best way to improve their work. In other words, workers know the technology and have the means to implement it. Research on accountability in education, however, suggests that teachers could need assistance to figure out how to best improve student achievement (Hamilton, 2005). Hamilton (2005) argues that accountability reforms are often accompanied by technical assistance to schools, but that this technical assistance might not be enough to compensate for insufficient capacity problems (e.g., insufficient material and financial resources), or, for the broader context in which some schools must operate. Aside from some well-documented findings, there is a general lack of knowledge about how to improve teacher practice (Hamilton, 2005).

Third, incentive programs assume that the benefit of obtaining a desired outcome outweighs the costs of measuring performance. This is less of a problem when simple tasks are involved, but when performance is multidimensional and involves a series of complex tasks (as is the case in education), measurement costs might outweigh the benefits (Asch, 2005). This is related to the premise (on which incentive programs are based) that there is an operational (and commonly agreed to) definition of performance (Klerman, 2005). The more precise and operational this definition, the easier it will be to design a system of incentives to reach it.

Fourth, because education is a multidimensional task, focusing on a single dimension (e.g., student test scores) is problematic. Some have criticized these programs for curtailing creative thinking or teaching to the test (Hannaway, 1992; Holmstrom and Milgrom, 1991). Programs could design ways to reduce these unintended responses, for example, by combining the use of outcome measures (e.g., student tests) and practice measures (e.g., classroom observations, interviews, and supervisor ratings).

Because there is certain to be some level of noise affecting each period's evaluation, rewarding the worker for performance during a single period might expose him to considerable risk (Prendergast, 1999). For example, the program could reward teachers whose performance during the evaluation period improved due to a positive shock in working conditions rather than increased efforts in a given year. Using repeated incentives could reduce this noise and improve the quality of the performance measure. However, the costs and feasibility of using more precise measures of performance needs to be weighed against its potential benefits.

Fifth, some argue that explicit incentives (e.g., salary incentives) can reduce productivity by eliminating intrinsic desire. Most of the incentives literature in business and economics assumes that effort is costly for the worker, but

other research argues that in some cases the pride or sense of mission workers derive from their work makes carrying out their tasks an enjoyable activity. Teaching might just be such a job. Teachers often cite a desire to work with young people and contribute to society as important reasons to enter the teaching profession (Guarino *et al.*, 2006). Some authors have found that incentive programs demoralize teachers and lead to lower effort (Fehr and Schmidt, 2004 cited in Duflo *et al.*, 2007) or harm their motivation and sense of duty and enjoyment (Kreps, 1997 cited in Duflo *et al.*, 2007).

Adverse and unintended consequences of teacher incentive programs

Other critiques of using targeted incentives to improve teacher quality center on the unintended, even adverse consequences of these kinds of programs. Upon deeper analysis of why some incentive plans improved student achievement, for example, it was found that teacher cheating (Jacob and Levitt, 2003), exclusion of low achieving students (Cullen and Reback, 2002; Figlio and Getzler, 2002), focus on the tested subjects in detriment of others (Hamilton *et al.*, 2002), teaching to the test (Koretz, 2002), or even increasing students' caloric intake on the day of the test (Figlio and Winicki, 2005) were largely behind the observed results.

Group incentives can also have adverse consequences by exacerbating the potential for free-riding of teachers. Research has shown that if an employee's share of the reward is small relative to the difficulty of the work, and if the effort of all team members is difficult to observe by the employer, an individual on the team will have an incentive to shirk his or her work while benefiting from the teams' work or free-riding on the effort of others. This phenomenon weakens the power of group incentives (Asch, 2005; Prendergast, 1999; Asch and Karoly, 1993).

Conclusions

The evidence regarding the impact of programs that offer teachers monetary incentives to improve student achievement is mixed. Some small-scale programs have found that incentives are effective at improving student learning, although in most cases these results are short-lived and not always the product of increased teacher effort or improved teacher practice. Some programs (notably the India case) have found positive effects of financial teacher incentives on attendance, but this has not always been the case in other countries. Individual financial teacher incentives used to improve recruitment and retention or increasing professional development, seem to have positive effects, but those used for other purposes, such as

increasing teacher attendance, have demonstrated mixed results. Still, even if their positive results are modest, targeted incentives are more cost-effective than traditional salary increases (which have also not shown consistent positive results on student learning) and are thus more likely to remain an attractive policy tool.

Years of incentive program design and implementation have yielded programs of very different forms and shapes. All the programs reviewed here used monetary incentives to encourage teachers, but some of the programs showing positive results mix individual and group (or school-based) incentives. None of the programs discussed here had sanctions for poor performance. Some were national in scale, some targeted only a few schools. Some rewarded student achievement only, some included other dimensions of a teachers' work.

In all cases and to improve its potential for positive effects the program should have a well-defined measure of teacher performance covering all outcomes of interest and including short- and long-term measures (Lavy, 2007). Value-added measures are preferred to absolute measures that can confound context and other factors (McEwan and Santibañez, 2007; Lavy, 2007). Perhaps a mix of group and individual incentives in addition to subjective (peer or supervisor review) with objective measures can be used to counterbalance criticisms about hindering teacher collaboration and the limited scope of standardized tests, respectively (Lavy, 2007).

Teacher Supply

P Dolton, University of London, Surrey, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

ITT (initial teacher training) – Those trainee teachers who have entered training but not yet qualified.

Nonpecuniary – Factors other than wages.

Opportunity wage – That wage that teachers could earn in the outside labor market in another job if they were not in teaching.

PIT (pool of inactive teachers) – The stock of qualified teachers in the labor market who do not teach.

PRT (pool of recoverable teachers) – The stock of teachers who have left the labor market or who are inactive but who could return to the profession.

PTR (pupil teacher ratio) – The number of pupils divided by the number of teachers.

Relative wage – The teacher wage compared to the opportunity wage (or another reference group – like the private sector).

Shortage – When demand exceeds supply.

Surplus – When supply exceeds demand.

Wastage – The flow of teachers who leave the profession.

A commitment to the education of the next generation means that the supply of high-quality school teachers must be one of the main education-policy priorities of any government. Any education system needs to recruit and retain high-quality teachers and understand the role of pay and other incentives intended both to attract people to the profession and to keep them.

Every country needs a relatively large number of teachers, as on average, in Organization for Economic Cooperation and Development (OECD) countries 2.6% of the total labor force are teachers (see OECD, 2004). In most countries, this means the education sector is the largest employer of university graduates. Accordingly, teachers pay is the largest component of a country's educational expenditure with an average of 63% of the educational budget.

In any consideration of the quality of teachers, we must be aware of the forces of supply and demand and the decisions governments choose to make about desirable pupil teacher ratios (PTRs), teacher working hours, the length and quality of teacher training, teacher pay and incentives, and the other nonpecuniary conditions in teaching

which must be affected by government educational-spending priorities.

Many countries have experienced recurrent crises in the recruitment and retention of teachers and in many there is a more or less continuous shortage of teachers, notably in secondary schools and in the most technical subjects. The shortage tends to be particularly acute in subjects such as math, science, and modern languages and in specific geographical areas, where the opportunity wage for would-be teachers is much higher.

The consequences of teacher-supply problem are inequitably felt across different socioeconomic groups in any society. It has been suggested (Darling-Hammond, 2000) that teacher quality is not only a major determinant of student achievement but also one of the most inequitably distributed resources as poor children invariably receive lower-quality teaching and poorer curricula.

The Labor Market for Teachers

The labor market for teachers can be thought of within a traditional supply-and-demand framework, with the additional complication that the government is virtually the sole hirer of labor. The demand for teachers can be determined by the number of children in the country of school age, and the government's desired PTR. For such a given ratio, the demand for teachers is therefore a constant, denoted by \bar{Q} in Figure 1. Under the reasonable assumption that the supply of teachers is a positive function of average teacher earnings, an upward-sloping labor-supply schedule can be drawn as S . In a perfectly competitive market, a teacher wage of W^* would therefore clear this labor market. However, the teachers' labor market is of course not competitive, and the government, in its role as (almost) exclusive purchaser of teaching labor, has other considerations, prime among which is the level of expenditure on teachers' salaries in total. For a given level of such expenditure, an inverse relationship can be plotted between teachers' earnings and the number of teachers hired, labeled E_1 in Figure 1; if the government wants to raise the salaries of teachers, it can afford to hire fewer of them, given a fixed budget. The number of teachers hired is therefore Q_g at average earnings of W_g , and the excess demand for teachers is $\bar{Q} - Q_g$. This can only be eradicated by a relaxing of the budget constraint leading to higher earnings, or other factors changing to

Figure 1 The labor market for teachers.

make teaching more attractive, so that more potential teachers supply their labor at any given wage.

Of course, the above analysis is simplistic in that it treats all teachers as being the same. In reality, within the same country, there may be teacher shortages in particular geographical locations or regions or in particular subjects, with an oversupply elsewhere. In addition, the real market position is very different for primary and secondary school teachers. We can amend **Figure 1** to allow for such possibilities by creating a simple distinction between different kinds of teachers. A simple analysis would suggest that the possibility of differential wages by subject, in different regions or between primary and secondary sectors could be adopted to solve the problems of short supply in particular areas. Whether this solution is actually viable, given the demands of teachers' unions and the rigid teacher-wage structures imposed in most countries, is another question.

Figure 2 shows the teacher demand-and-supply elements that may be used to determine if the teacher labor market is in shortage or in surplus. Demand is dependent of the number of pupils in the country and on the government's desired PTR. The higher the number of pupils enrolled in schools, or the lower is the PTR target set by the government, then higher will be the demand for teachers.

The supply of teachers as outlined in **Figure 2** can be divided into two: the current supply of teachers and the potential supply. The supply of teachers consists of those who are currently in service (*s*) which would include continuing teachers, new entrants (*e*) and reentrants (*rf*). New entrants are first timers teaching in public schools while reentrants are those with previous teaching experience, who left and are now returning to teaching. The number of students enrolled in the initial teacher training

(ITT) courses sustains the flow of new entrants as they can enter into teaching upon completion of their training. A shortage (*ex*) occurs when the demand for teachers is not matched by supply and a surplus occurs when the current supply of teachers exceeds the demand of teachers.

To complete the teacher supply-and-demand model, the outflow of teachers needs to be considered as well. Wastage makes up the outflow of teachers from the current supply. This group of leavers can be divided into those who leave at retirement age and those who leave for reasons other than retirement (i.e., those below the age of 60–65). When teachers (and those who are qualified to teach) leave the profession, they become inactive and enter the stock of potential teachers in the pool of inactive teachers (PIT). In addition to the leavers below retirement age, the PIT also contains the ITT graduates who do not enter into teaching. A second component in the potential supply of teachers is the pool of recoverable teachers (PRT) who are those who have left the profession but can be enticed to return to teaching and are therefore the main source of potential supply.

The Demand for Teachers

The first key element in the demand for teachers is the demographic pattern of pupil numbers which fluctuates all the time with changing fertility patterns. In most OECD countries, projected numbers of pupils is expected to fall over the next 5–10 years.

The second demographic trend affecting the demand for new teachers relates to the age distribution of the stock of existing teachers. **Figure 3** shows that in many OECD countries, the teacher stock is aging as an increasing proportion of teachers in the years 1992, 1996, and 2000 are over 50. This will lead to an increase in the demand for new teachers to replace those retiring over the next 10–15 years.

A third factor in the demand for teachers is the size of the class the government chooses for its pupils. This varies remarkably across countries as **Figure 4** shows that PTRs in primary and lower secondary schools are over 30:1 in some countries and as low as 16:1 in some countries. This will not only condition the demand for teachers but the quality of the teaching which is imparted to the children as larger classes may mitigate against individual pupil attention. In many OECD countries, PTRs have been falling. In the USA, average class size was 23 in 1965 – but this fell to 16 by 2000. This represents a dramatic growth in teacher supply over the last 35 years in the USA. Of course, what these aggregate figures hide are the increasing need for specialist teachers of subjects like information and communications technology (ICT).

A fourth factor in demand is the governments choice of the length of the working day for teachers and how many

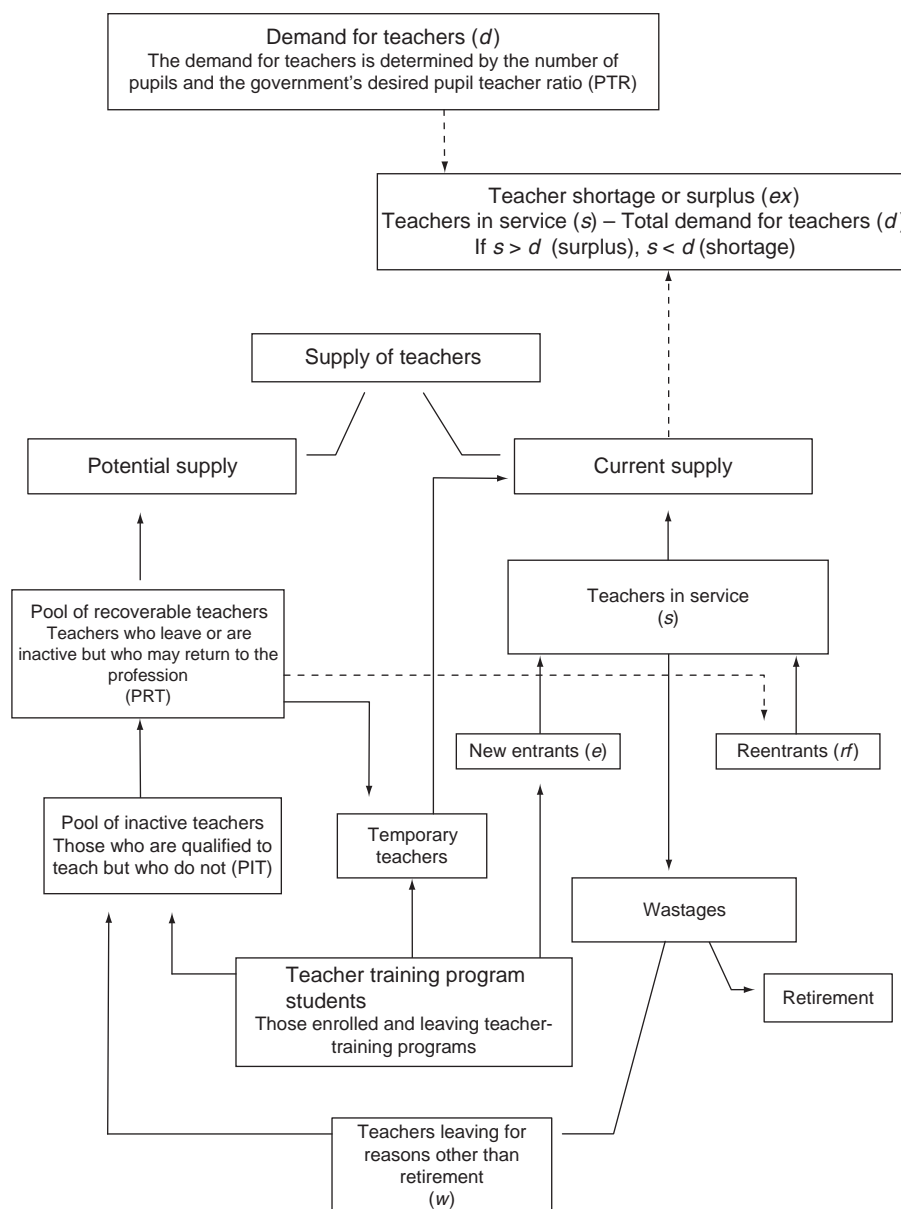

Figure 2 Teacher demand and supply.

teaching days there are in a year. Most countries make their elementary teachers teach between 650 and 800 h in the year but some teach a lot more – including those in the USA. **Figure 5** illustrates the variability of teacher hours in 2004 across countries and these differences must be reflected in the quality and intensity of the effort required of teachers in their job and hence the relative attractiveness of the job compared to alternatives.

Several other features may complicate the demand for teachers in different countries. First, if the financial administration of education is performed at a local level, resourcing decisions will depend on local and school-specific factors. Second, the determination of desired

PTRs and teacher recruitment may be influenced by educational criteria at the state or local level. Third, most governments control the nature of length of teacher training – this can and has been changed in times of crisis. Finally, different countries have different conventions about the extent to which school subjects, like mathematics may be taught by nonspecialists and principals have difficulty recruiting math and science teachers (**Figure 6**). Clearly, allowing nonspecialists to teach such shortage subjects will solve the short-run problem of having a teacher in front of a class – but at what cost to the quality of teaching? Ultimately, the demand for teachers will depend on the political will that creates the policy on

educational expenditure balanced with the importance on spending on health, welfare, defense, and other priorities.

The Supply of Teachers

The supply of teachers can be regarded as all those currently in teaching, plus those currently not teaching, but who are qualified to teach, and would consider teaching if the conditions were right. The supply issues at stake are therefore ones of recruitment and retention, as well as inducing the return of qualified individuals who have left

the profession. There are many factors that are likely to influence the supply of teachers, such as the relative earnings on offer in teaching and other careers, other labor-market opportunities, and varying relative non-pecuniary conditions of work. To a certain extent, some of these factors can be controlled by the government or federal authorities since it can determine how many places are provided on courses at universities to train teachers. In many countries, teacher training courses are not always filled, and attendance varies by subject. The measurement of teacher supply and most specifically the changes in teacher supply from year to year is problematic. Various studies have tried to measure teacher supply by changes in the pool of inactive teachers or the pool of recoverable teachers; changes in the stock of those teachers actually in service; the number of new entrants; or the numbers leaving teaching on teacher-training programs.

It is evident that the flow of newly qualified teachers does not necessarily indicate the level of overall supply. Focusing on those currently working as a teacher ignores individuals who are available for (and possibly seeking) work in teaching, but who are not currently employed as a teacher. Supply can be calculated as consisting of those entering the profession and those remaining in teaching from the previous year.

However, the difficulty is not just recruiting teachers but keeping them in the classroom. Some trainees drop out and others decide not to become teachers. Smithers and Robinson (2003) showed that only 88% of registered trainees passed the final examination, and only 59% were

Figure 3 The percentage of teachers aged 50 years and over, lower secondary education.

Figure 4 Average class size in educational institutions (public institutions only) by level of education (2004). Countries are ranked in descending order of average class size in lower secondary education.

teaching a year later. After 3 years, only 53% of the original trainees were still in the classroom. This wastage not only adds to the costs of providing teacher training but also has negative effects on child performance. The evidence is that

higher teacher turnover is associated with lower educational pupil outcomes (Dolton and Newson, 2003). This is of particular concern since we know that teacher turnover is highest in the most deprived areas.

Figure 7 Percentage of upper secondary students attending schools which use the following methods to respond to teacher vacancies, as reported by school principals. From OECD International Survey of Upper Secondary Schools (ISUSS) database, 2003.

Policies to increase the retention of trainees and new teachers have been on the forefront of the political agenda on education. The most prominent measures are repayment of student loans for up to 10 years and a hardship allowance for students in shortage subjects committing to become teachers, bursaries for undertaking and completing teacher training, and cash golden hellos for new teachers in shortage subjects.

It is hard to find direct evidence of the interrelation between teacher supply and shortage and the quality of teachers. One limited piece of evidence is that reported by the OECD (2004). **Figure 7** comes from the OCED website. It shows how schools react when faced with a teacher shortage. In the usual course of events, we would expect a school to advertise and hire a fully qualified teacher – if teachers are in short supply the school may resort to hiring a teacher with less than a full qualification; expanding the size of the classes; add hours to other teachers' courses; or cancel the planned course. **Figure 7** shows that these practices are frequently adopted in different countries. This must reflect on the quality of the teachers appointed and so it provides some evidence of the link between teacher shortage and teacher quality.

What individuals can earn as teachers, relative to what they could earn in alternative occupations (the opportunity wage), is one of the key determinants of the decision to become a teacher. In particular, the lower the relative wages (or wage growth) are in teaching, the less likely a graduate is to choose that career. Relative earnings affect both initial career choices, as well as choices made later in an individual's career. Dolton (1990) also found that there is considerable inertia to remain in teaching, and suggested that this effect may be partially due to the different individuals' subjective evaluation of the relative pecuniary and nonpecuniary rewards to teaching. It is also likely that nonpecuniary factors such as workload, job stress, physical surroundings, materials and resources, parental support, administrative support, access to further training, and related factors also play an important role in the decision to enter teaching or to leave if these working conditions change (see Hanushek and Rivkin, 2007; Boyd *et al.*, 2007).

While relative pay affects the decision to become a teacher, it also affects the decision to remain a teacher. Analyzing the decision to leave teaching, Dolton and Van der Klaauw (1995, 1999) show that higher the relative earnings of teachers, the less likely they are to leave teaching. Work using US data suggests that raising teacher

pay could improve the quality of the stock of teachers. But attracting more able students to teaching is not the only difficulty for policymakers. Since individuals with higher ability generally command higher wages, high-ability teachers are at a higher risk of leaving the profession than less-talented teachers. To negate the lure of improved outside opportunities on able-teacher retention, some countries have introduced fast-track programs with the aim of recruiting and retaining the most able graduates by shortening payscales and providing them with additional training, support, and supervision.

Another important aspect of teacher supply is that teaching is a career that is relatively popular with female graduates. In nearly all OECD countries, the majority of teachers are women particularly in primary education, where women consist of 80% or over of the teacher labor force. A crucial aspect of the distinction between male and female occupational choice is that often women are simultaneously making decisions about starting a family and hence deciding whether to participate in the labor market. This is particularly true in teaching since a teaching career has complementarities with family formation and in particular, the ease with which one can return to teaching after a career interruption. Hence, for women, the choice of teaching as a career is intimately related to the decision to participate in the labor market (Dolton and Makepeace, 1993).

Labor-market conditions at the time the occupational choice is made are also important. The most recent evidence from Dolton *et al.* (2003) look at time series data in

the UK and finds that aggregate labor market conditions, particularly unemployment levels, are important determinants of teacher supply. Notably, they find that the supply of graduates to teaching is countercyclical with most graduates' perception of teaching (and willingness to enter the profession) improving when teacher pay is high compared to alternative occupations and when graduate unemployment is high.

Teacher quality is extremely difficult to observe. That is to say – it is very difficult to accurately measure the amount of effort exerted or output produced by any individual teacher. This is important because teacher effectiveness is an important determinant of pupil attainment. It is unclear whether teachers with better qualifications are necessarily better teachers. There is some evidence in the UK (see Chevalier *et al.*, 2007) that teachers are being drawn from a lower part of the educational achievement or ability distribution than they were in the past.

What we seek to do is recruit the individuals with the most appropriate personalities to be good teachers. To some extent, this does not necessarily mean the most able individuals – but those with the capacities to be good teachers. What makes a good teacher is not something which can be easily measured. Naturally governments and state agencies should try to maximize the effective use of the taxpayers' money spent on education – this means that there should be appropriate attempts to monitor spending on teachers. The problem with this is that we do not fully understand: how to measure teacher quality, how teacher

Figure 8 Teachers' salaries (minimum, after 15 years experience, and maximum) in lower secondary education (2004). From Education at a Glance, OECD (2006) Chart 3.2. Statlink. <http://dx.doi.org/10.1787/083407611234>.

quality affects pupil performance, and how to measure effective teacher input or effort. Under these circumstances it is tempting for governments to try to introduce various incentive mechanisms and even performance-related pay for teachers. See Lavy (2004) and Dolton *et al.* (2003b).

Teachers' Pay

The most important determinant of teacher supply is the relative wage on offer. There is a large body of econometric evidence which finds that relative earnings of teachers is a major factor in an individual's decisions to become a teacher or remain in the profession. **Figure 8** shows how variable teachers' wages are with 15-years experience, across countries by graphing average teacher wage expressed in US dollars using purchasing power parity to facilitate comparison. This shows that there are some countries where teachers are earning approximately 4–8 times (Luxembourg and Switzerland) that in other countries (Poland and Chile). Most countries pay their teachers between 1.3 and 1.7 times the gross domestic product (GDP) per head, including the UK, USA, and most European countries. Clearly, in some countries being a teacher accords a much higher-earning status than in others. This reflects on the caliber of the people doing the job in that country.

Figure 8 also shows the range of salaries between the minimum starting salary and that at the top of the scale. This gap is largest in countries which pay their teachers more.

It is also of concern that the relative wage of teachers in many OECD countries has been falling in recent years. **Figure 9** shows the ratio of an experienced teacher

Figure 9 Ratio of salary after 15 years of experience to gross domestic product (GDP) per capita, public institutions, lower secondary education, 1994 and 2001.

with 15 years of service in 1994 and 2001. For many countries their wage – expressed as a proportion of GDP per head has been falling. Notable exceptions are Greece, New Zealand, and Turkey.

Tracking the relative pay of teachers over time in more detail is not straightforward in most countries. Dolton (2006) presents what has happened to relative teacher earnings over time in the UK and the USA. Often the process of public sector wage settlement is subject to delays and lags. This is reflected in the process of declining real wages in teaching which may then be followed, as was the case in the UK, with periods of catch up following a decline in relative earnings.

Another important but neglected aspect of remuneration is what individuals are paid over their working career lifetime. There is good evidence for the UK (Dolton and Chung, 2004) that the position of teachers has been getting worse. The earnings of male teachers were uniformly higher than earnings in the alternative occupation (for qualified teachers who choose not to teach) in 1975. However, over time, the earnings profile in the alternative occupation has been shifting up while that of teachers has been moving down.

There are many other areas in which our knowledge about teacher supply is scant. Although teacher shortage is widespread, we know from empirical evidence that many young people still choose to be teachers despite the low pay. Clearly, nonpecuniary factors matter in occupational choice but we know relatively little about this part of the process and how it operates. We know relatively little about the role of expected future lifetime earnings in the decision process and how people trade this off against a job which is rewarding. We also know little about young people's perceptions of teaching as a career or their real relative perceptions of earnings in teaching. In some countries, there are a sizable number of teachers who enter the profession in mid-career after working in the private sector for some time. It would be useful to know what motivates these individuals to make these choices and whether they are more effective teachers due to their outside perspective on the real world.

Summary

Examining the pattern of teacher supply across OECD countries, it is clear that there have been various trends. Teacher relative earnings have been declining and many countries have experienced teacher shortages particularly in subjects where graduates can earn a higher-opportunity wage. Countries can disguise these shortages in a number of ways including having more pupils taught by nonspecialist teachers. These factors might mitigate the quality of teachers.

Many governments have tackled their problems with teachers by reforming the training of new teachers or the retraining of existing teachers with professional-development schemes or trying to introduce teacher appraisal and various incentive schemes into teacher pay. Little is known about the effectiveness of these schemes compared to simply putting more government expenditure into education and teacher pay.

The overwhelming conclusion of research on the supply of teachers is that problems of teacher shortage could be alleviated with higher relative teacher salaries. If relative teacher salaries were higher, then the problems of teacher recruitment, retention, and duration could be alleviated.

It is clear that in most countries there are teacher-supply problems. There is evidence from different states in the USA and from other countries around the world that there are persistent episodic shortages of teachers. This manifests itself in terms of not enough recruits entering the profession and too many leaving it prematurely. However, it is also clear that there is not a universal shortage of all categories of teachers. Specifically, teachers are in short supply in difficult schools in areas with inner-city urban problems and in subjects which have a high-opportunity wages for those with specific technical skills. The problems seem to be worst in scientific and mathematical subjects. Hence, the real challenge of teacher supply is to get teachers into teaching the subjects and areas that are not appealing. The straightforward economic answer is to consider differential pay for those shortage categories. The problem in most countries is that there is a rigid wage structure in teaching. This limits the ability of school managers to effectively respond to relative wage differentials or target wage increases in difficult to recruit specialties. It is also unclear what the long-term consequences are of having children taught with temporary, nonspecialist, or low-quality teachers.

The perennial challenge for governments and education administrators is to establish a high-quality teacher labor force which is hard working and effective. Such problems could easily be solved by paying teachers higher wages. The problem, of course, is that governments are reluctant to throw more money at such problems and that even if they did it, is not clear what the outcome of increased expenditure is – precisely. Hence, more research on the relationship between educational-resource inputs, teacher quality, and outcomes must inevitably have important lessons for teacher supply. For example, if we knew categorically that the PTRs had no effect on pupil outcomes, we could simply solve teacher-shortage problems by having larger classes. In addition, we do not know in much detail, the effect of teacher working conditions on

their relative effectiveness. There are many unanswered questions relating to teacher supply.

Teacher Training and Preparation in the United States

M Podgursky, University of Missouri – Columbia, Columbia, MO, USA

M G Springer and R Hutton, Peabody College of Vanderbilt University, Nashville, TN, USA

Introduction

This article provides a brief overview of the current system of teacher preparation and training in the United States as well as a review of empirical research on the topic. It focuses on public elementary and secondary education in the United States, although some reference is made to international literature on teacher preparation and training. The review of relevant research focuses on study designs that employ randomization or control for prior achievement of students since studies without these features are likely unable to disentangle the impact of certification policies or programs from other factors that may be correlated with certification policies and programs.

To become a teacher in a public elementary or secondary school in the United States, it is usually necessary to obtain a state teaching license. This license is meant as an assurance to the public that a teacher has met a certain minimum standard of proficiency. Outside of K-12 education, licensing is commonly distinguished from certification. The former means that a practitioner cannot legally practice his profession or trade without a state-issued license. The latter refers to a situation in which a government agency, or, more commonly, a private body, certifies the skills of practitioner, but the government does not exclude noncertified practitioners from the market (Friedman, 1962). To further complicate matters, in K-12 education, endorsements refer to certification in a subspecialty. For purposes of this essay, we will treat license, certificate, and endorsement in K-12 education as synonymous.

When it is perceived that quality is low, some proponents have argued that teacher training and licensing should be the focus of reform efforts. The National Commission on Teaching and America's Future (NCTAF), the American Association of Colleges of Teacher Education (AACTE), and teacher unions have proposed reforms that would create national teacher testing standards, universal accreditation of teacher-training programs, creation of independent teacher licensing boards, and more entry restrictions into the teaching profession (NCTAF, 1996, 1997; Ballou and Podgursky, 2001). More recently, the federal No Child Left Behind (NCLB) act has devoted considerable attention to the topic of teacher training and licensing as a means of quality assurance, while further requiring states to phase out emergency, alternative, and other substandard types of teacher licenses so that all teachers are 'highly qualified' in their primary teaching

area. The US Department of Education has also funded development of a National Comprehensive Center for Teacher Quality to serve as a national resource on strategies for strengthening the quality of teaching and the teaching workforce.

Teacher training and licensing as a means of quality assurance assumes that how a teacher is trained and what type of license a teacher holds is an informative indicator of their classroom effectiveness and that higher standards in training and licensing will yield positive net benefits on student learning. Critics argue that teacher licensing, based on the currently proposed criteria, has not shown any significant impact in the short or long term on student achievement and other schooling outcomes. Moreover, these reforms may have significant costs in the form of expanded resources for teacher-training programs, more time spent fulfilling teacher-preparation program requirements, and, as a consequence, a reduction in the size of the teacher applicant pool.

Many critics further argue such reforms may also eliminate, or substantially downsize fast-track, alternative-route teacher-training programs, such as Teach for America and Troops to Teachers. Teach for America (TFA) recruits recent college graduates from top institutions of higher education across the country to commit 2 years to teach in urban and rural public schools and provides them with training and professional development throughout their 2 years of service. Troops to Teachers is a United States Department of Education and Department of Defense program that assists eligible military personnel with starting a career as a teacher in public elementary and secondary schools. If local decision makers have good information about the effectiveness of a teacher aside from their observed credentials (e.g., student teaching ratings, teaching portfolio, or recommendations), it may be that noncertified (or alternately certified) applicants are the more qualified candidate for a position (Goldhaber, 2004). Strict licensing requirements typically prevent a school district from ever hiring an uncertified candidate, if a fully certified candidate is available on the job market. Thus, an important part of the research agenda in this area is how well certification, or its component parts (e.g., tests or specialized teacher training), predict teacher effectiveness and whether more restrictive licensing requirements affect the teacher applicant pool and the quality of new hires.

The next section of this article provides a brief overview of the current system of teacher licensing in the

United States and then reviews the empirical literature on teacher training, preparation, and certification process.

Current Licensing Methods

There is a great deal of variation in licensing requirements from state to state, although there is a certain amount of commonality across particular components. All states require that new teachers possess a bachelor's degree; however, some states require an education degree from an accredited teacher-training program. In other states, teachers complete education courses while majoring in an academic discipline, or obtain a master's degree in education following completion of undergraduate coursework (NASDTEC, 2008; Education Week, 2008). Regardless of the path toward licensure, most teachers complete some education coursework in addition to student teaching before they have satisfied the professional requirements for permanent licensure.

In the majority of states, the power to license teachers is governed by the state board of education or state education agency. It has been proposed that this authority shift to independent professional boards such as those found in medicine and some states have enacted such certification reforms (NCTAE, 1997). However, unlike medicine or law, many approved teacher-training programs are not accredited by the principal private accrediting agency, the National Council for Accreditation of Teacher Education (NCATE). Few states mandate NCATE accreditation, although some have reached agreements whereby NCATE participates in the state's review of its training programs. In response to growing pressure from states for external accreditation of teacher-training programs, and concern by many private and research-oriented public universities with the NCATE approval process, a second accrediting body, the Teacher Education Accrediting Council (TEAC), was founded in 1997. TEAC's membership base is much smaller than that of NCATE, but is expanding.

Most states require teachers to pass at least one standardized assessment before they are admitted into a training program or granted a permanent license. These examinations fall into one of four categories: basic skills, general knowledge, pedagogical knowledge, and teaching field content knowledge. How many and which kind of examination a prospective teacher must take varies from state to state. NCLB seems to have stimulated the use of standardized teacher assessments through its requirement that teachers show evidence that they are highly qualified in their primary teaching field (ETS, 2007). Teacher performance on a standardized assessment is believed to offer proof of being highly qualified.

However, the emphasis that state and federal policies place on this supposition is far greater than one might expect given the current state of knowledge. The literature

on the relationship between a teacher's performance on a standardized test and their students' academic achievement detects a small, positive relationship of about 1–4% of a standard deviation (Goldhaber, 2007; Clotfelter *et al.*, 2007). It is unclear if standardized assessments offer a good screening tool for weeding out low-quality teachers or a sound signaling device for identifying high-quality teachers (Goldhaber, 2007; Podgursky, 2004).

One difference between licensing for teachers and other professions concerns the large number of teaching licenses. In medicine, law, dentistry, nursing, and other licensing professions, the state issues but one license. While many professionals, particularly in medicine, go on to earn certificates in highly specialized areas, these are not issued or required by states to practice. By contrast, the typical state education authority issues literally dozens of specialized teaching licenses (e.g., elementary education, secondary chemistry, secondary language arts, drama, various types of special education, and scores of different vocational licenses). This finely parsed system makes it difficult for a school, district, or state to make sure that every teacher in every classroom has the right certificate for that class. For example, if the certified chemistry instructor teaches an algebra class for which she is not certified, that teacher is out of compliance by teaching algebra. This problem has been exacerbated with the creation of middle schools which are typically defined by some combination of grades 5 through 8. Many middle school teachers hold elementary licenses and not newly created middle school licenses by specialty field, thus forcing them to complete additional training to remain eligible to instruct at the middle school level. Dee and Cohodes (2008) report that approximately 20% of mathematics and science teachers do not hold a certificate in their teaching field.

Research on Teacher Training and Licensing

Randomized experiments are widely recognized as the gold standard in social science research for determining causal relationships. By randomly assigning individuals or entire organizations to one or more treatment or a control group, unobserved factors that could lead to systematic differences between treatment and comparison conditions when estimating the relative effectiveness of the intervention are removed. The Institute for Education Sciences, the research funding arm of the United States Department of Education, is actively promoting randomized study designs in all areas of education research in light of the fact they have been underused in education research (Mosteller and Boruch, 2002).

With respect to teacher quality research, the most practical experimental design involves estimating the

effect of teachers with different credentials or training on an outcome of interest (typically student achievement) by randomly assigning students to classrooms of variously credentialed but otherwise comparable (e.g., experience) teachers within a school. Only one published study of teacher training employs a randomized design. Glazerman *et al.* (2006) compared the effect of TFA recruits with other new and experienced traditionally certified teachers within the same school at several sites around the United States. Students were randomly assigned to teachers participating in the study to maintain equivalence between TFA and non-TFA teachers on all factors believed to affect student achievement. TFA teachers were significantly more effective than other new recruits in math and equally effective in English. In substantive terms, Glazerman and colleagues concluded that the impact of TFA teachers on math scores was equivalent to about 1 month of instruction more than the impact of non-TFA teachers on math scores.

When randomization is not possible, and often it is not in education research, then researchers must rely on non-experimental or observational data to evaluate the effectiveness of an education policy intervention. In measuring the contribution of a classroom teacher on student achievement, it is necessary to control for prior achievement of the student before he or she enters the classroom. For example, researchers might pretest the students in the fall and test them again in the spring. The difference in fall and spring test scores, averaged over the classroom, would be a measure of a teacher's value-added. If students are not pretested in the fall, then it is also possible to use test scores from the previous spring, or for more than one previous year if longitudinal achievement data are available. Indeed, large longitudinal data files form the basis for the most sophisticated current research on teachers and teacher effects on student achievement (e.g., Sanders and Horn, 1994; Rivkin *et al.*, 2005; Boyd *et al.*, 2006; Aronson *et al.*, 2007). An excellent technical overview of the methodology of these education production function studies may be found in Todd and Wolpin (2003).

Even with longitudinal achievement data, there is still the potential for biased estimates of the effect of teacher training or licensing. For example, certain teachers may get assigned particularly difficult classrooms or students (Rothstein, 2008). These assignments may not be fully captured by prior student achievement or other covariates in large longitudinal data sets. Teachers who choose to participate in professional development programs may be more highly motivated and better teachers in the absence of the program. Again, these are variables that are not observed by the researcher or measured in data. Thus, researchers search for natural experiments, that is, situations in which assignment to a particular treatment is not subject to self-selection, and approximates a true experiment. Jacob and Lefgren (2004) exploited an arbitrary cutoff which assigned teachers to professional development to

estimate the effect of these training investments. They find that modest investments in teacher training do not increase the achievement of elementary school children in mathematics or reading.

Studies that do not have a rigorous study design, that is, with randomization or controls for prior student achievement, are likely to produce biased estimates of the effect of teacher certification or other teacher characteristics on student achievement. One reason is that these studies do not adequately control for the socioeconomic status (SES) of students in classrooms, and student SES is correlated with teacher credentials and strongly correlated with student achievement. In the language of econometrics, such cross-sectional studies of the effect of teacher credentials on student achievement suffer from omitted variable bias. Thus, our review of relevant research focuses on study designs that employ randomization or control for prior achievement of students.

It is also important to note that substandard certification tends to be relatively more common in schools with greater percentages of low SES students. Since SES has a very powerful effect on both student achievement levels and gains, unless the researcher has a very comprehensive set of controls for prior achievement and SES in a study of certification and student achievement, the resulting study is likely to yield an upward-biased estimate of the effect of certification. While this article discusses many studies that control for prior achievement, it is important that a reader remembers this study design is inferior to a study that carefully employs randomization.

The number of studies of teacher certification that meet the minimum methodological standards outlined above is limited. A survey of the literature by Wayne and Youngs (2003) found only two studies of teacher certification that were peer-reviewed, used longitudinal student-level achievement data, and controlled for student SES. Both studies were conducted by Goldhaber and Brewer (1997, 2000) and draw on the same nationally representative data provided by the National Education Longitudinal Study of 1988 (NELS:88). Their 1997 study concluded that students in tenth grade assigned to a teacher who held a mathematics teaching certificate, or earned a bachelor's or master's degree in mathematics, had higher test score gains than those students assigned to teachers with no mathematics certification.

The second study draws on a subset of students surveyed in the spring of tenth grade and then again in 12th grade to examine whether 12th-grade students assigned to teachers with probationary certification, emergency certification, private school certification, or no certification in their subject area have similar test score gains as those students assigned to teachers with traditional certification in their subject area. Goldhaber and Brewer (2000) conclude that 12th-grade students enrolled in a classroom taught by a traditionally certified teacher have larger test score gains

in mathematics than 12th graders taught by a teacher holding either a private school certification or no certification in mathematics. Interestingly, students enrolled in mathematics or science classrooms taught by a teacher holding emergency certification perform similar to those students taught by a traditionally certified teacher.

Darling-Hammond *et al.* (2001) criticize Goldhaber and Brewer's argument that standard certification should not be required of all teachers, since it does not appear to be a significant predictor of teacher effectiveness. However, in a separate survey of the literature focusing on high-quality studies that meet standards similar to those described above, Hanushek and Rivkin (2004) find little evidence linking teacher credentials to student achievement. For example, of nine estimates of the effect of teacher test scores on student achievement, six found no statistically significant effect. Of the three studies finding a significant effect, two were positive and one was negative.

Only a few studies that examine the impact of teacher certification on student achievement have appeared in peer-reviewed scholarly journals since Wayne and Youngs' (2003) and Hanushek and Rivkin's (2004) influential reviews. Boyd *et al.* (2006) examined whether teachers who enter the teaching profession through different pathways demonstrate greater effectiveness at improving student test scores when compared to those teachers who obtained a traditional teacher license. Alternative pathways included TFA, the New York City Teaching Fellows program, and the Teaching Opportunity Program. Using data on students and teachers in third through eighth grade from New York City school system, Boyd and colleagues find that students enrolled in classrooms taught by a TFA teacher had similar gains in mathematics and English language arts when compared to student test score gains of students enrolled in a classroom taught by a traditionally certified teacher. Moreover, students enrolled in a classroom taught by a New York City Teaching Fellow teacher or a teacher entering through the Teaching Opportunity Program had slightly lower test score gains. The authors note that the magnitude of these differences is relatively small. However, there is considerable variation in teacher effectiveness between classrooms – a point we return to later in this article.

Croninger *et al.* (2007) used data from the Early Childhood Longitudinal Study (ECLS), a national data set on children's status at birth and at various points after birth, to examine the relationship between characteristics of elementary school teachers and first-grade student achievement in mathematics and reading. Estimates do not indicate a statistically significant relationship between a teacher's certification status and their students' performance in reading or mathematics. Students taught by teachers with an elementary education degree, however, demonstrate greater reading test score gains than students taught by teachers with an early childhood education degree.

Dee and Cohodes (2008) draw on data from NELS:88 to extend earlier work by Goldhaber and Brewer. The authors emphasize that a student's assignment to a teacher with a particular teaching license may be correlated with the unobserved student effects that influence educational outcomes. They implement a student fixed-effect approach to condition on unobserved time-invariant characteristics of students which may be correlated with a student's ability and/or their probability of being enrolled in a classroom taught by a teacher with a particular teaching certificate. Findings suggest that assignment to a state-certified mathematics teacher increases an eighth-grade student's test score by about 10%, except for those students at the very bottom of the test score distribution where no effect is detected. Assignment to a state-certified social studies teacher for students across the entire ability distribution increased the probability an eighth-grade student had a high test score. Alternative specifications further indicated that state-certified teachers had the largest impact on male and high SES students and those enrolled in large, urban schools.

A recent, large-scale longitudinal study of Florida students by Harris and Sass (2007) was unusual in that the researchers had access to fairly extensive data on the educational and training background of Florida public school teachers. The sample included the census of teachers and students in grades 3 through 10 during the 1994–1995 to 2003–2004 school years. Harris and Sass find a consistent, positive correlation between content-focused in-service professional development and effectiveness of middle school math teachers. Nonetheless, they conclude that teacher training generally has little relationship to teacher productivity as most other relationships tested in the study were insignificant.

While the effect of measured teacher characteristics on student achievement is often small and statistically insignificant, one consistent finding is that there seems to be considerable variation in teacher effectiveness between classrooms. When we compare the effect on student learning of the top and bottom 20% of teachers ranked by performance, the effect is often quite substantial. For example, Hanushek and Rivkin (2004) report that if a student encountered five above-average teachers in a row, it could overcome the deficit typically reported between economically disadvantaged and higher-income students. However, these teacher effects are largely unrelated to traditional measures of teacher quality, such as licensing exam test scores, certification credentials, experience, or graduate degrees, a result highlighted in a survey of the literature by Goldhaber (2002).

A recent study of Chicago public school teachers by Aaronson *et al.* (2007) illustrates many of these points very well. Like other such studies, this work is based on a very large longitudinal data file of linked student achievement scores. This study is unique in that the authors also have extensive administrative data on teacher characteristics

that are unavailable in many other studies, including education, experience, types of teaching licenses, and selectivity of the teacher's undergraduate college. Aaronson and colleagues find that over 90% of teacher effects are not explained by any measured teacher characteristics. That is, characteristics of teachers that are not easily observable in their data explain the vast majority of teacher effectiveness.

While there are many descriptive studies of teacher training and licensing in other countries (e.g., conducted by the World Bank and Organization for Economic Cooperation and Development (OECD)), the number of rigorous evaluations using randomization or longitudinal designs with treatment and control groups is limited. However, given the growing evidence on student achievement and economic growth, and the availability of national and international data sets on student achievement in math and science, the limited number is likely to change (e.g., Angrist and Lavy, 2001; Woessman, 2003).

Conclusion

A new generation of studies based on large longitudinal data files on students and teachers finds large variation in the effectiveness of teachers as measured by student achievement gains. This variation is large in the sense that if an average low-achieving student were assigned to a teacher in the top quintile of effectiveness for several consecutive years, a substantial catch-up in achievement would occur. Unfortunately, little of this variation in teacher effectiveness is associated with traditional measures of teacher training or licensing, which makes identification of high-performance teachers using traditional credentials impossible. At the same time, there is growing recognition that the current system of training and licensing imposes costs on candidates and restricts entry into the teacher applicant pool. The challenge faced by education policymakers is to balance the benefits and costs of changing entry criteria into teaching. Growing use of large state longitudinal data files and more sophisticated scientifically valid studies are helping to shed light on the size and character of these benefits and costs.

Teachers in Developing Countries

F H Rogers and E Vegas, The World Bank, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Why devote a separate article in this encyclopedia to the issue of teachers in developing countries? While there are many similarities between teacher labor markets in developed and developing countries, the marked differences in context and education systems between the two groups have important implications for teacher policy.

Both the education challenges and the resources available to meet them are of a far different scale in the developing world. First, the challenges: Unlike in OECD countries, expanding access to basic education remains a major objective in the developing world. Reflecting this objective, the international community has officially committed to a millennium development goal (MDG) of achieving universal primary education globally by 2015. The MDGs grew out of the agreements and resolutions of world conferences organized by the United Nations during the 1990s. The goals were accepted as a framework for measuring development progress, and for most of them, the self-imposed deadline is 2015. There are eight MDGs:

1. eradicate extreme poverty and hunger;
2. achieve universal primary education;
3. promote gender equality and empower women;
4. reduce child mortality;
5. improve maternal health;
6. combat acquired immune deficiency syndrome (AIDS), malaria, and other diseases;
7. ensure environmental sustainability; and
8. build a global partnership for development (The World Bank, "Achieving the Millennium Development Goals").

Yet in sub-Saharan Africa, only 61% of children complete primary school, and the primary completion rate remains below 90% in South Asia and the Middle East/North Africa region. Rates of secondary school completion are even lower. Even when children are in school, in many developing countries their learning rates are very low. For example, in Argentina, Colombia, and Mexico, less than 50% of fourth graders reach even the lowest level of proficiency on an OECD-normed international literacy test – even though these are middle-income countries with more advanced education systems than the average developing country. Continued population growth will exacerbate these quantity and quality challenges in education: despite falling fertility rates, the population of children aged 5–14 in developing countries is projected to grow 16% between 2005 and 2025. (data from the World Bank Development Data Platform).

While developing countries are under great pressure to expand access and improve quality, their investment in education is substantially lower than in developed countries, both in absolute levels and as a share of GDP (see **Table 1**). Students' parents are often poor and have little formal education themselves, making it harder for them to compensate for weak schools through household investments in education. In addition, teacher compensation accounts for a larger share of total investment in education in developing countries – about 78%, compared to around 64% in Organisation for Economic Co-operation and Development (OECD) countries. Given these facts and the well-documented empirical finding that teachers have important effects on student learning outcomes, it is clear that good teacher policies can pay even larger dividends in developing countries than in developed nations.

Teacher Labor Markets in Developing Countries: Stylized Facts

Meeting the education challenges discussed above depends on recruiting motivated teachers with the necessary skills and ensuring that they are in classrooms everywhere, including in underserved rural areas. As in developed countries, the supply of teachers to developing-country classrooms responds to teacher salaries, working conditions, and opportunity costs, as well as the relative characteristics of the teacher and nonteacher labor market, including entry requirements.

Teacher Salary Levels: Mixed Evidence on Adequacy

When teacher salaries are high relative to those of other employment options, teacher retention and qualifications also tend to be high. In countries such as Taiwan and Korea, where admission to teacher training colleges is highly competitive, teaching attracts candidates with high academic qualifications and pays about as well as most other professions. What is the experience in most developing countries?

Assessing the adequacy of teacher salaries is not straightforward. By the standards of wealthier countries, teacher salaries in low- and middle-income countries may seem unjustifiably low. However, relative to per capita incomes they often look considerably better. The salary/income ratio varies greatly from country to country, but

Table 1 Education expenditures in developed and developing countries, 2003

	<i>Annual expenditure on educational institutions per student (in equivalent US dollars (PPP), by level of education, based on full-time equivalents)</i>		<i>Annual expenditure on educational institutions per student relative to GDP per capita (by level of education, based on full-time equivalents)</i>	
	<i>Primary</i>	<i>Secondary</i>	<i>Primary</i>	<i>Secondary</i>
Developing Countries	\$1066	\$1183	13	16
OECD Countries	\$5450	\$6962	20	26

Sources: UNESCO/UIS WEI (www.uis.unesco.org/publications/wei2006); OECD countries: OECD 2006 (www.oecd.org/edu/eag2006)
 Authors' calculations; data from the World Bank Development Data Platform.

on average it is much higher in poorer than in richer countries: 3–4 times per capita GDP in poor countries, and higher in Francophone Africa, compared with 1.8 times in the OECD (Bruns *et al.*, 2003). It would be preferable to compare teacher salaries with those of comparably skilled workers elsewhere in the economy, but the shorter work week, greater job security, and other benefits of civil-service teachers may make even careful comparisons misleading. Perhaps the best indicator of teacher salaries is whether there are long queues of qualified applicants waiting for a position. In many developing countries, there are in fact substantial numbers of qualified applicants, sometimes even for lower-paid contract teaching positions.

Teacher Salary Characteristics: High Rigidity and Fiscal Cost

As in many developed countries, teacher salaries in developing countries are set according to a relatively rigid scale that maps the teacher's education, experience, and sometimes also location of work into a given salary level. With few exceptions, the teacher's performance does not affect his or her salary progression, unless s/he is able to be promoted to principal or deputy principal. Teacher salaries are rigid in another sense too: in most systems, teachers have very high job security, so that even in cases of malfeasance they can retain their jobs and their salaries.

At the economy-wide level, teacher salaries have major fiscal implications. For many developing countries, teacher salaries claim more than 80% of recurrent education costs, and sometimes the share reaches 95%. In countries that have recently expanded access to primary schools, such as Uganda, Kenya, and Tanzania, ministries cite the high proportion of spending on teacher salaries as the biggest constraint on educational expansion and improvements in the quality of teacher recruits.

Poor Working Conditions

In developing countries, many teachers work in schools that do not have adequate teaching materials or basic

infrastructure, with on average many more children per classroom than in advanced countries (see **Figure 1**).

Often, developing-country teachers cite a lack of resources as a serious obstacle to effective teaching (Futrell, 2004). Data from the 2003 Programme for International Student Assessment (PISA) support this notion. As **Figure 2** shows, schools in Thailand, Mexico, Brazil, Uruguay, and Turkey were more much likely to report that shortage in supplies hindered instruction than schools in OECD countries.

Recent experimental evidence from Kenya finds that providing additional textbooks improves the learning of the top two quintiles of students (presumably, those whose background allowed them to benefit from books that were too hard for other students). Part of the effect appears to be mediated by teachers: textbook provision increased their presence in the classroom and caused them to use the books more frequently in class (Glewwe *et al.*, 2007). Even when poor conditions do not directly hamper the teacher's effectiveness, they are likely to reduce motivation and make it harder to recruit teachers, particularly to serve in poorer areas.

Teacher Entry and Assignment: Challenges for Quality and Equity

In many developing countries, the number of credentials formally required for new civil-service teachers is increasing, in a reflection of what governments see as rising skill demands on teachers and students. At the same time, in their attempt to meet demands for education under tight budget constraints, governments are resorting to hiring part-time, noncredentialed, or contract teachers. Some countries, such as Tajikistan, have also reduced the length of teacher training programs (Chapman *et al.*, 2005).

Once teachers have been recruited into the service, teacher assignment and sorting have major effects on education quality and equity. Most teachers prefer to work in areas with better working conditions and better students; in developing countries, this tends to mean a preference for urban schools. As a result, schools in rural areas often

Figure 1 Average Primary Pupil-Teacher Ratio, by Region (2003). Countries with populations of less than 1 million are excluded. Source: UNESCO Institute of Statistics Data (2003). Available at <http://stats.uis.unesco.org/unesco/TableViewer/tableView.aspx?ReportId=165>.

Figure 2 Percentage of schools reporting that shortage of supplies hindered instruction, by country. Source: Authors' graphic using data from the PISA 2003 database.

are staffed by less-qualified teachers. Rural students typically begin at a learning disadvantage, because their parents are less educated and school facilities are poorer than in urban areas; inequities in the distribution of skilled teachers exacerbate that disadvantage.

Inadequate Teacher Management

In many developing countries, public-school teachers are poorly managed, with little monitoring of their performance and few incentives for exerting effort. As a result, many

teachers perform at levels below their ability. Underperformance manifests itself most overtly in high levels of teacher absence: surprise school visits in 2002–03 found that 27% of primary-school teachers in Uganda and 25% in India were absent from their schools, with absence rates reaching roughly 40% in two Indian states (Chaudhury *et al.*, 2006). Even in countries with lower absence rates, teachers miss class at levels well above those that would be expected based on normal excused absence.

From a labor-market perspective, a lack of accountability reduces the opportunity cost of choosing teaching as a career. When out-of-class preparation and even school attendance are optional, teachers can supplement their incomes through outside jobs during school hours. This may make teaching more attractive as a career, for any given salary level, but it may not attract candidates with strong professional motivation to teach. If a teacher fails to give his or her best effort in the classroom, then the teacher-supply problem has been at best half-solved.

Teacher Policies and Their Effects

Developing-country governments face two major sets of challenges in teacher policy: attracting and retaining people with the necessary skills into the teaching profession, and managing them effectively so that their skills translate into more student learning. On the first challenge, budget constraints and a lack of capacity to train the numbers of teachers needed to fill the increasing number of classrooms have led to a range of reforms in developing countries. Some developing countries have introduced pay incentives to attract and retain qualified teachers, while also motivating them to perform better. Countries are also experimenting with devolution to the school of decision-making authority, including for teacher hiring and firing, in order to raise teacher quantity and quality. A third option is to rely more on hiring part-time, contractual, or assistant teachers. Finally, countries have historically used teacher training and professional development as a mechanism to raise teaching quality. The results of these policies on student achievement vary widely based on the context and country.

Teacher Pay

Although experts may disagree regarding just how important is the absolute level of teacher salaries in attracting and retaining qualified individuals to the profession, there is broad consensus that teacher salary level influences who enters the field and how long they remain in teaching. At the same time, other working conditions and regulations can counteract or amplify the influence of wages on teachers. In addition, the extent to which teacher

pay is linked to teacher behavior and student outcomes may affect the quality of those who choose to enter and remain in teaching.

Salary levels. Some evidence supports the intuitive notion that changes in mean teacher salary levels can affect the quality of teacher entrants and of individuals who remain in teaching. For example, a 2005 study documents that changes in teacher wage levels in Chile were accompanied by changes in the overall number as well as the quality of applicants to the teaching profession (Mizala and Romaguera, 2005).

Research also suggests that raising teacher salary levels can have beneficial impacts on student outcomes. In Brazil, a finance equalization reform that targeted redistributed funds to teachers (known as FUNDEF) resulted in smaller class sizes, fewer over-aged children in primary and secondary schools, and a diminishing gap between high- and low-performing students (Gordon and Vegas, 2005).

Salary structure: pay based on performance. Economic theory predicts that higher salaries alone may not improve teachers' effort, even if it improves the quality of new entrants, unless teachers are monitored and a higher level of performance is demanded of them. A few countries have recently experimented with nationwide performance-based pay mechanisms for teachers in an effort to raise teaching quality and student outcomes. Understanding how performance-based pay mechanisms are designed and linked to teacher performance is important in evaluating their impact.

For example, Chile and Mexico have both instituted very different performance-based incentives for teachers, with divergent results. In Chile, the SNED (National System of Performance Assessment) since 1996 has offered monetary bonuses to the schools that perform best in terms of student achievement, with the bonuses distributed among the teachers in the winning schools. A recent evaluation of the program's impact found preliminary evidence that the incentive has improved student achievement in those schools that face relatively good chances of winning the bonus, although the effect appears only cumulatively after a number of years (Mizala and Romaguera, 2005). By contrast, Mexico's *Carrera Magisterial* Program has apparently been less successful. *Carrera Magisterial* is a voluntary program that rewards participating teachers with higher pay based on assessments that include tests of their students and peer reviews of their teaching. Despite its promising design, the program does not appear to have improved student scores on the standardized exam, even though those scores directly affect teacher pay (McEwan and Santibañez, 2005).

An analysis of the characteristics of teacher incentive programs suggests that the size of the incentive matters for its impact on improving teaching quality and student learning. Often, a teacher's base salary accounts for a large share of her total compensation, and incentives for

desired behaviors (e.g., working in rural schools, serving children with special needs) account for only a small proportion of total pay. Even when countries have introduced pay-for-performance schemes for teachers, the majority of a teacher's pay is usually determined by years of service and education (Vegas and Umansky, 2005).

Recent randomized controlled experiments have yielded mixed but promising results of the impact of teacher incentives on improving student outcomes. An experiment in Rajasthan, India, monitored teacher attendance using cameras and then based part of the teachers' salary on their attendance rates. Not only did attendance improve, but so did student learning (Duflo *et al.*, 2009). An experiment in Kenya with incentive pay based on student test score gains found that the program increased learning, although perhaps primarily as a result of 'teaching to the test' (Glewwe *et al.*, 2003). By contrast, a larger-scale experiment in government schools in Andhra Pradesh, India, found that when teachers were paid bonuses (either individually or collectively) based on their students' learning rates, real learning accelerated significantly and cost effectively (Muralidharan and Sundararaman, 2009). (Surprisingly, the teachers' attendance did not improve.)

Rural-area incentives. As a mechanism to induce more and better-qualified teachers into rural and other disadvantaged areas, governments sometimes pay bonuses or supplements to teachers in rural areas. Little rigorous evaluation research has been done to assess the effects of these bonuses on teacher supply and student outcomes. One exception is a study of small location bonuses in Bolivia, which finds that they actually reduce labor supply somewhat and have no robustly positive or negative effect on student outcomes (Urquiola and Vegas, 2005). But despite the lack of evidence, governments believe that bonuses can pay off. In Indonesia, for example, the Parliament in 2005 passed a law providing for much larger bonuses – equal to the teacher's base salary, or roughly a 50–100% increase in compensation, depending on other qualifications – for teachers who agree to locate in special remote and underserved areas.

A policy challenge with rural pay bonuses, as with pay to poorly monitored rural teachers in general, is to ensure that the teachers receiving them do actually relocate to rural areas. Without good monitoring, some become ghost teachers who live in urban areas but draw rural bonuses, sometimes paying a less qualified substitute to take their place in the rural school. In addition, as the Bolivia case shows, many teachers who receive the rural bonus work in urban schools due to the expansion of urban areas.

An alternative strategy is to hire contract teachers from the local community. Even if these teachers are less qualified than their civil-servant counterparts, they may require less monitoring to be induced to stay in rural areas. A complementary approach is suggested by recent research on Pakistan: it finds that placing secondary schools in rural areas has had the effect of generating a supply of local

teachers, as many female secondary graduates go on to teach in their native villages (Andrabi *et al.*, 2005).

School-Based Management

Some developing countries have experimented with enabling schools to make teacher hiring and other administrative decisions, typically devolving power from the regional or central government level. The rationale is that by bringing these decisions closer to the school, and thus to parents and students, school-based management generates incentives and conditions that can improve teaching quality and student outcomes. A number of careful retrospective studies have tried to test the extent to which this works in practice.

In El Salvador, the EDUCO program appears to have improved management practices, teacher behavior, and student outcomes (Sawada and Ragatz, 2005). While many decisions continued to be made by central authorities, the power to hire and fire teachers had been devolved to the school level, with considerable power given to parents. Perhaps as a result, EDUCO schools had fewer school closings, less teacher absenteeism, more meetings between teachers and parents, and longer teacher work hours than did comparison schools. These changes, in turn, are related to higher student achievement in Spanish in EDUCO schools.

Honduras' PROHECO project, also a school-based management reform for rural primary schools, appears to have had beneficial effects as well (Marshall and di Gropello, 2005). Comparing PROHECO schools to similar schools in rural areas (using propensity score matching methods to construct a credible control group) reveals mixed program effects on attendance of PROHECO teachers, and it fails to identify differences between PROHECO and comparison teachers in terms of their classroom processes, planning, or motivation. Yet although PROHECO teachers are paid less and have fewer years of experience than comparison teachers, they teach more hours in an average week and assign more homework. Apparently as a result, PROHECO students score higher on math, science, and Spanish exams than students in similar non-PROHECO schools. These examples lend credence to the hypothesis that decentralized schools can induce greater teacher effort and efficiency.

While these evaluations have the strength of assessing reforms at a national level, they suffer from an inability to control for unobserved factors, such as dynamic school leadership or low teacher morale, that might influence both a school's selection into the program and its teacher behavior or student outcomes. Randomized controlled trials overcome this problem, although potentially at the cost of external validity, in that we cannot be certain the results apply beyond the subnational sample included in the experiment. A recent study in Kenya shows that

school-based management reforms can have significant payoffs, especially when they interact with other interventions. When school committees were given the power to monitor and review performance and to decide whether to re-hire contract teachers, test scores of students of civil-service teachers improved, apparently because the reform increased the teacher's effort.

Alternatives to Hiring Regular Teachers

Many developing countries are turning to contract teachers to address shortages. Contract teachers are typically graduates from regular teacher training institutes, but often receive much lower wages than do regular teachers and no benefits. In addition to being less costly to governments, contract teachers are often assumed to be more motivated. Unlike civil-service teachers, who have very high levels of job security, contract teachers know that performing poorly may prevent them from being re-hired in the future.

Only recently has rigorous evidence of the effects of contract teachers begun to appear. One approach uses retrospective data, as in the case of Togo, which recently reported that as much as 55% of its teaching force was contractual. The inception of contractual hiring at first reduced the supply of high-quality candidates, while also causing absenteeism and resentment over unfair pay. During this period, performance of students with contractual teachers lagged behind achievement of students taught by regular teachers, even after controlling for prior achievement, household characteristics, and school, classroom, and teacher variables in a retrospective evaluation. Not surprisingly, however, schools that can afford only contractual teachers (or can afford few regular teachers) also are disadvantaged in other ways: for example, they have less pedagogic supervision and poor facilities (De Laat and Vegas, 2005). Therefore, it is possible that estimates of contract teachers' effectiveness are biased downward by these variables that the researcher cannot observe. A more recent study of contract teachers in Togo, Mali, and Niger finds positive learning effects under certain circumstances – in lower grades and with less advanced students, and in cases (as in Togo) when teachers are hired and monitored locally rather than centrally (Bourdon *et al.*, 2007).

A recent randomized controlled experiment in Kenya overcomes problems with retrospective data by randomly assigning students to additional contract teachers provided to schools in the treatment group (Duflo *et al.*, 2009). Rates of teaching activity by contract teachers were 30 percentage points higher than those of civil service teachers, supporting the greater-effort hypothesis, and students of contract teachers showed more rapid learning gains. The addition of contract teachers reduced the effort of civil-service teachers, offsetting the beneficial effects on learning. This finding underlines the need to combine

contracting reforms with other reforms to increase accountability.

Countries are also experimenting with hiring assistant teachers, who often have fewer qualifications than do regular teachers and are paid substantially lower salaries. The Pratham community-based urban remedial education program in India reached over 15 000 students by hiring young women from the community without teaching certificates to teach basic literacy and numeracy skills to children who had not attained these basic skills by the third grade. A randomized evaluation found that after 2 years, the remedial education program increased learning by an amount equivalent to about half a year's worth of normal learning, with the largest gains among the least able students. This finding demonstrates that it is possible not only to retain poor-performing students but also to prevent them from falling behind. Because the program hires local high-school-educated women to teach classes of around 20 students, the average cost of the program is \$5 per child per year – far less than the average cost of outfitting classrooms with regular teachers (Banerjee *et al.*, 2005).

Teacher Training

The literature on the impact of teacher training programs on education quality is, at best, inconclusive. A survey of case studies in Latin America found consistently poor results from several methods of teacher preparation and training (Navarro and Verdisco, 2000).

To attract talented students to the teaching career, several Latin American countries have introduced scholarship programs. In Chile, a scholarship program for talented students covers 100% of tuition for up to 1 million pesos in exchange for a commitment to teach for 3 years. Priority has been given to candidates in natural sciences, mathematics, English, language, and basic education (Pogre and Lombardi, 2004). In Uruguay, where teacher education is free of charge, scholarships are provided to talented candidates from disadvantaged backgrounds to cover their living expenses during the 3 years of intensive training at regional teacher training centers (Vaillant, 1999).

Many developing countries have also made efforts to professionalize teacher education, gradually increasing the length of study from 3 to 5 years, and shifting teacher education from normal schools to higher education. However during the transition, multiple types of teacher training institutions operate simultaneously, creating teacher training systems that are fragmented and unsystematic. Another problem is that most teacher education programs in developing countries lack the flexibility to attract professionals from other fields, or candidates interested in a mid-career change. By contrast, most OECD countries offer multiple entry points to the teaching profession.

Some Lessons from Research on Teacher Policy in Developing Countries

From the stylized facts and empirical evidence presented above, we can draw some general lessons on teacher policy in developing countries. Many types of education reforms – and not just those usually considered as teacher policy – affect teaching quality and therefore student learning.

First, evidence from developing countries supports the intuitive notion that teaching quality is sensitive to the level and structure of compensation. Once teacher salaries are competitive, linking pay increases to teacher performance can improve teaching and accelerate learning. Both Chile's SNED program and smaller-scale experiments in developing countries have shown that this approach can work. The design of teacher incentive reforms is crucial, however. Even in nationwide performance-based pay reforms, often only a small proportion of teachers face greater incentives to improve learning in their classrooms. For an incentive scheme to work effectively, it must be targeted enough to recognize only teachers who truly exhibit the desired performance and results, but must also be generous enough to provide incentives for teachers who exert the extra effort.

The developing country evidence also suggests that changes in other aspects of teacher contracts can affect teaching quality and student learning, by influencing the characteristics of those who choose to enter and remain in teaching and, importantly, their work in classrooms. One important example is school-based management reforms, which devolve decision-making authority to the school. The Central American nationwide experiences and smaller-scale experiments have shown that these reforms can result in less teacher absenteeism, more teacher work hours, more homework assigned, closer parent–teacher relationships, and accelerated student learning. These are promising changes, especially in contexts of low educational quality.

A key lesson from research in developing and developed countries is that teachers do not always respond to incentives in predictable ways. Sometimes, programs that are specifically designed to reward teachers who adopt specific behaviors or achieve higher results fail to generate the intended behavioral response from teachers (Glewwe *et al.*, 2003; Clotfelter *et al.*, 2004; Koretz, 2002; Jacob and Levitt, 2002). For example, Bolivia's bonus for teaching in rural areas is not resulting in higher-quality rural teachers, and the apparently well-designed Carrera Magisterial is not improving student outcomes. These cases highlight the importance of design and implementation of teacher incentive reforms – and, finally, also the importance of rigorous evaluations that allow us to draw conclusions about their effectiveness.

Glossary

Collective bargaining – The negotiations between the union and an employer (in this case, the school district or school board) over employees' working conditions and/or wages.

Collective bargaining agreement – The agreement that is reached through the process of collective bargaining; the employer–union contract.

Good faith – A term indicating that both parties in contract negotiations acted with honesty and good intentions during bargaining proceedings.

Monopsony – A market in which there is only a single buyer facing many sellers. In the case of school districts and teachers, a district can be a monopsonist employer.

collective bargaining (CB). Teachers' unions bargain over the teachers' contracts with their districts, helping to set the minutiae of districts' school policies that regulate teachers' workdays. In light of unions' influence and import in education policy and politics, surprisingly little empirical research has been conducted on teachers' unions and the effects of their influence and actions, and few general conclusions about the effects of teachers' unions have been reached.

This article provides an overview of teachers' unions in the United States, explains the theoretical ways in which teachers' unions may help or hurt school and district outcomes, and summarizes the empirical literature on teachers' unions and their effects. Due to the complex structures and diversity of teachers' unions in nations other than the United States, this article largely focuses on teachers' unions in the USA.

Introduction

Teachers' unions are important actors at all levels of education policy. While the organizational structure of teachers' unions varies across nations, most developed and many developing countries have at least one organization whose role it is to collectively bargain for public school teachers. In the United States, the National Education Association (NEA) and the American Federation of Teachers (AFT), the two main teachers' unions, together have active affiliates in every state and in virtually every school district in the country, with a combined membership of approximately 4.6 million teachers and school personnel. The influence of teachers' unions does not come from their size alone; they also command considerable monetary resources. Since 1990, United States teachers' unions and their members have contributed over \$50 million to federal election campaigns, including almost \$5 million during the 2006 election cycle alone (Center for Responsive Politics). Unions also lobby legislators, target media with support messages, provide endorsements, draft policy recommendations, and supply campaign volunteers. Unions' size, reach, wealth, and level of organization combine to give them profound power in education politics.

However, regardless of their national- and state-level political influence, the most profound day-to-day impact of United States teachers' union activity occurs in districts where unions are empowered to represent teachers in

A Brief History of Teachers' Unions in the United States

Teacher unionism in the United States began in 1857 with the founding of the National Teacher Association, the predecessor to today's NEA. The first antecedent to the AFT was formed about half a century later, in 1897, as the Chicago Teachers Federation. Around this time, teachers in many large cities joined together in local city unions. Four of these city-level unions combined in 1916 to form the AFT. The AFT quickly affiliated with the American Federation of Labor and joined the growing labor movement. Although the early purpose of these two unions was to assist public school teachers in their negotiations with school administrators and boards, the AFT did not start collectively bargaining with school boards until the 1940s and the first collective bargaining agreement (CBA) between school officials and teachers was not enacted until 1962 as a consequence of a 1-day strike 2 years prior in New York City (Education Commission of the States (ECS), Unions/Collective Bargaining). Although New York City had the first agreement, New York State was not the first state with a CB law for teachers. Wisconsin passed the first such law for public employees in 1959, but it was not until 1964 that the first teachers' bargaining agent was certified in Wisconsin. New York's law, the Taylor law, was passed in 1967. Even as labor union membership declined in the private sector, teachers' union membership climbed throughout the 1960s,

growing from approximately 826 300 members in 1961 to 1.06 million members in 1965. Today, the NEA and the AFT, the United States' two major teachers' unions, together claim over 4.6 million members.

An Overview of Laws Regulating Teachers' Unions in the United States

Although teachers' associations and unions exist in every state in the United States, they do not hold the same legal status or rights throughout the country. Union activity varies by state, in large part due to different state-level regulations concerning teachers' rights to organize, strike, and collectively bargain, as well as the extent of state-level policies mandating the operation of districts and schools. Thirty-six states have CB laws that outline the bargaining rights for teachers. CB laws simply guarantee that teachers have the right to negotiate a contract and that the union will have a place at the bargaining table. These laws can vary substantially across states, but typically each law has four key sections:

1. *Union representation.* This section of CB laws specifies how a bargaining agent (i.e., the union) is identified, certified, and decertified by the covered employee population. A bargaining agent is most often certified or decertified as the result of a majority vote by the union membership. Who exactly belongs to a union varies by district and by state. State laws can prohibit different school personnel from belonging to the same bargaining unit. The general rule is that personnel in the same union must share a community of interests. District administrations and union leaders can then negotiate over exactly who is covered within the state-imposed constraints.
2. *Good faith.* CB laws also require that both parties (the union and the school district) bargain in good faith. States most often interpret good faith as meaning a negotiation process guided by fairness and cooperation between the two parties, although they vary in the amount of guidance given within the law as to what constitutes such actions.
3. *Impasse and strikes.* When negotiations fail to lead to a final contract between parties, a legal impasse occurs and active bargaining is usually suspended. State laws dictate the process that the parties must follow at this point, including mediation and arbitration options to overcome the impasse. The CB laws address the legality of strikes as well. About half of states' CB laws allow teachers' unions to legally strike, and those that do not allow for strikes outline the consequences for unions that illegally coordinate a teachers' strike.
4. *Scope of bargaining.* CB laws outline the scope of representation in the bargaining process. What aspects of a teachers' work day can be negotiated in the CB process

varies across states, but can be as broad as allowing unions and school districts to bargain over wages, hours, and terms and conditions of employment, and as restrictive as mandating specific topics such as leave or benefits.

Twenty-five states have no CB laws for teachers. This means that teachers in these states are employed at-will and have no contract to govern their employment. In states without CB laws, many of the regulations that are traditionally set in CBAs are instead set by state statutes or in district policies.

There is also a distinction between states with right-to-work laws and those without. Twenty-three states have right-to-work laws, which prevent CBAs from including clauses that require teachers and other employees to join the union and/or require employees from contributing union membership fees. These laws do not necessarily prohibit employees from voluntarily joining and paying union fees. In fact, 11 of the 23 states with right-to-work laws also have CB laws, allowing unions to form and represent employees but prohibiting them from requiring those employees to join and pay dues if they do not wish to do so.

Five states have laws actually prohibiting teachers from collectively bargaining contracts. Two states simply have no laws on the books regarding CB for teachers.

Theoretical Ways in Which Teachers' Unions May Enhance or Detract from Education

Unionism might have both positive and negative impacts on school district outcomes. That is, union activity has the potential to simultaneously enhance some parts of the educational process and diminish other parts. Whether the net effect is positive or negative is an empirical question, although a difficult one to answer. Scholars and commentators have made several arguments for ways that teachers' unions can both positively and negatively impact school district processes and outcomes.

Ways in Which Unions May Positively Impact School Districts

Proponents of teachers' unions cite multiple ways in which these unions enhance student and/or school or district performance. This list often includes attracting higher-quality teachers, giving teachers time to focus on teaching, improving the flow of information between classrooms and administrators, stabilizing the school and district, and correcting market imperfections.

Unions improve teacher quality by increasing teachers' well-being

There is little doubt that better teachers lead to better-educated students. Insofar as workers in labor markets

choose jobs that maximize the utility (provide them with the maximum amount of happiness) that they receive from pecuniary and nonpecuniary benefits, unions may draw better teachers to the field by increasing teachers' wages and enhancing their working conditions and benefit.

Unions allow teachers to focus on teaching

By serving as a decision-making agent for teachers, unions free up valuable time and energy that teachers might otherwise spend on legal issues, bargaining with school system management over personnel contracts and administrative minutiae. Eliminating some noninstructional tasks allows teachers to focus resources on instruction.

Unions improve information flows

Because teachers work much more closely with students than administrators or policymakers, they may have better information about how resources should be best allocated to improve student learning. Unions can collect information from members and disseminate it, potentially improving policy. In addition, they may serve a mediating role, transmitting good information from administrators to teachers, thus easing the flow of information in both directions.

Unions increase efficiency of resource use

Proponents argue that unions have the same basic objective that parents have; increasing student achievement. However, because teachers have better information regarding the efficacy of specific resources, unions are in a position to bargain for optimal allocations. Efficiency-enhancing teachers' unions thus use their superior knowledge to bargain for improved school productivity.

Unions stabilize school districts

School district administrations turn over frequently, and district policies shift with each new superintendent or governing board. Union-enhanced job protection can help to insulate school districts against frequent and, possibly, disruptive change.

Unions correct a market failure in the education marketplace

Public school districts often hold monopsony power over the employment of teachers; they are often the only employer of individual teachers in a given geographic area. This imbalance of power can allow districts to provide low salaries to teachers because there are no other large employers for their skills. In the absence of labor competition, teacher pay and benefits are held below classical equilibrium levels, and since lower pay reduces the quality of the available workforce, students suffer. Unions help to correct this market failure by providing teachers with bargaining strength, which can compensate for schools' demand-side monopsony power.

Ways in Which Unions May Negatively Impact School Districts

Critics of teachers' unions offer an alternative set of mechanisms whereby unions decrease inputs to educational production and detract from student learning. Included among this list is the assertion that unions decrease the efficiency of inputs, skew teachers' performance incentives, hurt communities, and create divisive and hostile relations between teachers and districts.

Unions decrease efficient allocation of resources

As rational economic agents, teachers want to maximize their own happiness, which, for example, may be best served through increased salaries and decreased workloads. Under fixed budget constraints in which districts must work within a set budget, elevated teacher salaries may mean fewer dollars spent on other educational resources that may increase student achievement more efficiently.

Unions disrupt incentives for teacher performance

In private-sector labor markets, the opportunity to command higher pay gives employees incentives to increase their productivity, or, at the least, the desire to avoid termination induces them to maintain a minimum productivity level. Because unions negotiate for rules that protect teachers from dismissal and increase returns to seniority, they may reduce incentives for good teacher performance and make it more difficult for school districts to replace low-performing teachers. This interference with incentives may lead fewer teachers to perform at a high level despite being paid wages that are perhaps above market levels.

Unions reduce communities' social welfare

Unions inflate school budgets, thus increasing community tax rates. This will reduce overall social welfare if it is not accompanied by a corresponding increase in student performance. In this case, housing values will suffer, reducing the amount of wealth held by the community and lowering districts' capacity for future school investment. In addition, contentious negotiations and strike threats may hurt community morale and community members' personal investment in schools.

Unions drive wedges between teachers and districts

The preferences of union elites may not represent the preferences of the average teacher, leading unions to misrepresent teachers' views to administrators and the public as well as to impede the flow of information to union members. By setting up teachers and districts as opposing forces, unions would promote distrust between

teachers and administrators, making the accomplishment of day-to-day operations more difficult.

Unions threaten democratic processes

Teachers' unions are unique in their ability to help elect the very management with whom they bargain. Because teachers often teach in the district in which they vote, they help to elect the school board that bargains with the union that represents them. Unions thus have incentives to mobilize to elect school board candidates sympathetic to union interests. Because unions are well organized and command resources other groups are unlikely to be able to employ in local elections, unions may disproportionately crowd out the voices of other interests.

Teachers' unions thus have the potential both to help and to hurt educational processes through these different mechanisms. Perhaps the essential question for policy-makers, then, is one of net effects, which are an empirical matter.

The Impact of Unions on District Outcomes: Evidence from Empirical Literature

At the district level, unions and district administrations bargain over wages, employment levels (more employees can also be seen as reduced class sizes or reduced student–teacher ratios), and other working conditions. As such, much of the extant literature on teachers' unions has focused on their impacts on teachers' wages, class sizes, and other working conditions such as preparation time and employment protection. All of these factors affect district spending, leading to examinations of the relationship between unions and overall district spending. While all of these relationships are important, there is an overarching desire to know what effects all of these have on the bottom line – student achievement. A good deal of the research on teachers' unions attempts to parse out how unionization is related to student outcomes. This section outlines what research has shown about the impacts of teachers' unions. As important as what is known about teachers' unions is what is still left unknown – the gaps in the literature are wide and there is much room for continued research.

The Relationship between Teachers' Unions and Teachers' Pay

Economic theory predicts that unionism will elevate teachers' wages because teachers will be able to collectively bargain with monopsonistic employers rather than attempt to negotiate separately with a wage-setting organization. Research has generally found this to be the case. Hall and Carroll (1973) examine teacher salaries in Cook

County, Illinois, for the 1968–69 school year and estimate that the existence of a CBA in a district was worth approximately \$167 to teachers, nearly the same amount as an extra year of teaching experience. Baugh and Stone (1982) find a positive and significant wage premium for union members as well as for all teachers in unionized districts and a 14 percentage point growth in the union district wage premium from 1974 to 1977. Kleiner and Petree (1988) compare states with greater and lesser unionization and find that CB coverage is associated with higher salaries for public school teachers. Zwerling and Thomason (1995) estimate the effect of the state density of teachers' unions on teachers' salaries. Using the 1984 Administrator Teacher Survey from the High School and Beyond data set, they find that a 10% increase in the state density of teachers' unions increases the highest teachers' salaries by 2.6% and the lowest salaries by 0.2%. The authors also argue that the spread of teacher unionism in a state has spillover effects for nonunionized teachers within that state, raising their wages even if they are not themselves union members. Hoxby (1996), using a differences-in-differences regression analysis, finds a 5.1% increase in teachers' salaries stemming from teacher unionization. When she instruments for unionization with the timing of the passage of laws permitting teachers to unionize, Hoxby finds that teachers' unions cause a 5% increase in teachers' salaries.

The Relationship between Teachers' Unions and Student–Teacher Ratios

In keeping with the theory that predicts that unions bargain to increase their total membership, much of the research on teachers' unions finds that unionization decreases student–teacher ratios. Hoxby (1996), for example, finds that unionization significantly decreases the student–teacher ratio by 1.11–1.7 students per teacher. However, not all of the extant literature points in this direction: Kleiner and Petree (1988) find that unionism is associated with higher class sizes for college preparatory students (those who take the Scholastic Aptitude Test (SAT) and/or American College Test (ACT)).

The Relationship between Teachers' Unions and Other Working Conditions

Teachers and their union representatives care about enhancing other working conditions in addition to class sizes. For example, teachers and unions may desire fewer class preparations, increased preparation time, and more flexible working schedules and leave-time policies. While not as much research has focused on these other working conditions, what research does exist has found that unions increase time and funds spent on these factors. For example, Kleiner and Petree (1988), Eberts and

Stone (1984), and Eberts (1984) all find that unionism tends to be associated with more preparation time for teachers. Eberts (1984) also finds that unionized teachers have 4% more preparation time than do nonunionized teachers, an average of 3 min per day.

The Relationship between Teachers' Unions and School District Spending

Increased teachers' salaries, decreased student–teacher ratios, and increased preparation time all cost school districts money. As such, it comes as little surprise that the extant research points to a positive link between unionism and school district spending. Essentially, unionized districts tend to have higher per-student budgets than do nonunionized school districts. Hoxby (1996) shows that unionization induced district spending to increase by 2.9–12.3%. Berkman *et al.* (2004) find that districts with strong local unions spend roughly \$353 more per student per year and that stronger union states spend approximately \$135 more per student per year, on average.

The Relationship between Teachers' Unions and Student Achievement

The relationship between teachers' unions and student achievement is perhaps the most important question in the teachers' union evaluation literature, although it is also one of the most difficult to answer. The literature examining this relationship in the United States provides mixed results as to whether unions and unionization help or hurt student outcomes. Eberts and Stone (1987), comparing education production functions in union and non-union districts, find an average test score gain in union districts of just over 3% greater than in nonunion districts. However, they find a nonlinear relationship between students' pretest scores and productivity gains in union districts. Specifically, they find that students scoring at the sample mean see an even greater productivity increase in union districts, of 7%; however, students at the tails of the distribution (who score very low or very high on pretest scores) appear to perform better in nonunion districts. Milkman (1997) also finds that there are differences in how minority and nonminority students fare in unionized versus nonunionized school districts. He finds that while the average minority student benefits from being in a union school, he or she benefits less than the average nonminority student. Hoxby (1996) finds that teacher unionization caused dropout rates to increase significantly, by 1.8–2.3 percentage points. This finding is in line with the rest of the literature and indicates that students at the tail ends of the performance distribution (dropouts tend to fall in the far left-hand tail of the performance distribution) perform worse in union districts.

Research on the relationship between teachers' unions and student performance across the world is limited in scope. Wöessmann (2003), using data on students across 39 countries from the Third International Mathematics and Science Study (TIMSS), finds that students in schools where teachers' collective organizations or teachers' unions have substantial influence on curriculum perform significantly worse than their peers in schools in which teachers' organizations have less authority over curriculum choices.

Summary

Teachers' unions and the contracts that result from teachers' unions and districts bargaining are thought to have strong implications for education policy at all levels of government. Although there is much speculation and discussion of the role of teachers' unions in education and policy, little is known about the workings and affects of teachers unions. Questions of teachers' unions' impacts on district and student outcomes are largely unanswered. What is clear is that teachers' unions do impact the districts and states in which they work by raising teachers' salaries and district spending as a whole, and by affecting the outcomes of individual students. More research is needed on how and why teachers' unions and their contracts affect students and districts, and what can be done to augment the productive and diminish the obstructive aspects of teachers' unions.

Adapted Physical Activity for Students with Special Needs

S R Hodge, The Ohio State University, Columbus, OH, USA

Glossary

Adapted physical activity – A comprehensive term encompassing, but not limited to, physical education, exercise, sport, recreation, dance, creative arts, medicine, rehabilitation, nutrition, and leisure to enhance physical activity goal achievement for persons of all ages with special needs due to various impairments, movement or activity limitations, and participation restrictions.

Adapted physical education – This describes educational services delivered to school-age children and youth with special needs, typically 3–21 years of age, in physical education contexts.

Culturally responsive (relevant) pedagogy – This promotes holistic student achievement while enabling and empowering students to accept and affirm their cultural identity as they develop critical understandings that challenge inequities in educational, legal, and social institutions.

Curricular adaptations – These denote any modification to the general education curriculum used to maximize student learning and performance.

Curriculum – The knowledge, skills, and learning experiences intentionally designed and provided to students within the school program.

Inclusion – This describes the many variations of educating children and youth with disabilities in general education settings with peers without disabilities. Specific to physical education, inclusive classes should provide all students access to high-quality physical activity experiences that promotes personal growth and achievement, teaches respect for difference, values diversity, and creates a sense of community in a supportive school culture.

Individualized education program (IEP) – As required by US law, the IEP document identifies a student's entire educational curriculum goals for each school year, and defines how the student will be

supported to reach those goals. An IEP sets the occasion for individualized instruction in general and inclusive settings. The IEP mandate was introduced in Public Law 94-142, the Education for All Handicapped Children Act of 1975 (now PL 108-446, the Individuals with Disabilities Education Improvement Act, 2004) for all students with disabilities to ensure a free and appropriate public education.

Individualized instruction – The personalized, student-centered instruction (e.g., teacher and student one-on-one interaction), which enables each student to progress at her or his own pace with consideration to the student's disability type and severity, abilities, learning style, culture, support needs, and any other relevant variables.

Instructional format – The ways in which teachers organize and deliver instruction and construct practice for students within various curricula.

Instructional modifications – The modifications made to the presentation of information, content, activity, or other instructional material.

Instructional task system – This refers to the subject-matter activity of physical education, the intended learnings students are to acquire by participating in the instructional activities.

Itinerant adapted physical education teacher – A teacher who travels from school to school to provide services to students with disabilities and special needs.

Managerial task system – The organizational and behavioral aspects of physical education – all the nonsubject-matter functions necessary for students and teachers to exist together over a period of time.

Student–social task system – The intentions for social interaction that students seek in physical education.

Task progressions – These refer to learning tasks that move students from less complex and sophisticated tasks to more difficult and complicated tasks by adding complexity and difficulty. Effective progressions require the blending of content knowledge and pedagogical knowledge such that teachers can communicate progressions to students through a series of informing, refining, extending, and applying instructional tasks within a lesson or unit, and across time.

Task system – A regularized pattern for accomplishing tasks. Common to physical education are three interactive task systems: (1) managerial task system, (2) instructional task system, and (3) student–social system. These task systems form the ecology of physical education.

According to the World Health Organization (WHO), there are an estimated 650 million people with disabilities worldwide. Disability is a complex term covering impairments, activity limitations, and participation restrictions. Impairment denotes a problem in an individual's body function or structure. Activity limitation denotes a difficulty encountered by an individual in executing a task or action. A participation restriction is a problem experienced by an individual involved in life situations (WHO, 2009). Disability represents interaction between features of a person's being and the systems of the society in which he or she lives (see WHO, 2009). In legal terms, for example, under Public Law 101-336, the Americans with Disabilities Act (1990), disability is defined as an impairment that substantially limits one or more major life activities.

Over the years, laws have been enacted in many countries that guarantee the rights of people with disabilities to education and other important areas of life. For example, in Ghana, West Africa, the Persons with Disability Act (Act 715) of 2006 was enacted. Act 715 covers areas such as civil rights, employment, education, transportation, healthcare and facilities, and more (Republic of Ghana, 2008). In the Asia-Pacific region, the Japanese government enacted Special Support Education policy in 2007 and guarantees an appropriate special support education to meet the unique needs of each youth, regardless of the type or severity of his or her disability (Ministry of Education, Culture, Sports, Science and Technology, 2002). In the United Kingdom, the Special Educational Needs and Disability Act 2001 addresses the education of persons with disabilities (Office of Public Sector Information, 2008). Likewise in the United States, Public Law 108-446, the 2004 Individuals with Disabilities Education Improvement

Act (IDEA) identifies 14 disability categories under which youth may be eligible for educational services. The disability labels and definitions guide how educational entities determine who is eligible for special education and related services. IDEA (2004) defines special education as “specially designed instruction, at no cost to parents, to meet the unique needs of a child with a disability, including (a) instruction conducted in the classroom, in the home, in hospitals and institutions, and in other settings; and (b) instruction in physical education” (p. 118). This is important because it means in essence that all students being served in special education must receive physical education instruction.

Importance of Physical Education

In 2005, the 2nd World Summit on Physical Education was held in Magglingen, Switzerland. The Summit organizers called for stronger international status of physical education in school politics and in everyday school life as essential and integral for education as well as for human and social development (International Council of Sport Science and Physical Education, 2005). Today in schools around the world, professionals work in collaboration to make school life meaningful for individuals with disabilities. Adapted physical education specialists and physical education generalists are among those who work with individuals with special needs in schools.

Physical education is a medium for guiding youth in the process of living a physically active life. To ensure high-quality physical education, teachers and service providers must develop instructional goals and design task progressions that lead to student achievement. High-quality physical education programs promote knowledge, positive social interactions, skill acquisition and improvement, regular moderate to vigorous physical activity (MVPA), and healthy sports. These activities are essential for children and youths' health and well-being and constitute important components of a healthy lifestyle, along with healthy dietary habits, tobacco-free living, and avoidance of other substances harmful to health (WHO, 2003). The WHO took the position that individuals with disabilities should be given ample opportunities and support to engage in physical activities and sports adapted to their conditions. Such opportunities are commonplace for students with special needs in physical education.

Physical Education for Students with Special Needs

Adapted physical education is the term commonly used to describe educational services delivered to school-age children and youth with special needs in physical education.

It is an individualized program of physical and motor fitness, fundamental motor skills and patterns, skills in aquatics and dance, and individual and group games and sports designed for students with special needs. These programs are usually designed and delivered by adapted physical education specialists or physical education generalists. Consistent with the least restrictive environment (LRE) concept, stated in IDEA, physical education may take place in integrated (e.g., general education) to segregated (e.g., self-contained) classes. Each school year, physical education goals must be identified in a student's individualized education program (IEP) in accord with the provisions of IDEA.

In the United States, physical education teachers are required to participate in the IEP process. A primary role is to evaluate, plan, and instruct students in the motor domain. Likewise in accord with Section 504 of Public Law 93-112, the Rehabilitation Act of 1973 (1973) and its amendments, an accommodation plan should be developed by a school-based assessment team for students with special needs (whether or not they have identified disabilities), but who are nonetheless in need of specialized services and accommodations. Sherrill (2004), a renowned scholar in adapted physical activity, asserted that the overarching aim of adapted physical education is to promote personal growth, self-actualization, and empowerment through meaningful physical activity experiences.

Historical Foundation

The history of the adapted physical education profession is a progression from medical gymnastics before 1905 through a transition to competitive sport, to an emphasis on corrective exercises to general physical education (Sherrill, 2004). In 1952, the American Association for Health, Physical Education, and Recreation gave official support to shifting curricular emphasis for students with disabilities from corrective exercises to adapted physical education. The common terminology changed from corrective exercises and gymnastics to physical education, and school-based curricula increasingly included sports, games, dance, and aquatics. In 1954, Arthur Daniels, professor at The Ohio State University (OSU) wrote the first textbook specific to adapted physical education. Since that time, many scholars worldwide have contributed to our understanding of teaching students with special needs in physical activity settings (Block, 2007; Doll-Tepper *et al.*, 1990; Dunn and Leitschuh, 2005; Hodge *et al.*, 2003; Jansma and French, 1994; Sherrill, 2004; Steadward *et al.*, 2003; Van Coppenolle *et al.*, 1993; Winnick, 2005).

During the 1950s, training clinics for professional preparation in working with children and youth with disabilities were introduced such as the OSU's Gym and Swim by Daniels in 1954 and the Children's Physical Development Clinic at the University of Maryland by

Johnson in 1957. In the 1960s, the Kennedy family facilitated professional preparation workshops on intellectual disabilities (cognitive disabilities) across the United States, founded the Special Olympics, and promoted the enactment of laws initiating professional preparation in physical education and recreation for children and youth with cognitive disabilities (Sherrill, 2004). In the 1970s, critical legislation was passed to support the education of students with disabilities. Of importance in the United States, Public Law 94-142, Education for All Handicapped Children Act (EHA) of 1975 was passed (now IDEA of 2004). Also during this era, leaders continued to emerge in adapted physical education teacher preparation. For example, Joseph P. Winnick, State University of New York (SUNY) at Brockport, founded the first master's level specialization in adapted physical education. In Canada, Patricia Austin, University of Alberta, pioneered in establishing teacher preparation in this field (Sherrill, 2004). In 1973, leaders from Canada and Belgium more broadly conceptualized the scope of adapted physical education to adapted physical activity and founded the International Federation of Adapted Physical Activity (IFAPA) in Quebec, Canada.

IFAPA is an international cross-disciplinary professional organization of individuals, institutions, and agencies supporting, promoting, and disseminating knowledge and information about adapted physical activity, disability sport, and all aspects of sport, movement, and exercise science for the benefit of persons who require adaptations to enable their participation (IFAPA, nd).

According to the bylaws of the IFAPA, adapted physical activity is a cross-disciplinary body of knowledge directed toward the identification and solution of individual differences in physical activity. It is a service-delivery profession and an academic field of study that supports an attitude of acceptance of individual differences, advocates access to active lifestyles and sport, and promotes innovation and cooperative service delivery programs and empowerment systems. Adapted physical activity includes, but is not limited to, physical education, sport, recreation, dance and creative arts, nutrition, medicine, and rehabilitation (IFAPA, nd).

Today, the IFAPA board has regional representatives from Africa, Asia, Europe, Middle East, Oceania, North America, and South/Central America. IFAPA's president Yeshayahu Hutzler and former president Claudine Sherrill asserted that in some countries adapted physical activity is not the preferred term, instead such descriptions as "sports for the disabled, sport therapy, and psychomotor therapy pertain to similar understandings" (Hutzler and Sherrill, 2007). They call for more communication and collaboration internationally across these areas in research and information sharing. Scholarly journals are an important medium for communication, research collaboration, and information sharing. In 1984, founded by Geoffrey D. Broadhead, the *Adapted Physical Activity*

Quarterly (APAQ) was first published. APAQ is now the premier international journal of adapted physical activity scholarship. It is the official publication of IFAPA and is published by Human Kinetics. Important also, information sharing on physical activity pedagogy for persons with disabilities has occurred across countries over the years. For example, textbooks such as *Adapted Physical Activity, Recreation and Sport: Crossdisciplinary and Lifespan* by Claudine Sherrill, and *Early Movement Experiences and Development* by Joseph P. Winnick have been translated from English to Chinese and Japanese, respectively. Since the 1990s, there has been advocacy and movement toward inclusive (integrated) programming where students with and without disabilities are educated together. Internationally, inclusion has become a progressive educational practice with support from educational and political advocates, policymakers, and legislators. Ideally, inclusion represents the placement of students who have various disabilities with proper accommodations and supports in integrated classes with classmates without disabilities for educational and social benefits. This philosophical shift from separate to integrated programs is about equitable opportunities, appropriate supports and accommodations, and the empowerment of students with disabilities. The emphasis is on student self-actualization and empowerment through meaningful physical activity experiences (Sherrill, 2004). Self-actualization and empowerment are situated in adaptation and humanistic theories.

Theoretical and Philosophical Underpinnings

Humanistic philosophy and adaptation theory have influenced our understanding of teaching children and youth with disabilities in physical education. Humanistic philosophy promotes individual uniqueness, morality, positive social relations, and defines success as individuals seeking to accomplish their personal best. In this philosophy, physical education teachers (specialists and generalists) typically endorse an abilities-based pedagogical approach, which emphasizes abilities, not disabilities and holistic and student-centered praxis. Adaptation theory suggests that teachers must develop instructional goals and design task progressions that create optimal learning opportunities within their particular class environments. This theory denotes the process by which teachers, students, and the environment reciprocally influence one another in dynamic and, oftentimes, in meaningful ways. In addition to inclusive, humanistic, and adaptation orientations, also supportive of student empowerment are culturally responsive (relevant) pedagogies.

In recent years, there has been increasing advocacy for culturally responsive pedagogy in physical education. Scholars have called for infusing diversity training (including disability content) across physical education teacher education (PETE) programs to ensure that

teacher candidates are culturally competent to teach a diversity of students. Gay (2000), a pioneer of culturally responsive pedagogy, explained that it has the following components:

- It acknowledges the legitimacy of the cultural heritages of different ethnic groups, both as legacies that affect students' dispositions, attitudes, and approaches to learning and as worthy content to be taught in the formal curriculum.
- It builds bridges of meaningfulness between home and school experiences as well as between academic abstractions and lived sociocultural realities.
- It uses a wide variety of instructional strategies that are connected to different learning styles.
- It teaches students to know and praise their own and each others' cultural heritages.
- It incorporates multicultural information, resources, and materials in all subjects and skills routinely taught in schools. (p. 29)

Earlier, Ladson-Billings (1995) stated that culturally relevant pedagogy empowers students through (1) academic success, (2) cultural competence, and (3) critical consciousness. Culturally responsive pedagogy uses the "cultural knowledge, prior experiences, frames of references, and performance styles" of culturally, ethnically, linguistically, and economically diverse students "to make learning encounters more relevant to and effective for them" (Gay, 2000: 29). Teachers and service providers, who implement culturally relevant teaching, empower students as they help them develop intellectually, socially, emotionally, and politically by using cultural referents to impart knowledge, skills, and attitudes (Ladson-Billings, 1992). Student empowerment translates into academic competence, confidence, and a will to act (Gay, 2000).

Effective Physical Education Pedagogy

The extant literature on teaching effectiveness describes specific teacher acts linked to achievement outcomes of students in physical education. To paraphrase, Siedentop and Tannehill (2000) noted that effective teachers should

1. have a belief in their own efficacy;
2. allocate sufficient time and opportunity to learn, and cover appropriate content;
3. communicate high, realistic expectations so that students can receive adequate instruction and practice time to learn their roles;
4. establish positive approaches to class management and student engagement;
5. design meaningful, success-oriented tasks;
6. create and sustain a brisk pace and maintain momentum;

7. communicate content with clear, brief demonstrations and explanations, followed by sufficient guided practice, and feedback for understanding;
8. actively supervise students' progress and practice;
9. hold students accountable for appropriate participation;
10. communicate with clarity and enthusiasm, and exhibit equitable support of all students; and
11. use students' inputs and ongoing assessment to inform their practice.

Clearly, effective teachers and service providers reflect to inform their practice. Moreover, educators must insist on teaching students with various disabilities with heightened emphasis on adaptations, modifications, and supports. Physical education teachers must have a sense of self-assurance that their teaching is effective.

Effective teaching means designing lessons to maximize the amount of time each student spends in direct practice at a level that ensures a continuing development of the skill compatible with a minimal number of errors (Webster, 1993). As Webster identified, a number of important indicators of effective teaching are applicable to teaching students with disabilities in physical education. These include:

1. finding ways to keep students appropriately engaged in subject matter for a high percentage of the time and do so without resorting to coercive, negative, or punitive behavioral techniques;
2. developing and maintaining positive class climate, whereby students have many opportunities to practice at levels appropriate to their abilities;
3. individualizing instruction for success-oriented and on-task behaviors of students, which includes adapting and adjusting strategies to match contextual variables;
4. using peer tutors to assist and give additional attention, which allows greater opportunities for students to practice;
5. using appropriate reinforcement strategies to motivate students;
6. providing congruent, specific skill and behavior feedback; and
7. organizing practices in a manner that promotes student learning and retention.

The time students spend in lesson activity should be directed at skill acquisition with clear accountability measures on learning outcomes through active participation. In lesson planning, teachers and service providers must design learning experiences that ensure their students actively participate in fun movement activities. It is important that teachers focus on students having fun while they move. However, they must also hold students accountable for correct forms of movement toward skill acquisition, development, or proficiency.

Instructional Strategies for Teaching Students with Special Needs

It is important that physical education teachers use curricular and instructional approaches that support inclusive and culturally responsive pedagogy. Many such curricular approaches are common to physical education using various instructional formats. These curricular approaches include the Fitness for Life model, I CAN and ABC models, Moving to Inclusion, Personal and Social Responsibility model, and Sport Education. In many countries, teacher educators encourage teachers to structure their curriculum and pedagogies around national standards for physical education. The National Association for Sport and Physical Education (NASPE, 2004) provided six national standards for physical education. These standards and essential components of a quality physical education program are presented in **Table 1**.

Physical education teachers can use different instructional formats to organize and deliver instruction and construct practice opportunities for students within various curriculum models. Some examples of instructional formats that could be used to support inclusive and culturally responsive pedagogy include active teaching, adventure education, teaching through questions, task teaching and learning stations, peer tutoring and reciprocal teaching, flexible groupings, and cooperative learning as well as self-instructional formats such as contract teaching and personalized systems of instruction to individualized instruction.

Active Teaching

Active teaching, also known as direct instruction, is an instructional format where the teacher controls the pace of the lesson through direct instruction and student practice opportunities. Direct instruction to the whole class, small groups, or individual students is followed by student guided practice and error correction. Next, students engage in independent practice where their activity is actively supervised. Important also, active teaching promotes a supportive climate where high, yet realistic, expectations are communicated to students and they are held accountable for performance and learning outcomes (Siedentop and Tannehill, 2000).

Adventure Education

Adventure education is an educational approach designed to teach students to solve problems and take responsibility for the outcomes of their decisions. In this model, the teacher serves as a facilitator of experiential learning. Its goal is to educate the whole child by developing his/her mental, physical, emotional, and social attributes.

Table 1 NASPE content standards and essential components of a quality physical education program*NASPE content standards^a*

Standard 1	Demonstrates competency in motor skills and movement patterns needed to perform a variety of physical activities
Standard 2	Demonstrates understanding of movement concepts, principles, strategies, and tactics as they apply to the learning and performance of physical activities
Standard 3	Participates regularly in physical activity
Standard 4	Achieves and maintains a health-enhancing level of physical fitness
Standard 5	Exhibits responsible personal and social behavior that respects self and others in physical activity settings
Standard 6	Values physical activity for health, enjoyment, challenge, self-expression, and/or social interaction

Components of a quality physical education (PE) program^b

Component 1	Is organized around content standards that offer direction and continuity to instruction and evaluation
Component 2	Is student centered and based on the developmental urges, cultures, tendencies, and interests of students
Component 3	Has physical activity and motor-skill development at its core
Component 4	Teaches management skills and self-discipline
Component 5	Emphasizes inclusion of all students
Component 6	Emphasizes instruction focused on the process of learning rather than performance outcomes
Component 7	Teaches lifetime activities that students can use to promote their health and personal values
Component 8	Teaches cooperative and responsibility skills and helps students develop sensitivity to multiple diversities

^aAdapted from NASPE (National Association for Sport and Physical Education) (2004). *Moving into the Future: National Standards for Physical Education*, 2nd edn. Reston, VA: National Association for Sport and Physical Education, p iv, with permission of NASPE Publications.

^bAdapted from Darst, P. W. and Pangrazi, R. P. (2006). *Dynamic Physical Education for Secondary School Students*, 5th edn. San Francisco, CA: Pearson Education, p 2.

Adventure education encourages risk taking based on holistic learning concepts to develop or improve self-awareness, confidence, self-esteem, emotional stability, and social skills through social interactions and group cooperation. This might include problem solving through group work and challenge activities (e.g., wall climbing, mountain biking, ropes course, and orienteering).

Teaching through Questions

Teaching through questions (Socratic method) is an instructional approach whereby tasks are communicated to students through questions that present scenarios that

guide student work toward specific goals or questions that pose problems to be solved. In this approach, teachers often use guided discovery or problem-solving activities. Teaching through questions is a variation of active teaching (Siedentop and Tannehill, 2000).

Task Teaching

Task teaching is an instructional format in which the class session is organized such that different students are engaged in different tasks at the same time, typically rotating among task or learning stations throughout the lesson. This format can accommodate student diversity in terms of skill level in particular, which holds well for students with disabilities as it sets the occasion for individualized instruction. Teachers and service providers should design tasks that have multiple levels of performance criteria to meet student skill and functional ability levels. They can use brief, simple descriptions on task cards, task posters (usually with pictures or drawings), and self-instructional materials to communicate the task for each learning station (Siedentop and Tannehill, 2000).

Peer Tutoring and Reciprocal Reaching

Peer tutoring and reciprocal reaching refer to instructional formats that use student pairings, triads of students, or small groups to provide basic instruction and guided practice. Students support one another, and engage in reciprocal teaching; and some will serve as tutors to classmates (e.g., higher-skilled students tutor lower-skilled students) in providing individualized attention and instruction, peer assessment, feedback, and social support (Siedentop and Tannehill, 2000). The use of peer tutoring helps improve achievement levels of students with disabilities.

Flexible Groupings

Flexible groupings, group variation, and small group instructional formats usually involve small groups of students working together on a common goal. The teacher identifies group member's responsibilities to shape the focus of their work to accomplish the assigned task (Siedentop and Tannehill, 2000). In this format, it is important that student work is structured such that there is interdependence in the achievement of group goals, as well as individual student accountability. In flexible groupings, students can be grouped or paired based on goals, interests, needs, or skills such that they have opportunities to share and learn from one another.

Cooperative Learning

Cooperative learning helps teachers put cooperation into daily practice in physical education. It is a teaching

approach where small groups or teams, each with students of different levels of ability (and potentially of different disabilities), use a variety of learning activities to improve their understanding of a skill, task, strategy, or content. Each team member is responsible for her/his own learning outcomes and for helping teammates learn, which creates an atmosphere of achievement. Students work cooperatively through the assigned tasks until all group members understand and complete them successfully.

Self-Instructional Format

Self-instructional formats set the occasion where students can progress through a sequence of learning experiences with purpose and direction. For students with disabilities, a teacher's knowledge, will, and ability to individualize instruction are essential. Individualized instruction is a personalized, student-centered instructional format, which enables each student to progress at her or his own pace with consideration to the student's disability type and severity, abilities, learning style, culture, support needs, and any other relevant variables. This involves task-analyzing skills and assessing performance, adapting lessons, modifying games and activities, accommodating the environment, and supporting each student with disabilities as needed. Individualized instruction results in improved physical activity engagement for students with disabilities. Individualizing instruction is recognized globally as beneficial to students with special needs. For instance, Japan's Special Support Education policy mandates the development of individual teaching plans for students with disabilities, which calls for individualized instruction (Ministry of Education, Culture, Sports, Science and Technology, 2002).

To individualize instruction, a physical education teacher must be able to task-analyze each student's motor skills by breaking his/her motor skills down into logical progressions, typically using sequential simple to complex skill progressions. In lesson planning, the teacher uses individualized task analysis to construct logical learning progressions based on the student's functional level, motor abilities, learning style and tendencies, and interests. I CAN is an individualized instructional model, which refers to individualized instruction, create social leisure competence, associate all learnings, and narrow the gap between theory and practice (Wessel, 1977). The Achievement-Based Curriculum (ABC) model is a refinement of Wessel's I CAN model (Wessel and Kelly, 1986). Other forms of self-instructional formats include contract teaching. This teaching format sets the occasion for individualized instruction whereby "students sign a learning contract to complete a sequence of learning tasks according to a predetermined set of criteria" (Siedentop and Tannehill, 2000: 299). Personalized system of instruction (PSI) is also a self-instructional format that can serve as a

medium for individualized instruction and student progress. Typically, the teacher or service provider will divide the unit content into small units of instruction wherein students are expected to meet specific performance criteria; and when successful, they then move on to additional units of instruction. In short, teachers (1) develop specific instructional tasks and explicit performance criteria, (2) allow students to practice the tasks until they meet the criteria, and (3) move then on to the next task (Siedentop and Tannehill, 2000). Clearly, effective physical education teachers who teach students with disabilities plan lessons, adapt, modify, and use supports to individualize instruction and promote student learning. In addition to exhibiting content knowledge and pedagogical skillfulness, a teacher must demonstrate skill as an efficient and effective manager of student behaviors.

Organization and Management

Class organization and management are integral aspects to teaching students with disabilities in physical education. A positive learning context typically (1) is well-planned and organized, (2) has rules and routines that promote on-task active participation, (3) has class activities that are set at the appropriate skill level for each student, and (4) has a class that promotes interesting activity experiences with smooth and short transition times. In creating a positive learning environment, teachers must establish rules and routines at the beginning of the school year. Establishing rules and routines helps students know what to do, what not to do, and when to do or not do something. At the start and periodically during the school year, the teacher discusses and posts the rules publically. In concert with establishing rules and routines to manage behavior, there are several other proactive organization and management strategies applicable to physical education. For example, setting up equipment before class starts is an important organizational strategy. Managing student behavior and addressing safety issues are usually handled by the teacher actively supervising students, emphasizing rules and routines, and enforcing established rules and routines. In addition to finding ways to create fun activities for students, teachers often use cooperation (teamwork) and promote socialization (good sports behaviors) as important lesson objectives. These objectives can be encouraged through thoughtful task structures, especially with station activities and team games. During their class sessions, teachers should regularly provide students with encouragement, and specific and corrective feedback. They should seek to establish good rapport with them by opening up to them and being approachable. Ensuring the safety of students is also a critical responsibility for all teachers. To avoid injuries and liability, teachers and service providers must be

mindful to ensure safety of the environment, equipment, and students (e.g., safety of students from collisions with one another as they participate in class activities).

Physical education environments can lead to challenges requiring the implementation of various behavior-management strategies. Behavior management must be taught to create a positive learning context that can help to prevent or minimize inappropriate student behaviors. There are a number of procedures used to influence student behavior. To increase desirable behaviors, teachers may use positive and negative reinforcement (Table 2). In addition, they may use a variety of reinforcement strategies to help maintain, strengthen, or teach new behaviors, which include shaping, chaining, token economy, behavioral contracting, and Premack principle. To decrease inappropriate or undesirable behaviors, teachers may use punishment (e.g., response cost, verbal reprimand, overcorrection, and time-out procedures), planned ignoring or extinction (Table 2), as well as reinforcement of other behavior, reinforcement of incompatible behavior, reinforcement of low response rates, and behavioral contracts or proclamations.

The psychodynamic and humanistic approaches to behavior management focus on teaching students the importance of respecting self and others and accepting responsibility through (1) understanding psychological causes of behavior, (2) developing a trusting relationship

between the teacher and student, and (3) teaching students self-control and social responsibility. Hellison's (1995) Personal and Social Responsibility model is a popular model in physical education. In this model, the student's responsibilities are to

1. recognize that his/her own behavior is a problem,
2. recognize why it is a problem,
3. understand what motivated the behavior, and
4. determine through discussion with the teacher (and schoolmates were appropriate) alternative ways to behave in similar situations.

Additional psychodynamic-humanistic approaches to behavior management include reality therapy, conflict resolution (e.g., talking bench), counseling methods, and positive coaching. These approaches to behavior management help students to analyze their own behaviors, respect others, plan strategies to change, and evaluate a behavior-change program. Ultimately, these approaches teach students to take responsibility for their own behaviors and promote positive social relationships.

Professional Preparation and Development

Internationally, professional qualification criteria for physical education teachers (specialists and generalists) vary by country. It is commonly held that adapted physical education specialists primary roles include (1) resource teachers who are assigned to a particular school, and team teach with generalist physical education teachers; (2) itinerant teachers who travel to and from different schools to provide direct instruction; and (3) consulting teachers who travel from school to school and do some direct service tasks but primarily consult with and provide support services to general education teachers and help them adapt instruction. In addition, these specialists may conduct in-service training (e.g., workshops for school district personnel). To properly carry out their job-related roles and responsibilities, physical education teachers need training whereby they can acquire skills and knowledge to meet the needs, interests, and abilities of their students.

Worldwide, PETE programs typically offer a 4-year course of study curriculum that culminates with student teaching (internships) at local elementary, middle, and/or high schools. In Ghana (West Africa), for example, two of the six public universities offer degree courses or programs in physical education. These are the University of Education at Winneba and the University of Cape-Coast. Both institutions are in the Central Region of Ghana and have oversight of the undergraduate and graduate programs in physical education. In addition, the Department of Health, Physical Education, Recreation and Sports at the University of Education at Winneba has a 2-year

Table 2 Descriptions of basic behavior management strategies

<i>Terminology</i>	<i>Description</i>
Stimulus control	A measurable event that might have an influence on behavior
Reinforcement	A stimulus event that increases or maintains the frequency of a behavioral response
Positive reinforcement	A behavioral strategy whereby a teacher offers a student something valued as a consequence of the student emitting a desired behavior, resulting in an increase in the frequency of the behavior by the student in the future
Negative reinforcement	A behavioral strategy defined as using reinforcement to increase a desired behavior by encouraging a student to perform that particular behavior in order to avoid something she or he dislikes
Punishment	A behavioral strategy carried out by either the presentation of an aversive stimulus or the removal of a positive stimulus The intent is to weaken or eliminate an undesirable behavior
Planned ignoring or extinction	A behavioral strategy where the teacher withholds reinforcement after a behavioral response that had previously been reinforced, which results in cessation of the particular behavior

diploma course of study program in coaching. In general, the physical education undergraduate course of study is a 4-year program typified with 4 weeks to 1 year of student teaching. Student teaching internship placements are at the basic education (elementary school), junior high school, or senior high school level. Prior to student teaching, physical education teacher candidates engage in on-campus teaching (micro-teaching) experiences at the university. At the University of Education at Winneba, students have three subject areas (i.e., major, minor, and cognate).

Scholars continue to raise issues of curriculum priorities of PETE programs. These revolve around professional preparation in training teachers to work effectively along with students with special needs. How teachers are prepared, and what happens during their professional careers in regard to their efficacy in teaching students with special needs are important questions. These questions must be considered in making decisions on policy, curriculum change, and teacher preparation and development. For example, PETE programs should ensure teacher candidates engage in micro-teaching episodes with small groups of students with disabilities (e.g., during practicum experiences) such that they develop a sense of personal mastery before teaching in larger classes as in their student teaching internships. Such strategies would build teachers' self-efficacy.

Obviously, teacher-preparation programs should follow competency-based guidelines. In 1993, the Adapted Physical Activity Council (APAC) of the American Alliance for Health, Physical Education, Recreation and Dance issued competency-related guidelines for adapted physical education teacher preparation. APAC's main purpose is advocacy for persons with disabilities through promotion of programs, policies, standards, and research (AAHPERD, 2008). There is pressing need and legal authority in special education to establish and maintain fully accredited teacher-education programs and to ensure ongoing professional development training to better prepare physical education teachers for working effectively with students with special needs. For practicing physical education teachers, district-wide professional development training focused on inclusive and culturally responsive practices in physical education should be made available on a regular basis. Such training would prepare teachers in a better manner to more effectively teach students with disabilities, give them an enhanced sense of confidence, and allow them to learn more about individualizing instruction to more effectively engage all students. Professional development activities should be offered and designed to equip teachers with advanced knowledge and skills necessary to teach students with various disabilities. Therefore, school districts should regularly engage teachers in relevant professional development training focused on teaching students with disabilities in physical education. Further, school districts should hold

teachers accountable for participating in professional development. Holding teachers accountable will promote a deeper appreciation for teaching students with disabilities as teachers' overall motivations and teaching effectiveness are likely to be enhanced.

Conclusion

Over the years, laws have been enacted in many countries that guarantee the rights of people with disabilities to education, including high-quality physical education. In schools worldwide, devoted physical educators (specialists and generalists) work to make school life meaningful for students with special needs. Physical education is a medium for guiding children and youth in the process of living a physically active life. In my opinion, effective teachers must reflect on their practice, thoughtfully plan lessons, adapt, modify, and individualize instruction to promote student learning. They must also exhibit skill as efficient and effective managers of student behavior. Physical education teachers may use different instructional formats to organize and deliver instruction and construct practice opportunities for students within various curriculum models. It is important that they use curricular and instructional approaches that support inclusive and culturally responsive pedagogy.

Unquestionably, there is a need to prepare future physical education teachers (specialists and generalists) to competently provide culturally responsive and informed instruction. Teacher candidates should have multiple practicums and field-based teaching experiences in a diversity of physical activity contexts. In our world's societies, teachers will have increased opportunities to teach culturally, ethnically, economically, and linguistically diverse students. They must acquire a strong experiential knowledge base to best serve all students. In the same vein, school districts should hold physical education teachers (both specialists and generalists) accountable for participating in professional development activities relevant to teaching students with special needs. In both policy and practice, accountability criteria should be built into annual teacher evaluations. This would help ensure that teachers appreciate the importance of regularly participating in professional development workshops, attending conferences, and engaging in continued learning to enhance their overall teaching efficacy. This would be a cost-effective means of helping to maintain a well-prepared teaching workforce.

Assessment Accommodations for Children with Special Needs

R J Kettler and S N Elliott, Vanderbilt University, Nashville, TN, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Alternate assessment – A set of methods (e.g., portfolio assessment, performance assessment, and comprehensive rating scales) that can be used to assess students with special needs, severe disabilities, or with extremely limited English proficiency.

Assessment accommodations – The changes in the standard assessment process made because an individual's disability requires changes for the test to be a valid measure.

Differential effects or boost – An attribute of assessment accommodations and the concept that if an accommodation is working appropriately, then it should increase the scores of students with disabilities much more than it increases the scores of students without disabilities.

Individual need – An attribute of assessment accommodations stipulating that students are to be provided assessment accommodations based on individual functional impairments, rather than based on group disability status.

Modification – The changes to a test that may alter the construct being measured, or at least the degree of complexity of the construct being measured, and are useful for students who have disabilities severe enough to preclude taking the typical assessment.

Proficiency – The level of competency or understanding of knowledge in an academic area.

Sameness of inference – An attribute of assessment accommodations stipulating that test alterations result in scores being more comparable to make decisions.

Unchanged construct – An attribute of assessment accommodations stipulating that assessment accommodations should not change the construct being measured, but should only provide access to measurement of that construct for students with disabilities.

school districts across the United States to involve only students without disabilities in school-wide assessments. Reasons for excluding students with disabilities from school-wide assessments, likely, included fears that performances of students with disabilities would reflect poorly on the school, students with disabilities would be frustrated by the testing process and content, and the tests typically used to measure proficiency would not accurately reflect proficiency of students with disabilities. The concern with regard to unfavorable comparisons with other schools should be alleviated by current law (i.e., the Individuals with Disabilities Education Improvement Act) requiring all students with and without disabilities to be included in annual proficiency testing to the extent possible. However, concerns that tests used for students without disabilities will cause more frustration and be less valid when used for students with disabilities remain relevant.

To include students with disabilities in large-scale accountability systems, educators have a number of options, including (1) having students with disabilities complete the same achievement test that is taken by students without disabilities without any changes made to the test setting, format, or content; (2) having students with disabilities complete the same achievement test with some changes to the test setting and format; (3) having students with disabilities be evaluated by an alternate form of assessment; or (4) evaluating students with disabilities by some combination of the aforementioned methods. The focus of this article is the second option – having students complete the same achievement test but with changes to the setting and format (i.e., accommodations).

When considering the challenge of validly including students with disabilities in large-scale accountability systems, one should be familiar with the terms alternate assessment, modifications, and assessment accommodations. Alternate assessment is an umbrella term for a set of methods (e.g., portfolio assessment, performance assessment, and comprehensive rating scales) that can be used to measure the abilities of students with severe disabilities or with extremely limited English proficiency. Modifications are changes to a test that may alter the construct being measured or, at least, the degree of complexity of the construct being measured, and are useful for students who have disabilities severe enough to preclude taking the typical assessment. Assessment accommodations are departures from the typical assessment that are not as extreme as either alternate assessment or modifications.

Assessment Accommodations for Children with Special Needs

Until the passage of the Individuals with Disabilities Education Act, in 1997, it was regular practice in most

Assessment accommodations are defined as changes in the standard assessment process made because an individual's disability requires changes for the test to be a valid measure. Effective assessment accommodations remove barriers that would otherwise hinder students with disabilities from demonstrating their true abilities.

Elliott *et al.* (2002) used the analogy of eyeglasses or contact lenses, needed for a driving test, to clarify the concept of a testing accommodation. On a hypothetical driving test that does not allow eyeglasses, a perfectly capable driver with no visual impairment would likely pass, whereas a capable driver with a visual impairment would likely fail. In the case of the driver with no visual impairment, the driving test would yield a valid score indicating driving ability. In the case of the person with the visual impairment, the barrier created by that disability would prevent the test from yielding a valid score indicating the individual's driving ability. It is important to note that having the person with no visual impairment wear eyeglasses during the test would not help that person perform better (in fact, that person might perform worse), and would not make the test score a more valid indicator of that person's driving ability. Accommodations – similar to the eyeglasses in this example – are alterations to the assessment procedure that should be helpful only to the individuals for whom they are designed.

Assessment Accommodations and the Law

The 1997 reauthorization of the Individuals with Disabilities Education Act indicated that all students must be included in large-scale school-accountability systems – to the extent possible. The 2001 No Child Left Behind Act increased the number of grade levels at which the achievement of all students must be measured. These policies emphasized the issue of how to meaningfully include and accurately assess students with disabilities in large-scale assessment programs. In recent years, there has been steady growth in the number of research studies focusing on testing accommodations. The reauthorization of the 2004 Individuals with Disabilities Education Improvement Act reinforced that students with disabilities should be provided access to the general education curriculum and its associated assessment procedures to the maximum degree appropriate for each individual. In fact, inclusion within the general education-testing program, likely, influences access to the general education curriculum.

While national legislation mandates the availability of testing accommodations to help students with disabilities to meaningfully participate in statewide and district-wide assessments, decisions with regard to which accommodations are permissible and appropriate are made at the state

and local levels. For example, while federal law indicates that testing accommodations must be made available for students with disabilities, as of 2003, accommodations were actually made available for all students in 12 states (Arizona, California, Hawaii, Kansas, Minnesota, New Hampshire, Oregon, Pennsylvania, Rhode Island, Tennessee, Vermont, and Wyoming). Individual discrepancies in state allowance of accommodations may contribute to the wide range among states with regard to the percentage of students who receive accommodations (between 8% and 82%). Perhaps no assessment accommodation is more controversial – based on variations in law from state to state – than having the questions on a test read aloud to students. While three states (Massachusetts, Missouri, and Vermont) allow this accommodation with no restrictions, five other states (Hawaii, Illinois, Kansas, Nebraska, and Ohio) do not allow this accommodation under any circumstances. The remainder of the states allows questions on a test to be read aloud to students only under certain circumstances, and in 14 of those cases an allowance has implications for scoring. Further information with regard to the types of accommodations allowable in one's state is available from the National Center on Educational Outcomes (NCEO), which maintains a website (included in this article) dedicated to state policies on testing accommodations.

Types of Assessment Accommodations

Assessment accommodations are typically classified within four categories: (1) accommodations in the presentation format, (2) accommodations in the recording or response format, (3) accommodations in the assessment environment or setting, and (4) accommodations in the timing or scheduling. Accommodations in the presentation format are changes in the way that the directions or content of a test is presented to students, and include oral reading, large print, or sign language. Accommodations in the recording or response format of a test offer students different options to provide answers on a test, and include use of a computer scribe, writing answers directly into a test booklet, or use of a calculator. Accommodations in the assessment environment or setting are changes to the place in which the test is given, and include individual administration, testing in the student's home, or providing noise buffers. Accommodations in timing or scheduling make the timing of an assessment more flexible, and include extended time, frequent breaks, or testing over multiple days. **Table 1** contains a list of accommodations organized by the aforementioned categories.

Gibson *et al.* (2005) performed a study of the most-often-recommended accommodations, and, in doing so, utilized two helpful frameworks for identifying and categorizing accommodations. They used the Assessment

Table 1 Assessment accommodations by category*Accommodations in presentation format*

Use an enlarger to facilitate vision of material
 Assist the student to track test items by pointing or placing the student's finger on items
 Oral reading (either by an adult or an audio device)
 Use audio amplification devices (e.g., hearing aids)

Accommodations in the recording or response format

Use an adult to record the student's response
 Use a computer board, communication board, or tape recorder to record responses
 Have the student respond directly in the test booklet rather than on an answer sheet
 Use organizational devices, calculators, or spelling and grammar-assistive devices

Accommodations in the assessment environment or setting

Administer the test in a small group or individual session
 Place the student in a room or part of a room where he or she is most comfortable
 Allow a special education teacher or aide to administer the test
 Test in the student's home

Accommodations in timing or scheduling

Administer a test in shorter sessions with more breaks or rest periods
 Space testing sessions over several days
 Administer a test at a time most beneficial to the student
 Allow the student more time to complete a test
 Change the testing schedule or the order of subjects

Accommodations Checklist (AAC) to help teachers, guided by individualized education programs (IEPs), to recommend assessment accommodations for students with disabilities. The AAC is a list of 67 assessment accommodations organized into eight categories. The tool was designed to assist teachers and IEP teams in selecting accommodations for use during testing. The other framework used by Gibson and colleagues was CTB–McGraw Hill's taxonomy for characterizing accommodations by the likelihood of test-score interpretation being changed. According to the taxonomy, testing accommodations should be divided into three categories: Category-1 accommodations are not thought to impact the interpretation of a test; Category-2 accommodations may affect the interpretation of either norm- or criterion-referenced tests; and Category-3 accommodations may affect the interpretation of both norm- and criterion-referenced tests – by altering the construct being measured.

Gibson *et al.* (2005) found that five Category-1 accommodations (i.e., provide a distraction-free space, arrange for a special education teacher to administer the test, provide verbal encouragement of efforts, reread directions for each subtask, and administer practice activities) were among the ten most-recommended accommodations. Of these ten accommodations, the two most commonly recommended accommodations (i.e., provide extra time and read directions) were both classified in Category 2. Two accommodations from Category 3 (i.e., simplify

language in directions and restate question with more appropriate vocabulary) were also included among the ten accommodations. One accommodation (read questions and content to student) was classified as being in either Category 2 or Category 3 – perhaps reflecting the controversial nature of reading accommodations across states and tests. When considering these findings, it is critical to remember that accommodations are rarely made in isolation, and that the argument with regard to whether an accommodation or package of accommodations should actually affect the interpretation of a score is construct specific, and is best resolved via empirical investigation.

Assessment Accommodations and Validity

At its core, the use of assessment accommodations is a validity issue. Appropriate assessment accommodations can change a test that yields valid scores for students without disabilities into a test that yields equally valid scores both for students with disabilities and students without disabilities. The intent is not just to give the scores of students with disabilities a boost, but rather to provide access to a test that will accurately measure these students' abilities. For example, suppose that a math test with story problems is given to a classroom of students – most of whom do not have disabilities, but several of whom have disabilities that affect their reading. While the average score on the test for the class is an 85, the average score for the students who have disabilities in reading is 70. One might suspect that – due to the reading intensity of this test – students with reading disabilities were not able to show what they knew in mathematics. A simple fix that would make the scores for students with disabilities appear more similar to the scores for students without disabilities would be to add 15 points to the score of each student who has a disability, making the mean scores for each group equal. This would not be an appropriate assessment accommodation. The aforementioned attempt to make scores of students with disabilities comparable to those of students without disabilities would not be appropriate because it would not change the degree to which the scores of students without disabilities reflect those students' respective abilities in mathematics. While the maneuver would make the two sets of scores seem more similar, because their means would be equal, this change would be superficial. The scores for students with disabilities would still provide the same information provided prior to the conversion.

As with any test score, the scores for aforementioned students with disabilities would be influenced by two types of variance: construct-relevant variance and construct-irrelevant variance. Construct-relevant variance is the

degree to which the true variance of the construct being measured – mathematical ability in this case – contributes to the total variance in a set of scores. Construct-irrelevant variance is the degree to which variance in factors other than the variable being measured (e.g., reading ability, concentration, test-taking skills) contribute to variance within a set of scores. Test scores are likely to be more reliable and the validity argument is better served when construct-relevant variance is maximized in comparison to construct-irrelevant variance. In the current example, the higher the proportion of the variance in the test scores that can be attributed to actual differences in student math abilities, the more valid the test is for measuring this construct. When 15 points are added to the score of each student with a disability, neither the variance of the scores nor the portion that is construct relevant versus construct irrelevant is changed. This does not, likely, accomplish the goal of using assessment accommodations to level the playing field by providing access to a fair test. Perhaps, our subsample of students with reading disabilities is a group of high performers in math, and if given a mathematics test without a reading load, they may have scored an average of 95 points. In this case, the 15 bonus points would not have been sufficient compensation. It is also possible that the group would have scored an average of 75 on a valid mathematics test, and that 15 bonus points is overcompensation. The most likely scenario is that individuals within the group with reading disabilities were not all equally affected by the reading load on the test, and that no single, universal *post hoc* operation would make their scores comparable. Therefore, the best way to make the scores comparable between students with disabilities and those without disabilities is through assessment accommodations – selected for individuals to reduce the amount of construct-irrelevant variance associated with each test score. For one student with a disability, this might mean more time is necessary to read the test. Another student might need to be allowed to read the test aloud. A third student with a disability might be able to best show her mathematics ability if the test is read aloud to her. Any of these accommodations could reduce construct-irrelevant variance from a source (i.e., reading ability) that would likely affect students with disabilities in reading differently than it would affect those without disabilities.

One source of evidence for determining whether a set of accommodations is working to produce valid scores is whether a differential boost exists between how scores are enhanced for students with disabilities versus those without disabilities. A differential boost is the concept that indicates: if an accommodation is working appropriately, it should increase the scores of students with disabilities much more than it increases the scores of those without disabilities. **Figure 1** depicts the ideal differential boost – showing scores from students with and students without

Figure 1 Ideal differential boost for valid assessment accommodations.

disabilities taking tests in accommodated and nonaccommodated conditions. Poor accommodations (e.g., adding 15 points to a score) would affect scores from persons without disabilities in the same way that they would affect scores from persons with disabilities. Effective accommodations are helpful to students with disabilities, and are unnecessary (e.g., reading aloud a mathematics test), or even harmful (e.g., wearing prescription eyeglasses) to persons who do not need them. A differential boost associated with an accommodation is one type of evidence that construct-irrelevant variance is being reduced.

Differential effects – or the aforementioned differential boost – are one of four attributes suggested by Hollenbeck *et al.* (2002) that help define appropriate accommodations. The other three attributes are unchanged constructs, individual need, and sameness of inferences. The attribute of unchanged constructs stipulates that assessment accommodations should not change the construct being measured, but should only provide access to measurement of that construct for students with disabilities. To evaluate this attribute, one must have a clear understanding of the

construct that the test is intended to measure. For example, having a reader may be a perfectly acceptable accommodation on a test designed to measure calculation, but it would not be an acceptable accommodation on a test designed to measure reading comprehension. The attribute of individual need stipulates that students are to be provided assessment accommodations based on individual functional impairments, rather than based on group disability status. While one student diagnosed with attention-deficit hyperactivity disorder (ADHD) might benefit from an extended time accommodation, because – after attending to distractions – she eventually returns to completing a test, another student with ADHD granted extra time may become increasingly frustrated with the length of the test session. Highlighted text and frequent breaks might be more appropriate for him. The sameness of inference attribute indicates that test alterations result in scores being more comparable to make decisions. A student with a disability – by receiving appropriate accommodations on a test – should obtain a score that is suitable for making inferences with regard to proficiency.

The Individualization of Accommodations

The Individuals with Disabilities Education Act requires that assessment accommodations be individualized, rather than recommended based on a disability category. IEPs are drafted – for all students with disabilities – by education teams that include regular and special education teachers, parents, test interpreters, and any service providers. Because of their involvement in the IEP process, teachers are often influential in determining which accommodations are appropriate for each individual student. However, current research indicates that teachers are not always accurate predictors of which students will benefit from testing accommodations or which testing accommodations will be helpful.

Fuchs and Fuchs (2001) developed a data-driven method to find individualized testing accommodations. The Dynamic Assessment of Testing Accommodations (DATA) is a brief instrument designed to help teachers determine whether an accommodation works for an individual student – by testing the student both with and without the accommodation. Available for both reading and mathematics tests, DATA is designed to test the effects of individual accommodations on individual students. The key determinant – with regard to whether an accommodation is considered valid for the student – is the presence of the differential boost. An accommodation is considered valid for the student with a disability if his or her score improves substantially more than the mean improvement found among students without disabilities in the normative sample. The system has been found to improve upon teacher selection of individualized accommodations.

State of the Field: Moving Forward

Thurlow *et al.* (2000) wrote a monograph for the NCEO to address the state of assessment accommodations research. The researchers indicated that future research should (1) focus on accommodations of most interest, (2) focus on students who comprise a large part of the population needing accommodations, (3) use students without disabilities as a group in any comparison designs, and (4) collect other measures to help clarify findings. Thurlow *et al.* (2000) identified four group research designs – all including participants taking tests under both accommodated and nonaccommodated conditions – to address the matter of whether assessment accommodations work. They also suggested item response theory, factor analysis, and criterion-related analyses, as well as a number of single-subject designs, as possible contributors to future assessment accommodations research. Their final suggestion was that work on assessment accommodations needs to be done as part of a program: “Even with the best research designs, we will not get nice answers unless we have a program of research to follow up with additional questions” (p. 28). Two such active programs of research – Fuchs, Fuchs, and colleagues and S. Elliott and colleagues – are discussed next.

Fuchs, Fuchs, and colleagues did a number of research studies on assessment accommodations – in addition to their development of DATA. In a meta-analytic study, Tindal and Fuchs (2000) found that the most effective accommodations included providing large print or Braille for the visually impaired, as well as reading problems aloud for students with disabilities in math. Rather than examining accommodations in packages, Fuchs *et al.* (2006) indicated that research should be done on one accommodation at a time – with work on packages only commencing after individual accommodations have been validated. Findings from their studies included that (1) extended time does not provide a differential boost, (2) reading a test orally helps students with disabilities more than it does students without disabilities, (3) heterogeneity among students with disabilities reduces the likelihood of one set of accommodations being appropriate for the entire group, (4) student demographic characteristics may influence teachers’ accommodation recommendations, and (5) students with severe disabilities and severe reading deficits may benefit from reading a test aloud. Based on a review of assessment-accommodations literature, Fuchs and colleagues concluded that decisions with regard to testing accommodations must be individualized, that the meaningfulness of test scores must be of primary importance when selecting accommodations, and that the mandated inclusion of students with disabilities in educational outcomes testing makes this area of research critical.

In the same vein, Elliott and colleagues did a number of studies utilizing both between-subjects and within-subjects designs – requiring participants to take assessments

in accommodated and nonaccommodated conditions. Accommodations packages used in these studies were selected using student IEPs and the AAC. Elliott *et al.* (2001) found an effect size for students with disabilities (0.88) much larger than the effect size for students without disabilities (0.44) on a performance assessment. Schulte *et al.* (2001) used the same design with a research version of TerraNova's standardized math test – finding that accommodations had a large differential effect on multiple-choice questions, but had no such effect on constructed-response questions. McKevitt and Elliott (2003) found that teacher-recommended accommodations from the AAC did not help students with disabilities or students without disabilities, and a read-aloud accommodation combined with teacher accommodations boosted the scores of both groups, when the outcome measure was a research version of TerraNova's standardized reading test. Kettler *et al.* (2005) also found a strong differential boost for fourth-grade students on the research version of the TerraNova reading test. The effect size for students with disabilities was 0.42, while the effect size for students without disabilities was 0.13. Lang *et al.* (2007) replicated this finding, and determined that students endorsed the fairness of testing accommodations, particularly when used among students with disabilities. Feldman *et al.* (in press) explored the relationship among the effects of testing accommodations, students' self-efficacy, and test performance. They determined that students with disabilities experience a differential boost in self-efficacy and motivation when provided accommodations, and that this boost corresponds with increases in test scores.

Sireci and Pitoniak (2007) published a review of assessment accommodations research that condensed the findings of previous reviews, recent studies, and studies not addressed in earlier meta-analyses. They concluded that assessment accommodations, sometimes help students with disabilities, help students without disabilities sometimes, and must be selected on an individual basis. They also emphasized the necessity of identifying the construct that a test is designed to measure to evaluate whether a specific accommodation is appropriate, and commended research in which students take tests in both accommodated and nonaccommodated conditions. With regard to the two most widely researched testing accommodations, Sireci and Pitoniak concluded that extra time is an appropriate accommodation when speed of response is not a construct being measured, and that having a test read aloud to a student is appropriate on tests that do not assess reading.

Conclusion

While recent years have featured a great deal of research activity on assessment accommodations, a number of

questions remain to be answered. Studies following the postpositive ideal of isolating and validating individual accommodations – coupled with studies following the pragmatic ideal of evaluating accommodations in packages and incorporating student feedback – will continue connecting pieces to solve from different sides the assessment accommodations puzzle. Perhaps, new techniques – such as the aforementioned item response theory, factor analysis, and criterion-related analyses (Thurlow *et al.*, 2000) – will provide breakthroughs in identifying individualized accommodations that provide access – for students with disabilities – to fair and valid assessment. Until such breakthroughs are made, teachers and IEP teams will rely on their knowledge of individual students and their familiarity with current assessment accommodations research and theory to select accommodations that make scores from students with disabilities comparable to those obtained from students without disabilities.

Assistive Technology and Educational Practice

H P Parette and G R Peterson-Karlan, Illinois State University, Normal, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Assistive-technology device – Any item, piece of equipment, or product system, whether acquired commercially or off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities.

Assistive-technology service – Any service that directly assists an individual with a disability in the selection, acquisition, or use of an assistive-technology device.

Cognitive demands – The amount of thinking required for performing tasks or for using a tool.

Compensation – To substitute for or perform a function (using a tool) that cannot be done by a person with a disability.

Consideration – A federally mandated team decision-making process focusing on selection, implementation, and outcomes monitoring of assistive technology for a student with disabilities.

Instructional technology – The technologies that are used to teach new skills, remediate deficiencies in skills learned, and/or to supplement or expand the curriculum for all students.

Outcomes – The effect or result of using an assistive technology tool.

Physical demands – The amount of muscle strength and movement needed to initiate, pursue, and complete a task or use a tool.

Social-linguistic demands – The amount of symbolic interpretation and processing required of a user to use a tool or complete a task.

Ubiquitous – Readily available or widely used.

Deeply embedded in the fabric of society is use of a wide array of technologies. Merriam-Webster, Inc. (2007) defined technology as both “a practical application of knowledge” and “a manner of accomplishing a task.” When viewed broadly, then, Peterson-Karlan and Parette (2008) observed that technology includes not only the things individuals use to accomplish tasks (e.g., overhead projectors, computers, cell phones, copy machines, dictionaries, and spreadsheet software), but also the procedures for how individuals use or operate them, and how they systematically proceed to accomplish tasks (i.e., use of strategies, such as rules for text messaging; dictionary

use rules; and writing steps of required tasks on a whiteboard). Acceptance of this broader context of what technology is – things, procedures, and strategies that help individuals complete tasks – is integral to understanding and effectively working with twenty-first-century students – both with and without disabilities – and education professionals (Peterson-Karlan and Parette, 2007).

Many technologies in society have become ubiquitous, that is, they are so prominent and accepted that they appear to be everywhere and used routinely by many people. Not many individuals would argue that ubiquitous technologies (e.g., light switches, cell phones, the Internet, information search software, electronic calculators, and word processors with spell-check features) are unimportant given their impact on the society’s quality of life, particularly with regard to how they increase effectiveness, efficiency, and comfort or ease of doing things, as well as productivity in the workplace. Sadly, however, the broad acceptance and inherent use of technology that permeates the broader world context, particularly in work settings, are much less frequently observed in school environments (Peterson-Karlan and Parette, 2008).

Presented in **Table 1** are three categories of primary technologies used in today’s schools accompanied by descriptions and examples. These categories, broadly, include (1) information and communication technology (ICT); (2) instructional technology (IT); and (3) assistive technology (AT).

Medical technologies, though a specific technology category by itself, are not included given the limited relationship to educational milieus. More detailed elaboration on the first two categories may be found elsewhere (cf., Grabe and Grabe, 2007; Lengel and Lengel, 2006; Roblyer, 2006; Smaldino *et al.*, 2005). In general, however, neither ICT nor IT by themselves enable all students to learn and participate in the general education curriculum (see **Figure 1**).

Students with disabilities are now included in general education classroom settings to a greater extent than ever before. Yet, these students often demonstrate gaps in their ability to perform at expected levels in various academic and life-skill areas (see **Figure 2**). Given the current pressures on public schools for all children to achieve (No Child Left Behind Act, 2001), the potential for technology to provide access to and support learning for students with disabilities and narrow the gap between abilities and expected educational performance levels has received considerable attention (International Society

Table 1 Categories of technology impacting schools

Category	Description	Examples
Information and communication	Helps to communicate and interact with others; produce work; problem-solve; find information; and manage ourselves, our homes and lives more efficiently and effectively across settings	Copy machines; word processing and graphics software; Microsoft® PowerPoint; cell phones; text messaging; blogs; Wikis; and the Internet
Instructional	Increases instructional <ul style="list-style-type: none"> • effectiveness (learning in a better way than without the experience) • efficiency (same amount of learning occurs but in a shorter time) • appeal (increases possibility that students will devote time and energy to the learning task) 	Computers; DVDs; projection devices; digital audio and video recording or editing devices or software used by teachers to prepare or present information; whiteboards; and educational software
Assistive	Compensates for difficulty in accomplishing functional tasks at an expected level of performance	Foam pencil grips; visual schedules; graphic organizers; electronic communication systems; wheelchairs; hearing devices; text-to-speech software; talking word processors; and seating and positioning systems

Instructional technology

Used to:

- Teach or learn functional skills
- Supplements or expands the curriculum
- Remediation of learning functional tasks

Assistive technology

Used to:

- Compensate for inability to perform functional tasks
- Help students do things they could not do at an expected performance level

Students can learn or perform functional tasks without IT

Students cannot learn or perform functional tasks without AT

Figure 1 Distinctions between IT and AT. From SEAT Center, ©2007. Understanding Assistive Technology.**Figure 2** Performance gap exhibited by students with disabilities across time, with AT compensating and closing the gap. From SEAT Center, ©2007.

for Technology in Education, 2005a, 2005b; SEAT Center, National Center for Technology Innovation (NCTI), and University of Kansas (KU), 2006; Thurlow *et al.*, 2007). For students with disabilities, AT (1) must be considered by education professionals when developing any individual education plan (IEP; Individuals with Disabilities

Education Improvement Act of 2004 (IDEIA, 2004); 20 U.S.C. 1401 § 614(B)(v)); and (2) is often required to ensure their inclusion and effective participation in the general education curriculum (Center for Technology in Education, Johns Hopkins University; and Technology and Media Division (TAM) of the Council for Exceptional Children, 2005).

Blackhurst (2005) noted that AT was developed for people with disabilities to (1) make the environment more accessible, (2) assist them in learning, (3) enable them to compete in the workplace, or (4) enhance their independence or otherwise improve their quality of life. The IDEIA 2004 defines an AT device as “any item, piece of equipment or product system, whether acquired commercially or off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities” (20 U.S.C. § 1401(251)). There are now more than 25 000 AT items, equipment, software, and product services (Abledata, as cited in Edyburn, 2000) to consider for use with over 6 million students of ages 6–21 with disabilities. However, AT also includes services that support the acquisition and implementation of the AT. IDEIA 2004 defines AT services as “any service

that directly assists an individual with a disability in the selection, acquisition, or use of an assistive technology device” (20 U.S.C. 1401 § 602(2)). Such services would include (1) evaluation of the child’s needs, including a functional evaluation of the child in his or her customary environment; (2) purchasing, leasing, or otherwise providing for the acquisition of AT devices by the child; (3) selecting, designing, fitting, customizing, adapting, applying, maintaining, repairing, or replacing of AT devices; (4) coordinating and using other therapies, interventions, or services with AT devices, such as those associated with existing education and rehabilitation plans and programs; (5) training or technical assistance for the child, or, where appropriate, the child’s family; and (6) training or technical assistance (20 U.S.C. 1401§602(2)(A-F)).

The IDEIA 2004 definition places emphasis on the compensatory nature of AT, that is, it compensates for something a child cannot functionally do or perform. A more easily understood, or working definition of AT for practitioners is that it is a tool (or strategy) that allows a person to do a task he or she could not do without the tool (or strategy) at the expected performance level (Parette *et al.*, 2007). While IT and ICT may be helpful to teach new skills, remediate problems demonstrated by students with disabilities, supplement the curricular experiences of students, and facilitate access to and the manipulation of digital information, it is not individualized. AT is individually matched to and uniquely required for a student to participate in the curriculum or classroom and make educational progress (Lewis, 1993; Rose *et al.*, 2005).

Considering AT

Since AT is compensatory and its use in educational settings should culminate in positive outcomes (i.e., progress toward educational goals; Parette *et al.*, 2007), how it is considered by education professionals when developing and implementing program plans is of paramount importance. Numerous planning frameworks and models for making decisions about AT have been proposed over the past two decades (cf., Blackhurst, 2005; Bowser and Reed, 1995; Center for Technology in Education, Johns Hopkins University; and Technology and Media Division (TAM) of the Council for Exceptional Children, 2005; Chambers, 1997; Parette and VanBiervliet, 1990, 1991a, 1991b, 1991c, 1991d, 1991e; Parette *et al.*, 1991; Scherer, 2002; Zabala, 1993; Zabala and Carl, 2005). While providing some degree of guidance for AT decision making, educators and service providers may sometimes be uncertain about the practicality of these differing approaches and their relevance to the day-to-day activities in public school milieus. Of particular importance is that some educators currently do not have a broad understanding

of how seemingly different elements of AT consideration (e.g., student and school environment characteristics, educational demands and tasks within specific environmental settings, and AT tools and their features) interface and lead to effective decisions about what AT tools children with disabilities receive.

To facilitate a better understanding about what must be considered to effectively choose and implement AT with students having disabilities, **Figure 3** presents a framework that incorporates (1) what the field knows about human factors (Cook and Hussey, 2002; King, 1999); (2) the relationship between human factors and educational activities in which children participate (Cook and Hussey; King); and (3) understanding of the nature of tools that can be used by students with disabilities to make progress in the curriculum (Cook and Hussey). The following section describes three specific dimensions of AT decision making that are integrally related: (1) activities and their embedded tasks, (2) the demands created by activities and tasks, and (3) the manner in which individuals can appropriately respond to demands.

Activities and Embedded Tasks

Education professionals working with students with disabilities are keenly aware of typical daily activities in which students participate and in which they must be successful to make progress in the curriculum. For example, preschool children may participate in activities such as opening activity, choice time, reading time, free play, and lunch. Elementary-age children would participate in daily activities such as language arts (reading and writing), mathematics, social studies, science, or art. High school students’ activities would include specific content courses such as American history, geometry, English literature, biology, and physical education.

Regardless of the age level, each activity in which a student participates has embedded tasks. For example, to participate in free play, the preschool child may have to complete tasks such as (1) scanning the available activities and choosing an activity in which to engage, (2) engaging in the activity in a meaningful way, and (3) terminating the activity, often by putting materials away. To participate in language arts at the elementary level, a student might (1) read a text passage and then write a story about his/her own similar experience, (2) engage in writing to include completing tasks of planning the topic and making a content outline, (3) transcribe an initial draft, (4) edit and revise the composition, and (5) finally submit it to the teacher. At the high school level, to participate in history class, a student might (1) participate in class discussions, (2) listen to a presentation or view a video, (3) take notes, (4) read a text assignment, (5) write assignments in a planner, (6) complete and/or submit homework, and (7) take exams. Thus, participation may be viewed as

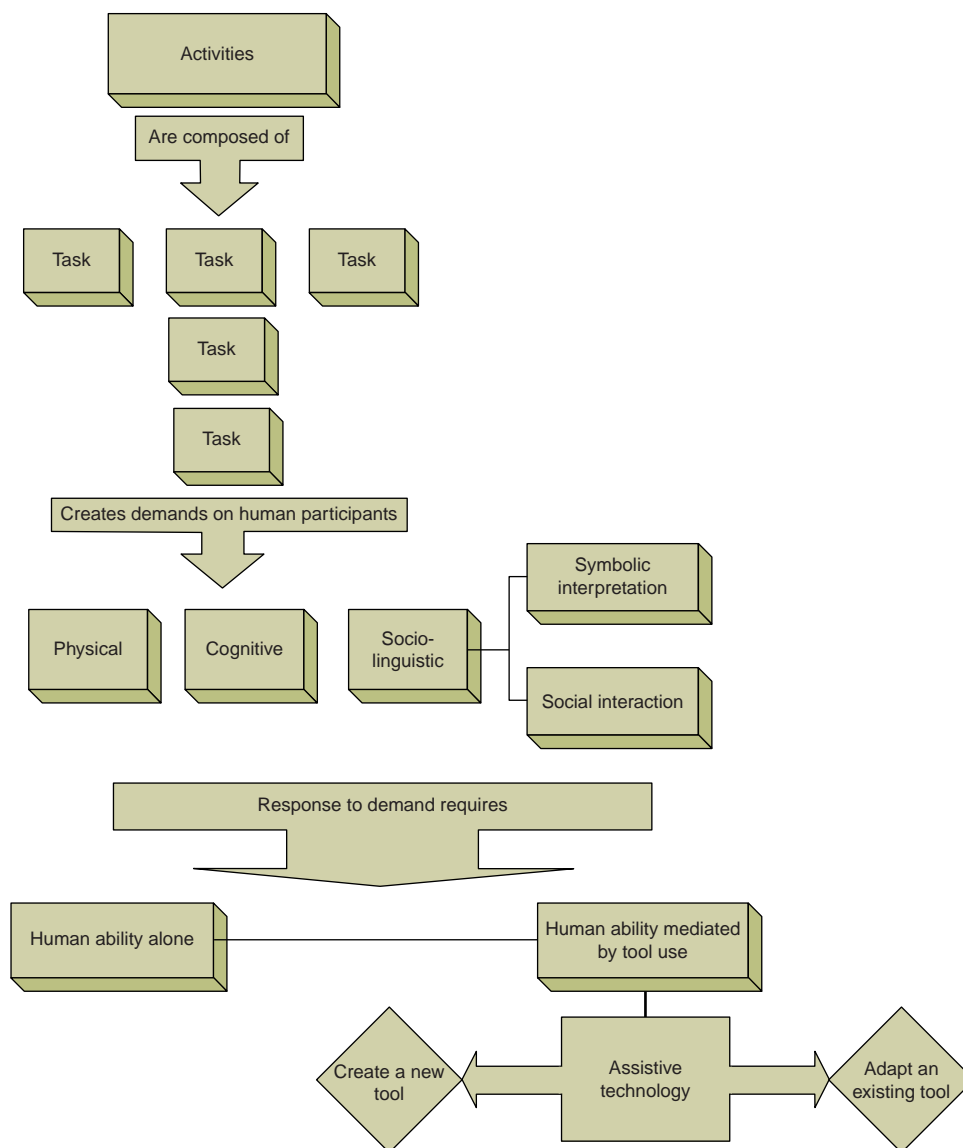

Figure 3 Relationship of tasks and their demands within activities to responses by humans to these demands. ©2009, G. R. Peterson-Karlan, Permission is granted to use my figure for this publication. GRP-K, 7/13/09.

a series of related tasks that culminate in successful completion of a specific activity by the student with a disability.

Demands on Human Users

Whatever the human activity in which students of any age and ability level participate, the embedded tasks present demands on students. These demands include (1) physical, (2) cognitive, and (3) sociolinguistic (King, 1999). Each is described in the following section.

Physical demands

Many tasks associated with school activities place physical demands on any human participant. King (1999)

described physical demands as the amount of muscle strength and movement “required to initiate, pursue, and complete a task” (p. 60). These demands would include such specific things as range of motion (i.e., ability to move joints, arms, and legs in various directions), resolution and repetition of movement, and sustained movement or position. For example, a preschool child participating in a lunch activity would be confronted with the task of sitting at a table. This demands that the student sit upright in chair at a table (which requires balance, hip stability, and flexion of the hip joints). To make a choice at the table, the child must coordinate muscles of the arms and hands to reach and grasp a preferred food item or manipulate a cup, plate, or utensil. These examples illustrate that many tasks within an activity require a student to do

something physically, and such demands may or may not present challenges to a particular student having a disability.

Cognitive demands

Generally speaking, most tasks that students are presented with in their school activities have varying degrees of cognitive demands (i.e., the amount of thinking required to complete a task). King (1999) noted that these demands may include (1) sensing (i.e., visual, auditory, and tactile-kinesthetic); (2) remembering (i.e., factual memory); (3) discriminating (i.e., differentiating); (4) analyzing (i.e., problem-solving); and (5) sequencing actions (i.e., sequential memory). For example, when a high school student participating in history takes notes (the task), he or she must be able to hear the teacher who is lecturing or see notes displayed with a liquid-crystal display (LCD) projector (sensing); must remember information from the reading homework; and must sort out unimportant information presented during the discussion from important content over which he or she might later be tested (discriminating). Finally, the student must write from left to right while note-taking using sequences of letters to spell words (sequencing).

Sociolinguistic demands

Tasks within school activities frequently present sociolinguistic demands on users. King (1999) stated that linguistic demands include “the amount of symbolic interpretation and processing that the user must invest” (p. 61). Linguistic demands posed by a particular task can also include interpretation of symbols and text. For example, when a young child is presented with a list of possible activities in which he or she may participate during choice time, both pictures and/or text representing the activities must be processed and interpreted. For some children, the text alone might not present an undue cognitive burden for interpretation, while for other children, both text and a picture (or picture alone) might be required for interpretation to occur. For a high school student presented with the task of note-taking, he or she would typically be presented with the linguistic demand of recognizing and understanding the meaning of text written by the teacher on a whiteboard.

Symbolic interpretation, however, often does not occur outside the context of a social interaction. For example, if a teacher uses a whiteboard to write a list of steps needed to complete a project, and then asks the class, “What do we do to complete this project?” There are social demands placed on all students to be able to participate in the task of responding to the teacher. First, the student must attend to the teacher who is asking the question. Second, the student must signal a desire to respond (e.g., raising one’s hand vs. blurting out an answer). Third, once the student’s signal is recognized by the teacher (e.g., “Johnny, can you tell us what we do next?”), the student must

appropriately communicate an answer to the question and terminate the communicative response appropriately. In other types of tasks, social skills such as turn-taking, civility, and use of manners are embedded in the activity and are important considerations to fully understand what a student must do to be successful in a targeted activity that has many tasks.

Response to Demands

When students with disabilities participate in school activities having a cadre of embedded tasks (with associated physical, cognitive, and/or sociolinguistic demands), they either do the task alone or use tools as a way to accomplish the task. In the former instance, many students with disabilities typically will exhibit some abilities to perform certain tasks within educational activities. For example, during math class in the elementary classroom, a student may be able to understand text in a story problem if it is read aloud and provide an answer, but has difficulty if asked to read the text in which the problem is detailed. In this instance, the student uses human ability alone to understand, process, and express an answer. However, because he has difficulty decoding (reading) the text – another task embedded in the activity – compensation is required to enable him to complete this more demanding task that requires a tool, such as digital text with speech output, which may not be typically used by others.

Human ability mediated by tool use

In many academic tasks, demands (whether physical, cognitive, and/or sociolinguistic) are typically met using a tool. Ubiquitous tools in school settings include things such as paper and pencils to record information for later use, the school planner, and a pencil or pen to record assignments and dates that must be remembered later, three-ring notebooks to organize materials and backpacks to help carry books and notebooks. Tools are used in school settings to (1) enhance effectiveness, (2) reduce effort, (3) reduce errors, (4) increase speed, (5) improve quality, (6) reduce physical effort, and (7) reduce cognitive effort. It is important to note that each tool created to help accomplish a task also imposes its own physical, cognitive, and sociolinguistic demands on the tool user.

When a tool must be used to compensate for functional inabilities to complete one or more specific tasks, it becomes an AT tool. Some AT tools are created specifically for persons with disabilities. For example, wheelchairs, hearing aids, and Braille are created specifically to compensate for the physical and sensory needs of persons with disabilities. Text-to-speech screen readers and web browsers are created to compensate for inabilities to differentiate between screen text by persons with visual impairments or to decode print by persons with learning disabilities. However, many existing tools can be adapted to provide

compensatory benefits for a student with a disability. In the case of a student with physical disabilities who has difficulty grasping standard eating utensils, oversized, padded handles or a change in the handle angle can provide the needed compensatory effect. For the student with a learning disability who has difficulty with spelling and word use, a spell checker and/or thesaurus with text-to-speech capability can provide needed compensatory effect.

AT Outcomes and Today's Classrooms

In today's school settings, ensuring the student's access to educational opportunities is not sufficient; successful participation of students with disabilities in the general education curriculum and monitoring that progress is of utmost importance (Thurlow *et al.*, 2007). More specifically, using research-evidenced and data-based practices in classrooms has become a singular focus in the field of special education (Gersten *et al.*, 2005; Horner *et al.*, 2005; Odom *et al.*, 2005; Parette and Peterson-Karlan, 2008). This is now true of AT consideration as well (Peterson-Karlan and Parette, 2007, 2008). There are three important phases in which data are crucial: (1) when identifying the problem for which AT is needed, (2) before making final a decision to acquire or purchase a particular AT solution, and (c) during long-term implementation of the AT solution (i.e., collecting data while the student uses the AT solution for the purpose intended; Parette *et al.*, 2007). Implicit in these phases are outcome questions for which data must be generated: Is AT needed? Is the AT effective? Over time, is the AT effective in supporting educational progress? Specific data-based strategies for assessing outcomes of AT consideration at each of the decision points have been reported elsewhere (see Parette *et al.*), but those strategies involve documenting the performance gap introduced in Figure 2, measuring the compensatory effect of the introduction of AT and monitoring the effect of continued AT use on educational progress. Concurrent time-series designs in which performance with and without AT tool use is measured at specific points (e.g., during trial implementation with the AT) and is repeatedly sampled over time (e.g., quarterly in the school year) are used to determine whether AT is effective, needed, and contributing to students' educational progress.

Conclusion

This article has emphasized the increasing role of technology in education settings, with particular emphasis on consideration of AT for students with disabilities. The legal mandate of IDEIA 2004 to consider AT when developing individual education programs, requires education professionals to better understand the compensatory nature

of AT within the context of human factors, educational activities, and the demands of tools on users (both physical, cognitive, and sociolinguistic). Of particular importance was the presentation of the concept of tasks being embedded within primary educational activities in which children participate. These various tasks present demands which require a student to use human ability alone or a tool.

The use of data in AT decision making has also been emphasized, typically occurring at three distinct phases. Each phase, in turn, has specific questions that education professionals must address to ensure that effective decision making for the student has occurred.

Augmentative–Alternative Communication

C Mason and K M Chinn, New Mexico State University, Las Cruces, NM, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Aided communication – Augmentative or alternative communication approaches that require a system or device to communicate.

Assistive technology – The use of any item, system, or equipment that is utilized to improve or maintain functional living skills and independence.

Digitized speech – Natural speech, which has been recorded and reproduced for use in voice output communication devices. However, these recordings are limited to recorded words or messages and limit the user's choice of messages.

Joint attention – When two or more individuals are focusing or attending to the same activity, object, topic, or thought process.

Switch access – When an individual is able to reach, activate, and utilize an external button or switch to create a cause-and-effect reaction.

Synthesized speech – Technologically generated speech which uses the linguistic patterns of digitized speech to create a speech system. This form of speech provides the user with much more choices and options in creating messages.

Unaided communication – Nonverbal communication approaches that utilize facial expressions and/or body movements, such as gestures, to communicate, for example, American Sign Language.

VOCA – The acronym for voice output communication aids, which is a group of devices that provides an alternative voice through recording or digitized speech.

Augmentative–alternative communication (AAC) provides individuals special needs with the means to express ideas, thoughts, concerns, and needs. Thus, the goals for AAC are twofold: (1) to make individuals more functionally independent by having the ability to express needs, wants, feelings, and preferences in a form that others can understand, and (2) to enhance communication skills and language skills, providing increased independence. Clearly, individuals with specific disabilities require AAC devices that provide accessibility specific to their needs. An individual who is deaf/hard of hearing not only may use a form of manual communication but may choose to use high-tech devices such as hearing aids and infrared listening devices available

in public settings such as theaters. In the educational setting, a child who is deaf may be provided with an FM unit to accompany the hearing aid. Cochlear implants are also a choice for individuals who are deaf. The individuals who are blind/visually impaired have Braille, print readers, and computers with large computer screens, and large font choices to aid in reading. Individuals who have cognitive deficits with communication effects may use more complicated to simplistic communication boards/switches. Individuals with cerebral palsy generally have communication boards/switches that are programmed to match the individual's physical abilities as well as cognitive level. Individuals with spinal injury at the level of the cervical vertebrae or advanced neuromuscular disorders such as amyotrophic lateral sclerosis (ALS) may have limited movement, and thus require AAC devices that use eye movement or head movement to signal letters with which words and sentences can be formed.

The American Speech-Language-Hearing Association defined AAC as a set of procedures and processes that maximize the individual's communication skills for functional communication. Separately defined, augmentative communication is any support system in a given situation that allows an individual to communicate independently, whereas alternative communication is specifically the use of nonvocal instruments and/or approaches.

The need for AAC spans socioeconomic, racial, ethnic, and age groups. According to the American Speech Hearing and Language Association, the prevalence of people with communication impairments severe enough to require AAC ranges from 8 to 12 in every 1000. Individuals that most frequently benefit from AAC include those who:

- are deaf or hard of hearing;
- have acquired neurological impairments such as TBI, cerebral palsy, or aphasia;
- have progressive neurological disorders such as ALS;
- have been diagnosed with an autism spectrum disorder (ASD);
- have motor speech disorders; or
- have been diagnosed with neurogenetic disorders.

Two distinct types of users include those with long-term need and those with temporary need for AAC. Individuals that have suffered a stroke and have developed aphasia may need temporary assistance through AAC until spontaneous recovery allows them to regain their speech, whereas individuals with ALS, otherwise

known as Lou Gehrig's disease, will need continued, long-term AAC support. These individuals may start with manual sign language or topic reference pictures to assist the listener understand the speaker's slurred speech more clearly. As the disease progresses and independence decreases, the individual with ALS will need a more sophisticated system.

Forms of AAC

AAC is found in many forms, from manual communication to low and high technology systems, and are further categorized as aided or unaided. Unaided systems, which require no external devices, might include, but are not limited to, gestures and sign language. Aided AAC devices might include picture systems and/or print (which are considered low tech) and computerized communication devices (which are considered high tech).

Manual Communication

Manual communication systems used for unaided communication are the most frequently used form of AAC. Manual communication consists of cued speech, American Indian Sign Language, American Sign Language, and various English signed systems such as Signing Essential English (SEE I), Signing Exact English (SEE II), Language of Visual English (LOVE), and pidgin forms of signed language. According to Mitchell (2006), there are approximately 11 000 000 individuals who are deaf or hard of hearing in the United States with 1 000 000 Deaf. ASL is the most frequently used version of manual communication as ASL is the language of the Deaf culture. Most other forms of manual communication, excluding American Indian Sign Language, are used in educational settings with children who are deaf or severely hard of hearing such that it precludes the use of speech and speech reading for communication purposes. SEE I, SEE II, and LOVE were specifically developed to assist deaf and severely hard-of-hearing children in learning English for the purposes of reading and writing.

Describing Low- and High-Level Technology

Lower technological devices, often referred to as low tech, are used with individuals that are unable to produce gestures and manual sign, due to motoric limitations. Forms of aided communication such as a communication board, picture schedule, eye gaze board, or other simple aids are not electronic, but offer a form of assistive technology. Assistive technology is a broad term which may include aids for daily living activities, vocational activities, or environmental controls. It may be used to refer to some forms of augmentative communication. A more detailed

list of low-tech, aided communication systems might include, but might not be limited to,

- Eye gaze board – where the individual moves his/her eyes in the direction of a specific picture or symbol to indicate a need.
- Alphabet boards – which provide the individual with the alphabet to spell out simple messages (example given the end of this article).
- Writing materials – to communicate wants, needs, thoughts, and desires.
- Communication book/dictionary – development of a gesture or communication dictionary provides the individual information on what the behaviors look like, what each gesture means, and how to respond to the message. The creation of the dictionary should include the primary caregivers input, and thus provide consistency in communicative attempts. These can then be paired with more conventional photos, objects, or symbols to help the individual expand his/her communication base.
- Picture exchange communication system (PECS) – a system that was designed to provide opportunities for individuals, primarily with autism, to begin initiating communication.
- Picture communication symbol systems – other systems, similar to PECS, which provide opportunities for communication and scheduling routines.
- Blissymbolics – another graphic meaning communication system originally designed for children who were deaf/hard of hearing that was applied to the general population.

Higher technological devices, referred to as high tech, are also forms of aided communication and assistive technology. These devices include different types of hand-held printers, word processors, and computers. Devices with voice output are referred to as VOCAs – voice output communication aids. These devices are not limited to voice output and may instead activate some other relevant objects in the environment. Examples of VOCAs used as high-tech-assistive devices may include some, but not limited to, of the following:

- Switches are various electronically controlled buttons of various sizes. These buttons are used to activate a device for speech or environmental controls. For example, the push of a button may turn on a television or personal fan, or it may ring a bell calling for someone's attention. These switches may be activated with various parts of the body from hand pressure to eye blink, depending on the abilities for movement of the individual.
- There are simple VOCA devices, in which, one single button activates a single message recorded on the system. This message is usually recorded by a peer or caregiver.

These systems are generally limited in the communication repertoire. This presents difficulties in the use of the system in all other communicative settings or situations.

- More sophisticated VOCA devices offer a variety of opportunities for communication, including keyboarding, word prediction, and programmed personalized information for ready-access. The devices may include direct selection opportunities, where an individual will push a single button for a message. This requires strength and the ability to access the buttons. The equipment will usually have the ability to scan different options with a single switch to hit as the item is highlighted on the system. These devices may also use recorded speech or synthesized speech, which is more robotic in nature. Although great advances have been made to the quality of the speech, we now have a variety of voices to provide a more appropriate vocal quality dependent upon age and gender.

Assessing the Need for AAC

Careful and thorough assessment of individuals, their needs, significant others, and lifestyle is necessary to determine the best mode of augmentative communication. Areas of evaluation would include all facets of the individual's medical history, premorbid state, current physical abilities, cognitive abilities, typical communication partners, lifestyles, and living environments. In assessing the individual, careful consideration should include the following: past and current medical history; cognitive abilities, including the ability to initiate conversation; as well as receptive and expressive language skills. The individual evaluating a client in need of an AAC should know the physical limitations of the individual and how these limitations would affect accessing a communication system. Consideration of the medical prognosis, including a progressive condition, may also impact the current and future levels of the individual's communicative needs. Further, what would be the medical prognosis of the condition? That is, is the condition a progressive disease, which may impact the current and future levels of communicative needs?

Determination regarding the permanence of the communicative disorder is important for choosing a device. If the disorder is progressive, how soon is the condition expected to worsen? As indicated above, if the individual has a progressive disease, this assessment process must take future needs into consideration. That is, what will the communication needs be at each level of the progression? In order to determine which AAC device is most appropriate, cognitive abilities and the ability to initiate communication must be evaluated. The therapist choosing and fitting the device must have information regarding the level of awareness of the individual who needs AAC. Further, the

ability to utilize joint attention with another individual must be assessed. Is this individual able to take turns in communication and gain the attention of others? Prior to choosing an AAC system, the individual's ability to recognize and understand at an object and photographic level, line drawing, or written word must be determined, as AAC devices vary in complexity based on individual abilities. For example, can the individual perform actions or use objects? Along with choice of complexity level, the number of items presented is also a consideration. Is the individual able to select one item out of how many choices?

Receptive and expressive language skills are part of the determination for an AAC device. The level of communication is an important factor for choice. What does the client understand? Is the client only able to use limited or telegraphic speech used by his/her communication partner? The ability to understand extended conversations and lengthy messages must be determined. Provided with opportunities through augmentative means, is the individual able to label, identify, or describe? Further, what types of messages is he/she able to relate? For example, can the individual make requests, negate information, refuse treatment, gain attention, report information, clarify messages, seek information, and/or express feelings and concerns? The range of physical motion and level of strength/endurance of the individual must be assessed to determine the appropriate type of AAC. The ability to move limbs, as well as the range of motion of limbs, fingers, head, feet, and eyes, are part of this assessment. Further, information regarding the ability to perform multiple tasks such as the ability to move while making decisions is important in the choice of AAC devices. Strength such as the ability to apply pressure on a switch or button must be determined. Does the individual being assessed for the device fatigue easily? The best time of day to utilize maximum strength to communicate must also be assessed. Some devices may require more dexterity along with the ability to make choices in a timely manner, as these scanning devices provide a limited time frame for item selection. Therefore, speed and accuracy may be factors in the selection of a device.

Positioning is important to ensure that individuals have sufficient support to allow them the maximum range of motion, provide clear contact with their device, and reduce fatigue during communication opportunities. An interdisciplinary team effort, including assistance and consultation with OT and/or PT, will provide input concerning the client's physical abilities and equipment needs, such as chair mounts, device portability and location on the walker or wheelchair, and optimal positioning for the client. Visual and auditory limitations should also be considered in selecting symbols for an AAC device. Regarding visual impairments, many devices are available

and assessment is needed to determine which system(s) best meets the individual's needs. In order to determine this, the diagnostician must assess how well he/she sees. If the individual can see print and line drawing, would a colored background assist in symbol recognition? How well can he/she scan multiple pictures for selection? How many choices can the individual maintain in his/her line of vision? The size of items on the communicative device also must be determined to meet his/her field of vision.

Since emotional status and level of motivation for communication affects the optimal use of the AAC device, the following questions must be addressed. Often individuals with particular disorders become depressed. Is this individual on depression medications, which may impact alertness? Does he/she have the desire and motivation to learn an augmentative communication system? What level of communication is important to him/her? Does he/she desire to carry on conversations, express only basic wants and needs, or be as independent as possible?

Assessing Communication Partners

Communication partners take on important roles in the life of the individual who requires an AAC device. The following questions must be answered regarding the communication partner. Who will be the primary conversation partners? Will the communication partner be willing to be involved in utilizing a new system? Even with the advancement in technology, conversational exchange using an AAC device remains much slower than natural speech, and will detract from the natural social exchange of information. Will the partner be able to display the patience in waiting for responses? Will the partner be committed to providing multiple communication opportunities for the individual? Will the communicative partner be able to understand and help the individual learn and program or change the device, dependent upon the situation? Lastly, during the evaluation, typical communication settings must be addressed. Where will the individual be communicating most frequently: in the home, school, or community? Will there be extraneous noise or will the setting be quiet? If there is extraneous noise, how loud will it be? To gather the most thorough and in-depth information in answering the aforementioned questions and in providing the optimum communication system for an individual, an assessment team should be organized. This multi-disciplinary assessment team may include: family and/or caregivers who are an integral part of the assessment, an audiologist, an educational specialist(s), an educational diagnostician, a physician, a psychologist, a speech-language pathologist, an occupational therapist, a physical therapist, a social worker, a rehabilitation engineer, a vision specialist, and/or a vocational counselor. Clearly,

the selection of the system will be determined by the observations and input from each of the evaluation team members, as well as the evaluation of the individual and interviews with the significant others. Information must be gathered by the diagnostic team; the potential user's feelings regarding the use of the equipment, such as possible embarrassment associated with the device, must be taken into account. Many of the high-tech devices are extremely expensive and require funding for affordability. If the individual does not have a payment source or personal funds, selection of a low-tech method may be more acceptable. Often, AAC vendors will assist with funding questions and paperwork. Along with this service, these individuals may also supply a variety of devices for trial and assessment. The user would have the opportunity to utilize the equipment in conversational trials to determine the best device, the number of selections available, and the best mode of access, such as scanning or direct selection as discussed above.

Initiating Communication

Many times as the individual is trained to utilize the alternative communication system, they become prompt dependent for responses. It is important that the educator or speech-language pathologist avoid prompt-dependent or cued communication interactions. The system must be as simple and unencumbered as possible to provide the easiest access for communication opportunities. The home, school, and other environments should be engineered for optimum communicative opportunities for the nonverbal individual and his/her communication partners. Vocabulary and access must be functional for the user and significant others. Lack of interest in communication may indicate that the individual is not being exposed to preferred activities or that the needs of the communicator are not being addressed with access of the system. The use of some AAC systems requires a myriad of skills and multi-tasking abilities. Skills necessary for responding to a simple question posed by the communication partner may require the user to (1) understand the question, (2) turn on and focus on the AAC system, (3) attend to symbols and perceive them accurately, (4) determine the locations and sequence to respond, (5) access the system, (6) determine if the communication partner has understood the message, and (7) repeat the communicative sequence in order to continue the conversation.

Early intervention makes a significant impact on the success of an alternative communication system. The earlier the child begins to use an AAC system, the greater the chance of acceptance and regular use. Current research documents the efficacy of communication services, reporting that services should begin before age 2 in children with severe disabilities. The use of AAC systems should be

considered as soon as the child demonstrates communicative needs. Although parents are sometimes concerned that introduction of AAC may preclude development of speech, numerous studies demonstrate that the opposite affect is found; this approach supports such development.

Communicating with Partners

Two different types of communication partners have been described. A partner-dependent user is one who must rely on another individual to manage the informational exchange. This situation requires highly familiar contexts. The user's partner may have to scaffold interactions by offering choices, provide visual input, or restructure the exchange for easier understanding. The second type of communication partner is an independent partner, who has relatively preserved or intact language skills and executive functions, and may be a candidate for more high-tech devices that will allow communication without the assistance of another individual. Teaching advocacy for the individual who uses the AAC device should be the responsibility of the entire evaluation/intervention team. Training should be shared with family members or caregivers.

Selecting Vocabulary for the Individual Using AAC

Vocabulary selection is imperative for the individual using the device. Without appropriate selection of terms, words, and labels, the individual will not utilize the system effectively. Vocabulary selection should focus on: frequently used words, culturally sensitive vocabulary that is used with significant others, commonly used names, phrases and needs, word prediction to make access faster; and personal data information, along with interests and experiences so that the individual may share personal information with others. Frequently used words would include those that are frequently found in the individual's environment and in the specific languages. These words are often pre-programmed in the device and are easily accessible through different menus, as well as in word-prediction keyboard access.

The vocabulary selection must be sensitive to cultural influences. A gesture may produce positive affect in one culture and an entirely different, perhaps negative message in another. There must also be sensitivity to language differences and environments. For example, a child may be Spanish dominant in the vocabulary utilized at home where no English is spoken, and may be English dominant regarding academic vocabulary spoken in the classroom setting. In order for a system to be utilized and effective, it must address concerns across cultures and environments. Personal information would include name, address, date of birth, physician's names, current medications, names of family members and friends, and other pertinent

information as desired by the individual. Most high-tech devices may also be programmed with jokes, personal stories, and even with speeches an individual may give during presentations. Along with their cultural style, personal information and language preferences, the individual's premorbid state must be taken into consideration when selecting vocabulary. The factors of educational status and experiences prior to the onset of the disease or accident are necessary in selecting items for the word bank. Based on the individual's language abilities, what parts of speech such as articles, conjunctions, and auxiliary verbs should be incorporated into the vocabulary, or would the individual benefit more from telegraphic speech such as isolated, simple nouns and verbs?

Using the AAC Device in the Classroom or Home and Community Settings

In order for a system to be effective in an academic setting, there must be consultation, education, and support for the classroom teacher, students, and the AAC user. Each setting must have the support and consultative opportunities for the system to work. In the home setting, the parents, siblings, and/or caretakers must be provided with training in how to utilize the system and must also be instructed in how to access additional information and resources. Training should be provided in functional settings. Acceptance of and use of an alternative method of communication is dependent upon all communication partners accepting and understanding the system. As stated previously, concerns by caregivers and parents that an augmentative communication system will deter the individual from using or developing speech are unfounded. The contrary is true. In fact, intervention approaches using AAC are found to facilitate natural speech. This information must be clearly stated and shared with all parties. It is important that the members of the AAC team who put a system in place continue to constantly monitor the user and communication partners for changes in the environment and the user's abilities and growth. Frequent modification and upkeep of equipment are also warranted.

Conclusion

Augmentative and alternative communication systems require in-depth assessment, taking many factors into consideration. The use of a selected system requires acceptance by all individuals working on the diagnostic and intervention teams, along with users, caregivers, and significant others. Careful support and maintenance of the AAC system should be ongoing to meet the changing needs of the individual and his/her environment.

A vowel-based communication chart is a low tech AAC system utilized with individuals who can spell and are able to communicate answers to yes/no questions with head nods or eye blinks. The system is used to spell out words by having the communication partner guess the letters. The communication partner will start determining each letter by asking for the appropriate vowel in a vertical line and then moving across, horizontally to select the consonants. Although this process is slow and methodical, it does provide an avenue when other methods of AAC are not available.

Community Integration and Employment of Youth with Special Needs

B A Ford and A W Daviso III, The University of Akron, Akron, OH, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Career/job exploration – The process of finding a rewarding career path, as well as specific jobs within a particular career path.

Community experiences – Educational activities provided outside of the school building or in a community setting.

Culturally and/or linguistically diverse (CLD) – For this article, this includes populations from African-American, Hispanic American, Asian American, and American Indian backgrounds.

Self-determination – The act or power of making up one's own mind about what to think or do, without outside influence or compulsion.

Significant Multicultural Community Resources (SMCR) – Not-for-profit systems of informal support such as service or social organizations, sororities, fraternities, clubs or agencies, religious groups or churches, and individuals who are local community residents perceive as providing valuable services.

Summary of performance (SOP) – An overview of academic achievement and functional performance, which includes recommendations on how to assist the child in meeting postsecondary goals.

Community Integration and Employment of Youth with Special Needs

Given the recent emphasis on accountability for quality educational services, the issue of community integration of students with special needs has become even more critical. Despite legal mandates, significant numbers of young adults with disabilities continue to exit high school ill-prepared to effectively integrate into their respective communities or engage in postsecondary activities that promote productive lives. The provision of community-based experience during the transition-planning process is deemed an important strategy to address this problem (Geenen *et al.*, 2001; Hughes, 2001; Johnson, 2004; Kim and Morningstar, 2005; Neubert and Moon, 2006). The present literature supports the relationship between community integration, employment, and community-based experiences for high school-level students with disabilities.

Yet, too often, the transition-planning process does not include participation in community-based experiences. Storms *et al.* (2000) defined community experiences as educational activities provided outside of the school building or in a community setting. Community-based work experiences, job exploration, banking, shopping, job-site training, transportation, and recreational activities are examples of community experiences. When, and if, school personnel include community experiences during the transition process, the involvement, generally, has centered on the formal, traditional, or official organizations and agencies, rather than informal systems of support. The limited networking with informal systems of support by school personnel is particularly evident when working with families from culturally and/or linguistically diverse (CLD) backgrounds.

Community-based experiences are beneficial for all adolescents and young adults with disabilities and their families. These are especially critical for those youth who are at higher risks for future unemployment or underemployment or enrolment in postsecondary programs. This group encompasses students who manifest moderate-to-severe disabilities. Due to multifaceted racial, cultural, socioeconomic, and political reasons, youth from CLD populations with disabilities at all levels (e.g., mild-severe) are also at great risk for poor postsecondary outcomes.

Literature critiquing the transition-planning research (Ford, 2002, 2004, 2006; Geenen *et al.*, 2001; Hughes, 2001; Kohler, 1994) delineates several barriers to the systemic provision of relevant community-based experiences and the utilization of informal systems of support during the transition-planning process for young adults with disabilities. Three dominant barriers are: (1) the inconsistent use of research-based practices as a framework to guide the transition-planning process, (2) the lack of a person-centered approach, and (3) the lack of attention to important cultural and/or linguistic diversity in families and youth. This article discusses the benefits of community integration and employment of youth with special needs.

Frameworks that Inform Transition Planning and Postsecondary Education

The majority of the literature on transition and postschool outcomes for students with disabilities has focused on

employment and postsecondary education because the primary, mainstream determinant of a high-quality life is a good education and a secure job with a salary that fosters independence. Recognizing the importance of a person-centered approach when addressing the unique needs of youth with disabilities, this mainstream perspective must not serve as the ultimate framework that guides decision making during the transition process. For many people with disabilities – particularly those with severe disabilities – issues of employment and community participation must be related to other aspects of adult life. The place of residence, access to transportation, a variety of recreational opportunities, a network of relationships, and necessary specialized supports and services are all connected to an adequate quality of life for adults with disabilities. In addition, scholars advocating on behalf of youth from CLD backgrounds with disabilities highlight the importance of attending to cultural differences in determining what constitutes successful outcomes of the transition-planning process.

Educators have debated, for some time, that preparation for independent living and community participation are significant functions of the educational process. In spite of this, educational interventions for community participation are commonly left out of the transition-planning process. Consequently, adults with disabilities and their families are left unprepared for the challenges they will confront following graduation from secondary education – when they are no longer eligible for a free appropriate public education (FAPE) (Baer and Daviso, 2006). Furthermore, transition planning has, traditionally, been designed and implemented from a monocultural perspective (Geenen, *et al.*, 2001; Kim and Morningstar, 2005). To this end, community experiences that may be particularly relevant to CLD youth and their families – such as interactions with significant informal systems of support – have not been included in the transition-planning process.

The patterns of regular paid employment for some young adults with disabilities have improved (National Center on Secondary Education and Transition, 2003). Overall, however, the literature continues to reveal poor outcomes. Unemployment, financial dependence, and the lack of social relationships are outcomes faced by many students with disabilities when they leave high school. Webb (2003) noted that unemployment rate among persons with disabilities remains a staggering 70%. With regard to race/ethnicity, The National Center on Secondary Education and Transition Study-2 (National Center on Secondary Education and Transition, 2003) reported that employment rates continue to be higher for white youth (62%) than for African American (42%) or Hispanic youth (36%). When employed, African American youth are more likely to earn lower wages than white youth. In addition, African American and Hispanic students with disabilities

have lower rates of enrollment in postsecondary education programs than white youth. Discrepancies in geographic location are also noted; data outcome for youth with disabilities in inner cities are not positive. They are less likely than their peers in suburban or rural areas to graduate from high school and are more likely to drop out of school.

The phenomenon of poor outcomes for adolescents with disabilities is reported in the international arena. Hughes' (2001) discussion of the challenges surrounding transition from an international perspective found similar rates of unemployment and disengagement from the community. Until serious attention is given to the examination of the multidimensional factors influencing a quality transition-planning process for young adults with disabilities – including those from CLD backgrounds – their future lives will remain compromised and limited. Community-based participation by youth (and their families) in formal and informal systems of support should be deemed important strategies during the transition-planning process. During this process, school personnel, often, advocate for and support families receiving assistance from formal systems of support (e.g., medical and mental agencies and social services). However, generally, school personnel are not aware of – or choose not to utilize – meaningful informal systems of support operating within communities of CLD youth. The present student demographic changes necessitate serious attention to cultural aspects of the educational delivery process, including transition planning. Over one-third of the students in US public schools are from CLD backgrounds; and the three fastest-growing groups are Hispanic Americans, African Americans, and Southeast Asian Americans.

The expectation of community participation – including employment – anticipated by an individual with or without disabilities can vary greatly. Social integration is a complex process including a person's cultural background, family expectations, socioeconomic status, and individual expectations. According to Partington (2005), a "participatory approach" suggests that people with disabilities and their families become involved in "naturally occurring networks within their own communities." Earlier, Garcia (1991) remarked that public schools are a community affair – made up of children who tend to reflect their human communities. The school's community consists of varied social groups that interact with each other, developing cooperative and interdependent networks of relationships. In Ford's (2004, 2006) discussion of quality school–community partnerships within culturally diverse communities, she used the term, Significant Multicultural Community Resources (SMCR), to describe these potential systems of support for youth and families. According to Ford, they include not-for-profit service or social organizations, sororities, fraternities, clubs or agencies, religious groups or churches, and individuals who local community residents perceive as

providing valuable significant services. The following list some benefits derived from the SMCR:

- Increased parental involvement.
- Avenues for sensitivity toward culturally relevant transition programming through face-to-face encounters between administrators, teachers, and CLD families and community resource persons (e.g., informal systems of supports).
- Resilience-enhancing resources through accessible adult role models, mentors, and advocates.
- Exposure to a network of community-based job opportunities and job-related skills and experiences.
- Reinforcement of school-related academic, life, and social skills.
- Exposure to self-enhancing/affirming activities (e.g., development of values and cultural group identity; positive decision-making skills; goal setting; rites of passage).
- Forum for dissemination and collection of information.

Legal Mandates for Community Integration and Employment

Students with disabilities receiving specialized services for employment and community participation in secondary education are served under the Individuals with Disabilities Education Act (IDEA), passed in 1990 and 1997 and, later, passed as the Individuals with Disabilities Education Improvement Act (IDEIA) of 2004. This later law defined the term transition services as a coordinated set of activities for a child with a disability that is designed to be within a results-oriented process, and is focused on improving the academic and functional achievement of the child with a disability in order to facilitate the child's movement from school to postschool activities (including postsecondary education, vocational education, integrated and supported employment, continuing adult education, adult services, independent living, and community participation). This law focuses on the individual child's needs, taking into account the child's strengths, preferences, and interests and includes instruction, related services, community experiences, the development of employment, and other post-school adult living objectives. Under section 606, IDEIA is written to ensure that professionals serving students with disabilities make positive efforts to employ and advance employment for qualified individuals with disabilities in programs.

Storms *et al.* (2000) argued that community experiences are educational activities provided outside of the school building or in a community setting. Community-based work experiences, job exploration, banking, shopping, job-site training, transportation, and recreation activities are examples of community experiences. They,

further, noted that employment services are supposed to assist in the preparation of an individual for participation in a future career or job placement. Therefore, for individuals with disabilities to reach their desired level of community integration and employment, they will need to attain the critical skills needed for success. The skills required for integrated community participation and employment overlap considerably with communication skills, self-determination skills, independent living skills, and recreational skills (Sitlington and Clark, 2006). These skills should be addressed as needed through the students individualized education plan (IEP). In the United States' public school system, planning for community participation and employment primarily occurs in the transition section of the IEP. At age 16, a transition plan is required for students served under the law. The IEP transition team is required to collect data from many sources. Assessments, community and classroom observations, nondiscriminatory formal and informal testing, medical evaluation, and family history may be used to create transitional goals and determine eligibility for adult services upon school exit. Clearly, this information may be used to generate the student's summary of performance (SOP) – which is required under the IDEIA, which states that “for a child whose eligibility under special education terminates due to graduation with a regular diploma, or due to exceeding the age of eligibility, the local education agency shall provide the child with a summary of the child's academic achievement and functional performance, which shall include recommendations on how to assist the child in meeting the child's postsecondary goals.” The transition plan and SOP should be designed to bridge the gap between secondary education and adult life.

The Search for Promising Practices for Successful Community Integration

Secondary education professionals have become increasingly concerned with the employment and educational outcomes that students experience after leaving high school. Employment status is just one valued adult role, but it is a critical indicator of adult success in the United States (Eisenman, 2003). The skills needed by workers to compete in today's workforce are complex and continually changing (Harvey, 2002). Complicating matters further, many adolescents and young adults with disabilities not only have limited knowledge of the career decision-making process, but also lack awareness of career options, and the adequate skills for employment (Hitchings *et al.*, 2001). There are a number of empirical and nonempirical intervention strategies that are labeled as best or promising practices in the provision of transition services because they help to facilitate successful movements of youth with disabilities from school to adult life (Greene and Kochar-Byrant, 2003).

Earlier, Kohler (1993) found that only four of the 11 key components of transition services that are considered to be best practices were supported by empirical data. She added that research-based recommended practices, such as community-based instruction, parent involvement, vocational training, paid work, and social skills training, have been found to be inconsistently implemented in secondary transition programs.

Lehman *et al.* (2002) identified a set of generally agreed-upon skills that society expects youth to achieve by the time they leave school. Among these are the ability to (1) live independently, (2) determine an initial career path, (3) find and maintain meaningful employment and/or postsecondary education, (4) establish fulfilling relationships with family and friends, and (5) choose leisure activities that enhance a rewarding adult life. Although these skills have been identified, most youth with disabilities still do not have the ability to make choices without additional influence from stakeholders in the educational process. Later, Baer *et al.* (unpublished) noted the lack of consensus concerning the purpose of education, and the unclear definition of transition services. They identified common themes and concepts recognized as promising practices by policymakers, advocates, and researchers in transition. These concepts include self-determination (social skills training), ecological approaches (use of formal and informal supports), individualized backward planning, service coordination (interagency collaboration), community experiences (paid work experience), access and accommodation technologies (assistive technology), supports for postsecondary education, systems-change strategies (vocational career education, secondary curricular reform, and inclusion), and family involvement in the transition process. Apparently, many factors contribute to postschool success for students with disabilities (Eisenman, 2003). The reality is that secondary education should avoid a constricted academic focus and focus on a comprehensive curriculum of academic study, vocational experiences, and life skills in order to improve the rate of high school graduation and the transition to postsecondary education and employment.

Conclusion

One lives in a rapidly changing, multicultural, highly technological society. Youth – including those with disabilities – must be provided with educational services that prepare them to function within their immediate community and/or the community at-large. At present, an unacceptable number of these youth remain at risk for poor postsecondary outcomes. The current emphasis on educational accountability demands that we address the barriers that both define and limit their successful transitioning from high school into contributing citizenry.

The transition-planning process serves as the educational technique to help ensure that young adolescents with disabilities – upon completing high school – are prepared to integrate into their respective communities (and families) or engage in postsecondary activities that promote productive lives. This article emphasizes the provision of meaningful, community-based experiences as a best practice during transition planning. Schools networking with and utilizing informal systems of support via significant multicultural resources is offered as a best-viable practice strategy when working with all students, including CLD youth and their families.

Glossary

Cooperative learning – A method where students are paired or grouped and work together to accomplish shared goals.

Cue – A prompt provide by the teacher to initiate a response from students.

Differential instruction – Teaching and assessing students according to readiness level, interests, and preferred mode of learning.

Inclusion – A process in which students with disabilities are educated with their same-age peers who are not disabled.

Reinforcement – An event following behavior that increases the likelihood of reoccurrence of that behavior.

Social interdependence theory – Premise that states that individuals in a group will work together to meet the group goal.

Socialization – A Process of inheriting or learning norms, customs; and ideologies to participate in society.

Cooperative Learning for Students with Special Needs

Cooperative learning is a concept that grew out of the field of social psychology. Because of its unique characteristics and effectiveness, it is commonly adopted as a teaching strategy in special education whereby students engage in collaboratively designed activities to achieve a common goal or task. Various theories have been associated with cooperative learning; and they have framed the context in which cooperative learning serves as an intragroup learning method that is outcome oriented. For instance, social interdependence theory has contributed to the development of cooperative learning theory. Kurt Levin – in the mid-1930s – was one of the first to introduce the concept of group dynamics and to show how each individual in the group contributes to a common goal, thus becoming a dynamic whole. This theory was fully conceptualized by Morton Deutsch, in 1949. He is recognized as the theorist

who fully conceptualized social interdependence theory and provided the fundamental concepts for cooperative learning. The primary principle supporting the theory is the notion that “humans are primarily concerned with developing organized and meaningful views of their world by perceiving events as integrated wholes rather than a summation of parts or properties” (Johnson and Johnson, 1989: 287). As a result, individuals within a group rely upon each other to achieve common goals. Deutsch penned two types of social interdependence: positive interdependence and negative interdependence. He referred to positive interdependence as the phenomena when individuals believe they can only achieve goals when there is an interactive group working toward a common goal. Negative interdependence exists when individuals believe they can accomplish goals only when their competitors fail to obtain their goals.

The cooperative learning strategy as used in education, generally – and, specifically, in special education – relies heavily upon the concept of positive interdependence. When operationalized, the social interdependence theory translates into a viable instructional method that requires the participation of several group members. The social identification theory is another theory that informs the cooperative learning-teaching strategy. This theory suggests that members of the group experience a collaborative awareness. Lau (1989) reported that group identification is essential to the social interdependence and social identification theories. During collaborative awareness, each member is aware of the group dynamics and responds as a contributor. To implement cooperative learning groups, group and social identifications are necessary. In group identification, individuals have a working relationship with each member in the group and there is a collective awareness of collective group membership; whereas, in social identification, individuals perceive themselves as being a part of a social group. Two key concepts come into play when considering cooperative learning: (1) task interdependence, and (2) outcome interdependence. Task interdependence implies that individuals collectively share the task, and all experience a mutual benefit. In order to complete the task, cooperation and input from several individuals are critical. Outcome interdependence – which is defined as “the degree to which the significant outcomes an individual receives depend on the performance of others” (Wagerman, 1995: 147) – encompasses the results achieved from efforts

contributed by each of the group members. In theory, there are a variety of dynamics during group interaction. When cooperative groups are convened, there is a specific job that needs to be done, and the function of that job requires the participation of a group wherein each member is assigned a specific task (Johnson and Johnson, 1989). In this article, the focus is on how cooperative learning can be utilized to help students with special needs.

Cooperative Learning: Definition, Types, and Fundamental Principles

Students work together to accomplish shared goals (Johnson and Johnson, 1989). Cooperative learning for students with special needs is, typically, a method to reinforce or supplement teacher instruction (Mercer and Mercer, 2005). In this age of inclusion, many general educators or co-teachers (i.e., general educators and special educators) can utilize this method to effectively instruct whole groups followed by individualization to reinforce skills. Generally, cooperative learning can be considered either formal or informal based upon the structure. Formal structures include a sequence of events, led by the teacher, which includes the following: (1) introduce a task or lesson; (2) assign students to groups based upon a pre-determination of members; (3) provide students with materials, resources, and clarity to complete tasks; (4) assign roles to group members; and (5) teach prerequisite skills. Based upon the task or roles, students then work as a group until the task is completed. It is important to note that the teacher is continuously monitoring and evaluating the progress of the groups. Once the task is completed, all group members – along with the teacher – process or reflect upon the strengths/weaknesses of group members. As opposed to formal structures that may take a measure of time to complete – thus strengthening the group dynamics – informal structures are generally shorter in scope, lasting only perhaps a class period/lecture. In this structure, a temporary group is formed for a short period of time to, perhaps, review lecture material (Johnson and Johnson, 1989). Whether formal or informal, cooperative learning has been represented in many different forms, types, and names, thus making an exhaustive list difficult. See **Table 1** for the most common types, characteristics, or uses of those types, and subtypes or common names of cooperative learning.

It is necessary to understand the five elements at the core of cooperative learning, irrespective of the type. The five elements include the following: positive goal interdependence, individual accountability, face-to-face promotive interaction, appropriate use of social skills, and group processing (Putnam *et al.*, 1996). The following sections discuss each element of cooperative learning:

Table 1 Types and characteristics of cooperative learning

Type	Characteristics/uses	Subtypes/common names
Tutoring	One-on-one student interaction with one serving as tutor and one as tutee Can be matched based on various criteria	Peer Cross-age Structured Team interviews
Class-wide peer tutoring (CWPT)	Classroom separated into dyads in which one-on-one tutoring takes place to reinforce teacher-led lesson	Peer-assistance learning strategies (PALS) Question answer relationships (QAR)
Class-wide peer tutoring (CWPT) with curriculum-based measurement (CBM)	Groups work on material that is geared toward individual needs	Class-wide student tutoring teams (CSTT)
Cooperative learning structures Student team learning model	Students assigned to heterogeneous groups/teams and given an assignment Teams divide tasks, approach task and are evaluated as whole group Group materials may be identical or individualized toward group members' abilities	Jigsaw Learning together Student-teams-achievement-divisions Teams-games-tournaments (TGT) Team-assisted individualization (TAI) – Mathematics, grades 3–6 Cooperative integrated reading and composition (CIRC) – Reading, writing, and language arts, grades 3–5 Academic controversy Group investigation

Element 1: Positive Goal Interdependence

This element follows the assumption that all individuals involved in a task recognize that, in order to succeed, all members must succeed. The failure of any one member leads to the failure of the group – thus, the term, interdependence. All students, including students with disabilities in cooperative groups must maximize their own productivity in order to maximize the productivity of the collaborative group (Johnson and Johnson, 1989).

For example, if teams are assigned to play a review game that consists of both students with special needs and those without, each student must play the game to his/her full potential or the team will not win the game.

Element 2: Individual Accountability

In addition to the interdependence among cooperative group members, there must also be individual accountability for performance. While all group members must work together toward the goal, each member (or student) is also accountable for his/her own contribution or lack thereof. Recognition of individual achievement is paramount. In the cooperative group, one is responsible for doing his/her best work, thus motivating other group members to do their best work. In the above example, the element would be recognized when each team member's role in the game is clear and success in that role is reinforced.

Element 3: Face-to-Face Promotive Interaction

Within the cooperative group task, each member must promote other team members. This element can take the form of encouragement, constructive feedback, and trust. In the above example, team members would cheer each other on – helping them to answer game questions when the need arises.

Element 4: Appropriate Use of Social Skills

Students with special needs, often, lack the appropriate social skill set to interact in cooperative learning arrangements (Mercer and Mercer, 2005). For this element to be recognized, all students must be taught the rules of socialization prior to placement in a cooperative learning group. In the above example, all students would learn the rules of the game and the appropriate reactions (verbal and nonverbal) to winning or losing the game, communicating, and turn-taking prior to team formation.

Element 5: Group Processing

During and following a cooperative learning task, all group members must reflect on and identify those actions and decisions that were effective or ineffective in a constructive manner. The purpose of this group processing is to continually improve the team; it is an ongoing process. In the above example – once the review game has ended – both the winning and losing teams would identify ways in which team members' efforts could be improved (e.g., studying, taking turns, encouraging players).

Using Cooperative Learning for Students with Special Needs

There has been an abundance of research conducted on cooperative learning as a best practice for students with special needs. In an era of evidence-based practice to meet federal mandates and differentiated instruction to meet the needs of a variety of abilities, many researchers and practitioners have identified methods based on the ease of use and on student gains. The majority of the research on cooperative learning centers on academic achievement and social impact.

The majority of research on cooperative learning has focused on its impact on the academic achievement of students with special needs. Researchers have conducted studies both at the elementary and secondary levels – with a focus on mild-to-severe disabilities, in a variety of content areas (although most focus on the elementary grades), and with regard to both those who have the disability and those who do not. Most types of cooperative learning arrangements have been studied. Interestingly, the results have been mixed; however, the predominant view is that cooperative learning as a best practice is effective since an increase in achievement is noted (even if there is no statistical significance). For example, Johnson *et al.* (2000) conducted a meta-analysis of 194 studies that involved impact of cooperative learning on academic achievement. The analysis summarized that all cooperative learning arrangements increased academic achievement to varying degrees. Further, the studies were coded as to the following: ease of learning, ease of initial use, ease of maintaining use over time, robustness, and adaptability, and the meta-analysis yielded a ranking of the most commonly used types. In a similar yet earlier meta-analysis of 65 studies, Cohen *et al.* (1982), examined – among other factors – academic performance on both tutors and tutees. Forty-five of 52 studies indicated that tutees had increased exam scores, six studies indicated decreased exam scores, and there was no difference in score in one study. Further, of the 65 studies, 33 indicated an increase in achievement for tutors; however, only ten were considered statistically significant. Perhaps, more interesting for practitioners were the following indirect findings that suggested that the most academic achievement was found under the following conditions: when the tutoring was more structured and shorter, when lower level skills were taught, with math achievement as the dependent variable, and on locally developed tests as opposed to standardized assessment.

Clearly, there are still many holes to be filled in the research on cooperative learning. When examining middle school science, Mastropieri *et al.* (2006) found increases in spelling, science, and social studies scores. Several trends and apparent limitations have emerged from the research on cooperative learning and academics. The first is that,

irrespective of method, all students must be taught the process. In other words, structure in planning and implementation are a must for success in academics. A second recommendation is that there must be frequent feedback, consistent expectations, cues, and reinforcement along with ongoing assessment. In many research studies, cooperative learning has been known to impact attitudes toward subject matter. Earlier, Cohen *et al.* (1982) found eight studies related to this, in which all eight reported an increase in positive attitudes toward the subject by those who were tutored; however, only one of those studies reported results that were statistically significant. Additionally, of five studies that reported on the effect of cooperative learning on the attitudes of the tutors, four reported more positive attitudes. Interestingly, one student in the control group also reported more positive attitudes toward the subject matter. Finally – in many other research studies – cooperative learning has been found to impact social adjustment including factors such as self-esteem, acceptance (by both students with and without disabilities), and social skills. As with the other two areas of research, there has been much variability in findings, and the same limitations apply. In the Cohen *et al.* meta-analysis, nine studies were found in which self-concept was studied, and none found statistical significance in relation to the tutees; however, four of 16 indicated statistical significant findings in relation to the tutors and self-esteem. The authors suggested that perhaps self-esteem could have been attributed to a variety of classroom variables and not necessarily the method.

Conclusion

Cooperative learning has proven to be an effective teaching and learning tool for students with special educational needs. The different types and uses of cooperative learning enable the teacher to select learning strategies based upon students' needs and styles of learning and the heterogeneous nature of the learning task. Clearly, task interdependence and outcome interdependence are critical to the success of cooperative learning groups, goals, and objectives. For those who would prefer a more comprehensive view of cooperative learning and children with special needs, please see the additional resources listed in the sections titled 'Bibliography' and 'Further reading.'

Co-Teaching

E D Cramer, Florida International University, Miami, FL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Co-teaching – When two or more professionals share instruction for a single group of students in the same class, it is known as co-teaching.

Parity – It refers to perceived equality.

Federal legislative changes, such as those described by the Individuals with Disabilities Education Improvement Act (IDEIA) reauthorized in 2004 (Pub. L. No. 108-466) and the No Child Left Behind (NCLB) Act of 2001 (Pub. L. No. 107-110), require that students with increasingly diverse learning characteristics have access to and achieve high academic performance in the general education curriculum. To illustrate the recent increase in student diversity, data from the US Department of Education (2005) indicated that between 1994 and 2004, the percentage of students with disabilities spending 80% or more of the school day in a regular classroom increased by nearly 49.9–50% in 2004. These proportions can be expected to increase given the national trends of the past three decades and IDEIA's requirement to include students with disabilities as full participants in rigorous academic and general education curriculum and assessment. This leads to a need for increased collaborative planning and teaching among school personnel attempting to comply with legal mandates. One increasingly popular vehicle to provide this service is co-teaching (Morocco and Aguilar, 2002; Murawski and Dieker, 2004; Villa *et al.*, 2004).

Many different definitions exist to describe co-teaching. A co-teaching team can be defined as two or more people sharing responsibility for teaching some or all of the students assigned to a classroom. It involves the distribution of responsibility among people for planning, instruction, and evaluation for a classroom of students (Villa *et al.*, 2008). Both educators on the co-teaching team are responsible for instructional planning and delivery, assessment of student achievement, and classroom management. Friend and Cook (2007) expanded this definition stating, “co-teaching occurs when two or more professionals jointly deliver substantive instruction to a diverse, blended group of students in a single, physical space” (p. 113). In their definition of co-teaching, they noted the importance of both parties being appropriately credentialed professionals. Salend (2008) referred to

cooperative or collaborative teaching as teachers who share responsibility and accountability for planning and delivering instruction, evaluating, grading, and disciplining students. The common theme among all of these definitions is that students are not removed from class to receive services but rather the services (i.e., academic instruction and supportive services) are provided in the general education classroom by two or more professionals who share responsibility for the students. This article focuses on this premise.

Rationale for and Elements of Co-Teaching Teams

Friend and Cook (2007) noted two rationales for co-teaching: to meet the educational needs of students with diverse learning abilities and to provide curricular access to students with disabilities. Co-teaching allows general and special education professionals to pool together their expertise. Most often, general education teachers have more in-depth knowledge about specific subject areas, whereas the special education teachers generally know more about differentiating instruction to meet the individual needs of students. This combined expertise provides both general and special education students with content knowledge taught effectively through group and individualized strategies. Although co-teaching professionals may not simply be general and special educators, (e.g., speech and language pathologists, occupational therapists, and literacy coaches), the fact that they are equal in credentialing and status ensures that they can, in fact, be partners in the classroom. In cases where a teacher and paraprofessional or classroom-volunteer work together to instruct students, supported instruction rather than co-teaching is occurring. While supported instruction can be a valid approach for instruction, it should not be confused with co-teaching. Similarly, when professionals are co-teaching, as both have equal and shared status, both should have equal and shared responsibility for instruction. It is a waste of resources to utilize a second licensed and trained professional in the room simply to have that person utilized as an assistant. Friend and Cook (2007) referred to situations such as this as “an inappropriate underuse of a qualified professional” (p. 115). In addition, when special education or related services personnel focus only on the student(s) with disabilities, more attention, stigma, or isolation of that student may occur therefore undoing some of

the possible social benefits of having the student included in a co-teaching situation in the first place. Under IDEIA 1997, any professional in the classroom can and should be working with all students, not simply those with disabilities.

Co-teaching is designed to minimize problems that typically occur with pull-out special education programs such as students missing academic instruction, lack of communication and coordination between professionals, scheduling problems, and fragmentation between general and special education curriculum (Wiggins and Damore, 2006). Co-teaching also potentially reduces the need for labeling students because all struggling students can benefit from the expertise of both teachers (Cramer *et al.*, under review; Wiggins and Damore, 2006). Villa *et al.* (2008) named five elements of co-teaching teams: (1) a common, publicly agreed-on goal, (2) a shared belief system, (3) parity, (4) distributed functions theory of leadership, and (5) cooperative process. A common goal may be for one particular outcome that teachers and service providers share for their students. A shared belief in the value of co-teaching is beneficial to the process. Parity refers to the perceived equality between true collaborators on a co-teaching team. In distributed leadership, both teachers make a conscious decision to share the leadership of and responsibility for the class. According to Villa *et al.*, the cooperative process finally is made up of (1) face-to-face interactions, (2) positive interdependence, (3) interpersonal skills, (4) monitoring co-teacher progress, and (5) individual accountability. Each of these elements can take place regardless of the model of co-teaching being utilized.

Friend and Cook (2007) described six approaches to co-teaching: (1) one-teaching-one-observe, (2) one teach-one-assist, (3) station teaching, (4) parallel teaching, (5) alternative teaching, and (6) team teaching. In the first and second approach, one teacher has the primary role of designing and delivering instruction while the other teacher moves around the room helping and observing individual students. In station teaching, the content of the lesson is divided between the teachers and every student moves to both teacher-led groups. Parallel teaching occurs when the class is divided and each teacher delivers the same content and instruction to his or her section of the class. Alternative teaching is employed when the special education teacher focuses on re-teaching, differentiating instruction, and making curricular accommodations and modifications for small groups of students with and without disabilities who may need extra assistance. This model can be flexible and permits any student who may need some additional help to receive additional instruction. Team teaching is used when teachers trade off roles and groups of students. For example, one teacher presents on an overhead the major events leading to the Civil War while the other teacher lists these events on a timeline on the whiteboard. In each of these models, even when

teachers are not both physically instructing students at all times, both should always be sharing the responsibility for planning and instructional decision making.

Benefits of Co-Teaching to Students and Teachers

Villa *et al.* (2008) listed some beneficial outcomes of co-teaching. They noted that:

- students develop better attitudes about themselves, show academic improvement, and enhanced social skills;
- teacher-to-student ratio is increased, leading to better teaching and learning conditions;
- teachers are able to use research-proven teaching strategies effectively;
- a greater sense of community is fostered in the classroom;
- co-teachers report professional growth, personal support, and enhanced motivation; and
- increased job satisfaction can be experienced because needs for survival, power, freedom of choice, a sense of belonging, and fun are met.

While co-teaching is an initiative that developed out of special education laws and with the needs of students with disabilities in mind, in co-teaching classrooms, all students have the benefit of two qualified professionals using a variety of teaching strategies to meet the needs of all learners. This can be particularly beneficial for students with special learning needs who may not have been identified as having a disability. This can include English language learners (ELLs), students who are socially or culturally diverse, gifted students, students at-risk for failure, or students with potential need for special education who simply have not yet been referred. Students of all abilities and levels should be integrated together in instruction. Classroom placement should not isolate 'these' students from 'those' students. If special education students are seated apart from the rest of the class, they are still, in a sense, socially isolated from their peers.

In addition, while at times, students will need to receive small homogenous group instruction, in inclusive classrooms, co-teachers should work with heterogeneous groups and allow students the opportunity to work cooperatively and learn from each other. Students who in the past would have been pulled out of the classroom can remain in one setting with their peers all day allowing them to have more smooth, uninterrupted instruction, and full access to general education curriculum. Co-teaching could be one way to increase special education students' time in and access to general education and to decrease reliance on special education placement to solve learning and behavior problems of culturally and linguistically

diverse students (e.g., Bahamonde and Friend, 1999; Cramer *et al.*, under review; Garrigan and Thousand, 2005; Salazar and Nevin, 2005).

Partnerships between highly qualified general educators who have demonstrated subject-area expertise and highly qualified special educators who have complementary expertise in specialized learning strategies could result in implementing the research-based curricular and instructional approaches required by the NCLB Act. All students need their teachers to learn and use the most effective teaching strategies, educational materials, and lesson formats currently known to educate all students. Teachers can accomplish this by exchanging such information and expertise through their co-teaching partnerships. Typically, the general educator is an expert of content and the special educator is an expert on adapting instruction. Each can learn and benefit from the expertise of the other. If other trained professionals are involved (such as a speech and language pathologist or a literacy coach), they bring even more specialized skills to the class. In addition, they have the emotional support of another colleague that they collaborate with on a daily basis and a partner to collaborate with on classroom decisions.

Meeting the Needs of Co-Teachers

While the majority of co-teachers see co-teaching as a beneficial experience, they are consistent and clear about what needs to be in place for co-teaching to work: planning time, compatibility of co-teachers, training, appropriate student skill levels, and ongoing administrative support (Cramer and Nevin, 2006; Cramer *et al.*, 2006; Scruggs *et al.*, 2007). Time is needed for planning, meetings, and professional development. Regularly scheduled meeting times should be built into the schedule for teachers to instruct students, plan, and reflect on what has occurred. The ideal would be reserved time each day through common planning time. In addition, teachers would like to have input on whether or not they co-teach and who their partner is. Co-teaching is often compared to a marriage and if the partners are not compatible with each other, the relationship will inevitably fail.

Most future teachers graduating from preservice teacher education programs today have little to no training in co-teaching; yet they are often expected to work at least part of the day in co-teaching teams. When asked, teachers consistently point out the need for more training. Another need that teachers often refer to is for students who are being included in co-taught classrooms to have appropriate skill levels to access the required curriculum. For example, teachers express frustration if students are expected to achieve the same state grade level standards and are functioning below grade level. Despite concerns over any of the aforementioned teacher needs, the perception of administrative

support (or lack thereof) can be the ultimate factor in determining whether or not teachers feel co-teaching is working. Administrators and school leaders need to believe in co-teaching as well as provide financial support. It is easy for a co-teaching class to become a special class (that is, where a disproportionate number of students in the class have special needs). When the administrator really understands what co-teaching is and buys into the concept, benefits occur for both special education and general education children (Cramer *et al.*, 2006).

There are many barriers to co-teaching. Some of the most common include (1) limited financial resources, (2) complicated logistics of assigning caseloads to service all students, (3) class size and ratios, and (4) maintaining a positive and collaborative relationship between professionals. Additional problems often arising at the secondary level (Salend, 2008) include (1) lack of time to plan and resources, (2) unclear roles of teaching team members, (3) resistance from colleagues, (4) scheduling, (5) increased workloads, and (6) increased responsibilities (Cook and Downing, 2005; Murawski, 2006). Lack of content-area expertise is also more prevalent at secondary level (Cramer and Nevin, 2006). To counteract co-teaching barriers, Salend recommended that co-teachers do the following:

- agree on goals and establish ground rules;
- learn about each other's beliefs and teaching styles;
- understand and coordinate responsibilities, expertise, and roles of others;
- utilize a variety of scheduling arrangements;
- understand cross-cultural perspectives;
- physically arrange the classroom to support collaboration;
- hold common expectations for grading academic, behavioral, and social performance;
- develop communication, problem-solving, and team-building skills;
- understand co-teaching is an ongoing process with stages;
- work toward equal status and shared workload;
- vary arrangements of teaching based on purpose, content, and student needs;
- include families in the process;
- communicate regularly to reexamine goals;
- address conflicts immediately;
- use a range of strategies;
- engage in self-evaluation and reflection; and
- acknowledge and celebrate success.

Co-Teaching and National Teacher Standards: Meeting Goals

Teacher education standards reflect the set of knowledge and skills of co-teaching. Standards from National Board for Professional Teacher Standards (NBPTS) (2005), the

Table 1 Analysis of standards from professional organizations

INTASC ^a	CEC ^b	NBPST ^c
Standard 3 requires teachers to understand how learners differ	Knowledge and skills in understanding characteristics of learners with different cognitive, physical, cultural, social and emotional needs	Teachers adjust their practice according to individual differences in their students
Standard 4 requires teachers to use a variety of instructional strategies	Competencies related to knowledge and skills for instructional content and practice	Teachers show multiple methods to engage student learning and to enable students to reach goals
Standard 10 asks teachers to collaborate and communicate with parents, families, colleagues to support student learning	Competencies related to communication and collaborative partnerships	Teachers collaboratively work with others and coordinate services

^c<http://www.ets.org/nbpts>

Council for Exceptional Children (CEC) (2005), and Interstate New Teacher Assessment and Support Consortium (INTASC) (2005) were analyzed for content with respect to inclusive education and collaboration or co-teaching. As shown in **Table 1**, there seems to be substantial agreement among these diverse boards with respect to knowledge and skills for differentiating instruction, working collaboratively with others, and supporting the education of diverse learners. For example, INTASC Standard 3 requires teachers to understand how learners differ; Standard 4 requires teachers to use a variety of instructional strategies; and Standard 10 asks teachers to collaborate and communicate with parents, families, and colleagues to support student learning.

In comparison, CEC standards for entry into the profession includes competencies related to knowledge and skills in understanding characteristics of learners with different cognitive, physical, cultural, social, and emotional needs; competencies related to knowledge and skills for instructional content and practice; and competencies related to communication and collaborative partnerships. These are strongly correlated with NBPTS Standard 1 – teachers adjust their practice according to individual differences in their students; Standard 3 – teachers show multiple methods to engage student learning and to enable students to reach goals; and Standard 5 – teachers collaboratively work with others and coordinate services. In the results of a study of the relationship between teaching standards and co-teaching (Cramer *et al.*, under review), co-teacher attitudes, beliefs, and actions appear to be correlated with the standards shown in **Table 1**. Since co-teaching clearly aligns with recognized professional standards in the field, teacher training at both the pre-service and in-service levels should focus on preparing professionals to work collaboratively toward the common goal of meeting the needs of all learners. This will address the needs of increasingly diverse learners, the legal requirements of access to the general education for all students,

and the practical need for all teachers to feel well-prepared and supported in their efforts to do so.

Conclusion

Co-teaching is a widely researched method of instruction whereby two trained professionals work collaboratively to plan, implement, and evaluate instruction for students with and without disabilities. Any necessary services for students with disabilities are provided inside the general education classroom and the general education curriculum is made accessible for all students with appropriate accommodations. While there are many accepted models for co-teaching, all involve the sharing of the responsibility for planning and instructional decision making.

Overall, teachers and administrators perceive co-teaching to be beneficial for teachers and for students, both with and without disabilities. However, sufficient planning time, compatibility of co-teachers, training, appropriate student skill level, and ongoing administrative support are necessary. While research has consistently been able to provide information about what occurs in co-taught classrooms and perceptions of key stakeholders, ongoing research is still necessary regarding the true implementation of co-teaching and its efficacy as a service for students.

Glossary

Awareness competency – Constant examination of one's own attitudes, biases, and assumptions that may interfere with the ability to work effectively with culturally and linguistically diverse exceptional learners.

Cultural competency – A set of congruent attitudes, practices, policies, and structures that are integrated to enable professionals to work more effectively with culturally, class, and linguistically diverse exceptional learners.

Cultural reciprocity – Exchange of knowledge, values, and perspectives between two or more individuals of different backgrounds.

Culturally responsive – Using the cultural knowledge, prior experiences, and performance styles of diverse students to make learning more appropriate and effective for them.

Disproportionality – The over- or under-representation of a given population group, often defined by racial and ethnic backgrounds, but also defined by socioeconomic status, national origin, English proficiency, gender, and sexual orientation, in a specific population category.

Knowledge competency – The acquisition of factual information about people from culturally distinct groups.

NCLB – The No Child Left Behind Act of 2001 is a national law that aims to improve the standards of primary and secondary schools by increasing the accountability for schools, and the flexibility in parent's choice as to which schools their children will attend.

Skill competency – Synthesis of awareness and knowledge competencies with the aim of developing culturally relevant strategies that promote teaching effectiveness and enhanced outcomes.

Worldview – This is a consistent (to a varying degree) and integral sense of existence and provides a framework for generating, sustaining, and applying knowledge.

A substantial body of evidence documents the overrepresentation in special education of students from certain minority groups. This iniquitous arrangement was documented as early as the 1920s by a small group of researchers and scholars of that era. It has been recently reconfirmed by the 2002 National Research Council Report (Donovan and Cross). It is important to note that this overrepresentation phenomenon exists primarily in classes for students with emotional/behavioral problems and those with mild mental disabilities, both disability categories that rely on subjective judgments and which are considered soft disability categories. Although this problem has been a historical one for many Latinos, Native American students, and certain Asian American groups, today African Americans, especially males, continue to be the most disproportionately represented group in the disability categories previously cited. This phenomenon is manifested in the early grades and is particularly virulent from the third grade through middle schools. Further, the growing achievement and behavioral gaps for many ethnic minority learners, those from low socio-economic environments and English language learners, provide a compelling reason for restructuring and transforming the traditional curricula and pedagogy used to educate and prepare teachers, administrators, and related service professionals in ways that respond to the cultural, class, and language needs of these learners. As such, this article provides an overview, rationale, essential conceptual designs, and necessary elements of an evidence-based cultural competency training model for special educators.

Education in general and special education in particular cannot be separated from its relationship to the cultural, class, language, and cross-cultural dynamics that shape the context of society in general and public education in particular. Today, all Americans live and work in a society that is becoming increasingly multicultural and pluralistic. Given these explosive demographic changes among students and their families and the increasing cultural, ethnic, and class homogeneity of today's teaching, and the administrative, and related professional workforce, the potential for the creation of significant cultural, class, and language disconnections among students, their families, their teachers, and curriculum and instruction are inevitable. In fact, while African Americans and, in certain environments, Hispanics, Native and Americans

and some Asian American groups (e.g., Vietnamese and Hmong) are generally overrepresented in certain special education classrooms, they are, at the same time, severely underrepresented in the special education teaching, administration, and related service professionals. Given the fact that education and schooling cut across cultural, class, and linguistic borders, these differences represent critical challenges in the current No Child Left Behind Act (NCLB) school reform movement. As a consequence, those who educate special education teachers, administrators, and related service professionals are called upon to prepare these individuals to learn how to accommodate and respond to the emerging demands of an increasingly culturally, linguistically, and socio-economically diverse, exceptional student population. One has to wonder, however, where the source of the training to deal with this avalanche of cultural diversity will come from, given the fact that only a handful of these preparation programs provide training in cultural responsiveness, much less cultural competence. Additionally, the changing teacher and student demographics and the disproportionate representation of African American, Latino/Hispanic, and Native American populations in classrooms for students with mild mental, emotional, or behavioral disabilities have created several ethical challenges. The extent to which America achieves the ethical, educational, and cultural conditions for effective education for students with special needs depends on the degree to which these preparation programs educate practitioners to be culturally competent and effective in diverse school contexts. Further, it is readily known that in order for educators to be effective, cultural competency awareness, knowledge, skills, and dispositions normally cannot be externally imposed upon them. Rather, these realities must be viewed as being of worth and important to prospective special education teachers so that they are able to own, learn, and experience the training necessary to make them culturally competent. Cultural competence, then, can become an organizing construct that can be used to guide the development of culturally competent and responsive teacher education training curricula that can respond to the challenge of cultural and linguistic diversity of children with special needs.

Understanding Cultural Competence

Valuing cultural and linguistic diversity involves being culturally competent since we can not divorce somebody's language from his/her culture. Social scientists have, of late, established a cultural competency knowledge base that creates a paradigm shift in the way special educators conceptualize culture, class, and language differences. New ideas generally build upon the traditional cultural diversity knowledge and awareness knowledge bases, but

distinguish themselves by creating a new model that embraces notions of deep, structured culture and competency that can be routinized by educators in natural settings. In this regard, various cultural competency models that represent important progress have been developed. According to Hanley (1999), these cultural competency models have emerged as significant ones in the fields of social work, mental health service provision, and education. This new form of preparation of special education personnel is designed to transform the preparation of special education teachers, administrators, and related service professionals – many of whom are frequently unaware of or have, wittingly or unwittingly, not examined their own cultural or ethnic identities. While the concept of cultural competency has been variously defined, Hanley defined cultural competence as a set of congruent attitudes, practices, policies, and structures that are integrated in a system or agency to enable professionals to work more effectively with culturally and linguistically diverse learners. In order to reduce disproportionality and achievement and discipline gaps, structural changes in special education must occur. To value culture and diversity, Pedersen's model of cultural competence seems to be useful. This work is described in the following subsection.

Pedersen's Model of Cultural Competence

Pedersen (1994) outlined a relevant model of cultural competence that can serve as an underpinning of the design of a training curriculum for all educators. This model includes three particular and interrelated domains of cultural proficiency: (1) awareness, (2) knowledge, and (3) skills. As such, each domain must be mastered prior to proceeding to the next. Mastery in each of these domains provides the foundation and bases for a culturally competent training curriculum for special educators, as well as general educators, administrators, and related service professionals.

Awareness competencies. Awareness competencies include the recognition and constant examination of one's own attitudes, biases, and assumptions that may interfere with the ability to work effectively with culturally and linguistically diverse students with special needs. Awareness competencies require that special education teachers, general education teachers, administrators, and related service providers (1) critically and continuously explore their own attitudes, perceptions, assumptions, and any possible biases toward this population; (2) examine how these realities may impact the learners they serve; and (3) more importantly determine those strategies and practices needed to effectively work with culturally and linguistically diverse students with special needs.

A second feature of the awareness domain of cultural competency includes training that provides prospective

educators with the knowledge to recognize certain sociopolitical issues that often impede educational outcomes for children from disenfranchised groups. For instance, oppressive forces or systems of domination and control such as power, privilege, racism, sexism, and linguicism can result in diminished prospects for culturally and linguistically diverse students with special needs. Frequently, these youngsters experience single or multiple forms of oppression. For instance, an African American male receiving special education services may experience racism, as a result of his defined race; sexism, as a result of his gender status; linguicism, if he fails to speak Standard American English; and an internalized sense of shame and embarrassment because of the stigma associated with a diagnosed mental or emotional/behavioral disability. All educators who are striving to be culturally competent must recognize that these structural forces in society impact children from marginalized groups. Schools operate as a microcosm of the larger society, such that culturally different students and students with disabilities experience the pernicious effects of oppression that frequently contribute to their orientation toward education and school outcomes. Social mirroring, or the tendency of youngsters to internalize the widely negative perceptions that others maintain about their performance and abilities, can have adverse consequences on educational outcomes for these learners. Recognition of one's own biases, and the sociopolitical contexts that impact the educational experiences of minority group members, are important correlates of cultural competence. All of these cultural awareness elements can serve as the first theme to include in a culturally competent training curriculum that should help special educators reduce disproportionality and the achievement and behavior gaps.

Knowledge competencies. Knowledge competencies involve the acquisition of factual information about people from culturally distinct groups. Moreover, children's learning styles often correspond to their cultural preferences. Consideration of the demographic, historical, social, cultural, and educational experiences of culturally distinct students with special needs should allow educators to integrate salient cultural features into the educational process, thus moving toward cultural competence. For instance, among many African American and Latino youngsters, relationships are highly prized. Failure to develop warm, nurturing interpersonal connections with youngsters can have a detrimental impact on educational outcomes. Ladson-Billings (1994) maintained that the cultivation of a hospitable classroom climate remains indispensable when learning is the anticipated outcome. She noted that successful teachers of African American youngsters respect the personhood of students by demonstrating simple kindness through praise, listening, smiling, and showing respect for other students. Healthy classroom climates rest upon a child's ability to feel a sense of connectedness, support, and security. Classroom

climates that lack this culturally responsive dynamic seriously undermine a child's ability to profit from the learning enterprise.

Cultural misunderstanding and misattributions between culturally and linguistically diverse students with special needs and educators contribute greatly to the preponderance of discipline referrals, suspensions, and expulsions. Students with high levels of ethnic affiliation exhibit a distinctive set of communication styles that often do not conform readily to the norms and expectations required in schools. Many learners may communicate with one another and with school personnel in a manner characterized as loud, intense, and confrontational even without having accompanying feelings of anger. Educators may regard this conduct as volatile and assume that hostility is impending. In marked contrast, many Caucasians rely on more dispassionate, impersonal, and emotionally restrained communication styles. Nothing is inherently wrong with either form of communication, but when interpreted outside a particular cultural context, certain interpersonal styles may be regarded as rude and inappropriate and lead to an increase in disciplinary referrals for some learners. For instance, educators who have knowledge of the rhythmic orientation of many, though certainly not all, African American youngsters can introduce more culturally responsive kinesthetic approaches to learning into the repertoire of educators' behaviors. Gay (2000) underscored the importance of addressing multiple sensory stimulation among students who respond better to strategies that rely on visual stimuli, tactile, and kinesthetic learning, as well as personal reinforcement. Teachers and service providers who employ engaging, energetic, and performance-oriented teaching approaches are more likely to sustain the attention and interest of African American learners. Such instructional pedagogy correlates with the oratorical and communication styles that govern social interactions within two prominent African American institutions, the church and the community. Adopting culturally compatible instructional strategies holds considerable promise for fostering academic achievement. Blatant disregard of certain cultural features on the basis that students should perform academically despite the classroom climate or the particular cultural frame of reference to which educators adhere may damage any potential prospects for learning and further deepen the academic and behavior gaps between these learners and those from the majority population.

Skill competencies. The third component of Pedersen's conceptual framework involves skills competencies. This domain of competencies builds upon the previous two and should serve as a basis for the design of the third theme for a culturally competent training curriculum. Essentially, skills competencies refer to the synthesis of awareness and knowledge competencies with the ultimate aim of developing culturally relevant strategies that promote teaching effectiveness and enhanced educational

outcomes for all students, especially those with special needs. It is common knowledge that deficit thinking, or the presumption that children from marginalized groups are uneducable, impedes educational progress. Such a bias often guides the decision making of school personnel. Because the culture of the school and the culture of children from diverse groups often differ so markedly, culturally competent educators, on the other hand, develop a skill set to recognize that cultural differences do not automatically translate into deficits.

Culturally competent educators possess the skill set that enables them to maintain high expectations for students from marginalized groups, especially those with special needs. Steele's (1997) research indicated that when a negative stereotype exists about a particular group (e.g., minorities and women), members of that group internalize the stereotype in a manner that can interfere with academic performance. For this reason, the content expertise of educators must be balanced with a skill set that includes awareness and understanding that implicit and explicit attitudes about students can influence educational outcomes. Educators can no longer afford to consign minorities and low socio-economic youngsters to the educational fringe. This stake becomes even higher for students with special needs. In addition, educators must validate and affirm their students' rich cultural backgrounds and use students' funds of knowledge to facilitate new learning. Banks (2001) argued quite persuasively that the incorporation of diverse perspectives should not be relegated to the coordination of multicultural feasts and the presentation of culturally diverse heroes. He also explained that multicultural education at the ultimate level should aim toward heightening meaningful social consciousness, awareness, and social change.

The recognition of the cultural knowledge and learning styles of students is important and must be included in the skill set needed by culturally competent educators. Much has been written about cultural styles and preferences of culturally diverse youngsters and that their styles often differ markedly from instructional orientations from which learning is routinely conducted. Educators and service providers must work diligently to incorporate cultural values and styles that resonate with students from diverse groups with the ultimate aim of helping them operate effectively and learn code switching skills.

Clearly, culturally competent educators self-assess and self-monitor to guarantee that they are not behaving in biased ways. This skill requires that they possess a certain level of social, political, and historical knowledge and consciousness about children from marginalized groups. Moreover, this form of consciousness is a necessary, albeit insufficient, condition for cultural competence. Accordingly, educators must act on this conscious raising learning and serve as agents of social, political, and economic change who advocate for their students and their

families. As a result, they must work in integrated ways with families and communities. Such alliances may include partnerships that schools establish with religious, civic, and social organizations, as well as private industry in order to promote mutual and reciprocal relationships. Such relationships must be aimed at improving educational outcomes for culturally and linguistically diverse youngsters, especially those with special needs. Schools can no longer afford to work as isolated entities that ignore valuable community resources and partnerships. These partnerships are more apt to be effective when reciprocity exists across all partner stakeholder groups.

Community Connections and Students with Special Needs

Schools connect with families when there is cultural reciprocity. Cultural reciprocity functions as an important dynamic involved in adapting to cultural differences. For instance, Kalyanpur and Harry (1999) identified cultural reciprocity as an essential component for developing skill competencies. Cultural reciprocity involves a willingness to consider the assumptions that culturally diverse individuals and families have that could impact the educational process for children. Kalyanpur and Harry (1999) noted four critical steps for developing cultural reciprocity: (1) identification of cultural values inherent in the educational practice, (2) consideration of family perspectives regarding educational issues that may differ from educators' conceptions, (3) demonstration of respect toward varying values and viewpoints, and (4) development of effective strategies that integrate professional interpretations and the family's value system. This model promotes educators' recognition and incorporation of cultural adaptations and family values and viewpoints into the educational process. More specifically, cultural reciprocity involves a willingness to consider the assumptions that culturally diverse individuals and families hold that could impact the educational process of their children. In other words, cultural reciprocity challenges the often-heard stereotype of the educator as expert.

Historically, the church has served a significant role in the socialization of children, especially African American and Latino youngsters. For instance, the church provided educational support, religious guidance, mentoring, financial assistance, and political activism as a mechanism for enhancing the life chances of members in African American and Latino communities. Civic organizations have often served as self-help groups designed to enhance quality-of-life issues for many culturally diverse members and their communities. Service represents the central organizing principle around many organizations such as fraternities and sororities that often sponsor enrichment programs for youngsters. Given the prominence of the church in many minority communities and the commitment to service of

many civic organizations, school representatives can work closely with religious and civic institutions to promote mutual and reciprocal relationships aimed at improving educational outcomes for minority youngsters with special needs as well as enhancing partnerships between the school and community.

Conclusion

This article focuses on cultural and linguistic diversity and students with special needs. We believe educators and service providers must respond to the cultural and linguistic diversity that students bring to school. To do this, they must be culturally competent. It is essential for all educators and service providers to constantly examine and mediate their cultural and class knapsacks as a precondition to acquiring cultural competence. While this process is necessary and essential, it is often difficult as we are trained to look for specks of gravel in other people's eyes while we may have boulders in our own. This self-exploratory process should result in an increased awareness of one's own cultural and class identities, thus enabling one to develop a deeper awareness and understanding of one's non-self, especially those who are most unlike you. With this increased and deeper awareness of the contents of one's cultural and class knapsacks (i.e., one's stereotypes about self and others, assumptions about others, and the like), essential positive changes of behavior should occur. This transformation provides the basis from which deep levels of cultural awareness, knowledge, and skills can be built to educate culturally and linguistically diverse students with special needs. Clearly, no transformation will occur unless educators and service providers are prepared and trained to be culturally competent. The cultural competency awareness, knowledge, and skill dimensions outlined in this article can and should be used in the education and training of persons involved in the education of students, especially those with special needs. In the end, cultural competency will materialize when effective partnerships with key stakeholder groups are reinforced and embedded in all special education programming.

Glossary

Appropriateness of assessment – Use of a variety of assessment tools and strategies to determine programming by relying on sound instruments that are non-discriminatory, valid, reliable, and administered by trained teachers.

Assessment – To measure and appraise students' instructional progress based on direct observation and data analysis.

Criterion-referenced measurement – Measuring an individual student's performance in terms of absolute mastery of particular skills.

Curriculum-based assessment – An assessment system used by teachers to identify, examine, analyze, and reflect on student progress and systematic instructional data in the local curriculum.

Curriculum-based measurement – A scientifically validated form of student progress monitoring in which teachers use standard methods for test development, administration, scoring, and data utilization with students involved in the curriculum, as teachers evaluate the effectiveness of instructional changes.

Curriculum measurement – Assessment involving direct or performance-based assessment linked directly to instruction.

Precision-teaching – A system for charting behavior frequency (or rate) against calendar days.

Problem solving process – Identifying a problem to be solved and alternative answers to the problem by implementing and testing alternative answers, revising unsuccessful answers, and terminating the problem-solving process.

Progress monitoring – Part of effective teachers' instructional decision-making process that uses data analysis to determine how students are learning based on predetermined instructional goals and objectives.

Assessment, a basic tenet of effective teaching, is fundamental to the instructional decision making of astute teachers. These teachers use multiple types of assessment data for a variety of educational decision making. This use of data, collected from assessment, tends to highlight important educational decisions collected about teaching-learning processes, on student or teachers' demographics,

and of relevant variables important to learning milieus in which instruction occurs. Accurate data help teachers to (1) become familiar with students' learning strengths, needs, and preferences; (2) design teaching-learning experiences that support students' growth and development; (3) adjust instruction in response to students' ongoing achievement; and (4) monitor students' progressions carefully.

In the United States, curriculum-based assessment (CBA) is known as a valuable assessment system that teachers employ to identify, examine, analyze, and reflect on student progress and systematic instructional data. CBA has a significant reputation, holding historical relevance to address student achievement, and teachers' careful consideration of instructional design and teaching-learning effectiveness. CBA retains continuing importance to students with special needs and effective instructional decision making.

CBA: Definition and Importance

CBA entails measurement that uses "direct observation and recording of a student's performance in the local curriculum as a basis for gathering information to make instructional decisions" (Deno, 1987: 41). CBA, with a history critical to, and highlighting, the special education movement in the United States, evolved during the last three decades into a system of ongoing measurement of student progress, and sound decision making about instructional practices. Today, it represents the collection of a solid research base that can be linked directly to teachers' instructional decisions. The application of CBA principles helps to ensure that individual students, in and outside of a classroom environment, achieve teachers' instructional objectives, regardless of the learning setting in which their instruction occurs. Clearly, teachers who implement CBA processes and procedures appropriately are able to design effective instruction. As they implement and manage instruction, they are able to gather assessment data, using frequent assessment of their students' progress across curricular areas in a systematic manner on critical curriculum objectives. These teachers, then, are able to reflect on their obtained data to make sound educational decisions about their own instructional effectiveness and classroom success.

Teachers employ ongoing assessment data to cover a range of skills in varied, academic core subject areas

(e.g., concept recognition, number recall, and rule differentiation in mathematics; letter naming, word recognition, and fluency in reading; and capitalization, punctuation, and subject–verb agreement in written expression). They view data over time (e.g., pre, during, or after instruction), and in a variety of settings (e.g., classroom, community, home, and work site). As teachers reflect on the usefulness of assessment linked to instruction, and as ongoing assessment continues in teachers' regular repertoire of reporting student academic progress over time, they, then, begin to involve students more directly and explicitly during teaching–learning processes. The use of reflective data, collected through instructionally relevant measurement by teachers and students, helps to inform whether or not students are making instructional progress. This helps to confirm whether or not students are demonstrating behaviors toward reaching levels of academic mastery. Such data use, also, helps to inform and confirm whether or not teachers are successful in educational decision making. Regardless of what skills teachers assess, the curricular standards that teachers employ, when they collect data, where they assess, how they measure, and/or the type of data teachers seek, instruction and learning analyzed by teachers lead to meaningful knowledge. Frequent analyses help teachers to (1) know critical skills for assessment that require teacher attention; (2) ensure valid and reliable data collection, (3) examine instructional data on an ongoing basis, (4) monitor student performance critical to student learning situations, (5) make reflective decisions about their own teacher effectiveness, and (6) improve students' academic achievement and self-instructional awareness.

CBA: Historical Context

Deno researched the use of assessment linked to instruction in the late 1970s with the goal of giving teachers of students with learning disabilities a simple set of evaluation procedures that would allow them to collect data on and graph an individual student's academic progress. Such measurement procedures sought direct observation and recording of a student's performance in a local curriculum as a basis for gathering information to make instructional decisions. In 1985, the Pine County Special Education Cooperative in Minnesota began field testing what was then referred to as curriculum measurement, a form of alternative assessment associated with special education involving direct or performance-based assessment typically using materials taken directly from instructional materials used with nondisabled students (Deno, 1985; Deno and Fuchs, 1987). Reading, mathematics, and written expression covered common applications. This research and testing showed assessment linked to instruction to be among the most reliable tools for accurate measurement

and evaluation of students' academic achievement, both to compare students to one another and chart individual student progress.

CBA expanded to refer to models of assessment that emphasized a direct relationship to an individual student, or group of students, within the curriculum. Curriculum-based measurement (CBM), a refinement of CBA, highlighted work by Deno and his colleagues by using repeated measures from students involved in the curriculum, to evaluate the effectiveness of teachers' instructional practices (Deno and Fuchs, 1987; Fuchs and Deno, 1991; Fuchs and Fuchs, 1984, 1985; Salvia and Hughes, 1990). Researchers collecting and analyzing data on atypical student learning reasoned that instructional changes by teachers may lead to more effective teaching methods and improved student achievement. CBM researchers, then, sought specific data on how achievement gains and academic progress change on generic tasks of constant difficulty (King-Sears, 1994; Salvia and Hughes, 1990; Salvia and Ysseldyke, 1991). Deno, his colleagues, and his team of graduate students extended their research by looking for and refining tasks that could serve as simple measures of student improvement. Academic tasks, such as reading words aloud or recalling rote multiplication facts, received research attention. These researchers began extensive testing on students with and without disabilities to make sure that their research provided consistent and comparable results with other forms of measurement over time (Deno and Fuchs, 1987; Fuchs and Deno, 1991; King-Sears, 1994). Extensions of assessment linked to instruction relied on principles of direct instruction (Becker and Carnine, 1980, 1981; Becker and Gersten, 1982) as refinements of observable and measurable student progress and teacher behaviors.

Researchers, also, began studying whether or not an increase in the behavior being measured on equivalent forms of the task would represent academic growth. Deno and Fuchs (1987) and Fuchs and Deno (1991) reported that CBM could be used in conjunction with a problem-solving process that included:

- identifying a problem to be solved (e.g., underachievement in reading or mathematics);
- identifying alternative answers to the problem (e.g., a new instructional method in reading or mathematics);
- implementing (e.g., teaching a new or different instructional strategy) and testing the alternative answers (e.g., assessing or evaluating the reading methods or mathematics methods);
- revising unsuccessful answers (e.g., continuing to make changes in the reading method or mathematics method); and
- terminating the problem-solving process (e.g., seeking to discontinue the special education services).

Other Systems of Curriculum Measurements

Application of assessment principles linked to curricular design became fundamental to progress reporting and academic monitoring, enjoying support from researchers and practitioners across the United States, including those in the Department of Education. Instructionally relevant measurement models, especially CBA and precision teaching, became the measurement and assessment tools of choice in numerous federally funded studies (Carpenter and King-Sears, 1998; Fuchs and Deno, 1991; Gersten *et al.*, 1995). Precision teaching, a system for charting behavior frequency (or rate) against calendar days has been used by measurement experts as a means to support practitioners, teachers, and students. Curriculum assessment linked directly to instruction spread into use around the United States and abroad as researchers began applying principles of instructionally relevant measurement models to other subject areas and age groups. Researchers began focusing on students of all ability levels with derivatives of CBA and CBM, such as in computer-based applications, and as measures of states' overall accountability programs (Blankenship, 1985; Carpenter and King-Sears, 1998, 2002; Cullen and Pratt, 1992; Fuchs and Deno, 1991; King-Sears, 1994).

The selections of critical skills for assessment and the use of CBA received researchers' attention (e.g., Blankenship, 1985; Salvia and Hughes, 1990). Researchers refined aspects of CBA, such as in the APPLY mnemonic, that synthesize steps for teachers' development and use of CBA in classrooms (King-Sears, 1994; King-Sears *et al.*, 1999) to analyze the curriculum, prepare items to meet curriculum objectives, probe frequently, load data using a graph format, and yield to results based on revisions and decisions (see King-Sears, 1994). Uses of various forms of instructionally relevant measurement, such as through implementation of the APPLY mnemonic, offered easy and reliable tools for measuring student progress in ways that allow for early intervention and assessment of teaching-learning effectiveness.

What CBA Means for Access to the General Curriculum

CBA can customize assessment for students in the general education curriculum. As a form of criterion-referenced measurement, CBA helps to pinpoint curricular objectives that act as the criteria for the identification of instructional targets and for the assessment of students' skills upon entry into an academic curriculum (Fuchs and Fuchs, 1984, 1985; King-Sears, 1994). Salvia and Ysseldyke (1991) identified criterion-referenced measurement as a system that measures a student's performance in terms of

absolute mastery of particular skills. Teachers use criterion-referenced tests to help when planning instructional programs and in monitoring students' mastery of skills. CBA acts as a guide for the development of individual goals, assessments, interventions, and accommodations. In addition, it allows for continual monitoring of students' developmental progress since it links assessment results to instructional interventions (Elliott, 1992).

Many assessment systems linked to instructional models, including CBA, CBM, and precision teaching, had their beginnings in the special-education discipline or in the educational-psychology domain. As it appears, alternative measurement tools provide an alternative to standardized norm-referenced measures. In many cases, the use of such standardized tools provides information more accurately to teachers at the eligibility and planning stages in the special education referral process. However, alternative measures, especially CBA and precision teaching, are more valuable tools for monitoring the progress of students in the curriculum of instruction, most often the general education curriculum (King-Sears, 1994; Salvia and Hughes, 1990). When using progress-monitoring devices in systematic ways, teachers evaluate student performance formatively in an academic skill area, specific to the curriculum used. Formative evaluation allows them to evaluate the adequacy of skills development. If progress is deemed inadequate, teachers then select and implement appropriate interventions. Conversely, if students perform beyond expectations, or criteria, teachers often have the information to make curriculum adjustments to challenge students at their appropriate level. For example, the fluency-assessment systems, the Dynamic Indicators of Basic Early Literacy Skills (DIBLES), developed by Good and peers, originated from monitoring students' accuracy and speed in curriculum materials typically used in general education literacy programs and has become widespread in current classrooms in the United States (Good and Kaminski, 2002; Good *et al.*, 2002).

In order to begin the process of designing instruction that is linked to assessment, teachers require an understanding of CBA's basic assumptions:

- observable behavior of critical student performances related to the curriculum being taught to underscore all data collection;
- data obtained represent frequent and brief measurements of student behavior prior to, during, and after instructional units;
- students and/or teachers display measurements graphically; and
- students and/or teachers use the graphic displays to make instructional decisions (Carpenter and King-Sears, 2002; Salvia and Hughes, 1990).

These assumptions view assessment as criterion referenced, curriculum embedded, ongoing, and programmatic.

As criterion referenced, teachers seeking to link instructional design and assessment measure students' performance in terms of absolute mastery of particular skills in a planned curriculum. Primary purposes of teachers' planning consider the link between instruction and documenting students' progress. These purposes entail: (1) identifying students' entry-level competencies, (2) monitoring student performance during instruction, (3) determining students' mastery of competencies at the conclusion of instruction, and (4) monitoring students' maintenance and generalization of competencies (Salvia and Hughes, 1990; Salvia and Ysseldyke, 1991). CBA assumptions are necessary prerequisites to ongoing processes of gathering information regarding students' strengths, interests, and emerging abilities related to important skills across content for the purpose of planning and monitoring instruction.

The construction of CBA occurs in the same way, regardless of the type of curricula that teachers employ when planning and implementing instruction (Idol *et al.*, 1996). First, the teacher (or CBA constructor) selects sample items from the curriculum or constructs sample items to match the curriculum. The teacher orders these items by difficulty, combining them within a single test. Consequently, the teacher provides the ordered items on the first day of student assessment (day 1). Then, the teacher constructs two or more forms of the same test, containing similar items and identical orders of difficulty. Next, the teacher administers these forms on the second and third days of student assessment (days 2 and 3). It is highly recommended that teachers construct CBA using three different forms on three separate occasions, to control for sporadic student response (Carpenter and King-Sears, 2002).

In administering the CBA, the teacher employing the CBA form tests the students across several levels of the curriculum. Ordinarily, the teacher measures their responses for speed or proficiency, as well as for accuracy. The teacher's use of continued and ongoing CBA assessment helps to record student responses over time. The teacher, then, focuses on performance criteria, established to determine acceptable levels of student performance or mastery. As it stands, normative sampling has been seen as a useful procedure for establishing mastery criteria in a general-education setting (Idol and Rutledge, 1993). This procedure involves taking samples of average and acceptable student performance in the general-education class as a basis for deciding what the absolute mastery criteria ought to be. Once this type of social validation occurs and the mastery criteria are established, the teacher administers the CBA, either to individual students or to groups of students.

Evaluating CBA

Researchers developed several characteristics to evaluate the effectiveness of CBA, common across models.

Embodied in these characteristics are the following strategic questions:

- Did teachers use measurement procedures to assess students directly using the material in which students received instruction? Were sampling items from the curriculum involved?
- Was teachers' administration of each measure generally brief in duration (typically 1–5 min)?
- Did the CBA design structure underscore frequent and repeated measurements as much as possible, as such measurements are sensitive to change?
- Did teachers and/or students display data graphically to allow monitoring of student performance?

Many teachers use CBA as a formative assessment to assist them during instruction. As they conduct formative assessment, many observe student results and are able to use the observational data to change their teaching. Graphically displaying those results, then, helps teachers in decision-making processes to increase their students' academic or behavioral achievement and to use the instructional time more productively. Various researchers compare procedures with those teachers not using any systematic data collection (Blankenship, 1985; Fuchs and Fuchs, 1984; Fuchs and Deno, 1991; King-Sears, 1994; Salvia and Hughes, 1990).

Motivating Students to Increase Self-Awareness of Learning and Progress

Instructionally relevant measurement helps to promote students' meaningful awareness of their instructional content and progress. Teachers can help students become part of their active learning by using direct and guided decisions regarding their progress. This can help students to become motivated about their own learning and achievement gains. Teachers and students, then, use the information gained from this awareness to (1) guide the teaching and learning process, (2) decide which instructional methodology is best suited to the instructional context, (3) examine and analyze instructional strategies and tactics, (4) consider and organize instructional materials, and (5) reflect on important instructional techniques used throughout instruction. Teachers support students as they guide students, fade their own presence, and help to establish students as independent and self-directed learners (See Blankenship, 1985; Deno, 1985; Fuchs and Fuchs, 1984; King-Sears, 1994, 1999; Salvia and Hughes, 1990).

By emphasizing CBA on a frequent basis, teachers can encourage student involvement in awareness and self-learning by teaching students how to set goals for learning and how to analyze data to self-evaluate actual performance. CBA has a long history as a driving force to help teachers develop meaningful ways throughout the

instructional process to assess students frequently and systematically on critical skills and to motivate them to become actively involved in the assessment process. Student motivation requires that teachers directly and explicitly instruct students on the use of observing, probing, charting, graphing, and analyzing data in order that students self-instruct with the teachers' direct or guided support. By using CBA techniques to inform and confirm students' knowledge of data-based decision making, teachers facilitate students' road to independence.

Steps for Using CBA

To use CBA effectively, general and special teachers should:

- analyze curriculum standards, identifying required academic skills and behaviors in a logical and sequential order;
- write performance objectives for each skill in measurable terms to enable data collection across time;
- determine mastery level for each skill;
- assess students' mastery of each skill before instruction;
- provide instruction on the identified skills;
- conduct frequent probes to assess students' mastery of each skill as it is taught;
- display the results in a simple graph form; and
- analyze performance trends to determine the effects of instruction on student learning.

Conclusion

Academic assessment has a long-standing tradition in education. Assessment historically involved measurement of student progress for the purpose of informing. One level of informing entails identification or eligibility decision making; a second level is that of informing instruction. Traditional assessment systems have limitations that restrict their application for instructional program planning (Blankenship, 1985; Fuchs *et al.*, 1990; Salvia and Hughes, 1990). Alternative assessment procedures appearing in educational literature in the past 20 years note the importance of CBA. Whereas traditional achievement tests tend to measure broad curriculum areas and/or skills, instructionally relevant measurement systems focus on specific skills currently being taught in the classroom, usually basic skills (Gersten *et al.*, 1995; Idol *et al.*, 1996). Interestingly, CBA has earned a reputation as an objective, empirically supported measurement system with characteristics of a technically sound and teacher-friendly measurement system. Throughout the last three decades, CBA has been found to be reliable, valid, time efficient, inexpensive, and easy to understand. It requires little training and uses multiple forms for repeated administration. Indicators of

student achievement help teachers and students to evaluate and graph baseline and intervention data. Astute teachers, then, use these data and predetermined data decision rules to decide when to make instructional changes. As they support students in learning and awareness, teachers help students to use the principles of data-driven assessment to inform and confirm students' academic achievement and progress over time. Such teachers become reflective as they link teaching and learning processes of what is assessed with what is taught.

Glossary

BASIC-ID or IB-the assessment in acronym form of the following modalities of a student –

Behaviors, affect, sensation, imagery, cognition, interpersonal relationships, drugs/biology.

Multimodal Behavior Assessment (MMBA) – Is a method used within psychological assessment that can be adapted to students with developmental disabilities.

Educators use the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV-TR, Fourth Edition, Text Revision) to diagnose students with special needs. The DSM-IV-TR allows one to make multiaxial diagnoses – one for each of five axes (DSM-IV-TR, 2000: 27–38). Axis I is used to diagnose the presenting problem for a student such as anxiety and depression. Axis II is used to diagnose personality disorders and mental retardation. Axis III is employed for general medical conditions, diagnosed by a medical practitioner, that are related to a student's performance. Axis IV is used for psychosocial and environmental concerns that may influence diagnoses on Axis I and Axis II. Negative life events that can produce interpersonal stress are diagnosed on Axis IV. Axis V is used to diagnose a student's overall level of functioning, and it is called the global assessment of functioning scale (GAF). This scale has values ranging from 0, inadequate information; to 10, persistent danger to self and others; 50, moderate symptoms; to 100, superior functioning in a variety of areas.

Multimodal Behavior Assessment (MMBA) is a method used within psychological assessment; it is a comprehensive intra-individually based assessment that can be adapted to students with developmental disabilities. Lazarus (1990) developed this assessment procedure. MMBA assesses seven modalities in acronym form called the BASIC-ID or IB, and this acronym assesses the following modalities: behaviors, affect, sensation, imagery, cognition, interpersonal relationships, and drugs/biology. It is common knowledge that diagnosis and assessment are never perfect, and they involve a collection of several sources of information on a student (Kendall and Hammen, 1998). For example, students will often fall within several diagnostic categories, and often they will have several comorbid factors that do not fit into clear categories. There are several factors to address when attempting to assess students with special needs (Sapp, 1999, 2002, 2006); however,

the two most important factors are reliability and validity, and these factors are not adequately addressed within the profession of special education.

Theories of Testing

The purpose of this article is to discuss the positive and negative roles of diagnosis and classification in special education. Before students with disabilities can be diagnosed and assessed, reliable and valid assessment measures must be employed. To illustrate, African American and Latino students are not adequately represented in most standardized assessments, and this is why great care must be used when attempting to diagnose and assess all students. In contrast to the general perception within education, reliability and validity are based on educational test score theories – not facts. Classical true-score theory, generalizability theory, and item response theory are the three dominant theories within educational assessment (Allen and Yen, 1979). Classical true-score theory is the dominant theory within education, and it states that a student's observed score (X) is an addition of the student's true score (T) and some error (E). The E is often misunderstood by educators, and it is not a mistake but a theoretical construct that takes into account the inability to measure concepts perfectly. Generalization theory extends classical true-score theory measurement by showing that it does not have to be restricted to the two-component linear model of a true score and error score – the true-score theory. Essentially, generalizability theory is concerned with the reliability of generalizing from a student's observed score on a test to his/her average measure that would occur under all possible conditions that are acceptable. Implicit in this assumption is that the student's measured attributes are in a steady state, and changes in the student's scores are not the results of maturation, learning, or development. Changes in the student's attributes are the result of multiple sources of error such as occasions, different test forms, different test administrators, and so on (Sapp, 2006). Item response theory is a form of item analysis, and unlike the group assessment model of the true-score theory, it is an individualistic model. For example, true-score theory is based on the number of students who pass a test item (item difficulty) and the extent to which test items discriminate among students (discrimination index), and all these factors are based on the norms of the standardization sample. In contrast, item

response theory makes no assumptions about the students involved and it does not rely on group norms; instead, a student's test score is the arithmetic multiplication of a student's ability and the student's item difficulty. As opposed to comparison to group norms, the greater a student's ability, the greater the probability that a client will get an item correct.

Test items are said to be valid when they measure what they purport to measure, and validity involves several forms such as face, content, criterion, and construct. Face validity is a nonstatistical aspect of validity that on face appearance items appear to measure what they purport to measure. Content validity is another nonstatistical aspect of validity, and it is the degree to which items assess relevant facets of a conceptual domain. For example, if an educator were interested in assessing word knowledge, he/she would want test items that sample the domain of word knowledge. Criterion validity is a statistical form of validity that has at least three forms such as predictive, concurrent, and retrospective, and criterion validity is also called empirical validity. Simply stated, criterion validity assesses the degree in which items from two tests correlate. Construct validity helps determine if a given educational measurement instrument actually measures the underlying conceptual construct that it was designed to measure. Construct validity must be constantly updated; and with minority students, often construct validity has not been assessed.

DSM-IV-TR Classification of Children with Special Needs

The DSM-IV-TR classifies children with special needs into the following categories:

1. *Mental Retardation (Cognitive Disabilities)*
 - 317 Mild Mental Retardation (Educable)
 - 318.0 Moderate Mental Retardation (Trainable)
 - 318.1 Severe Mental Retardation (Severe/Profound)
 - 318.2 Profound Mental Retardation (Severe/Profound)
 - 319 Mental Retardation, Severity Unspecified
2. *Learning Disorders*
 - 315.00 Reading Disorder
 - 315.1 Mathematics Disorder
 - 315.2 Disorder of Written Expression
3. *Motor Skills Disorders (Physical Disabilities)*
4. *Communication Disorders (Speech and Language Impairment)*
 - 315.31 Expressive Language Disorder
 - 315.32 Mixed Receptive-Expressive Language Disorder
 - 315.39 Phonological Disorder
 - 307.0 Stuttering
 - 307.9 Communication Disorder Not Otherwise Specified

5. *Pervasive Developmental Disorders (Autistic Spectrum Disorders)*
 - 299.00 Autistic Disorder
 - 299.80 Rett's Disorder
 - 299.10 Childhood Disintegrative Disorder
 - 299.80 Asperger's Disorder
 - 299.80 Pervasive Developmental Disorder
6. *Attention-Deficit and Disruptive Behavior Disorders (Emotional/Behavioral Disorders)*
 - 314.01 Attention-Deficit/Hyperactivity Disorder Combined Type
 - 314.00 Predominately Inattentive
 - 314.01 Predominately Hyperactive-Impulsive Type
 - 314.9 Attention-Deficit/Hyperactivity Disorder Not Otherwise Specified
7. *Conduct Disorder*
 - 312.81 Childhood-Onset Type
 - 312.82 Adolescent-Onset Type
 - 312.89 Unspecified Onset
 - 314.81 Oppositional Defiant Disorder
 - 312.9 Disruptive Behavior Disorder NOS
8. *Feeding and Eating Disorders of Infancy or Early Childhood*
 - 307.52 Pica
 - 307.53 Rumination Disorder
 - 307.59 Feeding Disorder of Infancy or Early Childhood
9. *Tic Disorders*
 - 307.23 Tourette's Disorder
 - 307.22 Chronic Motor or Vocal Tic Disorder
 - 307.21 Transient Tic Disorder
 - 37.20 Tic Disorder Not Otherwise Specified
 - Elimination Disorders
10. *Encopresis*
 - 787.6 With Constipation and Overflow Incontinence
 - 307.7 Without Constipation and Overflow Incontinence
 - 307.6 Enuresis (Not Due to a General Medical Condition)
11. *Other Disorders of Infancy, Childhood, or Adolescence*
 - 309.21 Separation Anxiety Disorder
 - 313.23 Selective Mutism
 - 313.89 Reactive Attachment Disorder of Infancy or Early Childhood
 - 307.3 Stereotypic Movement Disorder
 - 313.9 Disorder of Infancy, Childhood or Adolescence Not Otherwise Specified

Mental Retardation

The DSM-IV-TR defined mental retardation as significant below average intelligence with significant limitations in adaptive functioning in at least two of the following areas of skills: communication, self-care, use of

community resources, self-direction, functional academic skills, work, leisure, health, and safety. Mental retardation, known in many states and special education laws as cognitive disability, has a range from mild (50–55 to approximately 70 intelligence quotient (IQ)) to profound (below 20 or 25 IQ). Diagnostically, mental retardation can only be made with an IQ of about 70 and impairment in adaptive functioning. Adaptive functioning is a child's capacity to cope with life demands and how well a child meets standards of personal independence expected for his/her particular age group, sociocultural background, and community setting (Oakland and Houchins, 1985; Smalley, 1998).

Generally, intellectual functioning is an IQ or IQ equivalent assessed with one of the following individually administered standardized intelligence tests: Wechsler Intelligence Scales for children, 3rd Edition; Stanford-Binet 4th Edition; Kaufman Assessment Battery for Children. From a multicultural perspective, intelligence is a descriptive multivariate or multidimensional construct, and intelligence tests should be used to understand children and not to label them. In summary, mild mental retardation is an IQ level 50–55 to approximately 70; moderate mental retardation is an IQ level 35–40 to 50 to 55; severe mental retardation is an IQ level 20–25 to 35–40; finally, profound mental retardation is an IQ level below 20 or 25.

Learning Disorders

Learning disorders are diagnosed when a child's achievement on individually administered, standardized tests in reading, mathematics, or verbal expression is below his/her expected level for his/her age, schooling, or level of intelligence. To be diagnosable, learning disorders, known in many states and special education laws as learning disabilities, must significantly interfere with a child's academic achievement. Generally, a learning disability is defined by a discrepancy of two standard deviations (2 SD) or more between achievement measures in reading, mathematics, or written expression and IQ.

With children with limited English proficiency, such as African American and Latino children, the Test of Nonverbal Intelligence, 3rd Edition (TONI-3) can be useful (Brown *et al.*, 1997). The TONI-3 takes about 15–20 min to administer, and it measures nonverbally intelligence and visual-reasoning ability. Even though the TONI-3 is not based on any particular theory of intelligence, it has multicultural applications for assessing intelligence.

Motor Skills Disorders

Motor skills disorder, also called developmental coordination disorder and known in many states and special

education laws as physical disabilities, is the marked impairment in the development of motor coordination, and the diagnosis is made when impairment drastically affects academic achievement or activities of daily living. This diagnosis can be made if the coordination difficulties are not due to a general medical condition such as cerebral palsy, hemiplegia, or muscular dystrophy. With this disorder, younger children may display clumsiness and developmental delays in walking, crawling, sitting, tying shoelaces, buttoning shirts, and zipping pants. In contrast, older children may have difficulties with assembling puzzles, building toys, motor coordination while playing ball, and motor coordination difficulty with handwriting. The prevalence of this disorder is estimated to be about 6% of children in the age range of 5–11 years, and it is generally noticed when child attempts a motor task.

Communication Disorders

Communication disorders, known in many states and special education laws as speech and language impairments, are diagnosed through the assessment of receptive and expressive communication skills. Language refers to the verbal transactions that are used to receive and send messages for communication, and it is the essential way humans communicate thoughts and feelings. With children, expressive language refers to the ability to speak, write, or use sign language to communicate. In contrast, receptive language is when a child receives input from his/her senses and translates that into meaning.

Children with disabilities can display significant language deficits, and with school-age children communication disorder is a common disability. For example, with children under age 3, 10–15% experience language delays. With school-age children, 3–7% have language delays. Finally, developmental expressive language disorder is more common with boys than with girls (DSM-IV-TR). In terms of course of development, communication disorders can be noted by age 3, but expressive language disorder can occur at any age and can be due any form of organicity such as brain lesions, head traumas, or strokes. The assessment of communication disorders must take into account the child's culture and his/her language context, especially with children from bilingual homes.

Pervasive Developmental Disorders

The DSM-IV-TR classifies autistic spectrum disorders as pervasive developmental disorders, and these disorders are characterized by severe and ongoing impairment in reciprocal social interactions, communication skills, and stereotyped behavior. Under this category are autistic disorder, Rett's disorder, Asperger's disorder, and pervasive

developmental disorder not otherwise specified (American Psychiatric Association, 2000). As Dyches *et al.* (2004) pointed out, autistic disorder is an impairment in social and communication skills; and it can sometimes be referred to as infantile autism, childhood autism, or Kanner's autism.

Children with autistic spectrum disorders may have impairment with eye-to-eye contact, facial expressions, body postures, and gestures. Essentially, with this condition, children can have impairment in many nonverbal behaviors. Because autism is a developmental disorder, it has neurological origins that appear at birth or early development (Akshoomoff *et al.*, 2002; Dacey *et al.*, 1999; Filipek *et al.*, 2000).

The notion that autism is a broad spectrum disorder suggests that the skills and deficits vary from child to child. For example, some children with autism have normal or high IQs and others fall within the cognitive disability range. Moreover, some children with autism are highly verbal, while others do not have functional speech. Except for Rett's disorder, other pervasive developmental disorders are called autistic spectrum disorders (Atkinson, 1990; Atkinson *et al.*, 1992; Dyches *et al.*, 2004; Hviid *et al.*, 2003). Impairments in reciprocal social interaction, verbal and nonverbal communication, and restrictive, repetitive, and stereotyped behavior patterns are the major characteristics of autism (Autism Society of America, 2004). For instance, stereotyped behaviors include rocking, dipping, swaying, and clapping. Even a behavior as benign as a child walking on his/her tiptoes may contribute to the diagnosis of autism. The attachment to inanimate objects such as strings, rubber bands, and tin cans can also be indicators of this broad spectrum disorder.

The DSM-IV-TR defined adaptive functioning as the capacity a student has to cope with life demands and how well he/she meets the standards of personal independence expected for his or her particular age group, sociocultural background, and community setting (Oakland and Houchins, 1985; Smalley, 1998). The DSM-IV-TR reported the median rate of autism in epidemiological studies as 5 cases per 10 000 individuals and ranges from 2 to 20 cases per 10 000 individuals (Filipek *et al.*, 1999; Garnett and Attwood, 1997). The rate of autism is 4–5 times higher in males than females, and females with this disorder tend to have more severe cognitive disability than males. Diagnostically, the onset of autism is before the age of 3 years, and researchers are hoping to diagnose this spectrum disorder by 18 months so that interventions can occur (Ozonoff *et al.*, 2003). Familial patterns suggest that the probability of autistic spectrum disorder is increasing within families. For example, several individuals within a family may meet this diagnosis (Lord *et al.*, 2000).

The DSM-IV-TR described the diagnostic features of Rett's disorder as the development of multiple specific deficits following a period of normal functioning shortly after birth. At first, child development is normal through

the first 5 months of life. Even though at birth head circumference is normal, somewhere between 5 and 48 months, head growth decelerates. An associated feature of Rett's disorder is severe or profound cognitive disability, and in terms of prevalence, this disorder has only been reported with females. Finally, Rett's disorder has only been diagnosed in females.

The DSM-V-TR defined Asperger's disorder as impairment in social, occupational, and other areas of functioning, and unlike autistic disorder, there are no significant deficits in language acquisition. Very similar to autistic disorder, Asperger's disorder is defined as lack of social reciprocity, and eccentric and one-sided social interaction with others. Like other pervasive developmental disorders, the disorder is diagnosed at least 5 times more in males than in females. Even though there are no cures for autistic spectrum disorders, early assessment and interventions are critical for favorable outcomes. Experts recommend between 20 and 40 h of speech, occupational, and other interventions per week. Often, these interventions are not covered by private insurance and the cost can be as expensive as \$100 000 a year (Courchesne *et al.*, 2003; Volkmar, 2000; Wodrich and Barry, 1991; Yeargin-Allsopp *et al.*, 2003).

Developmental screening tests can be used to assess autistic spectrum disorders. Among the instruments that have been developed for screening are Checklist of Autism in Toddlers (CHAT; Baird *et al.*, 2000), the modified Checklist for Autism in Toddlers (M-CHAT; Robbins *et al.*, 2001), the Screening Tool for Autism in Two-Year olds (STAT; Stone *et al.*, 2000), and the Social Communication Questionnaire (SCQ; Berument *et al.*, 1999). The SCQ is used for children 4 years of age and older (Carter *et al.*, 1998; Couper and Sampson, 2003; De Bildt *et al.*, 2005; Ozonoff *et al.*, 2003). The first step for assessing an autistic spectrum disorder is to gather a developmental history from the parents of a child. Next, a professional must have direct interaction with a child. Finally, one has to review the child's records. Again, this level of assessment takes a team of professionals such as pediatricians, psychiatrists, psychologists, special educational teachers, audiologists, and parents (McEachin *et al.*, 1993; Stevens, 1986). In terms of research, the Autism Diagnostic Interview – Revised (ADI-R) is the gold standard for assessing autistic spectrum disorders, and it takes about 3 h (Lovaas, 1987; McDougle *et al.*, 2003; Ozonoff *et al.*, 2003). It is important that the SCQ (Western Psychological Services) is based on the ADI-R; but unlike the ADI-R, it is a parent-report questionnaire with empirically derived cutoff scores. In addition, a score of 15 distinguishes autistic spectrum disorders from nonautistic spectrum disorders. If a child receives a score of 11, additional screening is warranted. The SCQ has a sensitivity of 0.81 and a specificity of 0.73. A score of 22 distinguishes autism from other autistic spectrum disorders. Finally, a parent can complete the SCQ in about 10 min.

If one were to check the literature, it appears that there is a new Asperger's syndrome scale every month, but Ozonoff and her colleagues do not endorse any of these scales; however, she does recommend the ADI-R and SCQ. The difficulty with these scales is that they do not verify the diagnosis of Asperger's syndrome (Ehlers *et al.*, 1999; Scott *et al.*, 2002; Ottenbacher *et al.*, 1999; Tadevosyan-Leyfer *et al.*, 2003). Clearly, there are several instruments that can aid the diagnosis of autism spectrum disorders, and one may find a new one in the literature each month. The ADI-R is the gold standard for assessing autistic spectrum disorders, but it is a lengthy interview and takes about 3 h. Learners with autistic spectrum disorders tend to need very structured and specialized programs. It is critical to note that applied behavior analysis (ABA) is an evidence-based treatment that has been recommended for autistic spectrum disorders (Autism Society of America, 2004), and the ABA demonstrates the relationship between behavior and the environment (Sapp, 2004).

Attention-Deficit and Disruptive Behavior Disorders

In most states and special education laws, attention-deficit and disruptive disorders are partly the category, emotional/behavioral disorders (E/BD). This category encompasses conduct disorders, oppositional defiant disorders, and other emotionally and behaviorally related disorders. Specifically, attention deficit and disruptive disorders are characterized by inattention and/or hyperactivity-impulsivity, and children must display symptoms in school and home. Moreover, these symptoms must interfere with developmentally appropriate academic and social functioning. In terms of prevalence, 3–7% of school-age children are estimated to have these disorders, and these disorders are more dominant in boys than in girls. Even though behavior modification and stimulant medications are used to treat these disorders, within a school setting, these disorders can be enigmatic.

Conduct Disorders

The predominant features of conduct disorder are persistent patterns of behaviors that violate the rights of other children, and this disorder is broken down into two-types aggressive conduct that threatens the well-being of other children and nonaggressive conduct that results in property damage. The childhood-onset type of conduct disorder occurs before the age of 10, while the adolescent-onset type occurs after 10 years of age. The DSM-IV-TR reported prevalence rates ranging from less than 10% to more than 10%, and these rates are higher for boys than

girls. Likewise, boys tend to exhibit fighting, stealing, vandalism, and disruptions in school, and girls tend to display lying, truancy, running away, substance use, and prostitution. Finally, another pattern of this disorder is physical cruelty toward animals.

Oppositional Defiant Disorders

Even though conduct disorder and oppositional defiant disorder are both disruptive disorder in children, oppositional defiant disorder is a persistent pattern of negative, disobedient, or hostile behavior toward parents and teachers that last at least 6 months. A diagnosis of oppositional defiant disorder is made if a child has four or more of the following:

- Frequently loses temper.
- Frequently argues with parents or teachers.
- Frequently refuses to comply with rules or requests from adults.
- Frequently annoys others.
- Frequently blames other for his/her misbehavior.
- Frequently annoyed by others.
- Frequently anger and resentful.
- Frequently vindictive.

Feeding and Eating Disorders of Infancy or Early Childhood

Feeding and eating disorders of infancy or early childhood include Pica, rumination disorder, and feeding disorder of infancy or early childhood. Children or infants are diagnosed with Pica when they eat one or more nonnutritive substance on a regular period for at least 1 month. Younger children and infants tend to eat paint, plaster, cloth, and hair, while older children tend to eat sand, insects, animal droppings, leaves, and pebbles. In contrast, adolescents tend to eat mud or soil. Children with this disorder tend not to have aversion to food and the behavior has to be developmentally and culturally inappropriate. Before about 18 months, it is common for infants to eat non-nutritive substance and this would not warrant the diagnosis of Pica.

Ruminations disorder is the repetitive regurgitation and rechewing of food in a child and it lasts at least 1 month, but the condition cannot be due to an associated gastrointestinal condition such esophageal reflux. Fortunately, rumination disorder is rare, but when it happens, children can become malnourished. Feeding disorder of infancy or early childhood is characterized by the inability of an infant or a child to eat adequately for at least 1 month, and the result is significant weight loss; however, there cannot be medical conditions that account for the feeding disorder. Finally, children with this disorder tend to be irritable and withdrawn.

Tic Disorders

Tic disorders includes Tourette's disorder, chronic motor or vocal tic disorder, transient tic disorder, tic disorder not otherwise specified, and a tic is a sudden stereotyped motor movement or vocalization, and motor and vocal tics can be simple, involving a few muscles or a sound, or complex, involving many muscle groups, or many sounds. Simple vocal tics can be meaningless vocalizations such as grunting, sniffing, snorting, or chirpings; and complex vocal tics involve coprolalia (sudden vocalization of obscenities), palilalia (repeating one's own words), and echolalia (repeating the words of others). Complex motor tics include facial contortions, eye blinking, gestures, jumping, and twisting; and this disorder includes copropraxia (sudden tic-like vulgar gestures and echopraxia) tic-like imitation of another's movements.

Elimination Disorders

Encopresis and enuresis are the two most common elimination disorders with children that are not due exclusively to a medical condition. Encopresis is the elimination of feces into inappropriate places, while enuresis is the elimination of urine into inappropriate places. Encopresis cannot be diagnosed until a child is 4 years old and enuresis cannot be diagnosed until a child is 5 years old.

Other Disorders of Infancy, Childhood, or Adolescence

Often, disorders of infancy, childhood, or adolescence include separation anxiety disorder, selective mutism, reactive attachment disorder of infancy or early childhood, stereotypic movement disorder, and disorder of infancy, childhood, or adolescent not otherwise specified. separation anxiety disorder is excessive anxiety that a child has concerning his/her home or family, and this anxiety is not developmentally appropriate. Selective mutism, formerly elective mutism, is the failure of a child to speak in school, home, or with playmates. Reactive attachment disorder occurs when a child does not initiate or respond to social interactions with family members or friends, or the child shows a pattern of hypervigilance such as watchfulness or freezing in place.

Unlike pervasive developmentally disorders, reactive attachment disorder is not due only to developmentally delays. Stereotypic movement disorder, formerly stereotypy habit disorder, is repetitive nonfunctional motor behaviors that interfere with school or home activities, and these movements can include rocking, hand waving, head banging, self-biting, or a child hitting various parts of his/

her body. Finally, disorders of infancy, childhood, or adolescence not otherwise specified are disorders that do not meet criteria for a specific disorder with the classification.

Conclusion

From this article, scholars can conclude the following:

- Diagnosis and classification are complex multiaxial processes.
- MMBA is a comprehensive intra-individually based assessment that has multicultural appeal.
- Test score reliability and validity are based on educational test score theories, not facts.
- Prejudice can influence diagnosis and classification.
- Culture and language must be included within assessment processes.

This article discussed the intricacies of diagnosing and classifying children with special needs, and this is especially intriguing within a multicultural context. Moreover, minority children are seldom part of standardization samples for educational diagnosis and classification. Diagnosis and classification include processes of using tests and other measures to assess the educational needs of children with special needs. Unlike assessment in general education, assessment of children with special needs can be different for each child; and it must be an intra-individual appraisal of a child's needs. Finally, diagnosis and classification must be modified to fit the unique needs of children requiring special education (Venn, 2000).

Direct Instruction and the Education of Children with Special Needs

T Mehring, Emporia State University, Emporia, KS, USA

© 2010 Elsevier Ltd. All rights reserved.

For most students with exceptionalities, a broad array of explicit and implicit instructional techniques and strategies has been known to be helpful. Clearly, this broad array of techniques has the potential to help a diversity of learners acquire and use academic skills and content. One approach that has proven to be successful with many students with mild cognitive and learning disabilities is direct instruction (Ormrod, 2008), which is the focus of this article. This model can be used in inclusive classrooms to benefit all learners as well as in special education classrooms with individuals or small groups of students with special needs. Historically, this model emerged from the work of Siegfried Engelmann and his colleagues in the mid-1960s. The underlying assumptions of the model are:

1. all children can be taught;
2. the learning of basic skills and their application in higher-order skills are essential to intelligent behavior and should be the focus of a compensatory education program; and
3. the student who is not achieving at grade level should be taught at a faster rate than typically occurs if they are to catch up with peers (Engelmann *et al.*, 1988: 303).

Stein *et al.*, (1997) emphasized three essential teaching components for the direct instruction model: instructional design, presentation techniques, and instructional organization. Each of these is considered essential for successful teaching and learning.

Direct instruction is an instructional model designed to teach well-defined knowledge and skills that are needed for later learning (Eggen and Kauchak, 2006; Rosenshine and Stevens, 1986). It is a form of instruction that encompasses the use of a systematic lesson structure as well as a set of key instructional behaviors (Carnine *et al.*, 1990; Becker *et al.*, 1982). As an instructional approach, it ranges from a highly structured, nearly scripted approach (Carnine *et al.*, 2006; Koziuff *et al.*, 2000) to one that is more flexible and cognitive in its direction (Eggen and Kauchak, 2006; Rosenshine and Stevens, 1986). It uses a variety of techniques, including questioning, cueing, and reinforcement of students. In addition, direct instruction is most suitable for teaching information and skills that are well defined and that should be taught in a step-by-step sequence (Rosenhine and Stevens, 1986). When using direct instruction, teachers proceed with instruction

at a brisk pace. They are organized and prepared to conduct the lesson as expeditiously as possible. Large amounts of content are dissected into short lessons so that most students are able to succeed. Every student has a chance to participate, few students answer questions incorrectly, and transitions between activities in the lesson are brief and smooth. This approach is generally implemented more easily with individual students and/or small groups rather than with an entire classroom. When implemented appropriately, direct instruction can lead to significant gains in achievement of basic skills and higher-level thinking processes (Ellis and Rock, 2002). High student interest and self-efficacy for the subject matter in question and low rates of student misbehavior have also been demonstrated (Weinert and Helmke, 1995; Tarver, 1992; Rosenshine and Stevens, 1986).

Direct instruction is an approach that incorporates elements of both expository instruction and mastery learning. Varied techniques are used to keep students continually and actively engaged in learning and applying classroom subject matter (Tarver, 1992; Gagne, 1985; Weinert and Helmke, 1995; Englemann and Carnine, 1982). To some extent, direct instruction is based on applications from behavioral and cognitive psychology. Incorporating behaviorism, direct instruction requires learners to make frequent responses and provides immediate reinforcement of correct responses through teacher feedback. Cognitive psychology is incorporated into this teaching approach through focusing instruction on the importance of attention and long-term memory-storage processes in learning, focusing on working memory and the value of learning basic skills to automaticity (Rosenhine and Stevens, 1986).

Theoretical and Practical Underpinnings

Different theorists (Carnine *et al.*, 1997; Lerner, 2006; Mainzer *et al.*, 2003) describe and implement direct instruction differently. However, in general, these theorists agree that direct instruction involves small and carefully sequenced steps, fast pacing, and significant teacher–student interaction. Specific teaching behaviors that have been shown to impact student achievement are key ingredients related to successful implementation of direct instruction. According to Rosenshine (1986) and Rosenshine and Stevens (1986), direct instruction:

- teaches academic skills directly;
- is teacher directed and controlled;
- uses carefully sequenced and structured materials;
- provides students mastery of basic skills;
- sets goals that are clear to students;
- allocates sufficient time for instruction;
- uses continuous monitoring of student performance;
- provides immediate feedback to students; and
- teaches a skill until mastery of that skill is achieved.

Each lesson typically involves most or all of the following components:

1. *Review of previously learned material.* The teacher or service provider reviews relevant content from previous lessons, checks homework assignments, involving that content, and reteaches any information or skills that students have not yet mastered.
2. *Statement of the objectives of the lesson.* The teacher or service provider describes one or more concepts or skills that students should master in the new lesson. Teachers explicitly tell students what will be covered during instruction, establish performance goals, and engage students in determining their daily learning goals to produce higher levels of achievement (Ellis and Rock, 2002), and describe how current learning relates to what has previously been learned.
3. *Presentation of new material in small, logically sequenced steps.* The teacher or service provider presents a small amount of information or a specific skill. An advanced organizer, question, or scaffolding of students' efforts may be used to enhance the ability of students to process and remember the material. Modeling involving teacher demonstration of how a task is completed correctly is provided to assist students in learning new information. Thinking aloud while completing the model also helps students make a cognitive connection to the knowledge or skill to be learned. Modeling should also include many examples of what the expected behavior looks like. Nonexamples should be presented so that students can clearly differentiate expected performance. Teacher-directed questioning throughout the lesson serves as a check to determine whether students are acquiring knowledge.
4. *Guided student practice and assessment after each step.* Guided practice involves student rehearsal while the teacher closely supervises student work. Students are provided numerous opportunities to practice what they are learning. Practice may include answering questions, solving problems, or performing modeled procedures. The teacher gives hints during students' early responses, provides immediate feedback about performance, makes suggestions about how to improve, and provides remedial instruction as needed. After students have completed guided practice, the teacher checks to be sure that mastery of the information or skill has occurred. Unison response using signals (e.g., finger snap, hand

drop, clap, touching a board, or presentation material) are used to cue students to demonstrate knowledge of information. Typically, the teacher gives directions or asks a question, provides a thinking pause, and then cues the response. Using a signal to cue the response gives slower students in the group extra time (i.e., 5–10 s) to think about the answer. The overall pacing of direct instruction lessons is relatively quick. The idea is to present numerous examples in rapid succession so that students can see how the examples are similar to and different from one another. If presentation of examples is too slow, students may forget the earlier examples and will not be able to compare them to later examples (Adams and Engelmann, 1996).

5. *Independent practice.* Once students have acquired a specified benchmark of mastery (e.g., 85% of questions answered correctly), they engage in additional activities (either independently or in small groups) to learn the material to automaticity. Independent practice involves student performance of the new task without assistance.
6. *Frequent follow-up reviews.* The teacher provides many opportunities for students to review previously learned material through homework assignments, writing tasks, paper-and-pencil quizzes, or other appropriate activities (Lerner, 2006). Daily review at the beginning, middle, or end of a lesson can alert teachers to less-than-acceptable levels of learning. When unacceptable learning is detected, reteaching occurs.

It is critical to provide frequent and immediate feedback and correction to students as they are engaged in guided and independent practice. Verbal praise or other types of reinforcement for correct performance assure students they are correctly demonstrating critical elements of the task to be learned. Likewise, alerting students when they are not on target redirects them to correct task performance.

Two direct instruction methods have been used extensively with students with severe reading problems and are not typically used in general education classrooms. The Direct Instruction Reading Program (Carnine *et al.*, 1990) teaches basic decoding and comprehension skills. Lessons are highly structured and are based on carefully sequenced skill hierarchies that emphasize letter–sound correspondence, word identification, and use of words in stories. The program uses a synthetic phonics approach and emphasizes auditory blending to combine isolated sounds into words. The Corrective Reading Program (Engelmann, 1999) is designed for students in grades 4 through 12 and consists of two strands: decoding and comprehension.

Future Perspectives

Recent developments in the field of education, such as changes made to the Individuals with Disabilities Education

Act (IDEA), the promulgation of standards-based education, and the implications of No Child Left Behind (NCLB) legislation, are having a profound effect on the programs of students with special needs. Demonstration of and accountability for student learning are critical elements of each of these directives.

Several studies have documented the effectiveness of direct instruction with students who have special needs (Mainzer *et al.*, 2003; Carnine *et al.*, 1990). Students with histories of problems in automaticity, metacognitive strategies, memory, attention, generalization, proactive learning, and motivation have demonstrated learning gains when engaged in direct-instruction teaching approaches (Howell and Nolet, 2000). Direct instruction is particularly beneficial for students who have a rigid motivational pattern, lack significant prior knowledge, or encounter repeated failure on a task (Howell and Nolet, 2000). Stanovich (1994) found that direct instruction and teacher-directed strategy training are more effective for teaching word-recognition skills, especially for at-risk children, children with learning disabilities, and children with special needs. Numerous researchers have demonstrated that direct instruction helps students at risk for learning problems acquire reading and spelling skills (Moats, 2000; and Lyon, 1995). Slavin *et al.* (1994) found that direct instruction improved reading skills in students at risk for reading failure. Mercer *et al.* (1994) found that direct-instruction methods, such as description of procedures, modeling of skills, use of cues and prompts, direct questioning of students to ensure understanding, and practice to mastery, result in improved mathematics performance for students with math disabilities. Leinhardt and Pallas (1982) and Rosenshine and Stevens (1986) documented the effectiveness of direct instruction with students who have learning disabilities. Direct instruction was found to be effective in working with low achievers and students with exceptionalities (Kroesberger *et al.*, 2004; Troia and Graham, 2002).

Although the direct instruction model has been around for several decades, new applications and improvements continue to emerge. Direct-instruction programs may be used with all students from whom high levels of academic achievement are expected and desired (Tarver and The Division for Learning Disabilities and Division for Research Alerts Editorial Committee, 1999). The repetition, reinforcement, careful sequencing of skills, and correction procedures are helpful for all students but are critical for students with disabilities. This instructional model sets up students for success and ensures mastery-level learning prior to moving on to new content. This must continue to be the vision of the future in the education of students with special needs.

Conclusion

Direct instruction allows teachers to carefully plan and execute specific strategies and presentations to enhance

learning for all students. Through using direct instruction, teachers ensure that students are well informed about what is expected, what is being learned, why it is being learned, and how it can be used (Ellis and Larkin, 1998). Effective instruction takes place in classrooms in which students have frequent, sustained, and consistent opportunities to read, write, listen, and talk about what they are learning (Schmidt *et al.*, 2002). Direct instruction provides an instructional approach that results in student learning and student success.

The potential for giftedness exists among all racial, ethnic, cultural, and linguistic groups (Daniels, 2003, 2007), and for every segment of the population of students with disabilities (Bianco, 2005). However, prior to the 1970s, emphasis on students who are both gifted and disabled was virtually nonexistent (Grimm, 1998). It was during the 1970s that Maker (1977) increased educators' awareness of the needs of gifted students with disabilities. At first, the primary emphasis was almost exclusively on gifted students with learning disabilities, a cluster of students who soon became recognized as twice exceptional. Although it has long been realized that intellectual giftedness exists among many different populations of persons with disabilities, such as those with a learning disability (LD), physical disability, speech and language impairment, deafness or hearing impairment, blindness or visual impairment, autism, Asperger's syndrome, cerebral palsy, attention-deficit hyperactivity disorder, behavioral disorder, and other disabling conditions (Cash, 1999; Little, 2002; Hardman *et al.*, 2008; Karnes *et al.*, 2004; King, 2005; Neihart, 2000; Nielsen *et al.*, 1993; Reis and McCoach, 2002), the focus on gifted students with disabilities was not that widespread.

There are many prominent individuals with disabilities who have gifts and talents. Among them are actors, actresses, celebrities, singers, scholars, and world leaders. Helen Keller (author, political activist, and lecturer) had dual sensory impairment (deafness-blindness). Franklin D. Roosevelt (32nd US President) had polio and limited physical ability. Stephen Hawking (theoretical physicist) has amyotrophic lateral sclerosis (ALS), sometimes called Lou Gehrig's disease. Walt Disney (renowned cartoonist who produced the first full-length animated motion picture) was a slow learner and considered to be learning disabled. Albert Einstein (mathematician/physicist, provided the theory of relativity, and was also awarded the Nobel prize in physics) had (LD) and did not speak until age 3. Thomas Edison (American inventor) was deaf. Ray Charles (musician) was blind. Tom Cruise (actor, film producer, Golden Globe Award winner) and Whoopi Goldberg (Oscar, Grammy, Golden Globe, NAACP Image Award winning actress; comedienne, media personality, high school dropout) have dyslexia. Stevie Wonder (musician, singer) is blind.

Although the population of students with dual exceptionalities is a relatively new category among the gifted (Gallagher and Gallagher, 1994), they continue to remain underserved, underestimated, and underidentified. Problems

in identifying and determining the number of students with disabilities in gifted programs can be associated to a number of factors, including the differing definitions of giftedness, teacher biases, inadequate teacher training, the varying theoretical and political views, and assessment procedures. According to Karnes *et al.* (2004), the number of students with disabilities in gifted programs is estimated to "range from 120,000 to 180,000 (Davis and Rimm, 1998), to as many as 540,000 (Minner, 1990)" (p. 16). While there remains a sparsity of empirical data to support these estimates, it is well known that discrepancies in prevalence estimates do and can occur in all categories of exceptionality. In the case of students who are twice exceptional (gifted and disabled), these discrepancies seem more variable than most (Hardman *et al.*, 2008). This article focuses on how to identify gifted students with disabilities and how to help them to maximize their fullest potential.

Identifying Gifted Students with Disabilities

Giftedness is multifaceted, and identifying high-potential students who are twice exceptional can be a daunting and challenging task. Most identification strategies used for giftedness have focused primarily on cognitive abilities, with few considering creative behaviors (Clark, 1997). As giftedness is primarily associated with high intelligence quotient (IQ) scores and high scores on aptitude tests, these measures have not been particularly useful in identifying children with disabilities who are intellectually or otherwise gifted (Hardman *et al.*, 2008). However, what is known is that the assessment procedures typically used to assess giftedness in the general population are inadequate, without major modifications, for unmasking the hidden potential of gifted children with disabilities (Lovett and Lewandowski, 2006; Maker, 1977).

The best practices for identifying students with gifts and talents, including twice-exceptional students, are those that include multiple criteria. Multiple criteria, as explained by Coleman (2003), involve multiple types of information that provide indicators of the student's cognitive abilities, academic achievement, performance in a variety of settings as well as their interests, creativity, motivation, and learning characteristics/behaviors; multiple sources of information such as test scores, school

grades, and comments by classroom and specialty area teachers, counselors, parents, peers, and students themselves; and multiple time periods to ensure that students with gifts and talents are not missed, overlooked, or unidentified by one-shot identification procedures. Although attempts to identify twice-exceptional students (a term coined by James Gallagher) began during the 1970s, it was not until 2004 that federal law (the Individuals with Disabilities Education Improvement Act, P. L. 108–446) declared in Subpart 4, Section 681, (d), (3), (J) gifted and talented students with disabilities as a priority whose needs could be addressed with federal funding.

There are a number of barriers hindering the identification and referral of students with disabilities for gifted programs. Among the many barriers . . . are teachers' stereotypic beliefs (Cline and Hedgeman, 2001; Johnson *et al.*, 1997; Minner *et al.*, 1987; St. Jean, 1996) and inadequate teacher preparation (Davis and Rimm, 2004; Johnson *et al.*, 1997). According to Cline and Hedgeman, stereotypic expectations work against gifted students with disabilities in two ways: (1) misconceptions about the characteristics of gifted students with gifts and talents, and (2) low expectations for students with disabilities (see Bianco, 2005). Other factors that contribute to students with disabilities not being included in gifted education include:

1. the likelihood of not being identified as having an LD when the severity of the discrepancy between IQ and achievement is sufficiently high (MacMillan *et al.*, 1998);
2. students not being allowed sufficient (e.g., enough extra) time or appropriate (e.g., assistive) equipment during testing situations for them to demonstrate their talents in spite of their disabilities;
3. the inflexibility of states' regulations for education of the gifted (Grimm, 1998);
4. bias about some disabilities (e.g., cerebral palsy) that overshadow actual abilities and talents (Willard-Holt, 1998); and
5. the narrow views of some individuals that high abilities and learning problems cannot possibly coexist (Brody and Mills, 1997).

Thus, it is clear that identifying the hidden gifts and talents of twice-exceptional students requires the use of multiple assessment criteria, and the collaborative efforts of general-classroom teachers, special-education teachers, gifted-education teachers, and parents. Due to the complex nature of their dual exceptionalities, twice-exceptional students become at-risk youngsters because their diverse educational and social-emotional needs are often undetected; and they are overlooked or go unrecognized for long periods of time because teachers view them within the general population as underachievers or average learners (Nielsen, 2002).

Characteristics of Gifted Students with Disabilities

Twice-exceptional students are a highly diverse and very heterogeneous group. They face a number of challenges in the classroom and in their personal lives. Their unique characteristics, as seen by some (Nielsen and Higgins, 2005), thrust them into an emotional storm which become evident when they are expected to acquire specific academic skills that are underscored by prerequisite skills which they do not have or have not yet acquired; and, when they are expected to demonstrate appropriate social skills when these skills are beyond their reach. Initially, teachers view the abilities (e.g., high creativity and critical-thinking skills) of twice-exceptional learners as positive, exciting, and challenging, but their enthusiasm soon changes when they become frustrated with the inability of these youngsters to demonstrate academic skills, and with their recurring and sometimes extreme behavioral difficulties (see Nielsen and Higgins, 2005).

In the literature, twice-exceptional students are generally characterized as having gifts and talents in one or more areas of exceptionality (e.g., specific academics, creativity, and performing arts) and as having a disability, as defined by both federal and state law. Typical characteristics for this population are generally described as areas of giftedness and areas of challenge. In the areas of giftedness, twice-exceptional learners are characterized as having a wide range of interests that are often unrelated to school topics, an exceptional memory, a superior vocabulary, an unusual imagination, exceptional problem-solving and reasoning skills, an unrelenting sense of curiosity, an unusual sense of humor that may sometimes appear bizarre, an ability to manipulate situations to their own advantage as a means of compensating for their disability, a high level of creativity in their approach to tasks to mask or compensate for their disability, in-depth insight into complex issues, being resourceful, invoking lots of questions, and uninhibited in their expressions (Nielsen, 2002; Nielsen and Higgins, 2005). In the areas of challenge, twice-exceptional learners have uneven academic skill development, discrepant verbal and performance abilities, auditory and visual processing problems, a lack of organizational and study skills, low self-esteem, high levels of impulsivity and distractibility, poor social skills, deficits with long-term and short-term memory, and attention problems which are evident in areas of low interest (see Nielsen, 2002; Nielsen and Higgins, 2005).

Surprisingly, many twice-exceptional learners view themselves as primarily disabled because of the attention focused on things they cannot do well, which makes it difficult for them to believe they are bright, capable learners (Nielsen and Higgins, 2005). The continuous struggle between intellectual strengths and academic challenges has caused many of these youngsters to experience social

and emotional difficulties. Some develop low self-concepts (Swesson, 1994), have poor social skills, and experience difficulty fitting in with peers (Vespi and Yewchuk, 1992). They are easily frustrated and exhibit increased frustration from high expectations and standards for achievement that goes along with being gifted (Coleman, 2001). When faced with disappointments in the classroom, they may become disruptive or aggressive, argumentative, very opinionated, and inflexible (King, 2005; Nielsen and Higgins, 2005). When faced with difficult or challenging tasks, they are known to persevere when encouraged and supported (Vespi and Yewchuk, 1992). While it is evident that giftedness can, and does exist, across a broad spectrum of disabilities, only the distinguishing characteristics for students with learning disabilities, attention-deficit hyperactivity disorders (ADHDs), and emotional/behavioral disorders (EBDs) are discussed.

Gifted Students with Learning Disabilities

A student with an LD has a disorder in one or more of the basic psychological processes involved in understanding or in using spoken or written language. This disorder may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or to do mathematical calculations, including conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia. There are three types of gifted LD students—those with subtle learning disabilities who are less likely to be referred for special-education testing and who participate in gifted programs; those with severe LDs, who are rarely formally identified as gifted; and those who remain unidentified as either learning disabled or gifted because their disabilities conceal their gifts, and their gifts camouflage their disabilities (McCoach *et al.*, 2001).

Tannenbaum and Baldwin (1983) refer to gifted students, who also have LD, as paradoxical learners. These youngsters have high intellectual ability, but exhibit significant discrepancies in their level of performance in some academic areas (e.g., reading, math, spelling, and spoken or written language). This discrepancy, while not due to lack of educational opportunity or other health impairment, stems from differences in how the student's brain works and how it processes information. Although gifted students with LD exhibit patterns of behavior typical of other students who are gifted (e.g., high intellectual potential, excellent memory, and advanced vocabulary), they also exhibit characteristics common to students with ADHD such as distractibility, inattentiveness, inefficient learning strategies, and poor organization and study skills. Despite the high functioning level of gifted students with LD, most do not receive services for their gifts and talents because their giftedness masks their disability, or it provides them with the ability to compensate for their LD (Gargiulo, 2006). Unlike other gifted students, these

twice-exceptional learners have low self-knowledge and low self-esteem; and they often have conflicting thoughts concerning their capabilities and the expectations imposed upon them (Waldron, 1987). Therefore, it is not unusual for them to experience “frustration and have difficulty coping with the discrepancy between their giftedness and their learning disability” (King, 2005: 20).

Gifted Students with ADHD

ADHD is a common behavioral disorder of childhood. Children diagnosed with this disorder present a constellation of symptoms, including immaturity, impulsivity, inattention, and hyperactivity. Although gifted children with ADHD have intellectual characteristics similarly ascribed to gifted children without disabilities, little is known about their leadership ability, creativity, artistic talents, and musical abilities (Smith, 2004). What is known is that “many gifted children without ADHD exhibit symptoms similar to those seen in children with ADHD when they are bored or unchallenged” and that they “usually show variability in the quality of their performance on specific tasks, whereas gifted students are more consistent with their level of effort and performance . . .” (Reis and McCoach, 2002: 119).

Unlike their gifted counterparts, gifted students with ADHD differ in a number of ways. The most apparent being that of underachievement and high levels of non-conforming behaviors (e.g., inattention, impulsivity, distractibility, and high energy level), which mask their intellectual giftedness and make the probability of them being diagnosed as having giftedness and receiving services in a gifted program relatively low. It also creates the probability of them being diagnosed as either having ADHD or an LD. In terms of social and emotional maturity, these students lag behind their gifted peers. While some are able to compensate for their behaviors, others are seriously handicapped by them, thus adversely affecting their academic performance, causing challenges in their social interactions with others, and causing them to have low levels of self-concept or self-esteem. In addition, the low level of social and emotional maturity causes teachers to focus on their disruptive behaviors, subsequently creating situations that cause them to fail to see indicators of high ability.

Gifted Students with EBDs

Students with EBDs also exhibit behaviors that adversely affect their academic performance. They may display (1) an inability to learn that cannot be explained by intellectual, sensory, or health factors; (2) an inability to build or maintain satisfactory interpersonal relationships with peers and teachers; (3) inappropriate types of behavior or feelings under normal circumstances; (4) a general

pervasive mood of unhappiness or depression; and (5) a tendency to develop physical symptoms or fears associated with personal or school problems.

While some students with EBDs obtain measured intelligence in the gifted range of performance, they may not be referred or recommended for gifted programs; or they may be terminated from gifted programs because of their behavior (Reis and McCoach, 2002). The unpredictable and episodic behaviors and high dropout rates of gifted youngsters with EBDs are the defining features that differentiate them from the general population of students with gifts and talents. These behaviors usually result in inconsistent engagement and participation in learning opportunities, low levels of achievement, and a lack of opportunity for them to realize their potential. As the literature on gifted students with EBDs is sparse, more research is needed in this area to fully understand their diverse needs.

Educational Programming for Students Who Are Twice Exceptional

Academic and social needs of twice-exceptional learners can present a number of challenges for classroom teachers; and using teaching approaches not sanctioned by current research and evidence-based best practices can also present problems (Clark, 1997). According to the Individuals with Disabilities Education Act (IDEA), students with disabilities are entitled to a free and appropriate education in the least restrictive environment, which includes students with gifts and talents. However, in many instances, many twice-exceptional students are not receiving services that would allow for the full expression of their unique mixture of gifts, talents, and deficits. To ensure that dually diagnosed exceptional students develop their full potential, it will require the creation of appropriate curricula that addresses their gifts and talents as well as their disabilities. Thus, effective programming for the twice-exceptional learner requires collaboration between teachers of students with disabilities and teachers of children who are gifted (Clark, 1997). It also requires that teachers become aware of research and the current knowledge base that provide insight into strategies, interventions, and accommodations to meet the needs of these learners and that they gain access to enriched and accelerated instruction. Clearly, effective programming for twice-exceptional learners requires “a blending of instructional practices, such as cognitive training coupled with differential programming or curriculum compacting” (Gargiulo, 2006: 381). Earlier, Neu (2003) termed this form of instruction as a dually differentiated curriculum, and described it as a curriculum that “meets the needs of students who exhibit two contradictory sets of learning characteristics that creates “a balance

between nurturing the students’ strengths and compensating for their learning deficits” (p. 158).

Due to the unique characteristics of twice-exceptional learners, it is important that teachers and service providers provide them with appropriate curricular adaptations, accommodations, and interventions that respond to both their giftedness and their disabilities (Nielsen and Higgins, 2005). To succeed, these youngsters will need targeted services, programs, and interventions and a well-defined program model that ensures that services and interventions are tailored, well designed, integrated between special and gifted education, and consistent from year to year. The key elements that must be present in successful programs, according to Nielsen and Higgins are (1) implementation of an overarching program model, (2) use of interdisciplinary curricula, (3) intensive support for social, emotional, and behavioral needs, and (4) use of gifted education and special education strategies (p. 11). They also stated that the autonomous learner model (ALM) (Betts and Kerchner, 1999) and the Schoolwide Enrichment Model (SEM) (Renzulli and Reis, 1977) (p. 11) have been successful in maximizing the fullest potential of gifted students with special needs.

While there is no single best solution for meeting the needs of students with dual exceptionalities, Winebrenner (2003) noted that teachers and service providers should (1) teach students to appreciate, respect, and support individual differences; (2) understand that many students who have learning difficulties are global learners who prefer specific instructional formats for learning success; (3) when teaching content, always make sure that students see the big picture by introducing the concept first and the details second; (4) help students to become positively motivated by teaching them how to set realistic short-term goals and to take credit for teaching those goals, even if they represent the accomplishment of only part of the entire task; (5) teach students in ways that helps them to connect new learning with previously learned content or something they already know; (6) immerse all of the students’ sensory modalities in learning activities; (7) help students learn organizational skills by providing specific instruction in organizational techniques; (8) find and use all available technology to improve students’ productivity; and (9) allow students to take tests in diverse supervised environments that have the potential to enhance their concentration and performance. Moreover, effective teachers of twice-exceptional learners must understand how children learn. They must recognize that these children think differently from other children, and they must employ and use multifaceted and multidimensional approaches to assess learning. They must be knowledgeable of the subject matter they teach, the development of students, and the characteristics of learners. In addition, they must not adhere to a single theoretical perspective; but instead, they must adhere to both pedagogical frameworks in their teachings.

Clearly, effective teachers of twice-exceptional learners must be capable of transferring knowledge of subject matter and pedagogy into practice, not just focusing on students' disabilities but also on their abilities. They must use various technologies to support student learning as well as collaborate with teachers, parents, administrators, and other professionals. Effective teachers of twice-exceptional learners must develop personality traits that stimulate learning and understand that learning is a life-long process. These teachers must regularly monitor student learning, engage in ongoing assessments, and triangulate data from these assessments to seek and identify students' strengths and weaknesses. Moreover, they must be reflective practitioners who have a high sense of teaching efficacy.

Conclusion

The characteristics of students with gifts and talents are well documented in the literature. Among the common characteristics are (1) outstanding intellectual abilities, aptitude, and leadership; (2) extraordinary talents, creative abilities, and psychomotor skills; (3) abilities in the visual and performing arts; (4) advanced vocabularies, excellent memories, a great sense of humor, and vivid imagination; (5) highly verbal, quick learners, curious, and self-directed; (6) sensitivity to the needs of others; (7) good reasoning skills; (8) a remarkable ability to think logically, critically, and reflectively; and (9) high levels of independence, and a wide range of interests (Daniels, 2003, 2007). While we expect the occurrence of giftedness within the general population, it is often overlooked in the population of students with disabilities. Due to the complex nature in how giftedness masks or unmask itself among students with disabilities, educators need to look at these students holistically (in a variety of ways and in a variety of settings) and use a variety of approaches to provide opportunities for them to apply their strengths while ameliorating their deficits. For twice-exceptional children to maximize their potential, their intellectual strengths must be recognized and nurtured, and their disability must be simultaneously and appropriately accommodated using a dually differentiated curriculum that addresses both their disabilities and abilities to ensure that no child is truly left behind.

Glossary

Cultural sensitivity – The ability to work with and provide effective intervention for children and families from a variety of cultural backgrounds (i.e., racial, ethnic, gender, sexuality, ability, and religious).

Early childhood special education – Refers to educational interventions for children ages 3–8.

Early intervention – Refers to educational interventions for children birth to age 3 and their families.

Empirically-validated interventions – Interventions that are derived from careful, direct observation and experimentation.

IFSP – Or the Individualized Family Service Plan is a legal document that outlines service delivery measures for the young child and their family.

Target behavior – The behavior designated for change or intervention.

This article provides an overview of early-childhood special education (ECSE). A definition of early-childhood special education is offered with regard to current practice and special education law. Second, we present information with regard to the children and families who are served by ECSE professionals. Third, we note the type and location of ECSE services (including transition services) and provide characteristics of effective programs. Finally, we provide suggestions for the future both in terms of professional practice and preparing ECSE professionals.

Birth to kindergarten is a critical period for all children. Most children learn a remarkable amount from the time of their birth until they begin kindergarten. The development of young children is typically monitored across six domains; fine motor, gross motor, self-help/adaptive, communication, cognition, and social/emotional development abilities (Raver, 2009). Children experiencing delays in maturation across these domains may find themselves at increased risk of being diagnosed with a disability and school failure. Since one of the goals of ECSE professionals is to position children for school success, it is important to identify markers essential for young children's

school achievement. Children best prepared for school success are those who have developed age-appropriate language and social skills. For example, children who begin kindergarten with greater language skills are better positioned for academic success (Hart and Risley, 1995). In comparison, those children who enter school with significantly lower levels of language and/or deficits in social skills are at increased risk for school failure and possible special education placement (Adams, 1990; Walker and Severson, 2002).

Keogh *et al.* (2004) reported, in their 20-year follow-up study, that 3-year-old children identified as having developmental delays often continued to experience problems even into adulthood. Helping children to develop cognitive and social abilities during their early years is essential to their later success in school and beyond. In fact, a foundational belief of ECSE professionals is that early intervention is more beneficial to children and families than remedial interventions (Hooper and Umansky, 2009; Wolery and Bailey, 2002). For children with – or who are at risk for – disabilities, the developmental process that happens during their first 8 years of life is even more critical to their future success or failure than it is for their typically developing peers (Raver, 2009). Therefore, it is important to promote interventions and programs that support families in helping children with developmental delays to develop language, social, physical, and academic skills for the purpose of improving their ability to achieve success in their schools and communities (Sandall *et al.*, 2005).

Early Intervention/Early Childhood Special Education (EI/ECSE) services are typically available for children with special needs from birth to age 8. This period involves multiple developmental stages (as the child progresses from infant to school-age child) and environment changes (e.g., home–community, home–preschool, preschool–kindergarten, kindergarten–early elementary school). Young children must be assessed carefully with sensitivity to determine their abilities, needs, and environmental influences (including culture) (Linder, 2008). Beyond assessments, EI/ECSE professionals must also develop cogent interventions that are individualized for the children and families they serve. The quality of the early-childhood services has a direct impact on children's outcomes (Bowman *et al.*, 2000). Professionals must be careful in matching children, families, and EI/ECSE services. What is an

appropriate intervention for an infant and family is not necessarily appropriate for a preschooler (Wolery and Bailey, 2002). This sensitivity to the differing requirements for children and families related to age is one reason ECSE has evolved into two distinct service categories.

What Is Early Intervention/Early-Childhood Special Education (EI/ECSE)?

The two categories that provide services to young children and their families are early intervention and ECSE. The term early intervention is generally used to define services provided to children from birth to age 3 and their families (Part C of Individuals with Disabilities Education Act (IDEA)) (Raver, 2009). Thus, the focus of early intervention is family-centered with an emphasis on providing services in natural environments (Bruder, 2001; Wolery and Bailey, 2002). Early intervention seeks to address the special needs of infants and toddlers who have disabilities, developmental delays, or are at risk for disabilities (Bowe, 2000). It provides support to families including assisting them in understanding medical and educational information pertinent to their child and their child's special needs (Cartledge *et al.*, 2009). In addition, it should (1) be individualized for each child and family, (2) be systematic and regularly assessed for effectiveness, and (3) provide for a smooth transition to the child's next developmental stage, which may involve full classroom inclusion. In other words, effective early intervention should facilitate a seamless transition for the child and family to ECSE (Odom and Wolery, 2003).

ECSE usually refers to educational interventions for exceptional children 3–8 years of age (Part B of IDEA) (Bowe, 2000). Young children are eligible for ECSE services based on developmental delays or lack of development in communication, cognition, social/emotional behaviors, physical skills, or adaptive behaviors; that is, there is an increased focus on those children who demonstrate delays rather than those who are only at risk for delays. Similar to early intervention, parents are fully included in the development and implementation of interventions. It is during this developmental period that children often make the transition to school environments. Odom and Wolery (2003) recommended a unified theory of practice for professionals working with young children merging EI and ECSE. EI/ECSE involves the implementation of purposeful and systematic practices that are based on professional evidence, when available (Odom and Wolery, 2003). An interdisciplinary service perspective is helpful so that a seamless system is in place for exceptional children and their families across the developmental years of birth to age 8 (Bowe, 2000; Hooper and Umansky, 2009).

Services for Children

In order to address the needs of infants, toddlers, and families, each state has a system of EI/ECSE services designed to meet the special needs of children with disabilities, developmental delays, or who are considered at risk (Odom and Wolery, 2003; Hebbeler *et al.*, 2007). The goal of EI/ECSE services is to prevent or lessen the effects of disabilities or developmental delays on the lives of children and their families; that is, through careful planning and use of empirically validated interventions, children with or at risk for disabilities can develop skills that will promote success in their homes and beyond. The definition of EI/ECSE is not only limited to descriptions of the recipients of services and the services provided, but also involves the impact of those services on children and their families. In other words, intervention outcomes for children and families are an essential consideration for EI/ECSE professionals (Bruder, 2001).

The reality is that the effectiveness of ECSE interventions is at least partially defined by the ability to minimize or prevent the impact of disabilities on young children and the ability to assist/support families. This characteristic of EI/ECSE interventions making a positive difference in the lives of child is not always easily captured in quantifiable ways in applied settings. For example, it is not always possible to determine if an intervention was the sole cause for a child, previously considered at risk, who is now demonstrating typical developmental behaviors (i.e., prevent the manifestation of a disability). Possibly, the child's positive behavior is primarily a result of physical maturation. Similarly, it is not a simple matter to determine how well an intervention has diminished the potential negative impact of identified disabilities or developmental delays. The fact that a positive outcome is the most important variable in EI/ECSE. Effective interventions build on and enhance the natural physical and mental maturation processes that occur in children. Most EI/ECSE professionals reject the premise of simply waiting and allowing children with special needs to develop without intervention as a viable option. The early years of children's development are just too critical to take the risk that improvement will occur on its own (i.e., as a result of time and natural maturation).

There is a firm belief among professionals that EI/ECSE is needed and required for young children with special needs and their families to achieve positive outcomes. It is generally believed by early-childhood specialists that the earlier the intervention begins, the more positive the outcome for children (Raver, 2009). Therefore, the initial timing of the intervention is important. Not only is it important that interventions begin as early as possible in the lives of children at risk for or with disabilities, but that interventions have an empirical foundation and are designed to meet the unique needs of

each child (Odom and Wolery, 2003). Further, it is essential that interventions be closely monitored to determine the effects of the intervention on each child. If the period from birth to age 8 is critical, then every day without intervention or without effective intervention is not just unhelpful but potentially detrimental. The best way to determine the effectiveness of an intervention is by the careful assessment of important target behaviors across time. Clearly, ECSE provides a wide range of services designed to assist infants and young children with disabilities, developmental delays, or who are considered at risk to maximize their potential. Further, ECSE provides services designed to support and equip families of children with special needs in order to promote successful transitions into schools and beyond. Finally, the belief in early intervention is a strongly held conviction by EI/ECSE professionals (Guralnick, 2001; Hooper and Umansky, 2009). This belief in early intervention is not simply a concept held only by EI/ECSE professionals and the families of special needs children. Our society has also embraced the necessity for early intervention and laws have subsequently been enacted to ensure and protect the rights of children and families to EI/ECSE services.

Early Education Laws

Over 35 years ago, the first landmark legislation that impacted children with special needs and their families – the Rehabilitation Act (PL 93-112) – was signed into law. Passed in 1973, the Rehabilitation Act prohibited discrimination on the basis of disabilities by programs receiving federal funds. This prohibition includes programs serving young children (e.g., Head Start Programs). Section 504 of the Rehabilitation Act allowed children with disabilities or who are at risk for academic failure to receive specialized education services. This law was important in setting a precedent for later special education legislation. In 1975, the Education of All Handicapped Children's Act (retroactively renamed Individuals with Disabilities Education Act (IDEA)) was enacted to acknowledge the right of all children in the age range 3–21 to a “free and appropriate education, the right for parental participation in educational decision making, individualized educational plan, multifaceted evaluation, and placement in the least restrictive educational environment.” Initially, this law focused on the educational rights of school-age children. The subsequent passing of PL 99-457, in 1986, both amended and expanded PL 94-142. PL 99-457 focused on the rights of infants and preschoolers to services that could enhance their future opportunities. The purpose of Congress in enacting PL 99-457 was:

- To enhance the development of infants and toddlers with disabilities and to minimize their potential for delay;

- To reduce educational costs by minimizing the need for special education and related services after handicapped infants and toddlers reach school age;
- To minimize the likelihood of institutionalization of handicapped individuals;
- To enhance the capacity of families to meet the special needs of infants and toddlers. (20 U.S.C. Sec. 1471)

The reauthorization of IDEA, in 2004, continued the affirmation of the need for early intervention from birth to age 8 (Raver, 2009). **Table 1** provides information with regard to the minimum components required under IDEA for statewide early-intervention services. As discussed earlier, Part C of IDEA or the Program for Infants and Toddlers with Disabilities is a federal grant program that provides funding for states to develop and operate a comprehensive statewide program of early-intervention services for infants and toddlers and toddlers with disabilities. As it stands, the reauthorization of IDEA, in 2004, included – for the first time – the concept of response to intervention (RTI; Burns and Coolong-Chaffin, 2006). RTI is based on a students' ability to benefit from empirically validated instruction (McLoughlin and Lewis, 2008). The inclusion of RTI in IDEA has increased interest in school accountability (Ysseldyke *et al.*, 2006). Response to intervention allows professionals to use students' responses to scientifically based interventions to diagnose and determine instructional strategies for those with special needs (Burns and Coolong-Chaffin, 2006). Response to intervention was originally intended for children with learning disabilities or those at risk for learning disabilities; however, it has been increasingly adapted to children with a variety of special needs (Buysse and Peisner-Feinber, 2008). There are numerous models of RTI, but they all seem to involve multiple tiers (McLoughlin and Lewis, 2008). Tier 1 involves the core curriculum in general education classrooms where all children are provided empirically validated instruction. Tier 2 provides specialized and remediation instruction for students who are not making adequate progress within the core curriculum. Tier 3 involves an intensive systematic intervention for students who are experiencing significant difficulty compared to their peers. The multiple-tiers model theoretically allows not only for the identification of students who require additional instruction, but also assists professionals in targeting how to efficiently use instructional resources (Burns and VanDerHeyden, 2006).

At present, preschool professionals are beginning to develop RTI models (Buysse and Peisner-Feinber, 2008). One Pre-K model – termed Recognition and Response (R&R) – is similar to RTI in that it includes a core curriculum that utilizes research-based instruction, interventions that are targeted to the individual needs of children who meet screening criteria, and universal screening and progress monitoring (Buysse and Peisner-Feinber, 2008).

Table 1 Minimum components under IDEA for a statewide, comprehensive system of early intervention services to infants and toddlers with special needs (Including American Indian and Homeless Infants and Toddlers)

1. A rigorous definition of the term 'developmental delay'
 2. Appropriate early-intervention services based on scientifically based research, to the extent practicable, are available to all infants and toddlers with disabilities and their families, including Indian and homeless infants and toddlers
 3. Timely and comprehensive multidisciplinary evaluation of needs of children and family-directed identification of the needs of each family
 4. Individualized family service plan and service coordination
 5. Comprehensive child-find and referral system
 6. Public awareness program including the preparation and dissemination of information to be given to parents, and disseminating such information to parents
 7. Central directory of services, resources, and research and demonstration projects
 8. Comprehensive system of personnel development, including the training of paraprofessionals and the training of primary referral sources
 9. Policies and procedures to ensure that personnel are appropriately and adequately prepared and trained
 10. Single line of authority in a lead agency designated or established by the governor for carrying out:
 - a. General administration and supervision
 - b. Identification and coordination of all available resources
 - c. Assignment of financial responsibility to the appropriate agencies
 - d. Development of procedures to ensure that services are provided in a timely manner pending resolution of any disputes
 - e. Resolution of intra- and interagency disputes
 - f. Development of formal interagency agreements
 11. Policy pertaining to contracting or otherwise arranging for services
 12. Procedure for securing timely reimbursement of funds
 13. Procedural safeguards
 14. System for compiling data on the early-intervention system
 15. State interagency coordinating council
 16. Policies and procedures to ensure that to the maximum extent appropriate, early-intervention services are provided in natural environments except when early intervention cannot be achieved satisfactorily in a natural environment

The R&R model is a data-based model that allows professionals to make instructional decisions as seen in RTI models and is primarily designed for teaching reading and math. The Institute of Education Sciences has recently awarded a 10 million grant to University of Kansas to establish a national center for RTI for early childhood. For a more in-depth discussion of RTI in Pre-K, please see the special issue (vol. 35, no. 4) on early-childhood tier models in *School Psychology Review* (2006).

Who Receives ECSE Services?

Children and families come into contact with EI/ECSE professionals in a variety of ways. Some families will know before their child's birth that he/she has a disability. In this case, the physician or hospital often initiates contact with EI/ECSE professionals (Hebbeler *et al.*, 2007). Other children's need for early intervention becomes evident as they grow. In this case, a child's special needs may be first noticed by a physician, parent, child-care worker, pre-school teacher, or a family friend (Bowe, 2000). After a special need is suspected, each child is assessed and

evaluated to determine if there are disabilities or developmental delays that warrant intervention (Bowe, 2000; Hebbeler *et al.*, 2007). Hemmeter *et al.* (2005) recommended five professional guidelines when assessing young children: (1) actively solicit family and child's concerns and interests, (2) individualize assessments to address the unique needs of each child, (3) report assessment outcomes in a way that allows for the development of intervention objectives and permits parents to clearly understand the results, (4) use assessment materials that allow the child's authentic behaviors to be demonstrated during routine activities, and (5) follow all legal guidelines. Further, when assessing children, professionals should include multiple assessment sources in order to gain the most comprehensive information with regard to the needs of children (Neisworth and Bagnato, 2005).

Once a child is identified as needing EI/ECSE services, an individualized family service plan (IFSP) is created (Turbiville *et al.*, 1996). An essential component of any intervention for young children is the IFSP, which is integral in designing programs to address the unique needs of each child and family. The IFSP addresses the child's present level of performance in regard to physical,

motor, sensory, cognitive, communication, social-emotional, or adapted behaviors. This evaluation determines if the child is experiencing disabilities or developmental delays in one or more of the six domains. The IFSP involves a collaborative effort between families and EI/ECSE professionals to design and implement early interventions. The IFSP team must not only determine what services are to be provided but also where the services are to be provided (i.e., home, school, and community) (Bruder, 2001). IDEA advocates the delivery of services in natural environments (i.e., environments typical for children without special needs) whenever appropriate.

The family and team of professionals design an IFSP to assist the child in maximizing his/her ability to develop typical behavioral patterns based on professional knowledge and family desires. The selection of interventions is not only impacted by the type and degree of severity of the developmental delay but also by the family's circumstances (Hebbeler *et al.*, 2007); that is, some families may need more support for early-intervention services to be effective.

Families of children in need of EI/ECSE services are as diverse as the general population. Similar to the school-age population with disabilities, there are concerns of disproportionality with regard to who receives services. Boys tend to outnumber girls in early intervention. Approximately 61% of the children receiving early-intervention services are boys (Hebbeler *et al.*, 2007). Children from low-socioeconomic-status homes are also disproportionately represented among those receiving early-intervention services (Bowe, 2000). Ethnically diverse children receiving early intervention are more likely to be from African American families than white families (Hebbeler *et al.*, 2007). It is imperative that professionals are culturally sensitive to the unique needs of children and families. Hebbeler *et al.* (2007) reported that families overwhelmingly indicate that at least their first encounter with EI/ECSE professionals is positive. **Table 2** provides demographic information about children and their families who receive EI/ECSE services.

Service Delivery

Service delivery for exceptional children has always been characterized as meeting children and families at their point of need; this commitment does not waver with those that are the youngest members of the population. ECSE professionals have expanded their efforts over the past decade to include the needs of culturally and linguistically diverse families with various resources; ensuring that an individualized program of services is retained for all children (Bowe, 2000; Hooper and Umansky, 2009). As stated previously, public law mandates services to address the needs of young children with disabilities.

Table 2 Child's ethnicity, mother's education level, and household income for families of children receiving EI services and for the general population

Characteristic	EI Services Population, Percentage	General Population, Percentage
Child's race/ethnicity		
White	53	61
African American	21	14
Hispanic	16	18
Asian or Pacific Islander	4	2
American Indian or Alaska Native	1	1
Mixed or other	5	4
Mother's education level		
Less than high school degree	16	17
GED or high school degree	32	27
Some college	28	28
Bachelor degree or higher	24	27
Household income		
\$15 000 or less	27	21
\$15 001–\$25 000	16	16
\$25 001–\$50 000	29	31
\$50 001–\$75 000	16	16
Over \$75 000	13	16

General population data from National Household Education Survey (1999) for children up to age 3.

In all subsequent analyses, American Indians are included in the mixed race or other category.

Early Intervention for infants and toddlers with disabilities and their families: Participants, services, and outcomes. Final report of the National Early Intervention Longitudinal Study (NEILS). Table 2–2 (p. 2–7). Menio Park, CA: SRI International. Retrieved from http://www.sri.com/neils/pdfs/Neils_Final_Report_02_07.pdf

The challenge is to make sure that appropriate resources are available to meet the unique needs of each child. This challenge can be exacerbated by the fact that early-intervention services are not available in all public schools. Additionally, eligibility and concerns about best practice and empirical evidence often dictate what services should and can be accessed by families (Bailey and Simeonsson, 1988). The task of identifying appropriate services for children is daunting for professionals and is even more difficult for families, who may be overwhelmed and struggling to accept the challenges their child faces. Professionals need to help families through the maze of regulations and services so that valuable time is not lost as families try to determine best services for their children.

Not only it is critical to identify types of EI/ECSE services needed for each child, but is also critical to identify the environment where the services are to be delivered.

Programming can occur in day-care centers, children's homes, schools, or local community agencies. For children whose health needs dictate more careful care, hospital-based programs for high-risk infant care are among the choices for families (Hooper and Umansky, 2009; Peterson *et al.*, 1994). Hospital-based programs have similar advantages to center-based programs with the ready availability of therapists and medical personnel to provide a wide range of services (Crocker and Porter, 2001; Peterson *et al.*, 1994). The variety of services makes choosing an effective option for service delivery a difficult early decision. Early-intervention services are often categorized as home-based services, center-based services, and combination programs. The diverse needs of families cannot only be met with these options, but the varieties of approaches showcase the commitment that EI/ECSE service providers and teachers have for this population. When choosing the type of service delivery method, it is important to remember the focus of each method of service delivery and how what is offered will impact children and families that access those services. **Table 3** provides information about service locations for children receiving services during their first 6 months.

Before discussing differences between service-delivery methods, it is important to look at the history of service delivery for this population and the basis for providing services to this age group. Odom and Wolery (2003) suggested that service delivery for this population has followed societal values, and, therefore, service should be based on evidence-based practice, systematic observation, and decision-making priorities for early-childhood professionals and families. **Table 4** provides information

Table 3 Locations of early intervention services received during the first 6 months after the initial IFSP as reported by service providers

	Percent
In the family's home	78
In a family day care/preschool/nursery school	10
In a specialized center-based early-intervention program	28
In a clinic or office (e.g., hospital-based clinic, therapist office)	29
Another setting (e.g., inpatient services in a hospital)	5

Percentages sum to more than 100% because children and families could receive more than one service.

Percentages exclude 2.3% of children and families who received no services in the first 6 months after signing the IFSP.

Programs and Services received by children and families early intervention. Table III-14 (p. III-51). <http://www.ed.gov/about/reports/annual/osep/2001/section-iii.pdf>

about the types of services available for children and families. Parents may choose to participate in a variety of options to meet the needs of their exceptional children. As stated above, service delivery can be in the form of home-based options, center-based options, or inclusion options found in the general education arena.

Home-Based Options

Providing services in the homes has a long history in our society (Bailey and Simeonsson, 1988). The recent growth of home-based options has been attributed to the emergence of community-service agencies that focus on initiatives in child abuse, teenage pregnancy, children at-risk or disabled, as well as maternal and child health (Bailey and Simeonsson, 1988). Home-based options are based upon the belief that the most natural location for young

Table 4 Early-intervention services received by children and families during the first 6 months, as reported by service providers

children with special needs, such as infants and toddlers, is the home (Gargiulo and Kilgo, 2000). Bailey and Simeonsson (1988) defined home-based services broadly – as an approach to early intervention in which services are delivered in the home. Hesitant to define this option more specifically, they stated that the diversity, philosophical orientations, and goals involved in early intervention prevent a precise definition. Others define home-based services environmentally, such as where the natural environment occurs for those needing services. The natural environment affords the opportunities for caregivers, parents, and service providers to work in the same setting and meet as an interdisciplinary team (Bowe, 2000; Gargiulo and Kilgo, 2000). The term natural environment was added to Part C and can be thought of as the place where the principle of the least restrictive environment can be enacted (see Bowe, 2000).

The definition of natural environment is under constant explanation and revision by the federal government (Noonan and McCormick, 2006). In Part C, it is referred to as inclusive environments for young children, birth to age 3. Currently, it is defined as settings that are natural or that typical young children utilize (Hooper and Umansky, 2009; Noonan and McCormick, 2006). Noonan and McCormick defined natural environments as those that provide children with access to activities generally found in the typical environment (e.g., the sandbox at playgrounds, story-time at the library, children's gyms). The decision to choose home-based services most often depends on two ideals: the level of parent/caregiver involvement and the possibility of effective program implementation (Bailey and Simeonsson, 1988). The home allows service providers access to pertinent information with regard to environmental stimuli, routines, and family structure that are part of the child's regular environment. The natural environment has proven to be a viable location for successful intervention. For example, Chiang (2008) found that children with autism tended to respond more frequently on communication tasks coded as high on the spontaneity continuum in naturalistic settings (e.g., natural cues and little prompting needed). Accessing home-based services can vary by community. Some communities choose to emphasize home-based services while others prefer to consolidate resources in a center. In the past, local governments have provided services through mental health, human resources, boards of mental retardation, and child-care and preschool programs (Bailey and Simeonsson, 1988).

Center-Based Programs

Center-based programs are those places away from the homes of children with special needs that provide intervention services (Gargiulo and Kilgo, 2004). A common center-based option is the child-care setting – in which

children with and without disabilities are enrolled. Center-based care can also extend to hospital-affiliated programs, preschools, and local programs serving populations diagnosed with mental retardation and/or developmental disabilities (MRDD). Characteristics of center-based programs are increased social interaction with peers, availability of various service providers in one setting, and parent support (see Gargiulo and Kilgo, 2004). Program make-up can vary; some programs operate several hours a week and some are more similar to traditional child-care settings that offer care consistent with the needs of working families (Heward, 2008).

Combination Programs

An alternative to choosing either a center- or home-based program is a combination program. Combination programs seek to combine the advantages of both of the previously discussed options, in addressing the needs of children with or at risk for disabilities. These programs can be characterized by a young child attending school for a few days a week while also receiving services through home visits from service providers. EI/ECSE has a variety of well-known programs that may fit in one or more of these categories (e.g., Head Start). While not thought of as a program that serves the needs of children with special needs, the federal Head Start program has served as an option for children with special needs for decades. Begun in 1965, Head Start is touted as the longest-running, most successful school-readiness program. In Fiscal Year 2007, 49,400 classrooms served just under 1 million children, with more than 25 million children having benefited from its services since its inception (Administration for Children and Families ACF, 2007). Early Head Start, the infant/toddler portion of the NHSA, provides programming to children from birth to age 3 and pregnant women. NHSA is committed to serving children who are at-risk for disabilities and children with identified disabilities by reserving 10% of enrolment in its programs for them (US Department of Health and Human Services, 2008; Wall *et al.*, 2005).

Home-based services offer a variety of advantages for families. Bailey and Simeonsson (1988) organized advantages and disadvantages into four useful categories of outcome: child development, child behavior, family functioning, and child health. Additionally, it is helpful to add a fifth category – operational concerns – which cover the monetary and logistical issues families may face. Utilizing center-based services or another natural environment does not preclude effective intervention, but utilizing the home as a focal point offers service providers and families with important (otherwise unavailable) information about child development and behavior. Clearly, early-intervention services are sought by parents as a way to maintain and augment child development as well as the

behavior and health of their exceptional child. Developmental concerns (i.e., social, motor, and cognitive) can respond positively to intervention in the home, but there may be more advantages to accessing services in the community (Cook *et al.*, 2004). Center-based programs involve trained teachers and support personnel who are available to facilitate the learning of exceptional children (Heward, 2008). Parents may also desire center-based options because of the availability of specialized therapists (see Bailey and Simeonsson, 1988). A concern with intervention is generalization to other environments and a disadvantage to center-based services may be the generalization of skills from classroom to home, and vice versa (see Bailey and Simeonsson, 1988). An example of this may be the ability of a child to have similar social and behavioral demands (such as participation or conversational skills) in both environments (see Bailey and Simeonsson, 1988).

Family Functioning

Services provided in the natural environment for children promote family members involvement that can be significant in the interventional process. It places the child in a setting that is familiar and allows instruction by the child's first teacher and closest supporters like parents and daily caregivers (Gargiulo and Kilgo, 2000). It is this advantage – the use of the parent as the primary teacher – that may also be a disadvantage concerning home-based services. Parents may not desire to be the primary provider of service for their children or believe they do not possess the skills necessary to aid in the effective development of their children. The availability, skill level, and commitment of the parent to intervene can have an immediate and pervasive impact on the effectiveness of service delivery.

Advantages in selecting home-based service delivery extend to less cost to families in terms of transportation to access services, tuition for center-based services, and finding services that may be more responsive to the particular needs of the family (see Gargiulo and Kilgo, 2000). These cost savings can also be found in programming. As Heward (2008) noted, home-learning activities and materials can be more natural and appropriate for young exceptional children. This may be difficult for families as they are placed in a role that they neither feel comfortable with nor wish to assume (Gargiulo and Kilgo, 2000). The raising number of single-parent homes also affects the willingness and appropriateness of parents to act as sole caregivers (Heward, 2008). Researchers have begun to analyze variables that may enhance home-based interventions (e.g., parental engagement; Wagner *et al.*, 2003).

Advantages of center-based options are that they allow for the development of social skills and opportunities for

social interaction between typical and exceptional peers. Center-based options often allow for a family to access several service providers at one site. This multidisciplinary approach allows for team members to work together in a common environment to provide the most effective intervention for the exceptional child. Parents are still part of the intervention team and their participation is needed and beneficial to their children's development. In addition, center-based options are preferred because of the availability of specialized equipment, exposure to various ability levels that support learning, and the ability for parents to access support services for themselves through networking with other parents (Gargiulo and Kilgo, 2000). On the other hand, center-based programs are limiting for families because the cost of transportation to and from the center can be costly in expenses and time. For centers, maintenance of the center and equipment is often costly. Although centers provide for a social network for parents with other parents and service providers, in comparison to home-based programming, the depth of those relationships may be shallow (Gargiulo and Kilgo, 2000).

Personnel Preparation

Preparing EI/ECSE professionals is critical to the effectiveness of the field (Miller and Stayton, 2005). EI/ECSE as a field traverses the benefits of early-childhood initiatives and the strengths of special education. Those working in the field of special education may or may not be required to be licensed in special education, early-childhood education, pre-kindergarten education, or a combination of the above. Irrespective of the license requirements, EI/ECSE professionals need knowledge concerning both general education and ECSE (Hyson, 2003). The training of early-childhood special educators focuses on areas of child development and provides specialized knowledge about children with disabilities and their families (Winton and McCollum, 1997). Typically, EI/ECSE professionals' responsibility goes beyond the classroom as they serve on multidisciplinary teams during IFSP meetings (Bowe, 2004). Finally, ECSEs serve as advocates or social service liaisons by being key professionals working with families (see Bowe, 2004). The Council for Exceptional Children, Division of Early Childhood, recommends five guidelines in preparing EI/ECSE professionals (Miller and Stayton, 2005):

- Greater participation of families in the planning and delivery of training activities;
- An increase in the crossing of discipline boundaries to access appropriate preservice and inservice education and training;
- Greater emphasis on preservice and inservice educational opportunities that include students from both

early childhood and early childhood special education together;

- Increasing interest in interdisciplinary collaboration preparation practices;
- Support of family-centered preparation practices. (pp. 190, 191)

The aforementioned guidelines affirm the field's commitment to family-centered services and bring increased focus on the need for collaboration by all professionals who work with children with disabilities. Professional guidelines make it clear that inclusive services are vital for serving young children (Odom and McLean, 1996). The effectiveness of inclusive sites for interventions is directly impacted by the preparations of the professionals across essential disciplines (Able-Boone *et al.*, 2003). In other words, if we expect EI/ECSE professionals to deliver quality programs to young children in inclusive settings, then we must equip them with the knowledge and skills required for inclusive settings.

Itinerant Professionals

Itinerant professionals are those who travel from one site to another providing services for children with disabilities (Cook *et al.*, 2004). Itinerant services can follow a direct-instruction role as well as a consultation role. The direct-instruction role is similar to that of an ECSE teacher. Itinerant professionals, or teachers – as they are sometimes referred to – may provide direct services that do not include the child with his or her peers. Conversely, the itinerant consultant model is a role that is characterized by providing support to students in inclusive settings (see Cook *et al.*, 2004). A key feature of this role is the reciprocity that must occur in order for effective consultation to take place. Itinerant professionals often provide high-quality technical expertise, guide systematic evaluation and interventions, and serve as a liaison between working parents and special education staff (see Cook *et al.*, 2004).

Transition in ECSE

Two major transitions occurring in the lives of young children with special needs are those from early intervention to preschool and preschool to kindergarten. These transitions may be stressful for families of young children as the nature of services in the three settings is markedly different. Types of personnel, number of children, and the involvement of the family differ, as do the federal regulations with regard to the three settings. IDEA (1997) mandates planning for seamless transitions. Effectively preparing for transitions is of critical importance for children's future success.

The 1997 IDEA defines transition as “a coordinated set of activities for a student, designed within an

outcome-oriented process, that promotes movement from [one educational setting to the next].” Ensuring continuity of services, minimizing disruptions to the family system by facilitating adaptation to change, preparing children to function in the receiving environment, and fulfilling legal requirements are four major goals of transition planning (Wolery, 1999). The IDEA regulations from 1999 (Fed. Reg. Sec. 300) require states to have transition policies to ensure a seamless system of service delivery (Brandes *et al.*, 2007; Lillie and Vakil, 2002; Sainato and Morrison, 2001). A minimum of 6 months is required for the transition period from early intervention to preschool (Johnson, 2001). The IDEA mandates early-intervention and early-childhood professionals meet with families to discuss goals and objectives, timelines, and how to mitigate potential barriers in the transition process. At these meetings, a transition plan is written. Although transition planning is critical at both the early intervention-to-preschool and the preschool-to-kindergarten transitions, the two transitions have important differences.

Transition from Early Intervention to Preschool

A fundamental difference between early intervention and preschool is the governing section of IDEA. In early intervention, children are served under Part C of IDEA and services are provided based on the IFSP. Once a child turns 3, services are provided through Part B of IDEA and services are established with an IEP. Rosenkoetter *et al.* (2007) outlined critical differences between the two service delivery models, including a transition from a focus on the family to a focus on the child, home-based to center-based services, individual to small-group intervention, play-oriented to structured teaching approaches, and a developmental to an academic orientation. Two potential sources of stress for families in this transition is a discontinuity of services and ineligibility for services; that is, services available under Part C – such as respite care and home therapies – may not be available under Part B (Fox *et al.*, 2002). Further, children who qualify for services under Part C are not automatically eligible for services under Part B, and parents must be made aware of this possibility (Wolery, 1999).

The significant discrepancy in service delivery between early intervention and preschool causes stress for families and increases the need to plan for transition (Howard *et al.*, 2005). Lovett and Haring (2003) interviewed 48 families participating in this transition. Approximately half of these families (46%) reported they were comfortable with the transition process and a little less than half (43%) reported feeling uncomfortable with the process. The families reported that factors contributing to successful transitions were the early-intervention staff preparing them for the transition by setting up meetings with the

receiving schools, being involved in the IEP process, having choices about placements and programmatic issues, and feeling satisfied with the placements. Families who were uncomfortable with the process reported feeling unprepared and anxious, abandoned by their early-intervention staff, not understanding the process of transition, not involved in the IEP process, and not given choices about placements. Communication has also been reported as a factor leading to involvement by families in the transition process (Hanson *et al.*, 2000). Feeling involved and given choices can help parents feel comfortable with the stressful process of transition from early intervention to preschool.

As a means of promoting smooth transitions from early intervention to preschool settings, some states have developed local interagency coordinating councils (LICC)s that are responsible for writing interagency agreements (Sainato and Morrison, 2001). Wischnowski *et al.* (2000) interviewed members from transition teams to identify supports and barriers to writing interagency agreements that help smooth the transition process. Participants included early-intervention administrators, public school administrators, local education agency (LEA) coordinators, and parents. These team members suggested many critical variables supporting interagency agreement plans. Having skilled, involved key people with positive attitudes on the interagency team was reported to be the most influential variable. Process variables – such as writing plans with jargon-free language – were also important. The ability to change policies based on the needs of the team and effective ways of handling conflict resolution were also rated as important. Finally, training and access to technical assistance were considered to be important in promoting the writing of interagency agreements. Another critical source of continuity in the transition from early intervention to preschool is the use of independent therapy providers. Myers (2007) surveyed 103 occupational therapists, physical therapists, and speech-language pathologists who were independent contractors in Kentucky. These providers reported supporting the transition process by attending transition planning meetings and communicating with receiving environments. Early-childhood service coordinators were considered vital in supporting independent therapists to aid in transition. As independent therapy providers spend many hours of direct contact with families in early intervention, they are in a position to provide critical support to families during transition.

Transition from Preschool to Kindergarten

Just as there are many differences between early intervention and preschool settings, there are many differences between preschool and kindergarten settings (Rosenkoetter *et al.*, 2007). For example, there is much wider diversity of preschool settings than kindergarten settings: preschool can occur in home settings or center-based settings whereas

kindergarten is typically delivered in a school setting. Class sizes are often larger in kindergarten than pre-kindergarten and there are usually fewer adults in a kindergarten classroom. There are more expectations related to self-care in kindergarten and less one-on-one support available for students with disabilities than in pre-kindergarten settings. Large-group instruction and requirements for independent work occur more in kindergarten than in preschool. Finally, expectations for exhibiting appropriate behavior are higher in kindergarten than preschool. This factor can be an especially important consideration for students with disabilities (Stormont *et al.*, 2005).

Two critical variables in promoting smooth transitions from preschool to kindergarten are the anticipation by the preschool teacher of the dramatically different receiving environment of the kindergarten classroom and the preparation of children for that new environment. Troup and Malone (2002) conducted an ecological assessment of 11 inclusive kindergarten programs and reported features that preschool teachers should be aware of when preparing children for the transition. Findings were that the majority of programs sat students at small tables, about half of the programs clustered children on the floor for group activities, and about a third of programs required children to remain seated throughout assigned activities. In addition, most programs used assigned activities rather than child-choice activities, expected children to raise their hands to talk, and used workbooks and skill sheets. Preschool teachers should consider these aspects of kindergarten classrooms when preparing their students for transition. Preschoolers should not be expected to do kindergarten-type work as it would not be age-appropriate. However, if kindergarten students are, for example, expected to complete worksheets identifying size and color, preschool teachers should address these concepts in developmentally appropriate ways.

Numerous activities are available for promoting smooth transitions from preschool to kindergarten. La Paro *et al.* (2003) followed 80 families with high-risk children through this transition documenting the transition activities with which they participated as well as supports and barriers to the transition process. Families were given choices about transition activities consisting of visiting kindergarten classrooms, meeting with a specific or non-specific kindergarten teacher, meeting with an elementary school principal, participating in elementary school-wide events, and talking to preschool staff about kindergarten. When given the opportunity, most parents participated in these activities and reported that they were helpful. However, parents' work schedules were a common barrier to this involvement. Families prepared for the transition for kindergarten with their children at home by talking about behavioral expectations and working on pre-academic skills, such as reciting their address and phone number. Preschool teachers were also involved in transition

activities such as visiting the kindergarten classrooms with the children, holding spring orientations for families, and sharing written documents with kindergarten teachers. Kindergarten teachers were less involved in the transition activities and reported unpaid summer work and being given class-lists too late in the year as barriers to their involvement. As schedules were a barrier to participating in transition activities, La Paro and colleagues recommended schools offer creative ways for participation, such as offering evening parent-teacher conferences and conducting meetings via the telephone.

Transition to school for children with disabilities can present more problems than for typically developing children. McIntyre *et al.* (2006) assessed the intelligence, adaptive functioning, self-regulation, social skills, and student-teacher relationships of 24 children with intellectual disabilities and 43 typically developing children when they were 60-months-old and starting school. Results indicated that children with intellectual disabilities exhibited more problem behavior, less self-regulation, and more delayed social skills than typically developing children. Findings also suggested that social skills in preschool years predicted strong academic, social, and behavioral outcomes in school. Implications of these results are that preschool teachers should focus on increasing social skills and decreasing maladaptive behavior in children with intellectual disabilities to ensure their success in school-age settings. Clearly, transitions from early intervention to preschool and preschool to kindergarten can be stressful for families as the nature of services is considerably different across these three settings. These differences range from the physical setting to the number of children in the setting to the federal regulations mandating the services. Educators and service providers must smooth the transitions for families by setting up meetings with receiving environments, offering options regarding placements, and involving families in the IEP process. Having skilled people participate in local interagency coordinating councils (LICC) can also prepare families for the transition from early intervention to preschool. Preschool teachers can facilitate the transition to kindergarten by anticipating increased expectations for self-help, academic, and social skills and preparing students for those changes. Just as educators must provide a free and appropriate education for all children, they must also provide planned and seamless transitions for young children with disabilities and their families.

Recommendations for the Future

ECSE is a relatively young field that has made tremendous progress in the past few decades. Educators provide services to children with special needs across many different settings using a variety-service models. Professionals should

be trained to collect data on target behaviors and use data to both determine and guide interventions. Future EI/ECSE professionals must be prepared to meet the unique and diverse needs of children from culturally and linguistically diverse families (DEC, 2002). Professionals must respect and value the home cultures of all children and actively seek to engage each family in their child's intervention program. In order to work effectively with families and other professionals, EI/ECSE professionals require skills in collaboration. In other words, they must have skills in team building and goal setting as these skills are especially important when assisting children and their families in making transitions to new environments.

In addition to skills required for future EI/ECSE professionals, there is the need to continue a rigorous research agenda in ECSE. Research should focus on the identification of comprehensive and coordinated early interventions that will promote long-term benefits for children and families (Guralnick, 2005). Research in early childhood is needed to connect assessment and interventions in meaningful ways (DEC, 2006). Research is also needed to examine the effectiveness of delivery models across culturally and linguistically diverse families. Finally, the results of child and family outcomes need to be evaluated carefully, examining areas such as physical health, developmental learning, and social-emotional development (DEC, 2006).

Conclusion

ECSE is an exciting and growing field that has demonstrated past success in improving the lives of infants, toddlers, and young children with or at risk for disabilities. Future success depends on continuing to expand the knowledge base and on training professionals to meet the varied and complex needs of young children with special needs. As we move forward, the ability to determine children who need specialized intervention as early as possible and how to target resources to address the needs of each child will be critical in improving outcomes for children. The future of EI/ECSE holds the promise that we will be able to more effectively serve the needs of all children.

Early Intervention for Students with Special Needs

Early Intervention for Students with Special Needs

Infants, typically, are identified at birth for special services when they are suspected to have problems or special needs. Gearheart *et al.* (1993) suggested that early intervention means reducing the effects of existing disabilities and preventing or reducing the effects of secondary disabilities. Additionally, Carter (1999) reported that professionals and families whose children have exceptionalities find that, during the early years of childhood, the family is likely to be intensely absorbed with the inner workings of care and support for children with disabilities. Turnbull *et al.* (2006) noted that direct early-intervention efforts have targeted two major groups of infants and children – those with identifiable disabilities and those considered to be at-risk. These infants and children are served through organized center-based and home-based programs and through a combination of these two service-delivery models. In all instances, parent education and continuing parent involvement are essential ingredients for early-intervention programs. This article focuses on how best to use early intervention to help young children to maximize their potential.

Importance and Benefits of Early Intervention

Early intervention is the centerpiece of any nation's effort to help vulnerable children and their families (Guralnick, 1998). It produces mechanisms for mitigating stress generated by factors associated with family and child-risk or child-disability status that can adversely affect family-interaction patterns and, hence, the child's development. Earlier, Gearheart *et al.* (1993) contended that early-intervention support can provide assistance to parents and other family members as they nurture the child with disabilities. It may reduce feelings of guilt or inadequacy, prevent emotional problems in both parents and siblings of the child, and help hold marriages together. These benefits to the family mean direct benefits to the child with a disability.

Olive and McEvoy (2004) note that a critical tenet of early intervention/early childhood special education (EI/ECSE) is the belief that services for young children are designed and implemented with close involvement of families. Families should be decision makers for children

with disabilities. Their priorities should be used to drive early-intervention services. However, changing parental roles directly affect how intervention services can be provided. As a result, professionals must respect family choices to work outside the home, to home-school their children, or to enroll their children in private programs. Given changes in family demographics, it seems likely that a major service delivery model should be one where EI/ECSE personnel consult with a variety of programs where childcare is provided.

The importance of early intervention for children with severe and multiple disabilities cannot be stated strongly enough, (Friend, 2006). These children – because of the complexity of their disability – enter preschool without the basic skills that most children acquire without effort. Their communication skills are, sometimes, severely delayed. When a child's problems are recognized early, school failure can – to a large extent – be prevented or reduced (Lerner, 2003). ECSE programs (1) identify children ages birth through 5 who have special needs and are likely to encounter difficulty in academic learning and (2) provide an immediate early-intervention program. According to Lerner, early-intervention benefits the family of young children with special needs. In the family-centered-intervention approach, the child is viewed as part of the family system. When parents are empowered to be an integral part of the intervention process, they become essential elements in the process of reaching the child and improving child–adult interactions. Early-intervention programs offer a substantial financial savings for the community by reducing the number of children requiring special education services in the future. Specifically, it helps to:

- enhance intelligence;
- promote substantial gains, in all developmental areas (physical, cognitive, language, psychosocial, and self-help);
- inhibit or prevent secondary disabilities;
- reduce family stress;
- reduce dependency and institutionalization;
- reduce the need for special education services at school age; and
- save the nation and society substantial healthcare and education costs.

Honig (2004) presented a further rationale for early intervention. He suggested that, at birth, a baby's brain contains 100 billion neurons (as many as there are stars in the

Milky Way). During his/her first year, he/she will grow trillions of brain-cell connections – called neural synapses. Although an infant's brain does have some neurological hardwiring (such as the ability to learn any language), it is more pliable and more vulnerable than an adult brain; therefore, when one provides loving, language-enrichment experiences for a baby, he/she is giving the child's brain neural connections and pathways more chances to become wired together. In turn, the child will acquire rich language, reasoning, and planning skills. Additionally, Lerner (2003) argued that, perhaps, the most promising success stories in education today are the reports of special education programs for young children who have disabilities or are at risk. The underlying premise of ECSE is that early intervention makes a significant difference in child growth and development (Steel, 2006/2007). Professionals in psychological, medical, scientific, and educational fields have documented the importance of the years between birth and 5 for learning.

Concerns with Regard to Early Intervention

Perhaps one of the most touted studies in the area of early intervention was the Milwaukee Project. This study made some assumptions as to the role of deprivation in the development of intellectual disability. This study began in 1960 and was set in the Milwaukee Housing Project (Garber, 1988). The children identified for the study were determined as at-risk for mental retardation because they lived in low socioeconomic status (SES) development and because their mothers were identified as having an intelligence quotient (IQ) of 75 or below. Fifty percent of the children received intervention, while the other half did not. At regular intervals, the children were given a battery of tests. The groups were then compared to determine whether the intervention led to decreased rate of mental retardation among the children. The intervention package consisted of two parts – family rehabilitation and child stimulation. In the family-rehabilitation component, mothers were provided with paid instruction in job skills, followed by assistance in finding a job. The mothers (and some fathers) were also given instructions in daily-life skills – such as counting money, paying bills, and so forth. In this Milwaukee study, assessment information indicated that the children who received the intervention had IQs that averaged 30 points higher than those who did not. Additionally, they were significantly better at problem solving, exhibited more enthusiasm for learning tasks, and had significantly more advanced language skills. Follow-up assessments of IQ indicated that the difference continued through age 10 but the point range was smaller. Perhaps more startling, 60% of the control group children were classified as mentally retarded by the end of the

fourth grade, while none of the children who received the intervention package were so classified. The Milwaukee Project generated a great deal of enthusiasm about the prospect of early intervention. However, the interventions were intensive. Some children were placed in foster homes. The infant stimulation and preschool programs were run for 7 h a day, 5 days a week.

Unfortunately, the enthusiasm generated by the Milwaukee project would be marred by suspicion. Criticisms were made of the scientific rigor (or lack thereof) employed. Additionally, interested researchers had difficulty accessing the data for reanalysis (Smith *et al.*, 2006).

In *Miseducation: Preschoolers At-Risk*, Elkind (1987) expressed dismay at the fact that the age-inappropriate approaches to early education have gained such momentum despite the undeniable evidence that pushing children into formal academics and organized activities before they are ready does more harm than good. As he lamented, “In a society that prides itself on its preference for facts over hearsay, on its openness to research, and on its respect for ‘expert’ opinion, ‘parents, educators, administrators, and legislators are ignoring the facts, the researchers, and expert opinions about how young children learn and how best to teach them . . . When we instruct children in academic subjects, or in swimming, gymnastics, or ballet, at too early an age, we miseducate them; we put them at risk for short term stress and long term personality damage for no useful purpose” (pp. 3–4). Elkind further observed that those advocating early intervention in skills and early-out-of-home education rely upon youngsters who are very disadvantaged to tout early-education advantages. “Accordingly, the image of the competent child introduced to remedy the under stimulation of low income children now serve as the rationale for the over stimulation of middle class children” (p. 70). Dr. Jack Westman of the Rockford Institute, renowned child psychologist Dr. Stanley Greenspan, and brain researcher Jane Healey warn of the implications of forcing the childhood-as-a-race approach upon young children. According to Westman, there is the “hot housing movement” for infants and toddlers devoted to expanding their development. This is occurring in spite of the evidence that the long-term outcomes of early didactic, authoritarian approaches with younger children relate negatively to intellectual development (Pierce, 2007/2008).

Guralnick (1998) suggested that some critics have suggested that there is a lack of strong evidence for the long term effectiveness of early intervention services. Moreover, Rodis *et al.* (2003) reported that the merits of early intervention – as opposed to letting children outgrow their disabilities – is still a topic debated among scholars, educators, physicians, and parents. Marfo and Cook (1991) noted that the political context with which the earliest efficacy studies on early-intervention programs for children with disabilities were spawned accounted, in part, for the

remarkable tolerance of poorly designed interventions. However, it is important to review what has gone on in the past to try to have a clear picture of what is happening today and what may happen in the future. Two objectives undergirding these early studies are clearly discernible. There was certainly the twin scientific objective of seeking to (1) demonstrate that the progress and outcomes of early-intervention programs could be investigated with objectivity and scientific rigor and (2) generate data that could lead to the development of more effective intervention models and strategies. However, there was also a political objective – born largely out of anxiety to demonstrate to legislatures and policy-makers at a critical point in the fiscal history of the early-intervention movement that continued funding and possible expansion of services were justified. It is not surprising, therefore, that the vast majority of the research proclaiming the effectiveness of early intervention prior to the mid-1980s is now generally deemed to be methodologically flawed to be interpretable (Dunst, 1986; Dunst *et al.*, 1987).

Studies conducted over time have made us aware that politicization of inquiry at the consumption level has been equally problematic. A study conducted in Canada compared a group of 9-month-old Down syndrome children in a center-based development intervention program with a control group following 6 months of intervention for the experiment (Piper and Pless, 1980). Finding no statistically significant difference between the two groups on subtest of the Griffiths Scale, the researchers concluded that the efficacy of the form of intervention evaluated in their study was doubtful. For some 15 years, the Piper and Pless (1980) study was perhaps the most frequently criticized efficacy study on record. Among other scholars, Sheehan and Keogh (1981) observed that, by drawing this sweeping conclusion, Piper and Pless had gone beyond their data. The key elements of the various critiques are:

- The intervention was relatively short (Bricker *et al.*, 1981; Sheehan and Keogh, 1981).
- The sample size was small (Sheehan and Keogh, 1981).
- Neither the intervention effort itself nor the treatment variables under evaluation were described in sufficient detail to warrant precise interpretation of the findings (Bricker *et al.*, 1981).
- The Griffiths scale may not have been sensitive enough to register changes triggered by the treatment (Bricker *et al.*, 1981).
- The statistical techniques used in the study were not particularly powerful (Sheehan and Keogh, 1981).
- Given that the researchers did not collect any process data, they erred in interpreting the absence of experimental effects as evidence of inefficacy; their outcome could very well have been the result of factors related to the quality of treatment implementation (Marfo and Kysela, 1985).

Additionally, between 1984 and 1986, a series of meta-analytic reviews of early-intervention-efficacy studies – carried out at the Utah State University Early Intervention Research Institute (EIRI) – appeared in several sources (Castro and Lewis, 1984; Casto and Mastropieri, 1986; White *et al.*, 1984). The findings from these studies challenged and contradicted deeply entrenched beliefs and practices within the field. Among them were the following:

- Although parents can be effective intervenors, “they are probably not essential to intervention success” because “those intervention programs which utilize parents are not more effective than those which do not” (Casto and Mastropieri, 1986: 421).
- Contrary to the conventional belief that earlier exposure to intervention is better, it appears that – for children with special needs – later exposure is associated with better outcomes.
- More structured programs are only marginally superior to less structured programs.

As expected, these findings triggered much debate, controversy, and sharp criticism within the field. Donovan and Cross (2005) reported that there is substantial evidence with regard to both behavior and achievement that early identification and intervention is more effective than later identification and intervention. They further concluded that intervention programs have been known to address early biological harms and injuries –these have increased the potential to substantially improve developmental outcomes in young children.

Professional Preparation and Early Intervention

Olive and McEvoy (2004) reported, in 1997, that 77.8% of services for young children with disabilities were provided in outpatient clinic settings or through home-visiting programs. This implies that less than 13% of services in 1997 were provided in settings such as preschool programs and childcare centers where many young children spend most of their time each day. It appears that the predominant model for service delivery relies on bringing children to the service rather than providing the service in natural environments where they spend their time.

It is important to recognize that early intervention is driven based on the needs of parents who are confused about taking care of a child with a disability at such an early age and based on laws. The mandates of Individuals with Disabilities Education Act (IDEA) for inclusive and natural environment suggest that many children with disabilities will be served in preschool and childcare programs. Consequently, early-childhood educators should have formal training in serving young children with disabilities and

their families (see Olive and McEvoy, 2004). According to Olive and McEvoy, teachers of young children with disabilities must (1) become familiar with the range of settings where early-intervention services may be provided and (2) provide a range of services in their new classrooms whether they are public libraries, city buses, or neighborhood recreation centers. It is imperative that teacher-preparation programs design practicum that provide experiences across the continuum of placement options and collaborate with other agencies. Mandlawitz (2007) concluded that a Local Education Agency (LEA), annually, may use not more than 15% of its part B funds (part B, in combination with other funds to develop and implement services for students in grades K–12 (focusing on K–3)) who are not, at present, identified as needing special education and related services, but need extra academic and behavioral support to succeed in the general education environment.

Conclusion

Friend and Cook (2007) argue that collaboration is now central to all of special education, but it has been a defining feature of programs that meet the needs of young children with disabilities almost since the inception of that field. Perhaps, the best illustration of collaboration at the core of early intervention and preschool services is found in the IDEA rules and regulations that specify who participates on the team to develop the individual family service program (IFSP). In addition to the professional serving the child, the team must include the parents, other family members as needed, the service coordinator who has been working with the family or who has been assigned responsibility by a public agency, professionals who have assessed the child and professionals who are likely to provide services to the child. Thus, it is important that early intervention is initiated in a collaborative and constructive manner to help the child maximize his/her fullest potential. While there have been concerns about early intervention, the consensus opinion is that early intervention is a preventive method to reduce the intensity of future problems that may confront young children.

Early Transition of Children with Special Needs

S A Fowler, University of Illinois, Champaign, IL, USA

Glossary

Early childhood special education services – The services delivered to children between the ages of 3 and school entry (ages 5 or 6), with developmental delays or disabilities. These services are identified through the development of an individualized education plan (IEP) that identifies developmentally appropriate goals and objectives for the child and the services required to assist the child in meeting these goals. Services may include: access to a special education preschool teacher, paraprofessional, or therapists, such as speech and language therapy, occupational therapy, and physical therapy. Other related services include: audiology, vision therapist, behavioral consultant, transportation, and adaptive technology. Services may be delivered within a classroom designated for children with special needs or within community child care. Most prevalent models used in community child-care programs include co-teaching with a special education teacher or the use of itinerant services.

Early intervention services – The services delivered to children between birth and their third birthday, who have been identified as developmentally delayed or disabled and their family. The services are identified through the development of an individualized family service plan (IFSP) that identifies the strengths and needs of the child and family as well as priorities. Services may be delivered through a home-visiting model or in a clinic or community child care. Services may include developmental therapy focused on the parent–child relationship and overall development of the child or specific therapies, such as speech and language therapy, occupational therapy, and physical therapy. Other related services may include: audiology, vision therapy, behavioral therapy, nutritional support, or family support.

Individualized education plan (IEP) – A document developed by the special education, general education, and parents or guardians of a child who qualifies for special education and related services. It provides diagnostic information on the child's abilities and a plan for addressing the supports required to assist the child in learning and engaging in school-related activities. IEP addresses domains in which the disability has an impact and the goals and

objectives for addressing the child's learning needs. It also identifies the supports (e.g., paraprofessional support, functional behavior analysis, and extended time for assignments) that will assist the child in meeting the goals and objectives. The plan is updated annually and reevaluated every 3 years when eligibility is again determined.

Individualized family service plan (IFSP) –

A planning document in which the early intervention service providers and family identify the young child's and family's strengths, needs and priorities, as well as the outcomes expected from service delivery. IFSP is developed within 45 days of diagnosis and must be reevaluated every 6 months.

Interagency agreement – A document in which two or more agencies identify the ways in which they will cooperate and provide support to a family and child as they make the transition from one early service program to another. Typically, such documents address the roles and responsibilities of the sending program and receiving program to ensure that child and family services are not interrupted during the movement from one service agency to another.

Service coordination – This involves the identification of all services provided to a young child and their family and planning so that the services are delivered in a way that reduces conflicts around issues, such as scheduling services, the focus of services, and payment of services. The intent is also to ensure that information about all services is shared among the providers and family in a way that optimizes delivery of services and reduces redundancy.

Transition – A significant change in services that involves the child and family leaving one agency or primary provider and initiating services with another agency or primary provider.

In the world of early childhood special education, the term transition refers to the movement of young children and their families from one service delivery system to another. Transition is understood to be a process and not an event and one that requires planning and communication among the family, the sending programs, and the receiving programs as well as the agencies overseeing such programs. The process of navigating the transition

between programs may be simple or very complex, and depends on the local context, agreements among agencies, and family participation and expectations regarding child readiness for the change of services. The goal of a successful transition is to ensure the adjustment and success of the child and family in their new services or program.

What is known is that transitions between services can be very stressful for young children with disabilities and their families. For example, children who first enter preschool may show signs of distress, ranging from crying or social withdrawal to regressions in behavior and skills as they begin the adjustment and adaptation to new providers and settings. Most children show a return to prior levels of comfort and skills, but this return marks a process for many that may require days and temporary supports as they make the adjustment (Haymes *et al.*, 1994). Families often report a renewed sense of loss or grief about their child's disability as they recognize that changes that may appear fairly effortless for other families and children are not for their child or family. They may also find themselves in a position of needing to explain again their child's strengths and needs and advocate for appropriate services and supports. They may miss the relationships, which they developed over time with the sending program as they work to build rapport and trust with the staff of the receiving program.

The transition from one program to another may create discontinuity in a child's program due to differences in program philosophy, regulatory requirements, family or staff expectations, or simply the failure to share assessments and records about a child's current developmental status. This, in turn, can interrupt child progress. In the United States, young children, identified with disabilities or developmental delays are eligible for services from birth or shortly after the diagnosis has been made. As a result, many families begin receiving services for their child during the infancy and toddler years. Federal legislation in the United States has ensured services for infants and toddlers through the 1986 Early Intervention Program of the Education of All Handicapped Children Act (e.g., PL 99-457). The law calls for minimum components of a statewide intervention system for infants, toddlers, and their families but allows for state discretion in terms of organizing and structuring the services. As it stands, services may vary from state to state on a number of dimensions, including who is eligible for services, who provides services, and how services are coordinated across agencies within a community and within a state (Spiker *et al.*, 2000). In fact, research from a national longitudinal study on early intervention services, suggests that there is no typical early intervention service, but rather a range of services that may vary along different dimensions (e.g., setting for services, intensity of services, and focus of services) (Hebbeler *et al.*, 2008).

Because of the way in which the law was developed, most children with developmental delays or disabilities

and their families encounter a transition in services on the child's third birthday, when funding for early intervention ends and funding for preschool-age services begin (Malone and Gallagher, 2008). This involves the shift in services from early intervention providers to those provided through the local education agency for preschool. During this transition, children move from a service delivery model in which most services have been delivered through a developmental therapist and other specialists (e.g., speech therapy and physical therapy) in the context of the child's home, or in a clinic or child-care setting. New services are provided through the local school district and may take the form of a preschool program in which the child is enrolled or may be delivered through a consultation model to the child-care center attended by the child. The second transition, which typically occurs again during the child's fifth year of age, is entry to kindergarten and formal schooling. Again, this involves a change in services from preschool, which may or may not be located in the same place or under the same agency as the kindergarten.

This article addresses both the early transition to preschool and the later transition to formal schooling or kindergarten for children with disabilities as well as the evidence-based practices to increase the continuity of treatments and services for children and families across the first 6 years of life. Issues discussed include a conceptual framework for understanding the transition process, the role of agencies involved in the transitions, the role of the families, and the impact on the child.

Conceptual Framework

The current conceptual framework used to discuss transitions in the United States is one based on bioecological theory and organizational theory (Rous *et al.*, 2006). Bioecological theory focuses on the interaction between child development and the environmental context. This includes a consideration of the risk and resiliency factors evident in the developing child and the risk and resiliency aspects of the child's immediate environment: family, home, and community contexts (Bronfenbrenner and Evans, 2000). It also considers the timing of the transition process. **Figure 1** provides the ecological contextual factors first identified by Rous *et al.* (2006).

The underlying premise presented in **Figure 1** is that most services for very young children are delivered within the context of the family. That is, services are guided by the family's values, beliefs, and priorities, and are identified through a collaborative family and professional planning process. The child and family are a part of a larger community, and the availability and accessibility of services and resources within that community will impact what the family and child receive. For example, families

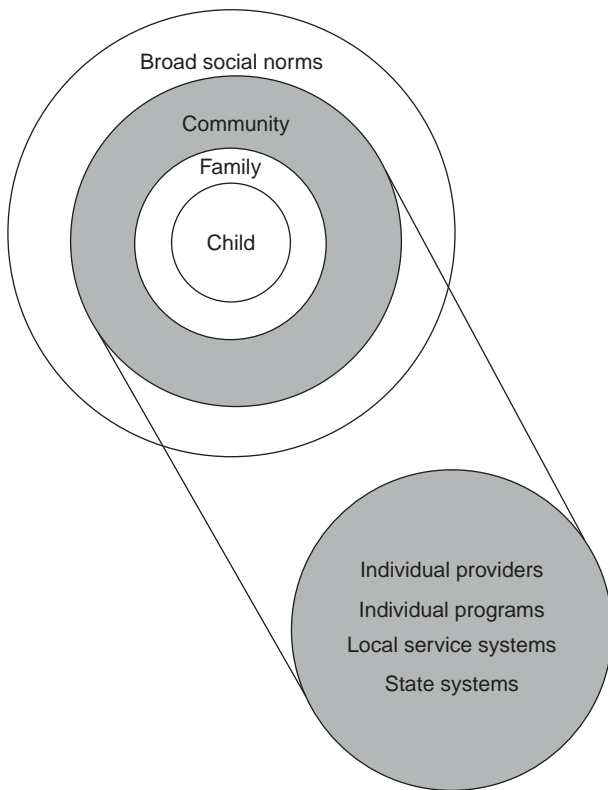

Figure 1 A conceptual framework for planning transitions in the early years.

who live in urban communities or densely populated areas are likely to have more choices regarding the programs that are available in their local service system as well as choices in the providers. In contrast, families in rural areas may have limited choice if few providers or only a single program is available.

In addition, the framework presented in **Figure 1** accounts for the influence of broad social norms, which dictate whether there are laws and adequate funding to provide early intervention services and to support the professional development of service providers. These norms also determine whether the community shares expectations about the process and outcomes for children and families who benefit from these services (Fowler *et al.*, 2006). As federal legislation established early intervention services in the United States more than 20 years ago, many citizens consider access to early intervention services as an entitlement and are likely to seek and accept services. However, research on service access indicates that not all families who are eligible participate. Their participation is influenced by cultural values, including the ways in which the families view disability, their beliefs about child rearing, and the role of individuals or agencies outside of the family and the family's community. Groups which are least likely to use early intervention services include immigrant families with limited English, families with limited education, and families

who live in isolated areas of the country (Crosby and Hatfield, 2008). The community, in turn, is impacted by the extent to which the larger governing bodies (states, provinces, and nations) provide an infrastructure to fund, support, and monitor the delivery of early intervention and special education services. In a transition, families navigate between providers and programs and sometimes even between service systems.

The transition process is depicted in **Figure 2** and illustrates the mediating variable of transition practices and activities to guide families and their children in preparing for transition and in adjusting to the transition. These practices and activities are determined through interagency agreements, that is agreements and plans made by agencies involved in programs from which the child is departing and programs to which the child is arriving (Rous and Hallam, 2006; Fowler *et al.*, 2000). This conceptual framework is further discussed within the role of the child, family, providers, and service system.

Early Service Transitions within the United States

Young children with disabilities or developmental delays, who are identified prior to age 3, are eligible for services, which are based on the development of an individualized family support plan (IFSP). The plan identifies strengths and resources of the family and child as well as needs of the family and child, which must be met to support the child's development. Children with significant disabilities are most likely to be identified early in life and receive early intervention for most of their first 3 years. Conversely, children with milder or less obvious disabilities or developmental delays may not be identified until they fail to reach normal developmental milestones, related to ambulation, speech and language, or social interaction. These children may be in early intervention for a year or less (Malone and Gallagher, 2008). Hebbeler *et al.* (2008) in their follow-up of over 3,000 children indicated that six services form the core of early intervention delivered in the United States. These include (1) speech-language therapy, (2) physical therapy, (3) occupational therapy, (4) special instruction for the child, (5) developmental monitoring, and (6) service coordination. The primary focus of the services may be the child and parent (or adult caregiver) or exclusively the child. They noted that the majority of families received services in the home. Within this group, more than half of the services focused on helping the parents to work with their child both during and beyond the therapist's visit. Oftentimes, families and early intervention providers form close relationships as they work together to foster optimal development in the child.

Transition planning is built into early intervention services and is a requirement in the United States. At least

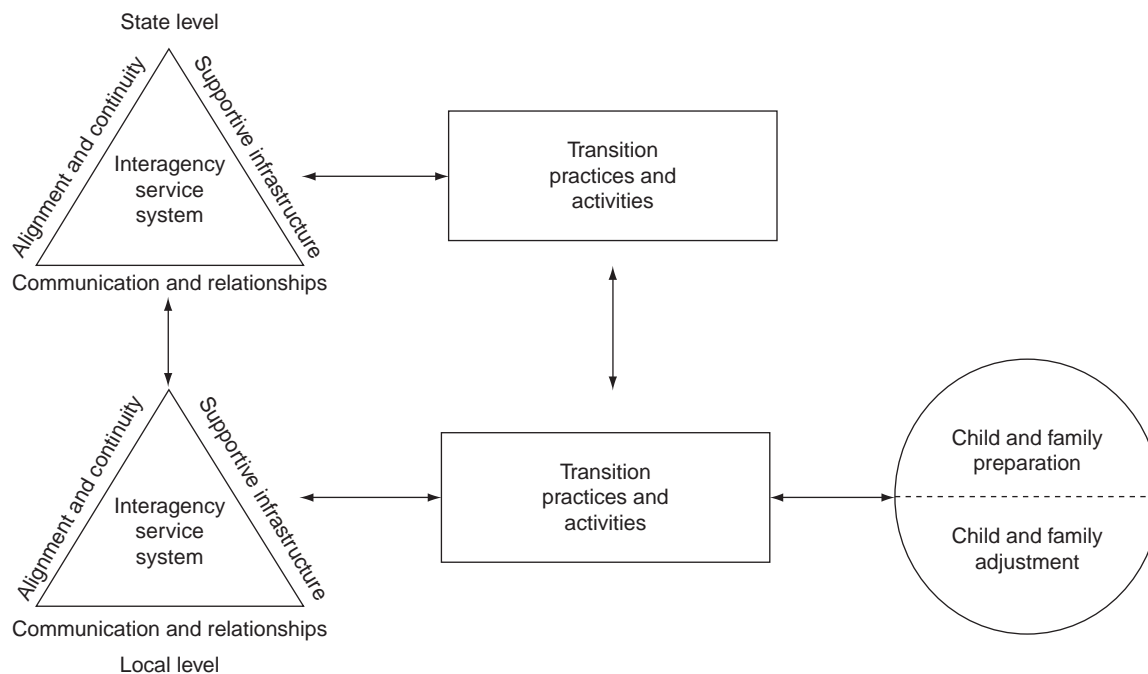

Figure 2 State and local factors that influence transition practices for young children and families.

90 days prior to the child's third birthday, the early intervention provider or agency, family, and local public school system must meet to plan the transition to preschool- or other public-school-funded services. In many states, the source of funding for services, as well as the method of delivering services, changes on the child's third birthday. As a result, the date of a child's transition does not reflect the child's developmental readiness or the family's readiness for change, but rather an administrative mandate tied to funding sources. For some children, the transition is seamless, if the early intervention agency and the public school program are either part of the same agency or have strong interagency agreements to ensure continuity of services. For many children, however, a disruption in service may occur. This disruption may be due to many variables, including a family decision to not initiate preschool, the time of year in which the child's birthday occurs, or the readiness of public schools to initiate services.

Factors that Influence the Age 3 Transition

The most common legal problems identified for age 3 transition include:

1. failure to develop or implement individualized education plans (IEPs) by age 3,
2. failure to establish eligibility for continued special education services,

3. lack of required assessments, and
4. absence of the required representative from the local education agency for the transition meeting (US Department of Education, 2004).

However, a range of child and family factors as well as local community and state factors should also be considered.

Child and Family Factors

Not all families may be ready for the change of services or willing to participate in the transition planning. In many communities, services for children aged 3–5 are provided in the context of a half-day preschool program located often in a public school. Some families may express concern that their child is too young or too vulnerable to begin a preschool program or to ride a school bus to such a program; or, they may not consider their child's developmental delay to warrant continued services, if these services mean a change in the family schedule, or a need to provide child-care services that can wrap around the half-day special education preschool program (Rosenkoetter *et al.*, 1994). In other cases, families who have been involved with services for child neglect or abuse may not want to further expose themselves to a system that monitors their child's development (Robinson and Rosenberg, 2004). Families, who are recent immigrants, may not understand or trust the referral process, which often

requires additional evaluations of the child and proof of residency.

Families who are supportive of the transition can play a critical role in easing their child's adjustment by participating in planning and by using recommended practices to introduce their child to the new program. Such recommended practices include:

1. providing opportunities for the child to learn to separate from the parent and play at a relative's or friend's home;
2. supporting the development of social skills;
3. establishing simple routines for the child to follow at home; and
4. reading to their child and expanding their child's language (e.g., Pianta and Cox, 1999).

Community Factors

In the United States, federal law requires that the early intervention program conducts a transition planning meeting with the family and a representative from the local education agency at least 90 days before the child's third birthday. At this meeting, they are required to include the following steps to support transition in the child's IFSP:

- discussion of future options with parents or guardians;
- procedures to prepare the child and to help the child adjust;
- transmitting information to the local education agency, with parents' consent; and
- explanation of how the families will be included in the transition plan.

The extent to which the community supports the transition is dependent on whether the early intervention programs and providers and local education agencies have developed agreements to cooperate or have a history of cooperation. Without a supportive interagency framework, it is difficult to ensure that relationships are built between programs that truly focus on serving the child and family. Communication is critical to ensure that a representative from the receiving program is at the transition planning meeting, or that appropriate records and assessments are both current and sent to the next program. If the eligibility criteria differ between the sending and receiving programs, then new assessments must be scheduled and conducted by the receiving or sending program. If assessments are not planned in advance and coordinated, then the child's entrance to new services may be delayed until evaluations are completed and eligibility established (Rous and Hallam, 2006). A national survey of public preschool teachers conducted by Rous *et al.* (2006) indicated that teachers engage in a variety of

Table 1 Frequently identified practices for supporting the entrance and adjustment to preschool

Talking with parents before school starts and/ or meeting with the parents after school starts
Sending a letter or informational brochure to parents before their child starts preschool
Conducting an open house before or after school starts
Reviewing written records about the child's prior experiences
Facilitating contacts between parents of children in the class

strategies to support a child's entrance to preschool services and subsequent adjustment. **Tables 1 and 2** contain the most frequently identified practices.

State, Provincial, or National Factors

Leadership at the national and regional level is essential to ensure that communities provide appropriate support and practices for families and children during the transition. In the United States, states provide such leadership through state policy, training, technical assistance, and funding.

Entrance to Preschool Services

Rous *et al.* (2007) have identified in their conceptual framework the concept of a "critical window of time" for children and families to adjust to a change in service delivery and programs. "This refers to the time it takes for the child to actively engage, adapt and continue along an appropriate developmental trajectory" (p. 144). They discussed the notion of three interdependent transition outcomes related to this critical window. These are:

1. the child's engagement in the program, as measured by his/her interaction with adults, peers, and materials;
2. the child's adaptation to the formal and informal rules of the program (e.g., schedule, routines, and behavioral expectations); and
3. the child's continued development socially, cognitively, and linguistically.

Children with these outcomes are most likely to have parents who view their program positively and are supportive of ensuring that their child attends services regularly.

Transition to Kindergarten

No federal regulations govern the transition to kindergarten in the United States. Children typically are eligible to enter kindergarten if they have turned 5 years of age before the school year begins or by a predetermined date. In many countries, entry to kindergarten is regarded as the first point of entry to formal schooling and may occur between age 5 and age 8. Attendance may be voluntary or compulsory, depending on local and national norms or laws. Many of the issues involved in the earlier transition to preschool services, are also common to kindergarten. The issues include recommended practices to prepare the child and family for kindergarten and to support adjustment in kindergarten. They also include the need for coordination and communication between the sending and receiving programs, which again, may be part of the same agency or represent different agencies. **Table 3** presents the most common practices identified in a survey of 3000 early childhood professionals by Rous (2008).

The issue of child readiness for school or the school's readiness for all children is often a debate in educational circles. The choice of child readiness versus school readiness may be determined by political, financial, social, and cultural factors. Many countries recognize a specific age

by which children are expected to start school. Readiness is an issue when schools expect children to enter with certain skills and when standardized assessments based on age norms are used. Children then are compared to their peers and not to their prior record or experiences. The debate in the United States was intense in the 1980s with many schools establishing pre-kindergarten programs or transitional kindergarten programs for children who did not meet certain age-expected norms. Recent trends have focused on the theory that schools should be ready for all children and the term readiness to a large extent has been modified to represent a "broad construct that incorporates all aspects of a child's life that contribute directly to that child's ability to learn" (Meisels, 1999: 62). Even so, across the United States, many states have implemented publicly funded pre-kindergarten programs for children identified as at risk for school learning problems based on risk factors such as poverty or English-language learning. The intent of these programs is to support children's readiness to learn.

Most children with disabilities are likely to enter kindergarten having already attended a preschool program in which special education services were provided or received services through their child-care program or at home. These children enter with an IEP, which is required for all children identified as having a developmental delay or disability. Children with IEPs are reevaluated every 3 years to determine the continued need for services and, if needed, may continue to receive special education services and support throughout the entire school career. Concerns most typically expressed by kindergarten teachers around the transition of children with developmental delays are (1) having time to plan and consult with special education and related services staff; (2) having support in the form of an assistant teacher or aide in the classroom as needed; and (3) receiving additional training to address the specific needs of the child (Rosenkoetter *et al.*, 1994). These needs are increased when a child's disability is significant or when several children with disabilities are enrolled in the same classroom. The need for communication between home and school and opportunities to discuss strategies with prior preschool teachers also have been identified as a need by some teachers in facilitating the adjustment of the child to kindergarten (Rous and Hallam, 2006). Transitions are not successful if supports are not provided to children with disabilities. This, then, can begin a cycle of failures and frustrating school experiences for the child, family, and teachers.

About two decades ago, Hains *et al.* (1989) also suggested that kindergarten teachers may have initially low expectations for children's entry skills to kindergarten, focusing primarily on self-help and social skills. These expectations grow significantly over the course of the year, as the curriculum changes and becomes more academic in nature with a focus on numeracy and literacy and greater

Table 3 Nationally validated transition practices for child and family preparation and adjustment

- Individual child and family transition meetings are conducted
- Staff follow-up on children after the transition to support their adjustment
- Transition team members share appropriate information about each child making a transition
- Transition plans are developed that include individual activities for each child and family
- Staff know key information about a broad array of agencies and services available within the community
- Children have opportunities to develop and practice skills they need to be successful in the next environment (program)
- Families are aware of the importance of transition planning and have information they need to actively participate in transition planning with their child
- Families' needs related to transition are assessed and addressed
- Families have information about and are linked with resources and services to help them meet their specific child and family needs

Adapted from Rous, B. (2008). Recommended transition practices for young children and families: Results from a national validation survey. *Technical Report #3*. Lexington, KY: University of Kentucky, Human Development Institute, National Early Childhood Transition Center, p 11.

self-regulation. The extent to which children with disabilities are able to maintain the same pace as their peers varies and may require additional supports, whether in the classroom or through the use of a resource room for specialized instruction. The issues then move from those of transition into kindergarten to issues of inclusive educational services and provision of special education in kindergarten and elementary school (Werts *et al.*, 1996). Transition is important at all levels of a young child's education. All hands must be on deck.

Conclusion

Transitions occur at significant points in a young child's life beginning with his/her diagnosis of a disability or developmental delay and entrance into early intervention services. The transition from early intervention to preschool services at age 3 marks a significant change for many children and families in the delivery of services. Children still eligible for services are most likely to enter a preschool program in which special education services are delivered. This program may be structured to enroll only children with delays or may be an inclusive program with typically developing children. Children then make a transition, universal for nearly all children, following their fifth birthday, to kindergarten and the beginning of a more academic focus in school. Transitions at each point in time require an assessment of the child's current performance and skills, planning for the expectations of the next program, implementing supports as needed to support the child's transition and adjustment to the new program, and an evaluation of how well the adjustment occurred. This cycle of assessment planning, implementing, and evaluating can provide important information if gathered over multiple transition points to ease a given child's transition throughout his/her school career. If systematically gathered for the entry of many children into preschool and kindergarten, then this information can also begin to identify patterns of successful adjustment and factors that contributed to or detracted from such adjustments.

Glossary

Asphyxia – A condition in which the lungs are unable to function normally enough to provide a sufficient amount of oxygen to the body.

CHARGE – This term is made from the initial letters of some of the most common features of this condition. For example, C = Coloboma, an eye defect caused by failure of the eye to form properly so that part of the structure within the eye is missing, resulting in a range of defects: a so-called keyhole pupil at the front of the eye, to very large defects at the back of the eye. In some cases, the defect may be so large that it results in a smaller or even absent eye; and E = Ear anomalies that can affect the external, middle, and inner aspects of the ear. Some common problems include hearing loss, fusing of the middle-ear bones, chronic middle-ear effusion, stenosis, or atresia.

Close senses – The senses of smell, touch, and taste.

Congenital – A condition present at birth.

Distance senses – The senses of vision and hearing.

Encephalitis – An infection, either bacterial or viral, in the brain.

Etiology – Origin or cause.

Exacerbate – To make worse.

Functional blindness – A degree of blindness in which one may be able to distinguish shapes, colors, and shadows and may function within a normal lifestyle.

Hydrocephaly – Excessive cerebral spinal fluid in the cranium; also called water head.

Low vision – A degree of visual impairment that results in the need for larger print and better lighting for access to the printed word.

Meningitis – A form of encephalitis but limited to the membranes that line and protect the brain.

Microcephaly – Unusually small head.

Perinatal – During birth.

Postnatal – After birth.

Prenatal – Before birth.

Retinitis pigmentosa – This is also called tunnel vision; a condition in which the eye's retina slowly deteriorates from the peripheral vision to the center of vision over time, resulting in limited vision or blindness.

Rubella – German measles also called 3-day measles.

Usher's syndrome – A genetic condition in which the individual is born with hearing loss and gradually develops tunnel vision.

Educating Children Who Are Deaf-Blind

Deaf-blind is the presence of a dual sensory impairment involving the auditory and visual senses. According to the US Federal Government,

Deaf blindness means concomitant hearing and visual impairments, the combination of which causes such severe communication and other developmental and educational needs that they cannot be accommodated in special education programs solely for children with deafness or children with blindness. (Office of Special Education and Rehabilitation Services, 2007: 12)

According to the Colorado Department of Education (2007), deaf-blindness occurs in three out of 100 000 births. It should be noted that not all individuals who have deaf-blindness are completely deaf and blind; nor are all individuals who have deaf-blindness born with the condition (National Consortium on Deaf-Blindness; NCDB, 2006).

Knowledge of History

Although the first mention of deaf-blindness was in the literature at the time of the Crusades, the history of deaf-blind education began in the early 1800s in Paris, France, with a young lady named Victorine Morriseau. Laura Bridgman was the first deaf-blind person educated in the United States in 1837 (Collins, 1995). She was educated at Perkins School for the Blind. The technique used was finger spelling of the American deaf alphabet in the palm of her hand and it was developed by Samuel Howe. Using this hand alphabet technique, words and concepts about the student's environment and world were taught. Of interest, Anne Sullivan was Bridgman's teacher. Sullivan later went on to teach Helen Keller using the same technique developed at the Perkins School for the Blind. Helen Keller became an author and lecturer on the education of children who are deaf-blind. Anne Sullivan remained Helen Keller's

friend and teacher until her own death (Keller, 2003). From the 1900s to 1950, the United States opened multiple programs for individuals with deaf-blindness. These programs were established at Perkins's School for the Blind, the New York Institute for the Blind, Overbrook School for the Blind, Michigan School for the Blind, California School for the Blind, the Travis State School for the Deaf-Blind, and Illinois Braille and Sight Saving School (Collins, 1995). Famous schools that were established in Europe during the same time period were Condover Hall in the United Kingdom, Russia's Zagorsk School, and St. Michielsgestel in the Netherlands (see Collins).

The greatest incidence increase of deaf-blindness occurred during the 1963 worldwide Rubella epidemic. This large increase led to the term rubella bulge indicating a larger than normal prevalence of children who were deaf-blind in deaf schools, blind schools, and deaf-blind schools. An important fact as to the specialized education and placement of these children is that rubella caused not only deaf-blindness but multiple secondary disabilities. Many of these children were placed in classrooms and programs not for children with deaf-blindness, but for children with severe to profound multiple disabilities with mental retardation being the most common of the secondary disabilities. According to Collins, the result of the rubella bulge and the large increase in residential school populations in the United States and Europe led to increases in training and services provided to teachers for children who were deaf-blind. These services were mostly provided at the level of residential institutions. Since 1975, with the enactment of Public Law 94-142, the Education of All Handicapped Children's Act and the subsequent amendments, the number of individuals with deaf-blindness served in residential facilities has decreased (Hammer and Carlson, 1996). More than two decades ago, the National Consortium on Deaf-Blindness and National Information Clearinghouse for the Deaf-Blind (1988) provided services and information on deaf-blindness in the USA while worldwide the International Association for the Education of Deaf-Blind People provided services and education for individuals (Collins, 1995).

Understanding the Condition of Deaf-Blindness

Being blind or deaf alone presents many difficulties for anyone especially preschool and school-age children. Being born deaf-blind exacerbates the difficulties for normal language development and educational processes (Stremel and Schutz, 1995). During the first year and a half of life, infants gather information from sensory experiences/exploration and cognitively categorize this information into an internal language (Bower, 1982). All babies communicate; and through this, communication relationships are formed and sustained (Gleason, 2002). Around the age of 18 months, this internal knowledge of

the infant's world transfers into a categorical system that uses the language of the infant's environmental world whether spoken or signed by family members (Bower, 1982). According to Bruce (2005), within the world of the child who is congenitally deaf-blind, there may be no concept of distance, defined as the separation of self from others. Distance must be directly taught to the child through exploration with environmental objects via a hand-under-hand approach. The lack of visual and auditory inputs also affects a child's language development, motor development, cognitive development, and emotional and social development. Teaching parents and others how to overcome these challenges is the primary goal of early intervention (Gleason, 2002). While infants have five functioning senses with which to process information, the majority of this information is processed through visual and auditory processes. However, the deaf-blind child must process that same information through touch (Chen *et al.*, 2001; Chen and Haney, 1995; Miles, 2005). In essence, the infant is deprived of the majority of the sensory inputs that allows him/her to develop language concepts incidentally. Thus, it is not surprising that this infant will be linguistically and communicatively impaired (Stremel and Schutz, 1995).

The Office of Special Education Projects (OSEP) of the U.S. Department of Education annually collects demographic data on infants, children, and youth receiving special education services in the United States. Due to the high incidence of secondary disability associated with deaf-blindness, students who are deaf-blind may be categorized under multiple disabilities and thus may not be counted by OSEP under deaf-blind (NCDB, 2006). The NCDB (2006) conducted a census that counts children with deaf-blindness who have additional disabilities. Thus, the OSEP count is lower in number of students with deaf-blindness than the NCDB census data (see NCDB, 2006). These census data were collected on children and youth in the USA, ages from birth through 21 years, who were deaf-blind. The census included data on ethnicity, etiology, additional disabilities, type of degree of hearing and vision loss, special education classification and placement, as well as living setting (see NCDB). According to the NCDB, there were 9746 children from the ages of birth to 21 years who were deaf-blind and were receiving special education services in the USA. Of those, 5639 or 58% were white non-Hispanic/Latino; 1639 or 17% were Latino; 1413 or 14% were African-American; 389 or 4% were Asian or Pacific Islander; and 188 or less than 2% were American-Indian or Alaskan Native (see Table 1).

Regarding the OSEP policy of classifying children who are deaf-blind only in the deaf-blind category if there is no secondary disability, the secondary disability with deaf-blindness results in the student being placed under the category of multiple disability (NCDB, 2006). Under IDEA, legally, children are deaf-blind if they have such

Killoran, J. (2007). *The national deaf-blind child count: 1998–2005*. Manmouth, OR: National Technical Assistance Consortium for Children and Young Adults who are Deaf-Blind (NTAC), Teaching Research Institute, Western Oregon University. <http://nationaldb.org/NCDBProducts.php?prodID=57>.

severe communication and other developmental and learning needs that they cannot be appropriately educated in special education programs solely for children and youth with hearing impairments, visual impairments, or severe disabilities, without supplementary assistance to address their educational needs due to these dual, concurrent disabilities (IDEA, Sec.622, 1990). Diagnostically, to be classified under deaf-blind, students must be diagnosed with a visual acuity of 20/70 or worse in the better eye with correction and an auditory deficit of 30 dB or worse in the better ear (NCDB, 2006; National Eye Institute, 2008).

Understanding Hearing Loss

Hearing loss is documented by perception of loudness levels called decibels (dB) across frequency ranges or Hertz (Hz). The psychological perception or layman's term for frequency is pitch. The frequencies used in audiological testing are in octave levels of 250, 500, 1000, 2000, 4000, and 8000 Hz (Martin and Clark, 2000). Hearing loss is classified in degrees of hearing loss based on decibel levels of slight, ranging from 16 to 25 dB; mild, ranging from 26 to 40 dB; moderate, ranging from 41 to 50 dB; and moderate-to-severe, ranging from 50 to 70 dB; severe, ranging from 71 to 90 dB, and profound, ranging from 91 dB to worse (Martin and Clark, 2000). The 2006, NCDB deaf-blind census data reported on a range of hearing losses from mild (26–40 dB) to profound hearing loss (91 dB and above). Clearly, the NCDB (2006) data revealed that, of the 9746 students in US schools who were reported to have deaf-blindness, 1743 (18%) had profound hearing loss; 1401 (14%) had severe hearing loss; 1074 (11%) had moderate-to-severe hearing loss; 1332 (14%) had moderate hearing loss; and 1423 (15%) had mild hearing loss. A large number of children – 2978 (30%) – had either incomplete diagnosis or missing information.

Understanding Legal Blindness

Classifications of visual impairment are different from hearing impairment, in that, degrees of impairment are not reported. Instead, visual acuity and field of vision are the means of defining visual functioning (Corn and Koenig, 2000). Holbrook and Koenig (2006) argued that the criteria used to determine eligibility for government disability benefits do not necessarily indicate a person's ability to function. The criterion for legal blindness in the United States is having a visual acuity of 20/200 or worse in the better eye with corrective lenses (20/200 means that a person at 20 ft from an eye chart can see what a person with normal vision can see at 200 ft) or having a visual field restriction to 20° diameter or less (tunnel vision) in the better eye (National Eye Institute, 2008). The definition of legal blindness is for the US system; depending upon the country of student origin the definition may differ.

The NCDB (2006) census data for children who were deaf-blind revealed that 2084 (21%) had low vision; 2543 (26%) were legally blind; 213 (7%) had light perception only; and 658 (7%) were totally blind. Five percent were functionally blind and data on 1718 children were missing or incomplete. How deaf-blindness affects a child's development depends on several critical factors, according to Bennett *et al.* (1995). These include the age of onset, the degree and type of visual impairment and hearing loss, the stability of each sensory loss, and the educational intervention provided. Few individuals are actually completely deaf and/or blind (Ferrell *et al.*, 1990). There are varying degrees of residual hearing and vision. Most individuals who are deaf-blind rely on one of these senses more than the other, usually the sense with more residual ability. Many individuals are born with the loss of only one of the two distance senses and lose the other distance sense later in childhood (Gleason, 2002). Distance senses are those that bond a child with the world that extends beyond his/her individual body space. The young child who is deaf-blind does not have entry to opportunities for significant learning as do sighted and hearing children, and the information that the child does get from communication with others and the environment is often lacking continuity. Touch, taste, and the balance senses are close senses, giving information only about what is happening now, within arm's reach (Gleason, 2002).

Children born deaf-blind are more limited to these close senses than are individuals who are born with one of the distance senses then lose the other sense later. An example of this would be an individual who had either early hearing impairment and then later accompanying visual impairment, such as children who have Usher's syndrome, Cockayne syndrome, and Cornelia de Lange, Maternal Rubella, and STORCH. On the other hand, an

individual may have been born with or acquired early blindness with normal hearing but then acquires hearing loss through a progressive deafening condition (Karp and Santore, 1983; Mazzoni *et al.*, 2003).

Knowledge of Etiology

Eyes and ears develop during the first 12 weeks of pregnancy. They develop at the same time using the same types of embryonic cells and tissues and are autonomically similar in many ways. Therefore, it is easier to understand why many of the same conditions and genetic syndromes affect development of both organs causing deaf-blindness (Holbrook and Koenig, 2006). The NCDB (2006) reported the etiology data for children ages birth through 21 years with deaf-blindness who were receiving special education services. There were 3233 individuals who were deaf-blind due to nonsyndrome and syndrome heredity disorders, such as CHARGE, Down syndrome (Trisomy 21), and Usher's syndrome, I, II, III. Sixty-five percent or 2096 of the heredity classifications were nonsyndrome-type heredity disorders. There were 1853 children who were deaf-blind due to prenatal congenital conditions such as maternal rubella, cytomegalovirus, hydrocephaly, and microcephaly. There were 2715 children who were deaf-blind due to postnatal, noncongenital events such as asphyxia, encephalitis, meningitis, severe head injury, and complications of prematurity. One thousand fifty-four children had unknown etiologies (see **Table 2**). The most common causes of deaf-blindness are described below.

The NCDB (2006) census determined heredity as the most common cause of deaf-blindness. Deaf-blindness due to heredity falls under two categories: those genetic or chromosomal anomalies with which a specific set of physical characteristics are present and those in which the expression of the hereditary condition is deaf-blindness only. Some of the more common syndromes with deaf-blindness include Usher's syndrome, I, II, III, CHARGE syndrome, Trisomy 21, and III, Neurofibromatosis. Genetic codes for the effected gene for genetic types of deaf-blindness are specific to the gene and loci; for example, in Usher's syndrome, CDH23, MYO7A genes [28] and [29] and USH2A are the genes and loci (Shasty, 2000). Viruses can infect the fetus causing deaf-blindness. Cytomegalovirus causes damage to the fetus when the mother

is exposed to the virus. In addition, herpes virus can cause deaf-blindness. Finally, retinopathy of prematurity caused by scarring of the retina due to oxygen given to the premature infant is a well-known cause of deaf-blindness (Holbrook and Koenig, 2006).

Focusing on Communication

The greatest challenge for individuals with deaf-blindness is communication (Stremel and Schultz, 1995). Regarding deaf-blindness, Bjerkan (1996) related that communication is a form of contact in which meaning is conveyed by the use of signals that are perceived and interpreted by a partner. For some children, using vision, hearing, and touch all at one time is too confusing and causes the child to rely upon only one sense at a time. Communication often depends on which distance sense is more optimal. Tactile senses are often used to explore environments and communicate. Different communication modes are used depending on ability. These include sign language, body language, and gestures, as they are often the primary means of expressive language. Hand-over-hand or tactile sign language is used with those who have less visual efficiency. For example, someone who grew up deaf and experienced vision loss later in life is likely to use a tactile mode of a sign language; others who grew up blind and later acquired deafness are more likely to use a tactile mode for their spoken/written language.

Mode of communication is a term used for the choice or options for receptive and expressive communication in deaf education (Moore, 2001). Receptive communication refers to an individual's ability to receive and understand communicative intent from others, while expressive communication is the choice or option with which an individual chooses to convey his/her thoughts and ideas to others. Miles (2005) reported that some common forms of communication modes are:

- Use of residual hearing (speaking clearly and using hearing aids) or sight (signing within a restricted visual field and writing with large print).
- Tactile signing – sign language or a manual alphabet such as the American Manual Alphabet, or deaf-blind alphabet (also known as two-hand manual with tactile or visual modifications).
- Interpreting services (such as sign language interpreters or communication aides).
- Communication devices such as Tellatouch – a manual Braille writer.
- Braille reading.
- Large-print reading.
- Tactile communication cards.

These are used by individuals when other options are not available (Engleman *et al.*, 1992; Miles, 2005). They may be used in conjunction with other modes of communication

Table 2 Etiologies of US school-age deaf-blind population

depending on the abilities of the individual with whom the deaf-blind person needs to communicate. Tactile cards are unique with each card representing an individual meaning. They may be used in the classroom, at home, in school, and in public for shopping, going to work, daily routines, and other traveling (Bourguin and Sauerburger, 2005). An example of the use of these cards is as follows:

An individual who is deaf-blind wants to go shopping and will need to take the bus to the mall. He/she will have previously gone through training for traveling around town and shopping for himself or herself. Cards have been made and arranged so that the individual can exit his or her apartment building and walk to the bus stop. At the bus stop he/she takes a card from his or her pocket that has a line drawing on it that has been memorized to represent the bus stop. In this situation, the individual who is deaf-blind holds up a card in an attempt to get the attention of a person at the bus stop. Printed on the card are the words, "Please, let me know when bus # 2 arrives." Another card in the individual's set of cards is marked for the bus driver. Printed on that card are the words, "Please, let me know when we are at the bus stop for the Mall." The deaf-blind individual hands the card to the bus driver as he/she gets on the bus. Other cards have been prepared for each step of the adventure. The drawback of this method is that someone may not be available to help the individual who is using the cards or that strangers may not readily volunteer to assist the individual who is deaf-blind. For this reason the individual must have practiced this routine with an assistant many times before they feel comfortable with the process. (Bourguin and Sauerburger, 2005)

Early Intervention of Students Who Are Deaf-Blind

Gleason (2002) reported that parent-infant training is imperative for families with children who have deaf-blindness. Parent-infant training is usually performed in the home of the infant who is deaf-blind. A parent-infant training program, SKI-HI, initially designed for deaf infants to educate parents and promote language development in deaf infants provides parent-infant services for families with infants who are deaf-blind (HOPE, 2006). In SKI-HI training, a parent-infant trainer works with the parents and educates them on the disability itself, communication issues and choices, mobility and orientation, anatomy of vision and hearing, language development, amplification options, sight development/visual awareness, functional living skills (dressing, feeding, and hygiene), and hearing development/sound awareness.

As mentioned previously, most deaf-blind children have some residual vision/hearing/vision and hearing. Placement in schools must be consistent with the child's need. Some children who are deaf-blind will be placed in

a deaf school as their vision is their primary sensory system for communication. They will use American Sign Language or other manual form of communication, while some children will perform more as a blind child and will be educated using a curriculum for the blind as their auditory and possible oral verbal system will be used for communication. Finally, some children who are deaf-blind will have multiple impairments such that education in either schools/institutions for the deaf, blind, and deaf-blind are not appropriate for the best education. These children may be placed in schools/classrooms for children who have severe-to-profound multiple impairments (Fredericks and Baldwin, 1987).

The NCDB (2006) noted the placement of children in the USA, labeled under the category of deaf-blind as following: Regarding infants and toddlers, 75% of infants ages 0–2 receive parent-infant services in the home. The remaining 25% are served in specialized service settings, residential facilities, and hospitals. Seventy-two percent of preschool services for ages 3–5 are provided in special education classroom separate schools, or residential schools; while 20% of the 3–5 children with deaf-blindness are served in general preschool inclusive classrooms; and 5% are educated at home. Finally, for school-aged children 6–21 years old, only 15% of children who are deaf-blind are educated in general education classrooms. Thirty-nine percent of these children are educated in separate classrooms, while 16% are educated in separate public schools. Ten percent of the children who are deaf-blind are educated in public or private residential facilities while 8% are educated in separate private schools. The remaining 7% and 5% are educated in hospitals and at home, respectively.

Multiple disabilities are common for children who have deaf-blindness; according to the NCDB census, children with deaf-blindness have been reportedly classified under every disability category in IDEA Part B, with the majority under multidisabled. The most common secondary disability to the deaf-blindness was reported as cognitive impairment (NCDB, 2006).

Targeted Inside Classroom Techniques

Consistent orientation and classroom order are critical in the educational setting for students who are deaf-blind. The student begins his or her day in an order of tasks that are laid out in a specific place and in a specific order. For instance, as the student enters his/her classroom, the student approaches a specific shelf that contains objects that represent activities that he/she will do during the day. A spoon may be used to indicate eat breakfast. The next item might be a toothbrush to indicate that the student should brush his/her teeth after eating breakfast. These items may be more abstract for students with more

cognitive abilities. That is, sometimes cards with Braille are used, or cards with raised lines or images; and they can also be used to communicate with others. Regardless, this shelf routine is consistent across the literature in the field of deaf-blindness (Engleman *et al.*, 1998).

Transitioning Students Who Are Deaf-Blind

Transition is a necessary avenue for persons who are deaf-blind as they near their formal education years and prepare for finding suitable work and living accommodations. We know that over 70% of persons with disabilities are unemployed and of the 29% employed, many work part time (Harris, 1998). For a person who is deaf-blind, this new era will require more than just one person or one agency. Collaboration between specialists and agencies is necessary to assist with such things as housing, rehabilitation and vocational requirements, deafness, blindness, orientation and mobility, medical needs, and mental health (Ferrell, 2008). The individual's interest, goals, and abilities are key in the planning of this transition. The person that is deaf-blind must be given the opportunity to self-advocate for his/her interest and direction in adult living/learning that he/she wishes to pursue (Agran *et al.*, 2007). Family members as well as skilled interpreters and friends can assist in assuring that adults have voices in their future.

To facilitate the transition process, many assistive and augmentative communication devices are necessary and have been developed for those individuals who are deaf as well as those who are blind. These devices include communication boards, alerting devices such as vibrating alarms that can be placed under a mattress, flashing lights for those who have more vision, hearing aids, cochlear implants (Turnbull *et al.*, 2007a) computers with closed-circuit televisions that can display large print, computer programs with synthesized speech and input from the keyboard in Braille, a Braille embosser, and various brands of print readers (Turnbull *et al.*, 2007b). The deaf-blind individual may use a combination of these devices. Assistive devices and their descriptions are presented elsewhere in the encyclopedia.

Conclusion

Deaf-blind is the presence of a dual sensory impairment involving the auditory and visual senses. The condition of deaf-blindness consists of varying degrees of hearing loss and visual impairment. Federal laws and OSEP projects have provided programs for children with deaf-blindness. Unique communication modes are necessary for these children as are stated above. Education consists of early intervention, unique classroom techniques for childhood education, and assistive and augmentative devices which

are important for the successful transition of these children into the adult world.

Glossary

Audiologist – A professional trained in the testing of hearing, detecting hearing defects and involved in their treatment or management.

Deaf – One who has a severe or profound hearing loss.

Hard of hearing – One who has a mild or moderate hearing loss.

Hearing loss – A dysfunction of the auditory system.

Neuroplasticity – The brain's natural ability to form new connections in order to compensate for injury or changes in one's environment.

options and perspectives are continually provided to families and their children with hearing loss, their teachers, and other professionals in the field. Controversies regarding the best strategy for instructions and services to address the various developmental needs of children with hearing loss have continued to be prevalent. However, we believe these children can achieve success in education if such controversies are set aside, and efforts are focused on providing appropriate services that will foster their development. We also believe these services should provide (1) support for families, (2) appropriate and effective early intervention, (3) language development and communication skills, (4) development of literacy skills, and (5) educational needs for multicultural learners.

Educating Children with Deafness and Hearing Impairments

In this article, important factors for understanding and enhancing the educational experiences, and outcomes for learners who have hearing loss are highlighted. We find it prudent to use hearing impairments/loss to include deafness and hard of hearing as a broad generic term for any hearing dysfunction that precludes successful processing of linguistic information through the ears regardless of severity, etiology, and age of onset. A discussion of various causative factors of hearing loss is beyond the scope of this work. A review of these factors can be found in Cole and Flexer (2007) and Marschark (2007). We are cognizant of the fact that the different degrees of hearing loss: mild, moderate, severe, and profound clearly suggest that children who have hearing loss have different communication and educational needs.

In the United States, Canada, United Kingdom, and other Western countries, there have been concerted efforts toward developing strategies for addressing educational needs of individuals with hearing impairments over the past decades. This has been due to increased understanding of people with such impairments, their communication methods, and ongoing changes and progress in pedagogy, psychology, psycholinguistics, and technology. Evidence suggests that more progress has been made in the education of children with hearing loss in the United States during the last 30 years than in the previous 300 years (Marschark *et al.*, 2002). Consequently, new

Support for Families

Evidence is consistent that the provision of support to enable families to participate actively in the development and education of their children with hearing loss is imperative (Marschark, 2007). A major argument for providing support to ensure active involvement of the parents in the education of their children with hearing loss is that 95% of these children are born to hearing parents who have no previous experience and knowledge of raising a child with hearing loss (Byrne, 2000).

The diagnosis of hearing loss in a child can be emotionally devastating to parents (Scheetz, 2001). In addition to their varied emotional reactions to the diagnosis, these parents also are concerned as to whether their children will be able to use speech, speak normally, go to school, obtain employment, and have a family. These parents need to be educated regarding childhood hearing loss and its consequences, and about the special needs these children require to ensure optimum development. They also need to know the options in communication and education available to them and their children (Marschark, 2007). Furthermore, evidence indicates that the support provided to families could make the biggest differences in their lives by empowering them to take the initiative to seek services that would help them and their children (Turnbull *et al.*, 2004). The family-centered approach calls for collective empowerment rather than a more traditional relationship where the professional had power over the family. Parents and families must become part and parcel of the decision-making mechanism. The fundamental beliefs

underlying focus on family and community are based on the premise that families are interrelated social systems with unique characteristics and needs. Whatever affects one family member has ripple effects directly or indirectly on other family members and community. Consequently, teachers and other service providers should consider the family constellation as the appropriate focal point of professional attention. Turnbull *et al.* (2000) concluded that the study of family must take into account family dynamics that include family characteristics, family interactions, family functions, and family cycles.

Although the importance of providing support for families is recognized in the literature, evidence indicates that, in many instances, such support may not be provided (Lane *et al.*, 1996). Professionals tend not to be concerned about the family as a whole (Lane *et al.*, 1996). They lack the resources to adopt a family-centered or ecological approach in service delivery. Their focus is often on the child's disability and not on the needs and wishes of the parents and other family members. The failure to provide support to families has adverse consequences. For instance, a family's ability to adapt to the child's hearing loss may be hindered by the lack of information about available services. Evidence clearly indicates that many parents are still not receiving adequate information and support during the critical early development years, and many remain uninformed and unable to assist their children at home. Lacking information, support, and knowledge, many parents are unable to make appropriate choices about the communication and educational needs of their children (Davila, 2004). Providing quality information is the critical modality of supporting families with young children who have hearing loss. When clear and unbiased information is provided, they will make informed choices that will address the developmental needs of their children. However, concerns remain about the nature of the information professionals provide to families. Evidence indicates that many parents are aware that they are not getting all the information they need, and that some of the information they receive is patently biased (Marschark, 2007).

Evidence from the Colorado Home Intervention Program (CHIP) and studies in the United Kingdom indicate that families with young children with hearing loss could benefit immensely from programs provided within their homes (Yoshinaga-Itano, 2004). Parents could be visited by professionals such as teachers, speech and language pathologists, audiologists, early childhood special educators, bilingual educators, psychologists, and social workers. These professionals provide information about counseling, developmental assessment, communication, and educational options. Targets should be established for timing of initial visit by professionals to the family of a newly diagnosed child with hearing loss. The visits should be carefully planned and conducted with the goal of giving unbiased information and empowering parents so that they can make

informed choices. Some parents may be experiencing emotional reactions to the diagnosis. Therefore, having sensitive professionals around who are willing to listen and answer questions clearly and without bias could significantly impact how quickly parents adjust to challenges of raising a child with a hearing loss. It is critical that professionals give contact information about local and national organizations concerned with hearing loss to the parents. These professionals, especially those with hearing loss, should be included in the team that makes the initial visit to families since they have first-hand experience of living with a hearing loss. Consequently, apart from providing information and mentoring families, they could give hope and inspiration to families and their children. Additionally, it is imperative that parents with newly diagnosed children have the opportunity of meeting and chatting with other parents who have been or are currently working their way through similar issues. These parents provide mutual and social supports to each other to cope better in meeting the challenges of having a child with a hearing loss. Such parents manifest better behavioral interactions and greater sensitivity to their children's communication and other needs (Turnbull and Turnbull, 2006).

Appropriate and Effective Early Intervention

Hearing loss has been described as one of the most common childhood disabilities in the United States. Cole and Flexer (2007) estimated that due to technological advances in testing hearing in infants and children under Universal Newborn Hearing Screenings, between 16 000 and 18 000 babies and toddlers are diagnosed with hearing loss annually in the United States. Early identification and prompt initiation of early intervention services could prevent or greatly reduce the communication barriers posed by hearing loss. These services are necessary because of their focus on language development, parent-child communication, social skills development, and support for the utilization of any residual hearing children may have. Furthermore, they provide parents with strategies for enhancing their children's educational development through sign language instruction, speech training skills, or both depending on the particular program (Mauk and White, 1995). The goal of early intervention must be to foster effective parent-child communication starting soon after diagnosis of hearing loss. This kind of communication is the best single predictor of success in virtually all areas of development of children with hearing loss, including academic achievement (Marschark, 2007). Clearly, effective interactions, with the most appropriate means of communication, between caregivers and the child will provide opportunities for involvement in most normal activities of children in both social and academic areas.

Learning becomes possible in humans by consistent language input and models. Thus, an important goal of

early intervention should be to provide children with hearing loss with the opportunity to acquire language in the appropriate modality (sign or spoken) by having accessible and competent language models. Consistent means of communication, in the appropriate modality that is congruent for the child, will create opportunities for positive social interactions critical for the social-emotional development and educational success of all children including those with hearing loss. Evidence indicates that children with hearing loss who are identified early and participate in intervention programs achieve significantly better language, speech, social, and emotional developments than those who are not identified early and who receive intervention at a later time (Yoshinaga-Itano, 1998). To provide effective early intervention for children and their families, the program should not be influenced by the controversy regarding the best communication approach that has characterized the education for the hearing impaired for decades. There is a common agreement with Marschark (2007) that there is no single correct answer about the best or superior method of communication for children with hearing loss. The communication and other needs of children are different and therefore, no one method can be applied to all or even most of them. The important thing is to establish, as early as possible, an effective mode of parent-child communication, one that the child can access fully (Calderon, 2000). This is the foundation for successful social, emotional, and academic developments of children with hearing loss. Through objective assessment, open-mindedness, and willingness to be flexible, the mode of communication that would be appropriate for each child could be found.

Language and Communication Skills Development

How should children with hearing loss communicate? What language should be used in educating learners with hearing loss? These questions sum up the main thrust of the controversies over the past two centuries and presently in the education of learners with hearing loss.

The problem with hearing loss is that it prevents sound signals from reaching the brain (Cole and Flexer, 2007). With technological advances in the development of amplification devices (e.g., hearing aids and cochlear implants), the auditory neural connections throughout the brain could be accessed, stimulated, and enhanced for the development of spoken language, reading, and academic skills in children with hearing loss. According to Cole and Flexer, listening experiences in infancy, especially during the first three and half years of life when neuroplasticity is greatest are important. Similarly, lots of practices are necessary for the development of speech and language in children with hearing loss. Parents should be skilled in providing a consistent listening and spoken language-learning

environment to foster the development of speech and language skills in their children.

On the other side of the argument, there are those who insist that learning and using sign language can fulfill all the requirements for language development and education for children with hearing loss (Marschark, 2007). Sources (e.g., Marschark) have observed that only a minority of children with hearing loss are able, with intensive aural/oral approaches, to acquire fluent spoken language. This could be because the task of learning to speak may be easier for those children with lesser degrees of hearing loss. However, for those with profound hearing loss, Marschark argues that the process of acquiring speech that can be understood by others is difficult and frustrating. Thus, sign language could be a better alternative for these children even if they are fitted with amplification devices. So far, there is no evidence which shows that using sign language interferes with the development of spoken language. We agree with Marschark that children are different in their abilities. Thus, while some children with hearing loss could develop spoken language skills and could be educated in oral programs with intensive auditory-verbal support, other children with hearing loss may be unable to do so. Forcing the procedures to develop speech on them could be frustrating, destructive to their self-image, and depriving them of options that would have allowed them to experience a more normal childhood. The concern of professionals and parents should be to ensure early success in language development and communication for children with hearing loss in whichever modality that works for each individual child. As such, it must be restated that to achieve this goal, parents must be provided unbiased information by professionals about these communication methods in terms they can understand and remember. This will enable them to make informed choices that will benefit their children and themselves.

Development of Literacy Skills

It is common knowledge that enhancing the literacy and academic achievements of students who have hearing loss has remained a major concern of educators and professionals in the field (Rodda and Eleweke, 2000). Good literacy skills (i.e., the ability to read and write well) are essential for academic achievement. This is because so much information in texts and other educational materials is in the printed form of the spoken language (e.g., English). Although learners with hearing loss can utilize American sign language (ASL) for meaningful communication and education, there is no generally accepted written medium for ASL as yet. Consequently, learners with hearing loss must acquire good English literacy skills in order to perform successfully at school like their normally hearing peers. It remains the case, however, that acquiring English

literacy skills is difficult for many learners who have hearing loss. The acquisition of a high level of critical literacy (i.e., the literate use of language for problem solving and communication) is dependent upon the acquisition of the conversational forms (spoken/signs) of language at the earliest age possible.

Clearly, a child who has hearing impairment from birth or thereafter, is unable to hear the speech of other people and will not learn speech and language spontaneously, as do children with normal hearing. This ability is critical for language acquisition and development because it enables them to monitor and assess their voices and those of others. A child with hearing loss does not have that ability! All the challenges that hearing loss poses to learning the vocabulary, grammar, and syntax of the English aside, being unable to hear one's own voice makes it difficult to assess and monitor language. Consequently, children with hearing loss may speak too loudly or not loudly enough. They may speak in an abnormally high pitch or sound like they are mumbling because of poor stress, poor inflection, or poor rate of speaking.

Since reading and writing involve graphic representations of a phonologically based language, the child with hearing impaired must strive to decode and produce text based on language for which she/he may have little or no understanding (Hulit and Howard, 2006). Thus, it is argued that the reading and writing difficulties of learners with hearing loss could be attributed to the problems encountered in acquiring the conversational form (spoken and/or signs) of the language (English) in which they are attempting to read and express via writing (Paul, 1998). Nonetheless, literacy is important for academic success and effective functioning in the larger hearing society by those with hearing loss. However, the basic question remains unanswered: What approach/strategy could produce useful outcomes for enhancing the literacy skills and academic achievement of learners with hearing loss?

Recent trends in the education of learners with hearing loss are focusing on bilingual models of teaching literacy. Paul (1998) observed that no widely accepted definition for bilingualism in the education of learners with hearing loss exists. For the purpose of this entry the term will be taken to refer to proficiency in two languages (ASL and print English). As a result of hearing loss which may preclude affected learners from acquiring English as a first language, some workers have argued for the development and use of language/English bilingual programs (see Paul, 1998). Essentially, it is considered that the bilingual approach could enhance the knowledge and use of written/spoken language, and enrich the social, emotional, and academic experiences of learners with hearing loss. Strategies for the development and implementation of bilingual programs for learners with hearing loss vary and are influenced by various philosophical and theoretical underpinnings. However, the objective remains the same,

what is to facilitate the development of English literacy skills (L2) in learners with hearing loss using sign language as the first language (L1). We agree with the approaches and specifically recommend some of the essential characteristics of a bilingual approach for teaching English literacy skills to learners with hearing loss outlined by Paul. These include presenting English via print only, by using (1) reading and writing activities and (2) ASL to explain the grammar of English. In other words, students use their knowledge and skills in their first language (signs) only to learn literacy skills in the second language (English). Careful planning is necessary to develop bilingual programs that would meet the needs of different learners with hearing loss. This requires the establishment of (1) realistic diagnostic assessment of educational needs, (2) instruction that focuses on specific needs, (3) assessment of growth, and (4) evaluation of instruction. Furthermore, it is important to define precisely what the student is currently doing, what he/she needs to know, and how it is best taught. We suggest that in order for such literacy programs to be effective, teaching of reasoning and literacy should be closely intertwined. To achieve this goal will require paying appropriate attention to results of previous research, the methodologies of bridging and metacognition, alternative forms of assessment, and the selection of programs or resources that are tested and supported by valid research. Addressing these issues would enable educators provide appropriate opportunities to learners with hearing loss and help them to achieve their full potential regarding literacy in its broadest definition.

Multicultural Learners with Hearing Loss

The number of culturally and linguistically diverse (CLD) children with hearing loss has continued to increase in multiethnic countries like the United States, Canada, and United Kingdom. A child with hearing loss from CLD may be faced with formidable challenges to accessing appropriate education and other services that would enhance the development of their potentials (Chinn *et al.*, 2007). Due to the lack of early diagnosis and timely provision of intervention services, CLD learners start school with lower language skills than their white counterparts. This lack of basic language skills significantly affects these children's access to educational opportunities. At home, parents may not be English-speakers nor (American) sign language users which, decreases the child's opportunities for consistent language experiences at home. CLD parents may lack adequate understanding of how the system works, or where to go for assistance and support. It remains the case that many educators do not have the knowledge of diversity and skills to effectively work with CLD learners hearing loss and their families.

Educational authorities and personnel should set up programs that focus on providing equal opportunities for

CLD learners with hearing loss and their families. Teacher training programs should include courses on diversity, multiculturalism, and ethnicity in their curriculum. This, we believe, will ensure that preservice teachers have the competences to provide appropriate educational experiences for those CLD children with hearing loss. Furthermore, workshops and seminars on working with these learners should be conducted regularly for teachers and service providers in all educational programs. With increase need awareness and knowledge of the needs of CLD learners, teachers and service providers would be more effective in educating them. In addition, specific projects aimed at fostering the acquisition of English and sign language (e.g., ASL), should be established in the communities.

Conclusion

Despite the tremendous progress being made in educating children with hearing loss, controversies as to which is the best method of communication still exists. Addressing these controversies demands objective use of research findings in planning and implementing educational programs for children with hearing loss. Commitment to continually learn more from sound research would reduce these debates and ensure that valuable time and resources are channeled to enhancing the educational experiences and outcomes for these learners. Evidence is clear that children with hearing loss will achieve success in education when their parents or families have the knowledge and skills to support them and ensure that they have equal opportunities. To achieve this goal requires that parents receive unbiased information about the developmental needs of their children so that they can make informed choices on issues such as method of communication and educational placement. When parents are provided information that is not biased on the various options available, we believe they can make informed decisions. The challenge is for educators and professionals in the field to rethink their methods and explore strategies that will result in optimizing potential for all families. They can do this if they uphold the need for diverse approaches to language development and recognize individual differences and needs for all learners with hearing loss. If they do this, it will be possible that families of these children receive (1) supports they need, (2) appropriate early intervention services which are available, (3) the supports for effective communication and language skills, and (4) appropriate strategies to facilitate literacy skills and academic achievement. Clearly, the stakes are too high to permit anything less.

Glossary

Asthma – A chronic pulmonary condition characterized by episodic inflammation and narrowing of the small airways.

Cancer – A large variety of disease in which the cell have the unique trait of unregulated excessive growth and have the ability to invade local or sometimes distant tissues.

Epilepsy – Also known as seizures disorders, a chronic condition in which seizures occur over time unprovoked from other conditions.

Neurological disorders – Impairments that occur in spinal cord, brain, or nerves.

Orientation and mobility – Problems students with physical disability encounter as they move inside and outside the classrooms.

Physical disabilities – A general term covering impairments activities limitations, and participation limitations.

Sickle Cell Anemia – One form of sickle cell disease that consists of anemia (fatigue), painful episodes, and complications.

Educating Students with Other Health Impairments

Some students have disabilities that are invisible and yet relate to health conditions. In Individuals with Disabilities Education Act (IDEA), students with these disabilities are categorized as having other health impairments, the term other differentiates this group from students with intellectual or other disabilities that also may affect health. Ideally, the definition of students with other health impairments includes characteristics related to having limited strength, vitality, or alertness, that result in limited educational opportunities (Zentall, 2006). Students in this category may have chronic or acute health problems such as asthma, attention deficit disorder or attention deficit hyperactivity disorder, diabetes, epilepsy, heart condition, hemophilia, cancer, leukemia, nephritis, rheumatic fever, sickle cell anemia, and HIV/AIDS. These conditions adversely affect children's educational performance and the ability to succeed

in other endeavors. This article focuses on how to help them to maximize their fullest potential.

Historical Perspectives

Students with special needs have been discriminated against, ostracized, labeled, and called demeaning names (e.g., stupid, imbecile, and retarded). In the United States, it is impossible to divorce the education of students with special needs from the Civil Rights Movement and the subsequent events that followed. To a great extent, the education of these students has been greatly influenced by social developments and court decisions in the 1950s and 1960s. For example, the landmark *Brown v. Board of Education of Topeka* (1954) case was a civil rights case that declared separate education as unequal education and unconstitutional (Obiakor, 2006). Consequently, this case opened doors of advocacy for students with special needs including those with other health impairments. The ruling of this case became a catalyst that prompted parents and professionals to lobby for equitable education for all their students.

In 1973, Section 504 of the Vocational Rehabilitation Act (PL 93-112) was passed to provide persons with special needs with (1) free and appropriate public education, (2) civil rights, (3) accessibility of programs, and (4) employability rights. In 1975, the Education of All Handicapped Children's Act (PL-94-142) was passed with the following fundamental ingredients: (1) education for students from 3 to 21 years, (2) free and appropriate public education, (3) identification of students, (4) nondiscriminatory assessments, (5) placement in the least restrictive environment (LRE), (6) confidentiality of information, (7) procedural safeguards, and (8) development of individualized education plans (IEPs). In 1986, PL 94-142 was amended to accommodate young children from birth to 3 years. This law (PL 99-457) was enacted to provide not just IEPs for children but also individual family support programs (IFSP) for parents and guardians. In 1990, PL-94-142 was renamed as the Individuals with Disabilities Education Act (IDEA; PL101-476). This Act involved funding for states to provide educational services to students from birth through 21 years, and ensured procedural safeguards for parents who guarantee meaningful participation in the evaluation process (Katsiyannis *et al.*, 2001).

Additionally, IDEA guaranteed improvement in the education of students with special needs through research training and technical support and transitional supports for student when they are 16 years. To challenge the private sectors, the American with Disabilities Act (1990) (ADA; PL101-336) was passed to provide more societal opportunities for persons with special needs. In 1997, IDEA was reauthorized as PL 105-17 to facilitate disciplinary procedures and reduce litigation costs. In 2001, the No Child Left Behind Act (NCLB; PL 107-110) was passed to educate all learners and quantifiably account for their progress at all levels. Later, in 2004, IDEA was again reauthorized as the Individuals with Disabilities Education Improvement Act (IDEIA; PL 108-446). Imbedded in IDEIA 2004 is the principle of accountability which indicates that schools should educate all students well enough that all children will demonstrate proficiency in certain core academic subjects (English, mathematics, and others). The technique for achieving this principle is to use the standardized state or local assessment of students' academic proficiency. The IDEIA makes provision for students with impairments and other disabilities to participate in these assessments. Those who may not participate due to severity of their condition are given alternative assessment based on what has been delineated in their individualized education programs. According to the provision of this law, teachers of students with special needs must be highly qualified, implying that they must be certified in the content areas that they are teaching (Turnbull *et al.*, 2004; Smith, 2005). In the following paragraphs we discuss seizure, asthma, ADHD, congenital hearts defects, cancer, and sickle cell anemia.

Students with Seizures

Seizure is a sudden, involuntary time-limited disruption of normal function of the central nervous system. Epilepsy refers to a chronic condition in which seizures occur over time and it occurs spontaneously. There are many types of seizures and epilepsy that can be characterized by altered consciousness, motor activity, sensory phenomena, or inappropriate behavior. Prior to seizure occurrence, the victim normally experiences an aura. Seizures are usually classified as partial or generalized seizures. Partial seizures begin in one area of brain, while generalized seizures occur in both hemispheres of the brain. Within each category, there are variations of seizures each with distinct characteristics, prognoses, and treatments. Seizures usually last from a few seconds to a few minutes and end spontaneously. It is critical for medical treatment to be provided once epileptic seizure occurs. Teachers and service providers should play an important role in identifying seizures in the classroom and taking the necessary steps to ensure that the child's safety and dignity

are maintained when they occur in the classroom. The important question is: How are teachers prepared to deal with seizures?

It is important that school personnel be acquainted with different types of seizures. In many instances, a teacher or service provider is the first person to identify a student as having a seizure, especially with more subtle seizures, such as absence seizures. He/she also may be the first person on hand to assist a student having seizure. If a student has generalized tonic-clonic seizure, which is more severe, the staff should be ready and need to know how to handle the situation. Information pertaining to seizure management should be provided to teachers and school staff. In-service training and provision of relevant literature should be available. In addition, teacher preparation programs have the obligation to educate those who can teach all children in spite of their health impairments.

Students with Asthma

The most common chronic illness among children is asthma, a lung disease that causes episodes of great difficulty in breathing (Gabe *et al.*, 2002). Asthma affects between 5 and 7% of all children in the United States. In recent times, the number of cases of asthma has been rising, and the severity of the disease is increasing. Parents and teachers should endeavor to protect children from known triggers to address and minimize the problem (Lemanek and Hood, 1999). Experts in the field advise parents to protect their children from known triggers such as tobacco smoke as one means of addressing this problem. For some children, asthma may be fairly benign while for others it can be chronic. For example, one child may have coughing spells when he/she laughs too hard. For another child, the condition can be much more serious. When exposed to certain triggers, these students' airways swell and they produce mucus that makes breathing difficult (Lemanek and Hood, 1999); and they may require emergency medical intervention. Asthma is hereditary in nature and in most cases if one of the parents has the disease, the child has 50% chances of inheriting it (see Lemanek and Hood, 1999). However, it is often triggered by allergens, including flowers, grass, pollen, dust, molds, animal dander, and food allergies such as eggs, seafood, and many other items, as well as by strenuous physical activity (Greiling *et al.*, 2005). However, asthma can be controlled through medication and the avoidance of environments that are likely to trigger it (Beers *et al.*, 2006; Taras and Potts-Datema, 2005).

There are two major treatment aims of asthma: (1) preventing the occurrence of an asthma attack and (2) treating an asthma attack when it occurs. Both require that child, family, and school personnel have a good understanding of this disease. Apparently, asthmas occur episodically, yet it is a chronic disease. Several medications are available, yet it is

often untreated. While it is perceived as a disease, it continues to be perceived by many as an emotional or hysterical condition. It is critical for teachers and service providers to have a clear understanding of the disease, its symptoms, and the action to take to manage asthma.

Students with Attention Deficit Hyperactivity Disorders

The IDEA does not represent attention-deficit hyperactivity disorder (ADHD) as a distinct category (Yell, 2004). For that reason, children with ADHD who do not qualify for eligibility for special education are served under Section 504 of the Vocational Rehabilitation Act of 1973. The IDEA is very specific while 504 is broad and subject to interpretation. Consequently, many administrators provide services for ADHD students who may not be eligible for special education services under the IDEA. Because of the condition of the students with ADHD, they require medication. Students with ADHD fall under the following classification:

- For some students with ADHD, inattention is the primary problem. These students might skip salient information of an assignment, may appear to be daydreaming during large group instruction, are disorganized, and generally seem forgetful both in school and at home. This variability of disorder is referred to as ADHD-predominantly inattentive type.
- For another group of students with ADHD, the salient symptom is a combination of hyperactivity—high amount of movement, and impulsivity—the ability to think before acting. Fidgeting is a common phenomenon for students with this type of ADHD. By looking at them one would think that they have an internal engine that does not stop and talks a lot. This type of ADHD is called ADHD-predominantly hyperactive-impulsive type.
- Some students with ADHD have symptoms suggesting that both inattentive and hyperactivity-impulsivity are part of this disorder. These students are referred to as having ADHD combined type.

As it stands, ADHD is considered neurological, chronic, long term, and acutely acquired. The primary trait of this condition is an inability to attend beyond what is typical for peers of comparable age. Significant impulsivity also may be a characteristic. The ADHD is not situational in that it affects children and adults who have it across all settings. However, the symptoms may be most conspicuous at school because of the structure and expectations there. Surprisingly, students with ADHD are more likely to have a productive deficit rather than an acquisition deficit. That is, they take information in and sometimes surprise their teachers by what they know. The greatest difficulty often lies in the production, that is, in completing their work. Apparently ADHD is not caused by

environmental situations or other disabilities, but may be present with them.

Since the goal of any educational program is to maximize the fullest potential of students, the use of medication, though controversial, has become the norm for students with ADHD. Some educators perceive the use of medication as a quick fix and argue that it is being overused. Other educators argue that medication is effective and calms down students with ADHD and thereby increases their productivity (Fornes *et al.*, 1999; Lloyd *et al.*, 2006; Molina and Pelham, 2001). According to the United States National Institute (2006), approximately 2.9% of all students aged 18 and younger in the United States take medication. Clearly, taking medication usually reduces significantly the amount of daydreaming or disruptive behavior. Stimulant medication such as Ritalin, Dexedrine, Cylert, Adderall, and Focalin are among the most common medication administered to students with ADHD. There are antidepressant medication such as Norpramin, Tofamil, Prozac, Zoloft, and many others that are administered for various reasons. As a result, it is critical for school personnel to observe their students daily and form opinions about the seriousness of their behaviors and what might be beneficial for them. However, school personnel do not have the expertise to recommend to parents what might help them. Teachers' preparation programs should endeavor to equip pre service teachers with techniques such as functional behavior assessment and analysis so that they can know how to positively deal with the disruptive behavior of ADHD students.

Students with Congenital Heart Defects

Congenital heart defects refer to a variety of conditions in which the heart is structurally impaired at birth. This might be as a result of hole in one of the chambers of the heart, a problematic valve, a misplacement of the vessel of the heart, or other abnormalities. Structural abnormalities of the heart occur during fetal development because of genetic factors, adverse environmental or maternal conditions, or other factors that are often unknown. Some defects are minor and often resolve on their own, while others require surgery. In normal heart, blood with oxygen enters the right side of the heart and is pumped through the pulmonary arteries to the lungs. From there, the new oxygenated blood goes into the left side of the heart, which pumps the oxygenated blood out of the body through the aorta.

Depending on where the heart defect is located, the defect falls into one of the two categories: acyanotic heart defects or cyanotic heart defects in which case oxygenated blood from the left side of the heart is incorrectly pumped to the unoxygenated right side of the heart due to an obstruction or uncorrected flow to the lungs. This causes a strain on the heart from pressure or volume overload

which can often lead to congestive heart failure. In cyanotic heart defects, there is a blue coloration of mucus membrane and skin because the defect causes some unoxxygenated blood from the right side of the heart to be pumped to the body (Cook and Higgins, 2004).

Inevitably, students who have not had their congenital heart defect repaired or who are not in the process of undergoing multiple surgeries to repair the defect will require close monitoring for signs of distress. Because of the lack of vitality, children will often limit activity on their own but can become easily fatigued and breathless if running, climbing stairs, playing, or walking for extended periods of time (Cook and Higgins, 2004). Adaptation such as using elevators instead of stairs may be a viable choice. Some students with cyanotic heart defects will periodically squat after motor activity to obtain relief and should be allowed to do so. Others may have cyanotic spells in which they become anxious and short of breath, hyperventilate, and have an increase in cyanosis due to their body having a sudden drop in oxygen. Depending on their condition, these students may need to rest, be given oxygen, or receive emergency care. Teachers and service providers should be alert and continuously monitor them. Clearly, children who have had repair of complex and cyanotic heart defects have shown deficits in exercise capacity with impaired exercise performance (Norozi *et al.*, 2005). Teachers and other professionals will need to verify with parents if there has been complete correction of the defect and if monitoring is required.

Students with Cancer

Cancer refers to a large variety of diseases in which the cells have the unique traits of unregulated, excessive growth, and the ability to invade local or, sometimes distant tissue. This can lead to tissue or organ damage that interferes with proper functioning of the tissue or organ being invaded. There are numerous types of cancers that vary depending on their location in the body and how they spread. Children often get cancer in the brain (brain tumor) and in the bone marrow (leukemia). Some other cancers are those affecting the lymph nodes, kidney, and bone. The type of cancer will determine how it affects the body, the form of treatment, and the prognosis. Although having a student with cancer raises fears about death and dying, it should be remembered that some cancers have a high cure rate and that others may go into long-term remission.

Students who have cancer that is treated by chemotherapy or radiation may experience side effects that the teacher or service provider will need to monitor and provide appropriate adaptation and support. For example, pain, stomach upset, sleep disturbance, and fatigue have been found in children with leukemia following chemotherapy (Gedaly-Duff *et al.*, 2006). Teachers and other professionals should carefully monitor and keep track of these symptoms,

provide breaks, or repeat instruction at a later time when the student is more alert and comfortable. Fatigue and other symptoms are often present in children who have end-stage cancer (Mooney-Doyle, 2006), which usually requires some type of adaptations such as rest breaks, shortened day, or homebound services. Further, children undergoing cancer treatment are usually more vulnerable to infections. Teachers and service providers need to be vigilant to sickness in other students and send them home so that the infection is not transmitted to the student who has cancer.

Students with Acquired Immune Deficiency Syndrome

Discussions on how to educate all children will be incomplete without mentioning the impact of acquired immune deficiency syndrome (AIDS) on children and their learning. AIDS is often thought to be a disease that merely makes one susceptible to fatal infections. However children with AIDS often acquire neurological problems as well, including intellectual disability, cerebral palsy, seizures, and emotional and behavioral disorders. AIDS is caused by human immunodeficiency virus (HIV). Although HIV infections can be spread in other ways, the primary means of transmission in adolescents and adults is sexual contact. Infants may contract the disease during the process of birth. Apparently, HIV does not often result in neurological damage and cognitive impairment. In some cases, the damage may be reversible with state-of-the-art drug therapies (Willen, 2006).

Sadly, most of the reported new cases of HIV are in the minority population and almost three-fourths of the new infections in the group aged 13–19 years are in the minority population (Rogers, 2001: 1). HIV/AIDS still carries considerable stigma in the society (Murphy *et al.*, 2002). As children and youth with AIDS and other virus and bacterial infections live longer as a result of improved medical treatment, there will be increasing need for special education and related services. Teachers and service providers should be cognizant of the fact that if reasonable procedures are followed for preventing infections, there is no serious concern regarding transmission of HIV in classrooms (Ainsa, 2000; Spiegel and Bonwin, 2002).

Students with Sickle Cell Anemia

Sickle cell anemia is one form of sickle cell disease that consists of anemia, painful episodes, and complications which lead to eye disease, spleen dysfunction, or stroke. This is a hereditary disease and mainly affects people of African descent. An abnormal type of hemoglobin (HBS) results in some red cells being shaped like a sickle instead of normal disk-shaped red cells with pinched-in sides. These poorly formed sickled red cells have a poor shorter life span, usually being broken down in approximately 20 days

instead of 120 days (Jakubik and Thompson, 2000) which results in chronic anemia and subsequent fatigue.

Apparently, teachers should try to prevent the triggers by events of vaso-occlusive crisis and monitor its occurrence. A vaso-occlusive crisis can be triggered by events that cause a decrease in oxygen, such as strenuous exercise, cold weather, dehydration, infection, or high altitude. When a vaso-occlusive crisis begins, some red blood cells change into a sickle shape. These deformed cells can plug the small blood vessels in the body, resulting in localized tissue hypoxia, which leads to further sickling of the blood cells. When blockage occurs in the blood vessel, it results in tissue death (Dorman, 2005). Intense pain ensues after a vaso-occlusive crisis. Coughing, shortness of breath, and severe abdominal pain follow. Teachers and service providers should be vigilant and monitor the situation carefully. Treatment for severe crisis may consist of rest, rehydration, pain medication, management of complication, and sometimes blood transfusion (Dorman, 2005).

Implications for Teacher Preparation

Clearly, educating students with other health impairments causes unique challenges. The big issues for teacher education programs is whether pre-service teachers are being adequately prepared to educate all learners. Special education in general is a multifaceted discipline; and teachers teach what and how they have been taught. Poorly prepared teachers cannot teach well. In many teacher programs, candidates are not exposed to courses that prepare them to meet the challenges presented by students with other health impairments. Collaboration with medical and health workers can be helpful to bridge the gap. General and special education educators should go beyond territorial protection and look for knowledge that would benefit their students. This is one way to move forward in this world of change.

Conclusion

While great strides have been made to provide education to all students including those with disabilities, there are many challenges that need to be met. Clearly many students with special needs are being educated, however, there are some gray areas when it comes to educating students with other health impairments. For example, students with HIV/AIDS (majority of whom are homeless), those with sickle cell anemia, and others in that category require more attention than they are currently receiving. Teacher education programs should adequately prepare teachers who can teach all students, including those in urban areas and other poor and disadvantaged communities. Education is a dynamic field and these programs must change with time.

Educating Children with Physical Disabilities

Z P Nkabinde, New Jersey City University, Jersey City, NJ, USA

Physical disabilities can affect a person's ability to move about, to use arms and legs effectively, to swallow food, and to breathe unaided (Black and Pretes, 2007; Hardman *et al.*, 1999). Such limitations may also be evident in other areas such as vision, cognition, speech, language, hearing, and bowel movement. In recent years, due to advancement in medicine and technology, more and more students with mild to severe physical disabilities are now served in regular classrooms. Hill (1999) stated that students with chronic physical and medical conditions are being integrated into general public schools alongside their age- and grade-appropriate peers in far greater numbers than in the past. Some have attributed this change, particularly for students with orthopedic impairments, to the removal of physical barriers in the school environment and to changes in attitudes and beliefs (see Hill, 1999). Since students with physical disabilities face many challenges during their school years due to their precarious physical and health situations, their education requires careful planning involving administrators, teachers, parents, and students (Smith, 2007).

It is important for students with physical disabilities to feel accepted in a school environment. When they feel valued and respected by their peers, their self-image improves for the better. Stein (1989) as cited by Hill (1999) made the following statement:

It has been suggested that children are our most precious resources and that a society can be judged in part or in whole by how it treats its most vulnerable members. Children with chronic physical conditions represent a vulnerable population, and the time has come for us to go beyond the recognition of that fact to remedy the problems and address the needs. At present we lag behind many other nations in our willingness to assure a wide range of services to children and their families. The challenge for all of us is to continue to make our own individual and collective contributions to caring for children with chronic illness and to assume a leadership role in setting a high standard for the provision of comprehensive and humane services to these children and their families. (pp. 25–26)

Related Services for Students with Physical Disabilities

Hill (1999) contended that P.L. 94-142 and its amendments emphasized the importance of the provision of related services to assist in the removal of any potential barriers to the successful inclusion of a child with special healthcare needs into the general education classroom. According to Palfrey as cited by Hill (1999), the following related services were included in P.L. 101-476:

Transportation and such developmental, corrective and other supportive services as are required to assist a handicapped child [a child with disability] to benefit from special education, and includes speech pathology and audiology, psychological services, physical and occupational therapy, recreation, early identification and assessment of disabilities in children, counseling services, and medical services for diagnostic and evaluation purposes. The term also includes school health services, social work services in schools, and parent counseling and training. (p. 21)

In addition, Hill stated that the same educational legislation defined medical services as “services provided by a licensed physician to determine a child's medically related disability that results in the child's need for special education and related services” and school health services as “services provided by a school nurse or other qualified person.”

Students with physical disabilities may encounter serious orientation and mobility problems inside and outside of a classroom. These problems can have a negative impact in terms of classroom activities and overall performance in a school setting. Thus, students who are attending regular school often need support from varied professionals such as physical therapist, occupational therapist, therapeutic recreation specialist, and an adapted physical educator in order to participate in different school activities (Eriksson *et al.*, 2007). The role played by each professional in the student's life differs according to the need and severity of the disability. Shapiro and Sayers (2003) contended that physical therapists are health professionals with specific

training in the remediation of a disability, dysfunction, or pain. As they noted, physical therapists may do the following:

- Restore and preserve range of motion.
- Evaluate muscle length and perform stretching exercises.
- Perform muscle-strength evaluation.
- Offer exercises to increase strength, endurance, and coordination for specific muscle groups or the entire body.
- Evaluate muscle tone.
- Evaluate and train sitting and standing balance, transfers, and mobility, including wheelchair use for ambulation.
- Evaluate and train users of lower extremity orthosis and prostheses.
- Assess skin integrity and sensation.
- Offer various physical therapy modalities (e.g., heat, ultrasound, and massage) to relieve pain, prevent deformity, develop or improve muscle strength or motor skills, and maintain maximal functional capabilities. (p. 33)

In a school setting, these professionals offer techniques that correct, facilitate, or adapt the student's functional performance in motor development (e.g., a student's gross motor skills and related locomotor activities), motor control and coordination, posture and balance, functional mobility (e.g., transfer skills from a desk to a walker, from a wheelchair to a bench, gait training, use of walkers, wheelchairs, crutches, prosthetics, and/or braces (Shapiro and Sayers, 2003).

Another service provider for students with physical disabilities is an occupational therapist. The role of this professional is to provide services to people with specific performance difficulties in self-care, work, and play activities that limit their ability to deal with tasks of everyday (see Shapiro and Sayers, 2003). Services provided by occupational therapists include the following (see Shapiro and Sayers):

- Evaluation and training in self-care activities, such as dressing, eating, bathing, and personal hygiene.
- Training in home management skills.
- Exploration of vocational skills and interests.
- Maintaining and improving joint range of motion, muscle strength, endurance, coordination, and dexterity in upper extremities.
- Evaluation and training for compensation for sensory, perceptual, and cognitive deficits.
- Training in use of upper extremity prosthesis.
- Evaluation and training in use of assistive technology systems. (p. 35)

Occupational therapists render services aimed at improving student performance in postural stability, sensory processing, organization and integration, motor planning and coordination, fine-motor abilities (e.g., arm and hand), self-help abilities (e.g., eating and dressing),

environmental adaptations, use of assistive devices, and social and play abilities (see Shapiro and Sayers). In the school setting, occupational therapists are likely to consider the role of the hand by facilitating or teaching a student to use his/her hand to improve handwriting skills and other hand-manipulation skills related to areas of the curriculum, such as art, music and band, and transfer skills. Additionally, they may contribute to independence in school by helping a student who uses a wheelchair learn to carry a lunch tray on his/her lap, manage a ramp to and from the playground, and move through the halls.

Another service provider for students with physical disabilities is a speech and language pathologist. Bowe (2000) noted that this professional has the role of:

- Screening for articulation, breathing, feeding, and related problems.
- Assessing ability to express oneself in speech and in other ways (gestures, sign language, and communication boards).
- Assessing ability to use age-appropriate language (e.g., muteness, echolalia, and language delays).
- Identifying goals and interventions.
- Monitoring progress toward goals.
- Identifying, ordering, adjusting, and training the individual to use adaptive devices such as communication boards.
- Serving as a team member.

Art therapists play a major role in the lives of students with physical, sensory, and health disabilities because of the nature of physical disabilities. Bowe (2000) described art therapy as a service that offers benefits similar to counseling. It is particularly helpful to individuals who are coping with strong emotions, like those who have spinal cord injury (SCI) or traumatic brain injury (TBI) and many who have muscular dystrophy or other fatal conditions. As Bowe pointed out, art therapists:

- Assess physical and cognitive abilities, including perception of others and self-image, and problem-solving skills.
- Set goals for treatment.
- Identify appropriate individual and group therapy interventions, including not only artwork but also discussion of one's work.
- Serve as a team member. (p. 51)

There is no doubt that collaboration in meeting the needs of students with physical disabilities is a necessity. Such students have complex needs ranging from environmental to health needs.

Intervening Early in Physical Disabilities

Young children from birth to 3 years may receive early intervention services if they qualify under certain

conditions (Johnson *et al.*, 2007). These conditions include a developmental delay in one of five developmental domains: cognitive development, physical development, social or emotional development, communication development, and adaptive development. Another criterion that can lead to eligibility is established risk conditions such as young children who may have a diagnosed physical or medical condition that may lead to a developmental delay. The list may include premature babies, those children with low birth weight due to chronic illnesses, or exposure to drugs and alcohol. Early intervention sets the stage for better language, physical, social, and cognitive development. It may reduce the impact of physical disability on learning if an intensive and comprehensive therapy is put in place. It may reduce stress in family when a student learns to be less dependent on his/her caregivers. In addition, early intervention is crucial for people who are born with disabilities or acquire them during the early childhood years. According to Bowe (2000), the IDEA's Part C early-intervention services can be very helpful. Specifically, students with physical disabilities who are struggling with speech, communication, social, mobility, and other academic issues presented by their condition can benefit from early intervention. For example, students with spina bifida may receive physical and occupational therapy services. For young children with spina bifida who also have learning disabilities, special instruction can help them to develop effective learning strategies. Peer acceptance is critical in decreasing the impact of a physical disability.

Smith (2007) noted that whether disabilities are physical or health related, early-intervention programs provide a strong foundation for the child and family. Parents and other family members may benefit from counseling and information services that help them both to cope with the child's disability(ies) and to take advantage of public services that will help the family and the child. Secondary disabilities can be prevented through early screening and early intervention. Surgical procedures, which are common for spinal cord injuries, often reduce the severity of the injury and contribute to positive outcome (Hardman *et al.*, 1999). Motor development and positioning and the development of communication skills are often target for young children with physical or health disabilities (Smith, 2007). Most early-intervention services are provided in the home; and some are offered in early-intervention centers. Homebound children such as those who are medically fragile and technology dependent are most likely to receive their treatment in hospitals and/or special facilities such as respite care.

Clearly, some disorders are confined to childhood such as dyspraxia, a disorder characterized by an impairment in the ability to plan and carry out sensory and motor tasks (Stansell, 2007). Dyspraxia can be a problem largely confined to childhood; but as long as children receive therapy,

they can be cured of their disorder. In early childhood education, assistive technology is extremely important. It could lead to increased active participation in family, school, and community, successful play with peers and toys, increased ability to communicate needs and ideas, opportunities to make independent choices, and increased ability to move independently. With so many schools and districts now placing students with severe disabilities, including those with physical disabilities in inclusive settings, interventions that facilitate full participation in academic and social activities are becoming ever more important (Wolfe and Hall, 2003). The ultimate goal of early intervention is to help students with physical disabilities become as independent as possible.

Increasing Learning Potential of Students with Physical Disabilities

Turnbull *et al.* (2004) contended that 93% of students with physical disabilities attend regular schools. Approximately half of these students are educated outside the general education classroom for less than 21% of the time. One of the many challenges facing general education teachers, administrators, and other service providers is ensuring that these students access general education curriculum without any environmental barriers. Maximum educational participation can only be possible with appropriate curricular adaptations, accommodations, and modifications dictated by learning and physical needs. It must be noted that some students do not have conditions that limit their learning. However, in other cases, students may have conditions such as cognitive disabilities that limit their learning. Adaptations may range from stabilizing material on a slant board to using an augmentative communication device (Heller *et al.*, 2009). Earlier, Smith (2007) cited classroom tips for teaching students with physical disabilities and urged educators and service providers to:

- Adapt the physical environment such as removing hazards; creating more work space; providing storage space for equipment; making furniture accessible; widening aisles; using positioning devices; changing seating arrangements; and rearranging furniture.
- Change student response mode, such as allowing speaking instead of writing; using a speech synthesizer; allowing writing instead of speaking; and allowing computer-print output.
- Alter materials and equipment, for instance, giving hand-outs; adapting writing tools; using special eating utensils; and exploring assistive and adaptive technology.
- Modify the activity, for instance, allowing more time to complete the assignments; abbreviating assignments; and creating a flexible schedule.

- Provide extra assistance, such as arranging peer tutors; having parents or family members help; finding volunteers to assist; video or audio taping lessons; and using e-mail for help sessions.

Many students with physical disabilities may not be able to participate fully or perform to their full potential due to their severe physical conditions. The types of disability (e.g., orthopedic impairments, multiple disabilities, traumatic brain injury, or other health impairments) in many instances will determine the impact on school performance. According to Gargiulo (2006), students with orthopedic impairments often have problems accessing materials; students with other health impairments are more likely to have problems of endurance and stamina. The severity of a disability will also play a role in determining its impact on school performance. For instance, motor limitations have an impact on how students with physical disabilities participate in a school environment. Gargiulo reported that a student whose disabilities limit the movement of arms, hands, and fingers may be unable to do school tasks involving writing or manipulating material without modifications. Optimal school performance may not be reached even with modifications. As an example, a wheelchair-bound student may not be able to participate in all academic projects such as field trips. What takes students without disabilities a shorter period of time might be time consuming for students with disabilities – these students may be forced to use compensatory strategies such as orally presenting their work instead of writing them or using the Internet to visit museums instead of personally visiting them. Another strategy is that of using peers as note takers and/or parents or volunteers. Such strategies require prior planning and working around the routine and schedule that best suit the student's needs. Assignments may also need to be adapted to avoid fatigue and inattentiveness that may be common for students with physical disabilities. Wheelchair mounting allows wheelchair users to have a desktop computer attached to their wheelchair for easy use. In this manner, students are afforded the opportunity to have their work areas.

Students with physical disabilities can have their books adapted to fit their physical needs. For example, e-books can be used for students with motor limitations. Adapted books can increase the school performance of these students and make reading more pleasurable and meaningful. Page turners and use of color coding, sentence strips, and sticky notes are all low-tech strategies that can compensate for students' limitations. Restricted communication can be a factor on school performance. Effective communication is a critical component for successful education of students with physical disabilities, primarily because some of these students face communication challenges (Howell and Gengel, 2005).

Assistive technology such as voice-recognition technology offers great hope for this population. However, for students who cannot spell or write, no augmentative communication device will help. Students struggling with writing tasks can benefit from using a speech-recognition system, a device that provides an alternative strategy for students who experience writing difficulties using standard methods for computer access to write efficiently (see Gargiulo, 2006).

Students with physical disabilities experience fatigue and endurance limitations that can negatively influence their school performance. Keyser-Marcus *et al.* (2002) stated that because many students with traumatic brain injury experience difficulty with fatigue, a modified school day (e.g., regularly scheduled breaks and shortened length of school day) may be necessary for optimal performance. Workload for this population can be reduced without compromising quality. Students can be given extra time to complete their assignments. Task analysis where complex tasks are broken into teachable units is also recommended. Additionally, for students with health factors such as juvenile rheumatoid arthritis or for students with poorly fitted artificial legs, there might be discomfort which in turn can interfere with school performance (Gargiulo, 2006). Students with physical disabilities and other health impairments tend to miss classes a lot and that may have a negative effect on their school performance. According to Gargiulo, students with severe speech and physical impairments (as in severe cerebral palsy) tend to be further behind in reading level than is commensurate with intelligence quotient (IQ). Clearly, self-concept and self-esteem issues can affect school performance of students with physical disabilities. How these students perceive themselves and how they are perceived by others play a role in their overall social well-being. Unlike other disabilities, being physically impaired means being aware of your difference earlier on since the disability cannot be concealed. Gargiulo acknowledged that students with physical and health impairments may feel like outsiders in everyday life; they may feel different, deprived, or unable to live like other children. While other children may view life as being filled with possibilities, these students may see life as filled with limitations. In some instances, these students may feel worthless and burdensome to those who care for them. Such feelings of helplessness may contribute to lowered self-worth.

When students have physical disabilities, assistive technology can provide them with opportunities to control their environments in areas such as communication and independent daily living skills both at school and at home. Bowe (2000) stated that technology has revolutionized the lives of Americans with physical, health, and sensory limitations in school, at home, in the community, and in the workplace. What was almost impossible to

accomplish by these individuals has become possible. For example, with today's technologies a student with physical disability can and often does take courses in inclusive settings in elementary and secondary schools, performing the same assignments and taking the same tests as do children and youth without disabilities.

Bowe noted two basic kinds of technologies, namely: (1) low-tech devices which are products that have one or no moving parts, rarely have any electronic components, and usually are low in cost; and (2) high-tech products which tend to have numerous moving parts, feature complex electronics, and cost several hundreds to several thousands of dollars. Below are some examples of low-tech devices (Assistive Technology and Children with Special Needs, 2007):

- Picture exchange communication systems are useful to create communication boards for students with limited communication skills.
- Dry erase boards are good writing tools.
- Clip boards can be used to create communication boards for students with limited speech. Pictures and symbols may be used, printed, or cut out and pasted on a communication board for easy access.
- Laminated photographs can be used as labels for objects in the home and classroom.
- Manipulatives/objects can be used as teaching tools for counting and to stimulate communication across settings. (p. 6).

Varieties of low-tech products are now available for students with physical disabilities including a large number of switches. The Alliance for Technology Access (1994) agreed that the placement of the on/off switch might seem a trivial matter, but if one has limited mobility, one may want the switch to be accessible. Mouth-sticks, head-sticks, foot-operated rocker switches, and many other switches make it possible for an individual who can make at least one voluntary motion with their bodies to activate a switch to gain some control over their environment (Bowe, 2000). Switch-activated toys are also available. According to Best *et al.* (2005), to use a switch effectively, individuals should (1) be properly positioned if nonambulatory, (2) demonstrate nonreflexive stimulation, and (3) exhibit voluntary movement on cue. Other low-tech products include can grabbers, adapted spoon handles, Velcro fasteners (Turnbull *et al.*, 2004). Assistive-technology devices can also be beneficial to students with mobility limitations in their hands and arms, making it possible for them to write. Adapted writing tools include (1) grips, foam material, or balls added to pencils or pens to enhance their grip and (2) attachments, templates, splints, or weights that enable students to hold writing tools at the proper angle. Dell *et al.* (2008) stated that between sophisticated high-tech and nonelectronic low-tech devices are items classified as

mid-tech devices. Mid-tech devices are described as electronic in nature but are much less expensive and require less training than high-tech devices. Examples of mid-tech devices include, but are not limited to, tape recorders, digital recorders, hand-held electronic dictionaries, and spell-checkers. Oversized calculators and calculators that talk are additional examples of mid-tech devices (Dell *et al.*, 2008).

Examples of high-tech devices (Assistive Technology and Children with Special Needs, 2007) include:

- Video taping: Class lectures can be taped to allow students to work at their own pace and to allow more time in the completion of classroom tasks. Since many students with physical disabilities are absent from school for days or weeks at a time having lessons on tape can provide them with instructions in the comfort of their homes or in hospitals.
- Computers including adaptive hardware, touch window where the computer monitor has a built-in sensors that provide activating computer programs with a finger-tip, rather than using a regular mouse; intellikeys provides a keyboard with large print keys; big keys, trackballs, and software.
- Accessory equipment such as digital cameras and scanners. (pp. 7, 8).

Video taping can be used for homebound students to allow them to keep up with classroom expectations. Classroom work can also be posted online and such a tool can allow students with physical disabilities to participate in classroom discussions without being physically present. Phone hook-ups can be used as another avenue to reach homebound students. Both low-tech and high-tech devices increase independence of students and adults with physical disabilities. Different types of assistive technology may be required for students with physical disabilities in order to benefit from their education programs (Heller *et al.*, 2009). As Heller *et al.* pointed out, these include devices for augmentative and alternative communication, mobility, life management, computer access, academic content areas, and play and leisure. Dell *et al.* (2008) stated that one of the most powerful applications of computer technology has been the development and ongoing refinement of devices that can speak. An example of a software that facilitates communication is communication boardmaker, a versatile software program provides speech for people unable to communicate orally (The Alliance for Technology Access, 1994). Communication boardmaker features a searchable database of more than 3000 universal picture communication symbols. Another communication device is a touch talker, a portable device with a computer-generated voice (see Dell *et al.*, 2008). Speech-recognition programs allow the computer to translate spoken word to text. Such programs allow for hands-free control of the computer and are useful tools

for students with motor limitations. Some students with physical disabilities have normal IQs but may have problems expressing their thoughts using traditional methods of a pen and paper. Another important application for individuals with motor impairments is word prediction (Edyburn, 2003). Word-prediction word processors, such as Co:Writer, reduce the stress of writing for those individuals with deficit motor skills. Writing that requires extensive use of fine motor skills which may result in excessive physical effort and fatigue is reduced. Evidently, assistive technology is not only useful in reducing environmental barriers for students with physical disabilities but also helps them on many different levels in the content areas. The Power of Assistive Technology (2007) identified the following tasks that can be accomplished:

- *Master grade-level content.* Technology presents the material in different forms (visually, auditorily, etc.)
- *Improve writing and organizational skills.* Technology can enable students with learning disabilities to do such things as develop a concept map for a research paper and write using grade-level vocabulary words they would not use without a computer due to poor spelling skills.
- *Read grade-level text.* The computer either reads the text digitally or represents it at a lower grade level for students with reading disabilities or visual impairments.
- *Take notes.* Many students with disabilities have difficulty taking notes in longhand because of poor spelling, writing, and/or hand-coordination skills.
- *Master educational concepts that would have been beyond their reach.* Students can experience abstract concepts such as the metamorphosis of a flower through 3-D simulations.

Conclusion

This article has focused on how to maximize the potential of students with physical disabilities. Numerous studies have indicated that these students have lower participation both in structured and unstructured school activities. Removing all barriers for these students will expose them to unique opportunities that will help them reach their full potential. In a supportive environment, such students will have a more positive school experience, more social contacts, less dependence on others, and will enjoy and benefit from their autonomy. Though the inclusion of these students both with or without severe disabilities has become a norm, Wolfe and Hall (2003) concluded that special education laws strongly encourage appropriate placements in least-restrictive settings. Our goal as professionals must be to create environmental and instructional supports that will help students with physical disabilities to overcome various challenges presented by their physical limitations.

Educating Children with Specific Learning Disabilities

Children with specific learning disabilities (SLDs) are those children who have a disorder in one or more of the basic psychological processes involved in understanding or using language – spoken or written – which may manifest itself in imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculations (Lloyd, 1996). Such disorders include conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia. Such a term does not include children who have learning problems – which are, primarily, the result of visual, hearing, motor disabilities, mental retardation, emotional disturbance, or of environmental, cultural, or economic disadvantage (see Lloyd). Hunt and Marshall (2002) indicated that, according to the federal law, a student has a learning disability if he/she (1) does not achieve at the proper age level and ability level in one or more or several specific areas when provided with appropriate learning experiences; and (2) has a severe discrepancy between achievement and intellectual ability in one or more of the following areas: (a) oral expression, (b) listening comprehension, (c) written expression, (d) basic reading skills, (e) reading comprehension, (f) mathematics calculation, and (g) mathematics reasoning. The key element to the federal definition is the emphasis on the performance of students with LDs which is, often, tied to their ability to receive or express information (see Hunt and Marshall, 2002).

The SLD category is relatively new. It was first recognized by the federal government in 1969. An understanding of the history of SLD provides a context for understanding the many issues facing the field. This history has been well documented (e.g., Hallahan and Mercer, 2002; Wiedherhold, 1974). The LDs story actually began when Samuel Kirk introduced the term at a meeting of parents advocating special educational services for their children who were having difficulty in school but were not considered disabled by mental retardation or emotional disturbance (Kirk, 1975). In earlier decades, these children's difficulties had been variously categorized as mild exogenous mental retardation (mild mental retardation caused by brain injury), minimal brain dysfunction (behavior associated with brain injury, although brain damage cannot be verified), perceptual impairment (persistent difficulty in making sense of sensory stimulation), hyperactivity (excessive and socially

inappropriate behavior accompanied by problems in learning), and slow learning (a child whose achievement is not far enough below average to indicate mental retardation) (see Hallahan and Cruickshank, 1973; Hallahan and Kauffman, 1977; Mann, 1979; Wiedherhold, 1974). In the present day, people from nearly every walk of life – and every ethnicity – recognize the term learning disabled, which is often used generically by the general public to indicate that someone's behavior is highly unusual or inadequate for the circumstances. LD is a separate category in the special education literature – a disability defined by federal and state laws, and a specialization for which teachers in many states must obtain special certification. The term has gained almost universal acceptance among regular educators, special educators, and the general public in the United States and in many foreign countries (Mazurek and Winzer, 1994; Winzer, 1993).

Hallahan *et al.* (1996) concluded that the history of LDs can be summarized in relation to themes that have emerged as the field has developed. These themes are critical to understanding that LDs (1) represent an interdisciplinary field that is international and multicultural in scope; (2) have a variety of possible causes; (3) are, in part, a social construct; (4) are heterogeneous in nature; (5) vary in severity and pervasiveness; (6) are characterized by intra-individual differences; (7) affect a diverse group of people; (8) may coexist with other disabilities or giftedness; (9) require training in systematic approaches to tasks; (10) require educators to minimize the contribution of poor teaching; and (11) are developmental disorders persisting over the life span (p. 25). Apparently, LD is a perplexing disability that requires general and special educators dedicated to helping students to utilize their fullest potential. This is the focus of this article.

Definitions and Prevalence of SLD

The field of LDs is complicated by controversy in the areas of definition, prevalence, and demographics. Kirk (1962) defined LD as follows:

A learning disability refers to retardation, disorder, or delayed development in one or more of the processes of speech, language, reading, writing, arithmetic, or other school subject resulting from a psychological handicap caused by a possible cerebral dysfunction and/or emotional or

behavioral deprivation, or cultural and instructional factors. (p. 263)

There are five components of Kirk's definition that have appeared in many of the later definitions of LD: (1) subaverage achievement (reading, writing, or arithmetic) or achievement related (speech or language) behavior; (2) intraindividual differences – the possibility that the sub-average achievement or achievement-related behaviors occur(s) in only some areas or one area, with average or above-average achievement occurring in the other areas; (3) reference to psychological handicaps (often referred to as psychological processes by Kirk and others) as causal factors; (4) reference to cerebral dysfunction as a possible causal factor; and (5) exclusion of other disabling conditions (i.e., mental retardation) and environmental conditions as causal factors:

Bateman (1965), Kirk's student, offered the following definition:

Children who have learning disorders are those who manifest an educationally significant discrepancy between their estimated intellectual potential and actual level of performance related to basic disorders in the learning process, which may or may not be accompanied by demonstrable central nervous system dysfunction, and which are not secondary to generalized mental retardation, educational or cultural deprivation, severe emotional disturbance, or sensory loss. (p. 220)

Bateman's definition differed from Kirk's in at least two important respects. First, it did not include reference to emotional factors as a cause of LDs. In fact, it mentioned severe emotional disturbance as one of the disabilities that does not cause LDs. No major definitions since Bateman's have mentioned emotional disturbance as a possible causal factor. Second – and even more important – it included reference to a discrepancy between intellectual potential and actual performance.

Hallahan *et al.* (1996) summarized several important definitions of LDs over the years to include the following:

- Definitions proposed by task forces organized by the federal government, in 1966, that emphasized medical explanations and, in 1969, emphasized intra-individual differences and discrepancy between potential and performance.
- The definition suggested by the National Advisory Committee on Handicapped Children 1968 referred specifically to children, added thinking disorders to the list of examples of LDs, and did not refer to emotional disturbance as a causal factor.
- The authors of the definition proposed by the United States Office of Education (USOE), in 1977, considered the notion of developing a discrepancy formula; this

idea was met with an immediate and negative response, but the authors still referred to an ability-achievement discrepancy in their evaluation criteria.

- The National Joint Committee on Learning Disabilities (NJCLD), in 1981, reacted negatively to the USOE references to psychological processes.
- A major organization – the Learning Disabilities Association of America – did not endorse the NJCLD definition; instead, in 1986, it emphasized the lifelong nature of LDs, did not exclude other conditions as causal factors, and mentioned that adaptive behaviors can be affected.
- The Interagency Committee on Learning Disabilities 1987 definition was essentially the same as that of the NJCLD, but it added social skills deficits as a type of LD and attention deficit disorder as a potentially co-occurring condition. In 1988, the NJCLD revised its definition to acknowledge the lifelong nature of LDs and include socialization problems as potentially co-occurring, but not as an example of a type of LD.

Clearly, a new political and educational movement had been initiated. One of its first tasks was refining the above description to provide a more educationally focused definition (e.g., Bateman, 1965; Cruickshank, 1966; Kass and Myklebust, 1969). To bring order to the proliferation of SLD definitions, the National Advisory Committee on Handicapped Children (NACHC, 1968), headed by Samuel Kirk, was formed with the task of writing a definition of SLD that was to be the basis for Public Law 91-230 (Children with Specific Learning Disabilities Act). The definition, however, failed to clear delineation of LD parameters (Hammill, 1974), but when Public Law 94-142 – the Education for All Handicapped Children Act – was passed in 1975, SLD became an official category within the NACHC definition. With only minor wording, the NACHC definition was the one issued by the USOE. To this date, it remains unchanged as the definition of SLD used by the federal government. The definition reads as follows:

The term specific learning disability means a disorder in one or more of the psychological processes involved in understanding or in using language, spoken or written, which may manifest itself in an imperfect ability to listen, speak, read, write, spell, or to do mathematical calculations. The term includes such conditions as perceptual handicaps, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia. The term does not include children who have learning disabilities which are primarily the result of visual, hearing, or motor handicaps, or mental retardation, or emotional disturbance, or of environmental cultural, or economic disadvantage. (USOE, 1997: 65083)

As it appears, the above federal definition did not specify how states were to identify students as SLD. To remedy this situation, the USOE issued regulations intended to provide criteria for determining eligibility. These regulations represent an operational definition of SLD and center on the presence of an ability-achievement discrepancy:

A team may determine that a child has a specific learning disability if:

1. The child does not achieve commensurate with his or her age and ability levels in one or more of the areas listed in (a) (2) of this section, when provided with learning experiences appropriate to the child's age and ability levels; and
2. The team finds that the child has a severe discrepancy between achievement and intellectual ability in one or more of the following areas: (i) oral expression; (ii) listening comprehension; (iii) written expression; (iv) basic reading skill; (v) reading comprehension; (vi) mathematical calculation; or (vii) mathematical reasoning (USOE, 1997: 65083).

Lokerson (1992) noted that although the definition in federal law governs the identification of – and services to – children with LD, there are variations between states and among school systems. In an attempt to clarify the identification, some states specify an intelligence range. Others add a concept of a discrepancy between potential and achievements, sometimes quantifying the discrepancy using test scores. These slightly different yardsticks are indicative of a lack of a clear consensus regarding exactly what LDs are.

According to the figures maintained by the federal government, public schools have identified approximately 2.3 million students (~6–21 years) of age as learning disabled, which represents 4.09% of those in this age range (US Department of Education, 1994). However, this is a slight underestimate, because students in private schools identified with LDs have tripled. Critics have suggested that this rapid growth is evidence that LDs is an ill-defined category; and even defenders of the field are concerned that much of the growth is indicative of the confusion over definition and diagnostic criteria. Others have noted that the increase in the numbers of students identified with LDs is inversely related to the numbers identified for several reasons. Hallahan (1992) speculated that there may be many reasons for some of the growth. The field of LDs was quite new, in 1976, when the government started maintaining prevalence data, and it may have taken professionals several years to decide how to identify children. Second, he noted that many social and cultural changes have occurred in the last 30 years to heighten children's vulnerability to develop LDs. Baumeister *et al.* (1990) suggested that an increase in poverty has

placed more children at risk for biomedical problems, including central nervous system dysfunction. Hallahan, further, concluded that stress on parents may result in them being less able to provide the social support necessary to help their children, who themselves are experiencing an increasing amount of stress. The result may be that children who – in a previous time of less stressful lifestyle and more support – would have gotten by in their school work are now experiencing failure.

Characteristics of SLD

Early Childhood

The SLD category is reserved for children who experience academic failure. However, a variety of cognitive and behavioral characteristics place children at risk for academic failure. For example, poverty, poor nutrition, and environmental hazards are risk factors for many disabilities. Because SLD includes multiple and complex causes that manifest themselves in a variety of conditions varying in type and severity, children younger than 6 years of age are, often, given a noncategorical designation such as developmental delay (Stichter *et al.*, 2008). The 1997 reauthorization of Individuals with Disabilities Education Improvement Act (IDEA) incorporated early-childhood special education laws that ensure the same rights for younger children (age range: 3–5).

Younger children may possess delays in one or more of the following areas: (1) physical development, (2) cognitive development, (3) communication development, or (4) adaptive development. Specifically, precursors of SLD may be found in the following areas: (1) gross motor skills, (2) fine motor skills, (3) auditory processing, (4) visual processing, (5) linguistic processing, or (6) attention problems. The general term developmental delay is useful because children may be at risk for SLD, mental retardation (MR), or EBD. The goal is not to identify a specific disability but, rather, to provide early intervention to prevent future problems.

Elementary Grades

The federal definition describes SLD as

a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, which may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculations.

An SLD is conceptualized as a deficit in one or more processes (e.g., listening, memory, perceptions, attention) assumed to be the underlying reason for academic difficulties (Stichter, 2008).

Academic difficulties may manifest themselves in reading, writing, and arithmetic. Severe difficulty in learning to read is alexia and minor is dyslexia; severe difficulty in learning to write is agraphia and minor is dysgraphia; severe difficulty in learning to solve mathematics is acalculia and minor is dyscalculia; and severe difficulty in learning to express oneself is aphasia and minor is dysphasia. Although possessing average or above-average intelligence, students with dyslexia have significant difficulties reading, spelling, understanding language, and expressing themselves in speaking and writing. Even though there is disagreement with regard to how dyslexia should be defined, there is agreement concerning the following (Hynd, 1992):

- dyslexia has a biological basis and is caused by a different anatomical brain structure;
- dyslexia persists in adolescence and adulthood; and
- dyslexia has linguistic, cognitive, and perceptual manifestations.

The National Reading Panel – in a comprehensive review of reading literature, in 2000 – determined that five areas in reading should receive primary instructional focus: phonemic awareness, phonics, fluency, vocabulary, and comprehension. These areas connect and build upon one another, leading to proficient reading. Regrettably, for nearly 90% of students with SLD (Kavale and Forness, 2000), reading problems are a significant cause of low performance. The basic nature of the problem is found at the linguistic level of phonology (Liberman and Shankweiler, 1985), where a critical aspect of reading involves manipulating phonemes – the smallest sound unit of language (Liberman and Shankweiler, 1991). The most basic deficit of students with SLD is the lack of phonemic awareness – the understanding that spoken language is composed of individual phonemes (Brady, 1997; Rack *et al.*, 1992). Without knowledge of the phonological structure of language, the student with SLD is likely to also lack phonological awareness, the ability to blend (connect sounds of individual phonemes into syllables and words), segment (dividing words into their individual phonemes), and rhyme (finding words that sound the same) (Blachman, 2001; Mutter, 1998; Wagner and Torgesen, 1987). In sum, a student's initial difficulties in phonemic awareness leads to difficulty with phonological awareness, which leads to decoding that is less than automatic. When students do not develop automaticity in decoding, they have to decode word-by-word, which reduces fluency. This reduction in fluency translates into inadequate comprehension, as students are expending so much cognitive energy on decoding that they have little left for comprehending what they are reading (Stichter *et al.*, 2008).

Students with an SLD perform poorly on written expression tasks, especially those involving vocabulary,

grammar, punctuation, and spelling (Newcomer, and Barenbaum, 1991). Students with SLD approach writing with minimal planning, effort, and strategic behavior (Thomas *et al.*, 1987). The consequences are found in difficulties in text production, limited knowledge of the writing process (e.g., drafting and revising), poor idea generation and organization, and improvised theme development (Graham *et al.*, 1991). Students with SLD may also experience difficulties with the mechanics of writing (handwriting) – as manifested in problems in letter formation and fluency. Additionally, students with SLD may experience math difficulties related to numerical reasoning and calculation. Compared to average-achieving peers, students with SLD perform more poorly in every aspects of arithmetic at every grade level (Crawley *et al.*, 2001). Notable are deficits in retrieving number facts and solving story problem (Geary *et al.*, 2000). Students with SLD progress slowly in math, and many plateau by age 12 (Crawley *et al.*, 1998).

Students with SLD demonstrate many processing deficits. In terms of cognitive styles (approaches to problem solving), students with SLD are, generally, more field dependent (i.e., influenced more by environment) and more impulsive (i.e., respond quickly with little reflection) (Blackman and Goldstein, 1982). Memory difficulties often occur in students with SLD. Short-term memory (ability to remember information immediately) tends to be more deficient in the auditory than in the visual realm (Hulme and Snowling, 1992). Reading and math problems appear to be more adversely influenced by deficits in working memory (ability to retain information while performing a mental operation) (Swanson and Ashbaker, 2000; Swanson and Sachse-Lee, 2001).

Motivation (i.e., activating, guiding, and maintaining behavior) is a problem area for students with SLD that results from three sources not limited to:

- An external locus of control in which the student with SLD waits for others to organize their behavior (Bryan and Pearl, 1979).
- Negative attributions (i.e., belief about the causes of success and failure) in which students with SLD are often not proud of success, minimize accomplishments, and are more prone to accept responsibility for failure. Such negative attributions tend to lower belief in self-efficacy (Tabassam and Grainger, 2002).
- Learned helplessness (i.e., belief that effort will not result in desired outcomes) which makes the student with SLD come to expect failure no matter how much effort he/she expends (Settle and Milich, 1999).

The presence of attention problems is an important component of SLD (Hallahan and Reeve, 1980). Behavioral problems appear at a higher-than-expected rate among students with SLD (Kavale and Forness, 1998).

The cause-and-effect relationship between behavioral problems and academic difficulties remains unclear. Additionally, many students with SLD demonstrate no behavioral problems. Students with SLD are more likely to manifest social deficits. Earlier, Kavale and Forness (1996) found that almost 75% of these students exhibited deficits in social skills. They appear less socially accepted because of difficulties in using language in social situations, in being sensitive to social cues, in correctly perceiving their social status, and in adapting to social situations (Sridhar and Vaughn, 2001). A fundamental difficulty contributing to poor social skills may be an inability to recognize emotions in others – in particular, nonverbal emotional expressions. Moreover, the same academic and social problems found in children with SLD are likely to continue into adolescence and adulthood (Kavale, 1988).

The most recent 2004 reauthorization of the IDEA, introduces a significantly different operational definition of SLD in which (1) the local education agency (school system) shall not be required to take into consideration whether a child has a severe discrepancy between achievement and intellectual ability, and (2) the local education agency may use a process that determines whether a child responds to scientific, research-based interventions. The proposed process is usually termed response to intervention (RTI), in which schools provide differing types and levels of instruction for low achieving students (usually in reading). The RTI model can be implemented in different ways that include variations in instructional interventions, levels of intervention before special education, and means by which students are deemed nonresponders (Fuchs *et al.*, 2003). Additionally, Graden (1989) suggested that the RTI model is best viewed as a pre-referral strategy in which instructional or organizational suggestions for enhanced achievement are provided prior to a referral for special education evaluation.

Assessing Students with SLD

The assessment of students with SLD remains as problematic as the definition itself. Ysseldyke *et al.* (1983) summarized several issues related to learners identified as learning disabled. In 5 years of research, they found no reliable psychometric differences between students labeled learning disabled and those who were perceived to be low achievers. In addition, identification as learning disabled depended on the criteria and definitions used. If that child moved to a different school district, he or she might no longer be identified as being learning disabled (Shea and Bauer, 1994). Algozzine (1991) argued that problems related to the identification of learners as learning disabled begin at the point of referral. The first problem is teacher reason for referral. For example, the
