To inform instructional planning, teachers rely on curriculum-based measurement's scores in graphed form. If a student's rate of improvement, as shown on the graph, is inadequate, the teacher revises the instructional program. Research (see Fuchs and Fuchs, 1998 for summary) shows that with curriculum-based measurement decision rules, teachers' instructional plans are more varied and are more responsive to student needs. Besides, their plans incorporate more ambitious goals for students and result in stronger end-of-year scores on standardized tests, including high-stakes state tests. In addition, when curriculum-based measurement systematically samples the skills in the year's curriculum, performance on the individual skills represented on each assessment can be analyzed. This kind of skills analysis has been shown to enhance the quality of instructional programming.

Curriculum-Based Measurement and Instructional Decision Making

Regardless of whether one adopts an overall indicator or a curriculum sampling approach to curriculum-based measurement, teachers use validated curriculum-based measurement decision rules to determine whether a student's academic development is adequate and, if not, to design an individualized instructional program that prompts better growth.

In **Figure 1**, we show a sample curriculum-based measurement report for one class. The first page shows a composite class graph. The bottom path on the graph depicts the progress of students in the bottom 25% of the class. The middle path shows the progress of students in the middle 50% of the class. The top path characterizes the progress of students in the top 25% of the class. Under the class graph, the names of 'students to watch' and 'most improved' in the past month are displayed. Next, the class report identified skills on which the class has made good progress in the past month and skills on which most students in the class should profit from instruction. At the bottom of page 1, students are identified for small-group instruction. On the second page of the report, each student's mastery status on each skill embedded in the annual curriculum is coded; the darker the box, the higher the mastery status. The teacher can look across a row to obtain the profile of skills strengths and weaknesses for a given student. The teacher can look down a row to determine how her class is performing on a specific skill. Page 3 shows students' slopes of improvement, and on page 4, names are listed of students who are noticeably behind their classroom peers in terms of the level of their current curriculum-based measurement score and their slope of improvement over time.

To determine whether a student's academic development is adequate, the teacher considers the student's slope

of improvement against the rate of improvement demonstrated by other students in the class or against national norms for expected rates of improvement. When a student is chronically identified as not making good progress, as identified on page 4 of the class report in **Figure 1**, curriculum-based measurement is then used to design an individualized instructional program. The goal is to promote better academic growth.

This is usually accomplished by the special educator or the reading or mathematics specialist, using curriculum-based measurement decision rules. These decisions rules are applied to the slope of the graphed scores, after the year-end goal has been set and placed onto the student's individual graph. A straight line connects the student's initial scores with that goal. This is called the goal line, which is compared to the student's actual rate of improvement or slope, referred to as the trend line. When a student's trend line is flatter than the goal line, the teacher revises the instructional program in some important way in an attempt to effect a better slope of improvement. After several weeks of implementing this instructional revision, the teacher analyses the student's graph in the same way, comparing the goal line against the student's new trend line. If progress looks strong enough to realize the end-of-year goal, the program revision is considered successful (although data analysis continues to ensure strong improvement across the school year). If, however, progress looks inadequate to ensure reaching the end-of-year goal, then the teacher experiments with a different method for revising the instructional program. Research (see Fuchs and Fuchs, 1998) shows that this kind of data-based decision making, based on curriculum-based measurement, results in more varied instructional programs that are more responsive to individual needs; that result in more ambitious student goals; and that produce stronger end-of-year scores on commercial, standardized achievement tests including high-stakes tests.

Progress Monitoring: An Essential Component for Responsiveness to Intervention

No instructional method, even those validated using randomized control studies, are universally effective. Therefore, when schools implement validated instructional programs, the effects of those programs on children's academic development must be assessed. That way, children who do not respond adequately can be identified promptly for different or more intensive intervention. For students who fail to respond to a second, more intensive level of programming, a third instructional tier, with greater individualization, is implemented. Throughout this process, the assessment of response continues. This assessment of response can be accomplished through curriculum-based measurement.

This iterative process, with which interventions of increasing intensity and individualization are conducted and their effects are assessed, describes the education reform movement known as responsiveness to intervention, which is conducted as part of a multi-tier prevention system. The first tier is primary prevention. The intensity of instruction reflects general education practice, with or without the use of individual accommodations and adaptations that fit within the general education program and can be managed by the general education teacher. The second tier is secondary prevention. Secondary prevention incorporates a greater level of intensity than

can be accomplished within general education. Typically, instruction is delivered in small groups of three to five students by well-trained, although not necessary, certified tutors, who use a prescriptive, validated intervention for 10–20 weeks. In some models, multiple doses of small-group, research-based tutoring are used to strengthen effects. If secondary prevention tutoring proves ineffective, then an even more intense level of intervention is conducted. This most intense level of instruction, referred to as tertiary prevention, is individually tailored. Instruction is delivered one to one or in pairs. It is often conducted under the auspices of special education resources, using

special-education certified teachers who are skilled in formulating individually tailored instruction.

Within a responsiveness-to-intervention system, therefore, progress monitoring plays three important roles. First, it is used to identify who should be targeted for special attention. Second, for those targeted for special attention, assessment is used to quantify responsiveness to intervention. Third, for the most unresponsive subset of children, assessment is used to tailor individualized programs. Curriculum-based measurement can be used for all three purposes.

Identifying Who Should Be Targeted for Attention

Within a responsiveness-to-intervention prevention system, the first assessment function is identifying a group of students who suspected to be at risk for poor learning outcomes. These students become the focus of the responsiveness-to-intervention system. Such screening is typically accomplished by administering a brief measure to all students at a given grade level. A cut-score is applied to these score. The cut-score indicates the score that is

Figure 1 A curriculum-based measurement class report for the half-month period starting on March 15. Page 1 shows (a) a class graph with the bottom path charting scores for the lowest quartile of the class, the middle path charting scores for the middle half of the class, and the top path charting scores for the highest quartile of the class; (b) a list of students to watch because their scores fall in the lowest quartile; (c) a list of students whose scores have improved in the most in the past half-month; (d) skills on which the class as a whole has improved in the past half-month; (e) skills on which the class as a whole can benefit from instruction in the upcoming half-month; and (f) skills on which small groups of students can benefit from instruction in the upcoming half-month. Page 2 shows (a) a skills profile in which the skills incorporated with each weekly assessment are summarized as mastered (black box), probably mastered (black box with a dot), attempted and partially mastered (plaid box), attempted but not mastered (striped box), and not attempted (open box) for each student in the class; (b) a frequency count of students in each mastery status for each skill; and (c) a rank ordering of students in terms of their most recent curriculum-based measurement score, with the student's slope of improvement through scores since the beginning of the academic year. Page 3 summarizes the class performance with (a) the average curriculum-based measurement score on March 15, the standard deviation around that average score, and the discrepancy criterion (i.e., 1 standard deviation below the mean, below which a student's curriculum-based measurement score may indicate difficulty); (b) the average curriculum-based measurement slope of improvement as of March 15, the standard deviation around that average slope, and the discrepancy criterion (i.e., 1 standard deviation below the mean, below which a student's curriculum-based measurement slope of improvement may indicate difficulty); and (c) a list of student(s) who meet the discrepancy criterion on both the average curriculum-based measurement score and the average curriculum-based measurement slope and therefore warrant attention to avoid poor long-term outcomes.

associated with inadequate performance on an important outcome measure, such as a high-stakes test, at a later time. All students scoring below this cutoff are designated as at-risk for poor outcome. Technically, screening, which involves a one-time test administration, is not a form of progress monitoring, which requires more frequent (typically, at least monthly) assessment. However, prominent screening measures have been borrowed from curriculum-based measurement tools due to the strong reliability and validity of curriculum-based measurement and because of its efficiency.

It is important to note that 1-time screening carries a significant danger of identifying false positives (i.e., designating students as at risk and in need of tutoring when, in fact, those students would develop strong academic skills without tutoring). In a first-grade responsiveness-to-intervention experiment (Fuchs *et al.*, 2006), for example,

50% of the control group, who had been designated at risk according to 1-time screening but who did not actually receive tutoring, made good progress by the end of the first semester of first grade. Such false-positive errors are expensive for responsiveness-to-intervention prevention systems because they waste costly resources on students who do not require them.

Because screening, especially at kindergarten and first grade, typically overidentifies students for secondary prevention tutoring, we recommend that 1-time screening constitutes only the first step in designating risk. Therefore, students who are suspected to be at risk, based on brief screening, are followed with 5–8 weeks of progress monitoring while Tier 1 general education is implemented. This short-term progress monitoring is used to gauge a student's actual response to Tier 1 general education and thereby confirm that the suspected risk, based on

screening, constitutes actual risk for reading or mathematics difficulties. Such short-term progress monitoring has been shown to increase the precision of designating who requires secondary prevention.

Quantifying Responsiveness to Intervention

Within a multi-tier prevention system, a second purpose for progress monitoring occurs with secondary prevention. With secondary prevention, tutoring is based on standard treatment protocol. With a standard treatment protocol, validated tutoring is conducted in small groups. The assumption, based on the validation research, is that most students should respond well to this tutoring. If a child responds poorly to instruction that benefits most students, then the responsiveness-to-instruction assessment process eliminates instructional quality as a viable explanation for poor academic growth and, instead, provides evidence of a disability. The purpose of progress monitoring at secondary prevention is, in part, to determine whether students do or do not respond to validated small-group tutoring and to identify students who do not benefit for a more intensive level of instruction. The students who fare well (and respond) are returned to general education, where progress monitoring continues to assess whether any additional tutoring is required.

Tailoring Individualized Instructional Programs

When, however, the secondary prevention progress-monitoring data indicate that the student has not responded adequately to secondary prevention tutoring, the student enters tertiary intervention, typically with special education resources and personnel. At the tertiary prevention level, instruction differs from secondary prevention because it is more intensive, involving longer sessions conducted in smaller groups or individually and because it is individualized, rather than relying on a validated treatment protocol. At tertiary prevention, progress monitoring is essential for two purposes: to inductively formulate instructional programs that are optimal for that student (as already described) and to determine when the student's response to tertiary prevention is adequate to return to the primary prevention general education program, possibly with accommodations or modifications, or to return to secondary prevention's small-group tutoring using a standard treatment protocol. In either case, progress monitoring continues so that tertiary intervention can be reinstated as needed.

Curriculum-Based Measurement Measures in Mathematics

At kindergarten in math, research has focused primarily on the overall indicator approach to curriculum-based

measurement. One promising measure is quantity discrimination. With quantity discrimination, students are shown a page with a series of pairs of numerals. The student has 1 min to circle the larger quantity for each pair. Another promising measure is number identification, with which students see a page of numerals and have 1 min to name the numbers. A third promising measure is missing number. With missing number, students are presented with strings of numerals, with the last numeral missing, and the student has 1 min to fill in the missing numerals. Some forms of validity have been shown to be strong (e.g., Baker *et al.*, 2002; Lembke and Foegen, 2006). Yet, some work suggests that when these measures are used for progress monitoring, students may learn these specific tasks and ceiling out of the test quickly, within 1 or 2 months (Lembke and Foegen, 2005). To address this problem, Seethaler and Fuchs (2006) developed and assessed a curriculum-sampling curriculum-based measurement approach at kindergarten. With this curriculum-sampling approach to curriculum-based measurement, a variety of computation and concepts/applications is systematically sampled on each alternate form. This study shows that the curriculum-sampling curriculum-based measurement systems, when used at the beginning of kindergarten, forecast students' development of math competence at the end of first grade with similar accuracy as do the overall indicator measures. Additional work is needed to determine which curriculum-based measure is sound for monitoring math progress over time at kindergarten.

At first grade in mathematics, most progress-monitoring research parallels the work conducted at kindergarten, using quantity discrimination, number identification, and missing number. As with kindergarten, although some forms of validity look strong, the threat of students reaching the top score on the test quickly looms larger even at first grade than at kindergarten. An alternative approach, using a curriculum-sampling approach to curriculum-based measurement, has also been used at first grade. It has been shown to index progress effectively and to forecast the development of serious math difficulties at the end of second grade (Compton *et al.*, 2006; Fuchs *et al.*, 2005). In a similar way, research at grades 2–6 (Deno *et al.*, 2006) demonstrates the validity of a curriculum-sampling curriculum-based measurement approach, and other research (see Fuchs and Fuchs, 1998) illustrates how teachers can use the curriculum-sampling curriculum-based measurement approach in math to design more effective instructional programs.

Curriculum-Based Measurement Measures in Reading

As already stated, curriculum-based measurement can take one of two forms. It can rely on a single behavior

that functions as an overall indicator of competence in an academic area or it can systematically sample the annual curriculum. In reading, most well-researched curriculum-based measurement systems take the overall indicator approach.

At kindergarten in reading, there are three major alternatives for curriculum-based measurement: phoneme segmentation fluency, rapid letter naming, and letter-sound fluency. With phoneme segmentation fluency, the tester says a word, and the child says the sounds that constitute the word (i.e., the tester says, *rat*; the child says, /r/ /a/ /t/). The tester administers as many items in 1 min as the rate of the child's response permits. With rapid letter naming, the tester presents a page showing lower- and uppercase letters randomly ordered, and the child says as many letter names as possible in 1 min. With letter-sound fluency, the tester also presents a page showing lower- and uppercase letters randomly ordered. This time, the child says sounds for 1 min. Compared to phoneme segmentation fluency, rapid letter naming and letter-sound fluency are easier for teachers to learn to administer, and reliability tends to be stronger. Yet, compared to rapid letter naming, phoneme segmentation fluency and letter-sound fluency are better instructional targets. They relate more transparently to what children need to learn for reading. Therefore, phoneme segmentation fluency and letter-sound fluency may guide the kindergarten teacher's instruction more effectively, although such studies have not been conducted.

For first-grade reading, two curriculum-based measurement measures have been the focus of study. With one approach, students begin the year on the nonsense-word fluency task and move to passage-reading fluency in January. With nonsense-word fluency, students are shown a page with consonant-vowel-consonant pseudo-words (such as *gav* or *jum*). They have 1 min to decode as many as they can. With passage-reading fluency, students are presented with first-grade text, with each weekly alternate form of roughly equivalent difficulty. The student reads aloud for 1 min.

As an alternative, schools use word-identification fluency across all of first grade. Students are presented with a page showing 50 high-frequency words. Each alternate form systematically samples high-frequency words in random order, and students read as many words as possible in 1 min. Nonsense-word fluency offers the advantage of mapping onto beginning decoding instruction and may therefore provide teachers with input to form instructional plans. The disadvantage of combining nonsense-word fluency with passage-reading fluency across the school year is that changing the measure at mid-year precludes calculating slope or modeling student development over first grade. Word-identification fluency, by contrast, can be used with strong reliability, validity, and instructional utility across the entire first-grade year, also making it possible to model the development of

reading skill across the entire time frame. In a study that contrasted nonsense-word fluency to word-identification fluency (Fuchs *et al.*, 2004), the technical features of word-identification fluency exceeded those of nonsense-word fluency.

In reading at grades 2 and 3, the curriculum-based measurement task of choice is passage-reading fluency. It is the most-studied curriculum-based measure, with strong technical features and utility for instructional planning. Each week, one passage is administered. The student reads aloud for 1 min. Then, the tester counts the number of words read correctly. The accuracy (reliability), meaningfulness (validity), and instructional usefulness of this simple measure have been demonstrated repeatedly (see Fuchs and Fuchs (1998) for summary).

It is important to note, however, at grades 4–6 – as students move from learning to read to reading to learn – studies suggest that the validity of the curriculum-based measurement passage-reading fluency task decreases (Espin, 2006). Therefore, beginning at grade 4 or 5, the use of a different measure, which more directly taps comprehension, may be indicated. One option at the higher grades, which is efficient for teachers to use on a regular basis, is curriculum-based measurement maze fluency. With maze fluency, students work on a passage from which every seventh word has been deleted and replaced with three choices. Only one option makes sense in the blank. The student has 2 or 3 min to read and restore meaning to the passage by replacing blank with words. The score is the number of correct replacements. Espin (2006) provided evidence that maze fluency demonstrates strong accuracy (reliability) and meaningfulness (validity) and models reading development well beginning at fourth grade, continuing through eighth grade.

Future Directions

An essential component of classroom assessment is systematic progress monitoring. Teachers use progress monitoring for two purposes: to determine whether a student's academic development during an academic year is proceeding well and, when a student is not progressing adequately, to design an individualized instructional program that promotes better academic growth. Curriculum-based measurement is the form of progress monitoring with the strongest scientific evidentiary base. A large literature shows that curriculum-based measurement produces accurate descriptions of student development in reading and math. In addition, randomized control trials in real-school settings, in which teachers are randomly assigned to plan instruction with and without curriculum-based measurement, document that when teachers use curriculum-based measurement to inform their instructional decisions,

students achieve better. Research on the use of curriculum-based measurement for the purpose of identifying students with learning disabilities, within a responsiveness-to-intervention framework, represents a new avenue of inquiry. Moreover, there is ongoing research exploring methods to expand curriculum-based measurement to other grade levels and content.

Rasch Models

D Andrich, The University of Western Australia, Crawley, WA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Location – The value of a parameter of a person, or a threshold of an item, on a continuum.

Parameter – A variable whose values govern the responses in a probabilistic model.

Polytomous response format – A format in which there is a response in one of more than two mutually exclusive categories.

Sufficient statistic – A function of the responses with respect to a parameter such that, conditional on this statistic, the resulting distribution is independent of the parameter.

Threshold – The location where the probability of a response in either of two adjacent categories is identical.

Introduction

This article explains the unidimensional Rasch model (RM) for two or more ordered categories. It considers the rationale for the RM and principles of parameter estimation and tests of fit, but is not concerned with details of these procedures. There are a number of software packages that implement the RM at an advanced level. Detailed studies of the theory and applications of the RM can be found in Fischer and Molenaar (1995), Engelhard and Wilson (1996), Van der Linden and Hambleton (1997), and Smith and Smith (2004). The article begins with the simplest of these models for the simplest response format, that of two ordered categories, with just two items. It then proceeds to generalize the model for more items and more than two ordered categories in standard formats. The article comments on the distinctive paradigm of the data–model relationship in the application of the RM and shows some relationships between the RM and traditional test theory (TTT).

Standard formats involve one response in two or more categories deemed *a priori* to be ordered on a hypothesized continuum, often termed a latent trait. They are used in quantifying achievement, performance, attitude, and status in the social sciences. A common dichotomous response format in assessing achievement is multiple choice where only one of the given options is correct. Another is that of scoring an extended response to a

question as pass or fail. Table 1 shows typical formats for four ordered categories which are extensions of the two ordered categories, and which may be extended further. Such formats are termed polytomous. Figure 1 shows the format on a continuum that is envisaged when models such as the RM is applied to the response data. The case of two categories, for example, fail or pass, is simply a special case of more than two categories, for example, fail, pass, credit, or distinction as in Figure 1.

The Case for the RM

To increase the validity and precision beyond that which can be achieved with just one item, tests generally have many items, the number constrained by the time available due to administrative and fatigue factors. In assessing whether the items are working consistently with each other to separate persons on a single continuum, the RM was derived from the following requirements of invariant comparisons:

- The comparison between two stimuli should be independent of which particular individuals were instrumental for the comparison.
- Symmetrically, a comparison between two individuals should be independent of which particular stimuli within the class considered were instrumental for comparison (Rasch, 1961: 332).

Equivalent requirements for invariance were articulated by Thurstone (1928) and Guttman (1950), but Rasch was the first to formalize it in the form of a probabilistic mathematical model (Andrich, 2005). Thus, the model has the inherent requirements of the invariance of comparisons. Then to the degree that the data, too, conform to the model, to that degree the data have the property of invariance. In addition, mathematical derivations that rest on this requirement can lead to insights for measurement and test design that go beyond those that could be obtained descriptively. An illustration is provided at the end of the article.

The Item Characteristic Curve

The dichotomous RM takes the form

$$\Pr\{X_{ni} = x\} = (\exp x(\beta_n - \delta_i)) / \gamma_{ni} \quad [1]$$

where $X_{ni} = x \in \{0, 1\}$ is an integer random variable of the responses; β_n and δ_i are, respectively, the parameters

of person n and item i characterizing their locations on the same continuum; and $\gamma_{ni} = 1 + \exp(\beta_n - \delta_i)$ is a normalizing factor that ensures that the two probabilities in eqn [1] sum to 1.

Figure 2 shows the probability of the positive response $X_{ni} = 1$ as a function of β for three items with location parameter estimates δ_i equal to -1.01 , -0.07 , and 0.94 , respectively. These functions are known as item characteristic curves (ICCs). The probability of the positive response increases as a function of the location of the persons. Notice that the ICCs are parallel (Wright, 1997). This is a distinctive property of the RM and reflects the property of the invariance of comparisons. Further, the location of the item is identified as the position on the continuum where a person has equal probability of responding 0 or 1. From psychophysics, these locations are known as thresholds. In educational measurement, they are referred to as item difficulties and the locations of persons are referred to as abilities. This article also uses the generic term locations for these parameters.

Table 1 Standard response formats for more than two ordered categories

Fail	Pass	Credit	Distinction
Never	Sometimes	Often	Always
Strongly disagree	Disagree	Agree	Strongly agree

Figure 1 Graphical representation of contiguous intervals for ordered categories.

Figure 2 Item characteristic curves for three items.

In any analysis, the common slope of the ICC curves is a kind of average of the discrimination of the items. This rate of change is often termed the discrimination.

Implications of Dimensionality and Response Independence

Equation [1] shows that, because there is only one person parameter, the model is unidimensional, that is, that persons can be distinguished on just one continuum. It also implies that the responses of a person to more than one item are statistically independent in the sense that

$$\Pr\{(X_{ni}) = (x_{ni})\} = \prod_{i=1}^I \exp x_{ni}(\beta_n - \delta_i) / \gamma_{ni} \quad [2]$$

where (x_{ni}) denotes the vector of responses of person n to items $i = 1, 2, \dots, I$.

Thus, only the person's and item's locations govern each response. Clearly, the greater the ability of the person, the more likely is a positive response to all items; and the greater the difficulty of an item, the more likely is a negative response from all persons. This implies that the responses among items for a sample of persons with different abilities will be correlated. Nevertheless, statistical independence holds according to eqn [2]. This independence is often termed local independence.

Sufficiency of the Total Score and Invariance

The formalization of invariance of comparisons rests on a sufficient statistic for a parameter (Rasch, 1961). A sufficient statistic implies that, conditional on that statistic, the resultant distribution of responses of a person to the items is independent of the parameter. The sufficient statistic for the person parameter β_n is simply the total score

$r_n = \sum_{i=1}^I x_{ni}$. For a vector of responses (x_{ni}) of person n to I items,

$$\Pr\{(X_{ni}) = (x_{ni}) | r_n\} = \frac{1}{\gamma_r} \exp\left(\sum_{i=1}^I x_{ni}(-\delta_i)\right) \quad [3]$$

where $\gamma_r = \sum_{((x_{ni})|r_n)} \exp\left(\sum_{i=1}^I x_{ni}(-\delta_i)\right)$ is the summation over all possible vectors of responses of person n given a total score of r_n . Equation [3] is clearly independent of the person parameters β_n , $n = 1, 2, \dots, N$.

Estimates of Item Parameters

As it is central to appreciating the model, the implications of eqn [3] are illustrated in **Table 2** with 50 persons responding to just two dichotomous items. There are two sets of data. The responses are taken as either correct or incorrect.

Equation [3], which is a probability statement conditional on the total score r_n , has only one response pattern (0,0) for $r_n = 0$, and only (1,1) for $r_n = 2$. Therefore, $\Pr\{(0,0)|r_n = 0\} = 1$ and $\Pr\{(1,1)|r_n = 2\} = 1$, making both patterns uninformative regarding the relative difficulties of the items. For $r_n = 1$, however, there are two patterns, (1,0) and (0,1). Then eqn [3] becomes

$$\begin{aligned} \Pr\{(1,0)|r_n = 1\} &= (\exp(-\delta_1))/\gamma_1; \\ \Pr\{(0,1)|r_n = 1\} &= \exp(-\delta_2)/\gamma_1 \end{aligned} \quad [4]$$

where $\gamma_1 = \exp(-\delta_1) + \exp(-\delta_2)$.

The responses in which $r_n = 1$ are themselves dichotomous – the person is correct on only one or other of the items. Thus, with N_{12} persons with $r_n = 1$ and s_1 correct responses on item 1, the resultant distribution is binomial:

$$\Pr\{s_1 | r_n = 1\} = \binom{N_{12}}{s_1} \pi_{12}^{s_1} (1 - \pi_{12})^{N_{12} - s_1} \quad [5]$$

where $\pi_{12} = (\exp(-\delta_1))/(\gamma_1)$; $1 - \pi_{12} = \pi_{21} = (\exp(-\delta_2))/\gamma_1$.

With just two items, to estimate (δ_1, δ_2) equate the proportions in **Table 2** to the ratio of the corresponding probabilities of eqn [5]. In the case of set 1, this gives

$$\frac{\Pr\{(1,0)|r_n = 1\}}{\Pr\{(0,1)|r_n = 1\}} = \frac{\pi_{12}}{\pi_{21}} = \frac{\exp(-\delta_1)}{\exp(-\delta_2)} = \frac{10/30}{20/30} = 0.5 \quad [6]$$

Taking logarithms of both sides of eqn [6] gives $-\hat{\delta}_1 + \hat{\delta}_2 = \ln(0.5) = -0.69$. That is, $\hat{\delta}_1 - \hat{\delta}_2 = 0.69$ indicating that item 1 is more difficult than item 2. This is evident because of the 30 persons who answered both items correctly, only 10 answered item 1 correctly while twice as many, 20, answered item 2 correctly.

Notice that only the difference $\hat{\delta}_1 - \hat{\delta}_2$ is estimated, not a value for each of $\hat{\delta}_1$ and $\hat{\delta}_2$ individually. The estimates in the RM are comparisons, and not absolute values. To obtain a single value for each item, the additional constraint $\hat{\delta}_1 + \hat{\delta}_2 = 0$ is generally imposed. Then the respective estimates are $\hat{\delta}_1 = 0.345$; $\hat{\delta}_2 = -0.345$. In the case of I items,

the constraint is generalized to $\sum_{i=1}^I \hat{\delta}_i = 0$. This constraint sets the origin of the scale arbitrarily at 0.0.

Relative Item Difficulties and Conditional Estimates

Notice that the relative difficulties of the items are not given by taking the ratio of the total number correct obtained on each of the items. The numbers correct on items 1 and 2, respectively, are 15 and 25; this ratio gives $15/25 = 0.60$ rather than 0.5. To further consolidate the idea as to how the estimate of the relative difficulties of the items is independent of the abilities of the persons, consider data set 2 of **Table 2**. The ratio of eqn [3], conditional on the total score of 1, is the same as for set 1. However, the total number correct for both items is greater, 18 compared to 15 for item 1, and 28 compared to 25 for item 2. Thus, overall the persons in set 2 are more able than those in set 1. In addition, the ratio of the total number correct changes from $15/25 = 0.60$ to $18/28 = 0.64$. However, the difference in difficulties between the items remains the same as in set 1. This is the sense in which the comparison of the items is invariant relative to the locations of the persons, where the latter may show greater or lesser values overall.

The conditional maximum likelihood solution equation based on eqn [5], of which eqn [5] is a special case, is

$$s_i - \sum_{r=1}^{R-1} n_r \Pr\{x_{ri} = 1 | r\} = 0 \quad [7]$$

where s_i is the total number of correct responses to item i , n_r is the number of persons with a score of r , and

Table 2 Responses of 50 persons to two items: sets 1 and 2

Set 1					Set 2				
Item1	Item2				Item1	Item2			
	1	0	15			1	0	18	
	5	10				5	10		
Item1	0	20	15	35	Item1	0	20	15	32
	25		25	50		28		22	50

$\Pr(x_{ri} = 1|r)$ is the probability that a person with total score r answers item i correctly. This equation gives consistent estimates in the sense that as the number of persons increases, the estimates converge to the correct value, always with the condition that the data fit the model. However, in many educational data collection designs, for example, those concerned with equating and linking which are considered in the section titled 'Applications in test equating and linking,' not all persons respond to all items. Other methods of estimation have been employed to overcome some of the complexities that ensue with this situation. One method that gives consistent estimates and can handle missing data is that of conditional pairwise estimation. This takes the responses of persons to every pair of items, and generalizes eqn [5] directly (Andrich and Luo, 2003) to give the solution equation

$$s_i - \sum_{j, j \neq i} N_{ij} \Pr\{x_{nij} = 1 | r_{nij} = 1\} = \sum_{j, j \neq i} N_{ij} \left\{ \exp(-\delta_i) / (\gamma_{ij}) \right\} \quad [8]$$

where $x_{nij} = 1, r_{nij} = 1$ are, respectively, a correct response of person n to item i and the condition that the total score of the person on items i and j is 1, N_{ij} is the number of persons who have a score of 1 on item i when paired with any other item j , s_i is the number of correct responses to item i among these N_{ij} persons and summed over all items $j \neq i$, and $\gamma_{ij} = \exp(-\delta_i) + \exp(-\delta_j)$. The equation essentially handles missing responses by not summing into either N_{ij} or s_i a person who does not respond to one or both items i and j .

Estimate of the Person Parameter

Comparisons of persons could be estimated by eliminating the item parameters in the way shown above for the comparisons of items. However, because there are generally many more persons than items, this is not feasible. Therefore, estimates of persons are obtained using the item-location estimates as given. This approach also lends itself to conceptualizing two stages in educational measurement: first, the calibration of the items and the check that they are operating as required, and, second, the measurement of the persons. It, too, exploits the sufficient statistic for the person parameter.

From eqn [2] the likelihood L of the vector of responses x_{ni} for a person gives

$$\begin{aligned} L = \Pr\{(X_{ni}) = (x_{ni})\} &= \sum_{i=1}^I \exp(x_{ni}(\beta_n - \delta_i)) / \prod_{i=1}^I \gamma_{ni} \\ &= \exp(r_n \beta_n - \sum_{i=1}^I x_{ni}(\delta_i)) / \prod_{i=1}^I \gamma_{ni} \quad [9] \end{aligned}$$

where the coefficient r_n of the parameter β_n is simply the person's total score. Differentiating eqn [9] with respect to β and setting the derivative to 0, gives the solution equation

$$r_n = \sum_{i=1}^I \exp(\beta_n - \delta_i) / \gamma_{ni} = \sum_{i=1}^I \Pr\{X_{ni} = 1\} \quad [10]$$

Equation [10] needs to be solved iteratively. Notice that for fixed values of (δ_i) , and irrespective of the pattern of responses, the ability estimate will be the same. However, two other points need to be noted simultaneously. First, the required and expected pattern of responses is that the person tends to answer the easier items correctly and the harder items incorrectly. Thus, for ten items ordered in difficulty and a total score of 5, the vector (1,1,1,1,0,1,0,0,0,0) is consistent with the model, while the pattern (1,0,0,1,0,1,0,0,1,1) is not. Fit to the model is considered further under the section titled 'Test of fit of the data to the model.' Second, the person's estimate is based on the items that the person has completed. Therefore, if different persons completed different items from the same set of items, then for the same total score they will have different ability estimates – for the same score, a person who answered more difficult items will have a higher ability estimate than a person who answered easier items. This is an important property of the RM in linking and equating tests which is considered further in the section titled 'Applications in test equating and linking.'

Equation [10] gives the direct maximum likelihood estimates which are slightly biased for a fixed number of items and methods for reducing the bias have been devised.

The locations of the items and persons are said to be in logits.

Standard Errors

With every estimate, there is a standard error. Based again on the theory of maximum likelihood, good approximations are given for the item and person parameters, respectively, by

$$\hat{\sigma}_i = 1 / \sqrt{\sum_{n=1}^N (\Pr\{X_{ni} = 1\})(1 - \Pr\{X_{ni} = 1\})} \quad [11]$$

and

$$\hat{\sigma}_n = 1 / \sqrt{\sum_{i=1}^I (\Pr\{X_{ni} = 1\})(1 - \Pr\{X_{ni} = 1\})} \quad [12]$$

Applications in Test Equating and Linking

The Rasch class of models was developed from a design in which students with reading problems were to be monitored for reading improvement. A scale was to be developed which could measure a range of abilities so that as students improved in their reading ability they could be measured on the same scale. However, as their abilities

increased, they had to be given more difficult texts to read. To construct the scale, students in different grades were given different tests with difficulties similar to the students' abilities (Rasch, 1960).

A modern example of such a situation is placing students in different year groups onto the same achievement scale. Suppose students in years 5 and 6 are to be assessed for their reading ability on the same scale and there was time to give 30 items to each class. To construct the scale, a typical design would have easier items for year 5, more difficult for year 6, with some items in common. The common items, called link items, would typically be more difficult than the majority of items for year 5 and easier than the majority of the items for year 6. For example, suppose 250 students from years 5 and 6 each are assessed on 30 dichotomously scored items and that there are ten linking items. The total number of different items is therefore 50. The person by items data matrix would have structurally missing responses – year 5 students would not have completed items 31–50, and year 6 students would not have completed items 1–20, while both year groups would have completed link items 21–30. Nevertheless, because of the properties of the model and of the solution algorithm for the estimates, the location parameters for all items and all persons could be estimated simultaneously on the same scale.

Table 3 shows summary estimates of such a design. Notice that the mean of the items for year 5 is less than that for year 6, and that the mean of the year 5 students is less than that of the year 6 students.

Figure 3 shows the distribution of student estimates in the two year groups relative to the distribution of item estimates. It is evident that the students' distribution is bimodal reflecting the abilities of the two year groups.

From eqn [10] it is possible to present readily the transformation of every total score to its corresponding location estimate. **Figure 4** shows the transformation functions for the linking design data of **Table 3**. For example, as shown in the **Figure 4**, a score of 25 on the year 5 (easier test) is equivalent to a score of 12.80 on the year 6 (more difficult test). Of course, no student could score 12.80; therefore, 12.80 is interpreted as the expected value (theoretical mean) of all persons who score 25 on the year-5 test.

Test of Fit of the Data to the Model

As illustrated above, invariance of the locations of the items relative to the locations of the persons is a property of the model. Whether or not it is a property of the data is to be tested empirically. In principle, because it is a

Table 3 Estimates of item and person locations

	Item locations			Person locations	
	Year 5 items 1–30	Year 6 items 21–50	Link items 1–10	Year 5	Year 6

property of the model, to check if it is a property of the data, the focus is on checking if the data fit the model.

No test of fit is necessary and sufficient and different tests of fit have different power in detecting misfit. The power of the tests of fit depends on the relative locations of persons to items, on the sample size, and how specific the particular hypothesis of misfit is.

The greater the distance between the person and item locations, the greater is the power to detect misfit. However, items close to a person's location provide the smallest standard errors of measurement. Thus, there is a trade-off between precision and the power of the test of fit. One general and one specific test of fit are described below. There are different kinds of test of fit. In this article, only those that can be generalized immediately to polytomous responses are summarized.

A Unified Approach to Differential Item Functioning and General Fit

A general test of fit, which capitalizes on the ICC, is to divide the persons into class intervals according to the

estimates of their locations, and then to compare the proportion of persons in these class intervals who score 1 on the item with the theoretical probability of scoring 1 given by the ICC. The left panel of **Figure 5** shows such information graphically for item 22 in the linking design.

A specific test of fit considers the responses of persons defined in two or more different groups, for example, students in years 5 and 6 in the linking design. In this case, it is necessary to establish that the link items are functioning equivalently across the groups, that is, that they show no differential item functioning (DIF). Again the ICC can be exploited to check this invariance. The requirement is that, irrespective of the year group, the same total score should imply the same probability of success. The right panel of **Figure 5** shows the same information as the left panel for item 22 (a link item), but now divided by the year group to which the students belong. For the first two class intervals, there is little difference between these proportions, but for the last three, the year 6 answers the items correctly at a higher rate.

This graphical test of fit can be complemented statistically. For each response, the standardized residual can be formed.

$$z_{ni} = \frac{x_{ni} - E[X_{ni}]}{\sqrt{V[X_{ni}]}} = \frac{x_{ni} - \Pr\{X_{ni} = 1\}}{\sqrt{\Pr\{X_{ni} = 1\}(1 - \Pr\{X_{ni} = 1\})}} \quad [13]$$

If the data fit the model, then these residuals should have a mean of 0 and a standard deviation close to 1.0. The resulting matrix can be partitioned by class intervals and groups giving a two-way structure for the residuals. This structure can be analyzed by analysis of variance (ANOVA) to indicate whether there is any effect (1) across the class intervals irrespective of groups, (2) across the groups irrespective of class intervals, and (3) whether there is an interaction between the two. The first of these checks the fit across the class intervals and therefore the continuum irrespective of DIF, the second checks for possible DIF, called uniform DIF, irrespective of fit across the continuum, and the third checks for an interaction between the two, commonly called nonuniform DIF.

The number of class intervals is arbitrary, but ideally there should be more than 20 persons for each cell of the two-way matrix of residuals. The ANOVA is robust against violations of its assumptions and takes into account the sample size. If different numbers of class intervals makes a difference in the decision that would be made regarding a significant effect, that suggests that the significance is marginal, and should be interpreted as such.

This ANOVA can be summarized readily in a single table to provide a unified test of fit. **Table 4** shows a summary of this analysis for the ten common items in the linking design used above. There is only evidence of very marginal misfit at the item level in **Table 4**. Item 23 shows marginal misfit across the class intervals, and item 22, which is displayed graphically in **Figure 5** and shows the worst uniform DIF, has $P < 0.08$. No item shows a significant nonuniform DIF. There are 30 tests of fit in **Table 4**, and therefore at the 5% level, up to two could be significant just by chance. Thus, these data fit excellently according the ANOVA analysis and for the given sample size. Excellent fit is required of linking items in such designs.

The same residuals can be studied in other standard ways to detect various violations of the data to the model. For example, they may be correlated, and large correlations between pairs of items would indicate some kind of dependence between the items, for example, either they assess a second dimension or they violate statistical independence.

Relationship to TTT

The RM is seen as part of the general area of item response theory (IRT). In this construction, it can be seen as in opposition to TTT (Lord and Novick, 1968). Conversely, it can be seen as formalizing the principles of TTT, in so doing, resolving two of its paradoxes.

The key identity between the RM and TTT is that the

total score, $r_n = \sum_{i=1}^I x_{ni}$, for a person is the key statistic that

indicates the relative status of the person. It is this by definition in TTT, while it arises from the requirement of invariance in the RM. Tests of fit to the RM can be seen as providing a check on whether the total score can be used meaningfully. Then the logit estimates from transformed raw scores in the RM, which are additive in the person and item parameters, satisfy the conditions of interval measurement for purposes of calculating means, variances, and correlations, better than do the raw scores (Embretson, 1996). In this sense, the RM improves upon TTT.

Reliability

In TTT, the key statistic for the assessment of the operation of a test is its reliability, often denoted as r_{tt} . This statistic is anchored in the sample (or population of the sample) to which the test is administered and defined generically as the proportion of true variance relative to

Table 4 Statistical analysis of item fit for the link items

Class interval (CI)					Year (uniform DIF)				CI by year (nonuniform DIF)			
Item	MS	F	DF	P<	MS	F	DF	P<	MS	F	DF	P<
21	0.70	0.85	7	0.55	2.14	2.57	1	0.11	0.49	0.59	7	0.77
22	1.62	1.86	7	0.07	2.64	3.03	1	0.08	0.33	0.38	7	0.91
23	2.32	2.50	7	0.02	0.03	0.03	1	0.86	0.82	0.88	7	0.52
24	1.07	1.12	7	0.35	1.19	1.25	1	0.26	0.58	0.61	7	0.75
25	0.71	0.70	7	0.67	0.84	0.83	1	0.36	0.66	0.65	7	0.72
26	0.65	0.68	7	0.69	1.78	1.86	1	0.17	0.79	0.83	7	0.56
27	0.95	1.00	7	0.43	0.12	0.13	1	0.72	0.88	0.92	7	0.49
28	1.56	1.53	7	0.16	1.90	1.86	1	0.17	0.95	0.93	7	0.48
29	1.30	1.56	7	0.15	0.68	0.81	1	0.37	0.55	0.67	7	0.70
21	1.15	1.21	7	0.30	0.06	0.07	1	0.80	0.70	0.73	7	0.64

the total variance (which includes the error of measurement). It takes the form

$$r_{tt} = \frac{\sigma_{\beta}^2}{\sigma_{\beta}^2 + \sigma_e^2} \quad [14]$$

where, using the notation of the RM above, σ_{β}^2 is the (true) variance among the persons in the relevant population and σ_e^2 is the error variance. This relationship is based on the fundamental equation of TTT:

$$r_{tt} = \beta_{tt} + \varepsilon_{tt} \quad [15]$$

where ε_{tt} is the error between the observed score r_{tt} and the ability β_{tt} .

There are different ways of estimating r_{tt} , a common one being Cronbach's α which can be calculated from one administration of the test and which is therefore an index of the internal consistency of the items relative to the sample of persons. An index α_R which is comparable to α , both in concept and in value, can be calculated from an RM analysis constructed as

$$\alpha_R = \frac{\hat{\sigma}_{\beta}^2}{\hat{\sigma}_{\beta}^2 + \hat{\sigma}_e^2} = \frac{\hat{\sigma}_{\beta}^2 - \hat{\sigma}_e^2}{\hat{\sigma}_{\beta}^2} \quad [16]$$

where $\hat{\sigma}_{\beta}^2$ is the variance of the estimates of the person parameters obtained from eqn [10], and $\hat{\sigma}_e^2$ is the mean error variance obtained as the mean of the squares of the standard errors obtained from eqn [12].

This index, as the traditional reliability, is a function of the internal consistency of the items and, in the same way as the traditional reliability, a function of the true variance of the sample. It is a useful index to check the degree to which the test separates the persons in the particular sample. Depending on the circumstances, this may or may not be required to be high.

In the RM, this is also an index of the power of the test of fit of the data to the model. Thus, if the value of α_R is low, for example, 0.5, then it indicates that the persons have not been separated very well by the test and the power to detect misfit is not high. Therefore, before reporting good fit to the model, this index should be checked. Therefore, also, when a test is being developed, it is necessary to have a relatively high value, of the order of 0.9, in order to check the functioning of the items in the test.

As the RM handles missing data, this index can be readily calculated and interpreted in the presence of missing data.

Resolution of the Attenuation and Standard Error Paradoxes

In TTT, the goal is to maximize the reliability of a test. One paradox of TTT is that as the reliability becomes higher beyond a certain point, then the validity becomes lower. This can be seen from the condition of maximum

Figure 6 ICCs of two items and observed proportions in five class intervals.

reliability which arises when (1) all items have the same difficulty (2) their difficulty is the mean of the person abilities, and (3) the correlations among the items is 1. In this case, every person has the easiest half of the items correct and the most difficult half of the items incorrect. However, now the validity of the test is that of just one item with all other items redundant!

To see how the RM resolves this paradox, it is helpful to consider explicitly the idea of the discrimination of an item. **Figure 6** shows ICCs of two items and the observed proportions in five class intervals. Even though the observed proportions in both items are relatively small, and unlike item 22 in the left panel of **Figure 5**, they show a systematic deviation from the ICC. For item 4 they are flatter than the ICC, and for item 5 they are steeper. The former item is said to discriminate less than the ICC and the latter to discriminate more than the ICC, which, as noted earlier is a kind of average of the discriminations of all items.

The attenuation paradox can be related to the RM by recognizing that a set of items shows greater reliability as the discrimination of the items increases; also because reliability is to be maximized in TTT, items with lower discrimination are eliminated and those with higher are retained. For example, item 4 of **Figure 6** might be eliminated, but item 5 would be retained. As this process is continued with item selection, the items will have a greater average slope, be more correlated with each other, and lead to higher reliability but eventually to lower validity. In contrast, with the ICC as the criterion for the observed proportions in the RM, those items with a very high discrimination as well as those with a very low discrimination would be considered for modification or elimination. Thus, the average discrimination of the original items is retained rather than being successively increased.

It is stressed that when an item is identified as having an anomalous discrimination, it should be studied for a substantive explanation of the anomaly. If it is understood, then the item can be modified or discarded. In general, an

item with a discrimination greater than the ICC suggests that it has very much in common with the other items and is possibly redundant; items with a discrimination less than the ICC suggests that a construct other than the dominant one is being assessed by the item.

A second paradox of TTT has two related aspects: first that a difference between a pair of total scores has the same numerical effect across the continuum; and second that the standard errors of measurement are calculated to be identical for every score. However, it is commonly appreciated that at the extremes, where persons have most items correct or incorrect and a floor or ceiling effect operates, the same difference in scores must have a different meaning from the middle scores of the test and that the standard error of measurement must be greater than in the middle scores of the test. The linearization of raw scores in the RM, as is shown in **Figure 4**, takes account of the former paradox; higher standard errors at the extreme scores than in the middle scores follow directly from eqn [12].

Controversy and the RM

The construction of a model based on *a priori* requirements and independent of data involves a different paradigm from the traditional one in the data-model relationship. In the traditional paradigm, if the model does not fit the data, then the task is to find a model which accounts for the data better. In the case of dichotomous items, this generally means applying a model which has a discrimination parameter, in addition to the location parameter, for an item (Birnbau, 1968). In the Rasch paradigm, the emphasis is on whether the data fit the chosen model, and if not, then the task is to understand the features of the items or the test administration that might have created this misfit with a view to modifying the data collection in some way. This modification of the data collection is intended to increase the validity of the data as well as the fit to the model.

Advocates of the RM consider that its properties of fundamental measurement (Brogden, 1977; Wright, 1997), which are found in physics, are important in improving the quality of social measurements. The disclosure of problems in data as anomalies in measurement that are to be considered qualitatively and substantively, rather than as a problem with the model, is consistent with the role of measurement in physical science (Andrich, 2004). However, some controversy, which has also been discussed in Andrich (2004), has arisen from this distinctive paradigm of the RM.

Short biographies of Rasch can be found in Andersen and Olsen (2000), Andrich (2005), and Wright (1980) and a more extensive study of Rasch's contributions to statistics is provided in Olsen (2003).

The RM for Polytomous Ordered Categories

The RM for polytomous ordered categories is a direct extension of the model for just two categories. It is often termed the polytomous RM. Following a sequence of derivations in Rasch (1961), Andersen (1977), Andrich (1978), and Wright and Masters (1982), the model may be expressed in the form

$$\Pr\{X_{ni} = x\} = (\exp(x\beta_n - \sum_{k=0}^x \delta_{ki})) / \gamma_{ni} \quad [17]$$

where (1) $X_{ni} = x \in \{0, 1, 2, \dots, m_i\}$ is an integer random variable characterizing $m_i + 1$ successive categories, (2) δ_{ki} , $k = 1, 2, 3, \dots, m_i$ represents m_i thresholds for item i which divide the continuum into $m_i + 1$ ordered categories with $\delta_{i0} \equiv 0$, and (3) $\gamma_{ni} = \sum_{x=0}^{m_i} (\exp x\beta_n - \sum_{k=0}^x \delta_{ik})$ is again the normalizing factor that ensures that the probabilities in eqn [17] sum to 1. The thresholds are points at which the probabilities of responses in one of the two adjacent categories are equal. If $m_i = 1$, which is the case of two categories, then eqn [17] specializes to eqn [1].

The Latent Structure of the RM

In a response design, such as that with four categories shown in **Table 1**, there is only one response in one of the categories. However, it can be envisaged that a judge making a decision into one category considers adjacent categories in pairs, decides in which of the pairs the object of assessment is to be categorized, and then settles on a decision between one final pair, and gives a response. These pairwise decisions must be latent as they are never observed. To understand this latent structure, let $X_{ni} = x \in \{0, 1, 2, \dots, m_i\}$ be an integer random variable characterizing the response in category x , and let the probability P_x of a response x in the higher of the two successive categories $x - 1$ and x be deemed a successful response. Then this probability can be written as

$$P_x = \frac{\Pr\{X_{ni} = x\}}{\Pr\{X_{ni} = x - 1\} + \Pr\{X_{ni} = x\}} \quad [18]$$

and its complement

$$Q_x = 1 - P_x = \frac{\Pr\{X_{ni} = x - 1\}}{\Pr\{X_{ni} = x - 1\} + \Pr\{X_{ni} = x\}} \quad [19]$$

It can be shown readily that

$$\Pr\{X_{ni} = x\} = P_1 P_2 P_3 \dots P_x Q_{x+1} Q_{x+2} \dots Q_m / D \quad [20]$$

where $D = Q_1 Q_2 Q_3 \dots Q_m + P_1 Q_2 Q_3 \dots Q_m + P_1 P_2 Q_3 \dots Q_m + P_1 P_2 P_3 \dots P_m$.

From eqn [20] it is evident that the particular response $X_{ni} = x$ implies successes at the first x thresholds and failures at all the remaining thresholds. This is compatible with the decision in one of a number of ordered categories, in the sense that if there is a failure at a particular threshold, then there is an implied failure at all the thresholds that are further along the continuum; and if there is a success at a particular threshold, then there is an implied success at all the preceding thresholds. The response in a category is between a success and a failure at two successive thresholds. It is also evident from eqn [20] that the probability of a response in any category is a function of the latent probabilities of success and failures at all categories.

Equation [18] does not rest on the application of the dichotomous RM. However, let the

$$P_x = \exp(\beta_n - \delta_{ni}) / \eta_{ni} \quad [21]$$

where $\eta_{ni} = 1 + \exp(\beta_n - \delta_{ki})$. This is simply the RM of eqn [1] at each threshold x . Then inserting eqn [21] in eqn [18] gives the RM of eqn [17].

The left panel of **Figure 7** shows the probabilities of responses in each score x , which corresponds to the successive categories of **Table 1**, fail (F), pass (P), credit (C), and distinction (D), known as category characteristic

curves (CCCs). It also shows the location of the thresholds between adjacent categories which are points of equal probability of response between two adjacent categories.

The right panel shows the expected value curve, given by $E[X] = \sum_x x \Pr\{X = x\}$, which specializes to $E[X] = \Pr\{X = 1\}$ in the dichotomous case. $E[X]$, whose values can range from 0 to m_i , can be used analogously to the ICC curve in tests of fit, including DIF. The panel shows observed means of persons in five class intervals.

The Latent Thresholds

It is instructive to consider the interpretation of the latent dichotomous responses of eqn [18]. These are shown as dotted lines in the left panel of **Figure 8** superimposed on the CCCs of **Figure 7**, and then on their own in the right panel of **Figure 8**. Importantly, these latent dichotomous responses are equivalent in theory to observed dichotomous responses at the same thresholds which are independent. Specifically, they are equivalent to three different judges deciding independently whether the performance was successful or not in meeting the standards of pass, credit, and distinction, respectively. In the case of independent dichotomous judgments of that kind, and with the dichotomous RM applied, the thresholds are

Figure 7 (Left) Category characteristic curves and (right) the expected value curve for an item with four ordered categories.

Figure 8 (Left) Category characteristic curves and (right) latent dichotomous responses for an item with four categories.

Figure 9 (Left) Category characteristic curves and (right) latent dichotomous responses for an item with four categories with reversed threshold estimates.

better notated as $\delta_{\tilde{P}/P}, \delta_{\tilde{C}/C}, \delta_{\tilde{D}/D}$ where $\tilde{P}, \tilde{C}, \tilde{D}$ indicates not meeting the respective standards. This notation indicates that the decisions are in just two categories, success or lack of success, at each of the three different standards. In terms of the two notations, the equivalence of the responses gives

$$\{\delta_{F/P}, \delta_{P/C}, \delta_{C/D}\} \equiv \{\delta_{\tilde{P}/P}, \delta_{\tilde{C}/C}, \delta_{\tilde{D}/D}\} \quad [22]$$

If the judgments were indeed independent, for example, three different judges made judgments independently at each of the standards of the same performances, it would be required that the threshold estimates show natural difficulty ordering, that is $\delta_{\tilde{P}/P} < \delta_{\tilde{C}/C} < \delta_{\tilde{D}/D}$. For example, it would be untenable that the judge at pass had a higher standard than a judge at credit. However, from eqn [22], this means that in the standard design, it is required that $\delta_{F/P} < \delta_{P/C} < \delta_{C/D}$, that is, that the thresholds in the RM are in their natural order.

Reversed Thresholds

If in the above example three judges did respond independently with a judgment at each of the grade levels, in principle, it would be possible for the data to show that $\delta_{\tilde{P}/P} > \delta_{\tilde{C}/C}$ or $\delta_{\tilde{C}/C} < \delta_{\tilde{D}/D}$. That is, if the judge at pass operated at a higher standard than the judge at credit, there is nothing in the analysis that would preclude the estimates $\delta_{\tilde{P}/P} > \delta_{\tilde{C}/C}$ to be observed. In this case, the threshold estimates are reversed relative to their natural order.

Interestingly, and importantly, if the data are collected in the standard ordered category format of Table 1, then the threshold estimates can show reversals. Figure 9 shows the same information as Figure 8 but for an item with reversed thresholds. The threshold estimates of Figure 9 violate the requirements of eqn [22]. Therefore, it would be necessary to examine the reasons for the inconsistency of the application of the relative standards. Any number of factors can contribute to such anomalous responses, with the factors depending on the item and the context of its administration. If the categories are not working as intended, it calls into question the understanding what it means to have more or less of property as operationalized

by the categories. The property of the RM to disclose whether or not the empirical ordering of the categories is working as intended is a major justification for using the model. These interpretations have arisen from the mathematical derivations that follow from Rasch's formalization of the requirement for invariant comparisons and are unlikely to have been arrived at in any other way.

Scoring Rubrics

J A Arter, Educational Testing Service, Portland, OR, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Analytic rubric – A type of rubric that provides ratings of a performance or product along several different, important dimensions. The term is used to describe one type of general rubric. This is also called analytical trait. Contrast this with holistic rubric.

Assessment of learning – Student assessment, the goal of which is to provide information to judge the adequacy of the level of student learning at a point in time. This is also called summative assessment. Contrast this with assessment for learning.

Assessment for learning – Student assessment, the goal of which is to provide information used to improve student learning while the learning is occurring. Assessment for learning includes actions on the part of teachers such as using assessment information to plan the next steps in instruction and actions on the part of students such as student self-assessment and goal setting. This is sometimes called formative assessment. Contrast this with assessment of learning.

General analytic rubric – A general rubric that results in several judgments about the quality of a product or performance, one for each important dimension of the product or performance.

General holistic rubric – A general rubric that results in a single overall judgment about the quality of a product or performance.

General rubric – A scoring guide designed so that it can be used across tasks measuring the same student learning goal(s). This contrasts with a task-specific scoring guide, which can be used for a single task only. A general rubric is useful for reasoning, performance skills, and product-learning goals. General rubrics can be holistic or analytical. See definitions of the terms general holistic and general analytical.

Holistic rubric – A type of rubric that results in a single, overall rating for an entire performance or product. The term is used to describe one type of general rubric. Contrast this with analytic rubric.

Knowledge-learning goals – The learning goals for students that require them to learn information, including bodies of knowledge and how information interconnects.

Performance assessment – An assessment based on observation and judgment. One of several methods of assessment useful in the classroom. Particularly apt for assessing student reasoning proficiencies, performance skills, and products. Rubrics are used to help make this essentially subjective form of assessment as objective as possible.

Performance-skills learning goals – The learning goals for students which require a behavioral demonstration of competence. For example, reading fluently, giving an oral presentation, playing a musical instrument, and working productively in a group.

Product-learning goals – The learning goals for students that require them to make something. Examples are graphs, laboratory reports, visual arts, and maps.

Reasoning-learning goals – The learning goals for students that require them to use information to solve a problem, analyze, compare, infer, make a decision, and so forth.

Rubric – The written criteria that define the characteristics of quality reasoning, performance skills, or products. Good rubrics have levels defined using indicators and/or descriptors. A rubric can be used across tasks assessing the same learning goal(s). See also general rubric, general holistic rubric, and general analytic rubric.

Scoring guide – A written set of statements that describe how student performance on a task will be evaluated. All rubrics are scoring guides, but not all scoring guides are rubrics. For example, task-specific scoring guides are not rubrics.

Task – The activity, assignment, or exercise given to students to do, the results of which will be evaluated using a rubric. The role of the task is to elicit the desired reasoning, performance skill, or product, so that evaluation using the rubric is possible.

Task-specific scoring guide – A scoring guide designed to be used with only a single task. This contrasts with a general rubric, which can be used across tasks measuring the same learning goal(s). Task-specific scoring is best used for extended written response assessments that focus on student knowledge.

The Role of Scoring Guides

Performance assessment is assessment based on observation and judgment (Stiggins *et al.*, 2006: 92): an evaluator observes a performance or product and makes a judgment as to its quality. The challenge with performance assessment is to make this essentially subjective form of assessment as objective as possible.

Promoting objectivity is the traditional role of scoring guides and rubrics. Good ones define the characteristics of various levels of quality of a product or performance so clearly that different judges can independently agree on an evaluation of quality. However, good scoring guides and rubrics have come to play other important roles as well. They can do the following:

- Define complex student learning goals so that teachers have a common vision that guides instruction. Examples are oral presentations, writing, mathematical problem solving, laboratory reports, literary and music criticism, research reports, music production, group collaboration/teaming, and speaking a foreign language.
- Help students understand characteristics of high-quality products and performances so that they, too, can incorporate those features into their own work.

This evolving use of scoring guides and rubrics has paralleled the evolving notions of assessment of and for learning. Assessment of learning occurs when assessment information is used to judge the adequacy of the level of student proficiency at a point in time, as with a grade or meeting a standard. Assessment for learning occurs during instruction to provide feedback to teachers and students on how to improve performance prior to the next assessment of learning event.

Assessment of learning is summative in nature while assessment for learning is formative. Formative assessment traditionally has meant actions on the part of adults to improve student learning. Groups of teachers might, for example, examine student work to determine who is getting it and who is not so that remediation can take place. However, assessment for learning includes students as data-based decision makers too; they use assessment information to take actions to improve their own learning.

There is growing body of research that shows that when assessment for learning strategies are used – both those involving teachers and those involving students – learning dramatically improves (e.g., Black and Wiliam, 1998; Black, 2003; Black *et al.*, 2002; Brookhart, 2005; Hattie and Timperley, 2007; Dochy *et al.*, 1999; Shepard, 2001; Guskey, 2005). Rubrics are the classic example of tools to promote assessment for learning because they assist students to (paraphrased from Sadler, 1989: 119): see where they are going, discover where they are now, and

close the gap between the two. The impact of rubrics on student learning forms a prominent subset of the research cited above.

Types and Uses of Scoring Rubrics

Scoring guides and rubrics come in several different forms, all of which are viable options depending on the learning goals to be assessed and the purpose for doing the assessment.

Task-Specific versus General Scoring Guides

One important distinction is the difference between task-specific and general scoring and when to use each.

Task-specific scoring guides provide a list of specific facts, features, or information to look for in student responses to a task. This results in either assigning points for the presence of specific facts (as in **Figure 1**) or determining a level of quality based on the presence of certain features specific to the task (as in **Figure 2**). Note that the task in **Figure 1** asks students to detail their understanding of the carbon cycle. Responses are scored on the presence of specific pieces of information. The scoring guide cannot be used for any other task, it is task specific. The task in **Figure 2** asks students to write a story based on a picture prompt. The quality of the writing is largely judged based on features specific to this prompt. Most of the scoring guide could not be used to judge any other piece of writing; thus, major portions are, again, task specific.

General, or generic, rubrics can be used with any task designed to assess the same student-learning goal. Examples are in **Figure 3** (the 6+1-trait writing-assessment rubric), **Figure 4** (analytical trait rubric for mathematical problem solving), **Table 1** (analytical trait rubric for oral presentation), and **Table 2** (holistic rubric for inferences). The 6+1-trait rubric can be used for any writing, the inference rubric can be used for any inference, the math rubric can be used for any math problem, and the oral presentation rubric can be used for any oral presentation.

Task-specific scoring is a good choice only when assessing knowledge using extended written response forms of assessment, as in **Figure 1**. Such scoring can summarize the current level of student understanding (assessment of learning) or pinpoint areas of student understanding and where continued study is needed (assessment for learning). When assessing products (as with writing), performance skills (as with oral presentations), or reasoning (as with mathematical problem solving or making inferences) – where it is necessary to judge the level of quality of work rather than the presence or absence of specific knowledge – general rubrics should be used, especially if the purpose is assessment for learning.

Task:

Based on your understanding of the carbon cycle, please describe why we need to know about it and how it works. Be sure to include:

- Why it is important to understand the carbon cycle: 5 points, one for each reason.
- The four major places (reservoirs) we studied where carbon is stored: 4 points.
- At least six ways that carbon gets transferred from one place to another: 6 points.

Task-specific scoring guide:

Why it is important to understand the carbon cycle. One point for any five of the following:

- Carbon is stored in the atmosphere in the form of carbon dioxide.
- Carbon dioxide in the atmosphere can cause greenhouse warming of the planet.
- In recent times geologically, carbon has stayed in balance: the amount of carbon being added to the atmosphere is balanced by the amount of carbon lost from the atmosphere.
- A balanced carbon cycle keeps the planet from warming up or cooling down.
- Humans could cause this system to become unbalanced through burning fossil fuels and other activities.
- A carbon cycle out of balance would add more carbon to the atmosphere than is being removed through natural means and could lead to global warming.
- The extent to which global warming due to human activity is actually occurring is currently being researched and debated among scientists.

The major reservoirs of carbon. One point for each of the following:

Atmosphere, oceans, land/sediments, and plants/animals

How carbon moves from one place to another. One point for any six of the following:

- Carbon moves from the atmosphere to plants through photosynthesis.
- Carbon moves from the atmosphere to oceans by dissolving in places it is cold.
- Carbon moves from the oceans to the atmosphere by evaporation where it is hot.
- Carbon moves from plant/animals to the atmosphere through breathing/respiration.
- Carbon moves from land to the atmosphere through
 - ✓ Fires
 - ✓ Volcanic eruptions
 - ✓ Burning fossil fuels
- Carbon moves from the land into the oceans through erosion.
- Carbon moves from plants/animals to oceans when animals die.

Figure 1 Example of assessing a body of knowledge with extended written response – the carbon cycle. Adapted from Arter, J. A. and Chappuis, J. (2006). *Creating and Recognizing Quality Rubrics*, p. 21, Princeton, NJ: Educational Testing Service, with permission from ETS.

Writing prompt:

Here is a picture of a kangaroo in Australia. Look at the picture for a while. What do you think is happening? Where do you suppose the kangaroo came from? Where do you think he is going? Look how high he jumps! Why do you suppose he is jumping over the fence? Write a story about what is happening in the picture.

Score-point categories:

(please note that the task-specific portions of the scoring guide are highlighted)

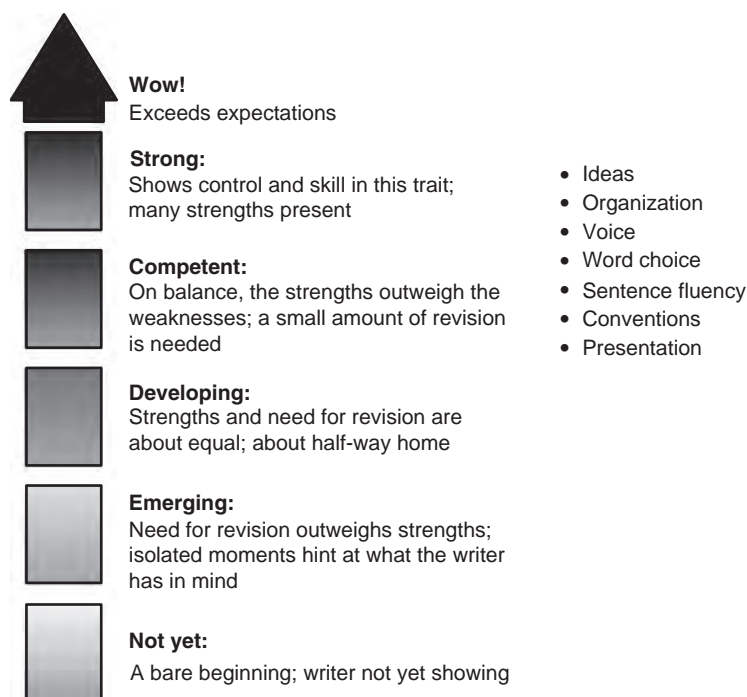

Score of 4 = These writers will enter into the picture imaginatively using such devices as dialogue and character names. There will be clear structure and a sense of drama, which will answer the what and why of the question. The where may or may not be described, but the paper will have a sense of substance. The writing will usually have some spelling and sentence construction errors but will show a clear sense of English syntax.

Score of 3 = These papers will leave out parts of the picture, such as the fence or the jump, and will have less completeness or drama than the 4 paper. They may give commentary or explanation rather than a story. They will have substance, some sense of drama, and some imagination, and they will deal with the what and the why of the question.

The writing need not have much subordination or syntactic fluency, but it will not be so filled with errors as to be difficult to read.

Etcetera ...

Figure 2 Kangaroo – task-specific scoring guide for writing. Adapted from Educational Testing Service (1990), with permission from ETS.

Ideas and content (development)

5. This paper is clear and focused. It holds the reader's attention. Relevant anecdotes and details enrich the central theme.
 - A. The topic is narrow and manageable.
 - B. Relevant, telling, quality details give the reader important information that goes beyond the obvious or predictable.
 - C. Reasonably accurate details are present to support the main ideas.
 - D. The writer seems to be writing from knowledge or experience; the ideas are fresh and original.
 - E. The reader's questions are anticipated and answered.
 - F. Insight – an understanding of life and a knack for picking out what is significant – is an indicator of high level performance, though not required.
3. The writer is beginning to define the topic, even though development is still basic or general.
 - A. The topic is fairly broad; however, you can see where the writer is headed.
 - B. Support is attempted, but does not go far enough yet in fleshing out the key issues or story line.
 - C. Ideas are reasonably clear, though they may not be detailed, personalized, accurate, or expanded enough to show indepth understanding or a strong sense of purpose.
 - D. The writer seems to be drawing on knowledge or experience, but has difficulty going from general observations to specifics.
 - E. The reader is left with questions. More information is needed to fill in the blanks.
 - F. The writer generally stays on the topic but does not develop a clear theme. The writer has not yet focused the topic past the obvious.
1. As yet, the paper has no clear sense of purpose or central theme. To extract meaning from the text, the reader must make inferences based on sketchy or missing details. The writing reflects more than one of these problems:
 - A. The writer is still in search of a topic, brainstorming, or has not yet decided what the main idea of the piece will be.
 - B. Information is limited or unclear or the length is not adequate for development.
 - C. The idea is a simple restatement of the topic or an answer to the question with little or no attention to detail.
 - D. The writer has not begun to define the topic in a meaningful, personal way.
 - E. Everything seems as important as everything else; the reader has a hard time sifting out what is important.
 - F. The text may be repetitious, or may read like a collection of disconnected, random thoughts with no discernable point.

Figure 3 Continued

Organization

5. The organization enhances and showcases the central idea or theme. The order, structure, or presentation of information is compelling and moves the reader through the text.
 - A. An inviting introduction draws the reader in; a satisfying conclusion leaves the reader with a sense of closure and resolution.
 - B. Thoughtful transitions clearly show how ideas connect.
 - C. Details seem to fit where they're placed; sequencing is logical and effective.
 - D. Pacing is well controlled; the writer knows when to slow down and elaborate, and when to pick up the pace and move on.
 - E. The title, if desired, is original and captures the central theme of the piece.
 - F. Organization flows so smoothly the reader hardly thinks about it; the choice of structure matches the purpose and audience.
3. The organizational structure is strong enough to move the reader through the text without too much confusion.
 - A. The paper has a recognizable introduction and conclusion. The introduction may not create a strong sense of anticipation; the conclusion may not tie up all loose ends.
 - B. Transitions often work; other times connections between ideas are fuzzy.
 - C. Sequencing shows some logic, but not under control enough that it consistently supports the ideas. In fact, sometimes it is so predictable and rehearsed that the structure takes attention away from the content.
- D. Pacing is fairly well controlled, though the writer sometimes lunges ahead too quickly or spends too much time on details that do not matter.
- E. A title (if desired) is present, although it may be uninspired or an obvious restatement of the prompt or topic.
- F. The organization sometimes supports the main point or story line; other times, the reader feels an urge to slip in a transition or move things around.
1. The writing lacks a clear sense of direction. Ideas, details, or events seem strung together in a loose or random fashion; there is no identifiable internal structure. The writing reflects more than one of these problems:
 - A. There is no real lead to set up what follows, no real conclusion to wrap things up.
 - B. Connections between ideas are confusing or not even present.
 - C. Sequencing needs lots and lots of work.
 - D. Pacing feels awkward; the writer slows to a crawl when the reader wants to get on with it, and vice versa.
 - E. No title is present (if requested), or if present, does not match well with the content.
 - F. Problems with organization make it hard for the reader to get a grip on the main point or story line.

Voice

5. The writer speaks directly to the reader in a way that is individual, compelling and engaging. The writer crafts the writing with an awareness and respect for the audience and the purpose for writing.
 - A. The tone of the writing adds interest to the message and is appropriate for the purpose and audience.
 - B. The reader feels a strong interaction with the writer, sensing the person behind the words.
 - C. The writer takes a risk by revealing who he or she is consistently throughout the piece.
 - D. Expository or persuasive writing reflects a strong commitment to the topic by showing why the reader needs to know this and why he or she should care.
 - E. Narrative writing is honest, personal, engaging and makes you think about and react to the author's ideas and point of view.
3. The writer seems sincere, but not fully engaged or involved. The result is pleasant or even personable, but not compelling.
 - A. The writer seems aware of an audience but discards personal insights in favor of obvious generalities.
 - B. The writing communicates in an earnest, pleasing, yet safe manner.
- C. Only one or two moments here or there intrigue, delight, or move the reader. These places may emerge strongly for a line or two, but quickly fade away.
- D. Expository or persuasive writing lacks consistent engagement with the topic to build credibility.
- E. Narrative writing is reasonably sincere, but doesn't reflect unique or individual perspective on the topic.
1. The writer seems indifferent, uninvolved, or distanced from a the topic and/or the audience. As a result, the paper reflects more than one of the following problems:
 - A. The writer is not concerned with the audience. The writer's style is a complete mismatch for the intended reader or the writing is so short that little is accomplished beyond introducing the topic.
 - B. The writer speaks in a kind of monotone that flattens all potential highs or lows of the message.
 - C. The writing is humdrum and risk-free.
 - D. The writing is lifeless or mechanical; depending on the topic, it may be overly technical or jargonistic.
 - E. The development of the topic is so limited that no point of view is present – zip, zero, zilch, nada.

Figure 3 Continued

Word choice

5. Words convey the intended message in a precise, interesting, and natural way. The words are powerful and engaging.
 - A. Words are specific and accurate; it is easy to understand just what the writer means.
 - B. The words and phrases create pictures and linger in your mind.
 - C. The language is natural and never overdone; both words and phrases are individual and effective.
 - D. Striking words and phrases often catch the reader's eye and linger in the reader's mind. (You can recall a handful as you reflect on the paper.)
 - E. Lively verbs energize the writing. Precise nouns and modifiers add depth and specificity.
 - F. Precision is obvious. The writer has taken care to put just the right word or phrase in just the right spot.
3. The language is functional, even if it lacks much energy. It is easy to figure out the writer's meaning on a general level.
 - A. Words are adequate and correct in a general sense; they simply lack much flair and originality.
 - B. Familiar words and phrases communicate, but rarely capture the reader's imagination. Still, the paper may have one or two fine moments.
 - C. Attempts at colorful language show a willingness to stretch and grow, but sometimes it goes too far (thesaurus overload!).
 - D. The writing is marked by passive verbs, everyday nouns and adjectives, and lack of interesting adverbs.
 - E. The words are only occasionally refined; it's more often the first thing that popped into my mind.
 - F. The words and phrases are functional – with only a moment or two of sparkle.
1. The writer struggles with a limited vocabulary, searching for words to convey meaning. The writing reflects more than one of these problems:
 - A. Language is so vague (e.g., it was a fun time, she was neat, it was nice, we did lots of stuff) that only a limited message comes through.
 - B. Blah, blah, blah is all that the reader reads and hears.
 - C. Words are used incorrectly, making the message secondary to the misfires with the words.
 - D. Limited vocabulary and/or frequent misuse of parts of speech impair understanding.
 - E. Jargon or clichés distract or mislead. Persistent redundancy distracts the reader.
 - F. Problems with language leave the reader wondering what the writer is trying to say. The words just don't work in this piece.

Sentence fluency

5. The writing has an easy flow, rhythm and cadence. Sentences are well built, with strong and varied structure that invites expressive oral reading.
 - A. Sentences are constructed in a way that underscores and enhances the meaning.
 - B. Sentences vary in length as well as structure. Fragments, if used, add style. Dialog, if present, sounds natural.
 - C. Purposeful and varied sentence beginnings add variety and energy.
 - D. The use of creative and appropriate connectives between sentences and thoughts shows how each relates to, and builds upon, the one before it.
 - E. The writing has cadence; the writer has thought about the sound of the words as well as the meaning. The first time you read it aloud is a breeze.
3. The text hums along with a steady beat, but tends to be more pleasant or business like than musical, more mechanical than fluid.
 - A. Although sentences may not seem artfully crafted or musical, they get the job done in a routine fashion.
 - B. Sentences are usually constructed correctly; they hang together; they are sound.
 - C. Sentence beginnings are not all alike; some variety is attempted.
 - D. The reader sometimes has to hunt for clues (e.g., connecting words and phrases like however, therefore, naturally, after a while, on the other hand, to be specific, e.g., next, first of all, later, but as it turned out, although, etc.) that show how sentences interrelate.
 - E. Parts of the text invite expressive oral reading; others may be stiff, awkward, choppy, or gangly.
1. The reader has to practice quite a bit in order to give this paper a fair interpretive reading. The writing reflects more than one of the following problems:
 - A. Sentences are choppy, incomplete, rambling or awkward; they need work. Phrasing does not sound natural. The patterns may create a sing-song rhythm, or a chop-chop cadence that lulls the reader to sleep.
 - B. There is little to no sentence sense present. Even if this piece were flawlessly edited, the sentences would not hang together.
 - C. Many sentences begin the same way – and may follow the same patterns (e.g., subject–verb–object) in a monotonous pattern.
 - D. Endless connectives (and, and so, but then, because, and then, etc.) or a complete lack of connectives create a massive jumble of language.
 - E. The text does not invite expressive oral reading.

Figure 3 Continued

Conventions	
<p>5. The writer demonstrates a good grasp of standard writing conventions (e.g., spelling, punctuation, capitalization, grammar, usage, paragraphing) and uses conventions effectively to enhance readability. Errors tend to be so few that just minor touch-ups would get this piece ready to publish.</p> <p>A. Spelling is generally correct, even on more difficult words.</p> <p>B. Punctuation is accurate, even creative, and guides readers through the text.</p> <p>C. Thorough understanding and consistent application of capitalization skills present.</p> <p>D. Grammar and usage are correct and contribute to clarity and style.</p> <p>E. Paragraphing tends to be sound and reinforces the organizational structure.</p> <p>F. The writer may manipulate conventions for stylistic effect and it works! The piece is very close to being ready to publish.</p> <p>Grades 7 and up only: The writing is sufficiently complex to allow the writer to show skill in using a wide range of conventions. For writers at younger ages, the writing shows control over those conventions that are grade/age appropriate.</p> <p>3. The writer shows reasonable control over a limited range of standard writing conventions. Conventions are sometimes handled well and enhance readability; at other times, errors are distracting and impair readability.</p> <p>A. Spelling is usually correct or reasonably phonetic on common words, but more difficult words are problematic.</p>	<p>B. End punctuation is usually correct; internal punctuation (commas, apostrophes, semicolons, dashes, colons, parentheses) is sometimes missing/wrong.</p> <p>C. Most words are capitalized correctly; control over more sophisticated capitalization skills may be spotty.</p> <p>D. Paragraphing attempted; may run together or begin in the wrong places.</p> <p>E. Problems with grammar or usage are not serious enough to distort meaning but may not be correct or accurately applied all of the time.</p> <p>F. Moderate (a little of this, a little of that) editing would be required to polish the text for publication.</p> <p>1. Errors in spelling, punctuation, capitalization, usage and grammar, and/or paragraphing repeatedly distract the reader and make the text difficult to read. The writing reflects more than one of these problems:</p> <p>A. Spelling errors are frequent, even on common words.</p> <p>B. Punctuation is often missing or incorrect.</p> <p>C. Capitalization is random and only the easiest rules show awareness of correct use.</p> <p>D. Errors in grammar or usage are very noticeable, frequent, and affect meaning.</p> <p>E. Paragraphing is missing, irregular, or so frequent (every sentence) that it has no relationship to the organizational structure of the text.</p> <p>F. The reader must read once to decode, then again for meaning. Extensive editing (virtually every line) would be required to polish the text for publication.</p>
Presentation	
<p>5. The form and presentation of the text enhances the ability for the reader to understand and connect with the message. It is pleasing to the eye.</p> <p>A. If handwritten (either cursive or printed), the slant is consistent, letters are clearly formed, spacing is uniform between words, and the text is easy to read.</p> <p>B. If word-processed, there is appropriate use of fonts and font sizes which invites the reader into the text.</p> <p>C. The use of white space on the page (spacing, margins, etc.) allows the intended audience to easily focus on the text and message without distractions. There is just the right amount of balance of white space and text on the page. The formatting suits the purpose for writing.</p> <p>D. The use of a title, side heads, page numbering, bullets, and evidence of correct use of a style sheet (when appropriate) makes it easy for the reader to find the desired information. These markers allow the hierarchy of information to be clear to the reader.</p> <p>E. When appropriate to the purpose and audience, there is effective integration of text and illustrations, charts, graphs, maps, tables, etc. There is clear alignment between the text and visuals. The visuals support and clarify important information or key points made in the text.</p> <p>3. The writer's message is understandable in this format.</p> <p>A. Handwriting is readable, although there may be discrepancies in letter shape and form, slant, and spacing that may make some words or passages easier to read than others.</p> <p>B. Experimentation with fonts and font sizes is successful in some places, but begins to get fussy and cluttered in others. The effect is not consistent throughout the text.</p>	<p>C. While margins may be present, some text may crowd the edges. Consistent spacing is applied, although a different choice may make text more accessible (e.g. single, double, or triple spacing).</p> <p>D. Although some markers are present (titles, numbering, bullets, side heads, etc.) they are not used to their fullest potential as a guide for the reader to access the greatest meaning from the text.</p> <p>E. An attempt is made to integrate visuals and the text although connections may be limited.</p> <p>1. The reader receives a garbled message due to problems relating to the presentation of the text.</p> <p>A. Because the letters are irregularly slanted, formed inconsistently, or incorrectly, and the spacing is unbalanced or not even present, it is very difficult to read and understand the text.</p> <p>B. The writer has gone wild with multiple fonts and font sizes. It is a major distraction to the reader.</p> <p>C. The spacing is random and confusing to the reader. There may be little or no white space on the page.</p> <p>D. Lack of markers (title, page numbering, bullets, side heads, etc.) leave the reader wondering how one section connects to another and why the text is organized in this manner on the page.</p> <p>E. The visuals do not support or further illustrate key ideas presented in the text. They may be misleading, indecipherable, or too complex to be understood.</p>

Figure 3 6 + 1 Trait writing-assessment rubric. Adapted from Northwest Regional Educational Laboratory (1999), with permission from NREL.

Trait 1: Mathematical concepts and procedures

5. I completely understand the appropriate mathematical operations and use them correctly.

- I understand which math operations are needed.
- I have used all of the important information.
- I did all of my calculations correctly.

3. I think I understand most of the mathematical operations and how to use them.

- I know which operations to use for some of the problem, but not for all of it.
- I have an idea about where to start.
- I know what operations I need to use, but I'm not sure where the numbers go.
- I picked out some of the important information, but I might have missed some.
- I did the simple calculations right, but I had trouble with the tougher ones.

1. I wasn't sure which mathematical operation(s) to use or how to use the ones I picked.

- I don't know where to start.
- I'm not sure which information to use.
- I don't know which operations would help me solve the problem.
- I don't think my calculations are correct.

Trait 2: Mathematical problem solving

5. I came up with and used a strategy that really fits and makes it easy to solve this problem.

- I knew what to do to set up and solve this problem.
- I knew what math operations to use.
- I followed through with my strategy from beginning to end.
- The way I worked the problem makes sense and is easy to follow.
- I may have shown more than one way to solve the problem.
- I checked to make sure my solution makes sense in the original problem.

3. I came up with and used a strategy, but it doesn't seem to fit the problem as well as it should.

- I think I know what the problem is about, but I might have a hard time explaining it.
- I arrived at a solution even though I had problems with my strategy at some point.
- My strategy seemed to work at the beginning, but did not work well for the whole problem.
- I checked my solution and it seems to fit the problem.

1. I didn't have a plan that worked.

- I tried several things, but didn't get anywhere.
- I didn't know which strategy to use.
- I didn't know how to begin.
- I didn't check to see if my solution makes sense.
- I'm not sure what the problem asks me to do.
- I'm not sure I have enough information to solve the problem.

Trait 3: Communication in mathematics

5. I clearly explained the process I used and my solution to the problem using numbers, words, pictures, or diagrams.

- My explanation makes sense.
- I used mathematical terms correctly.
- My work shows what I did and what I was thinking while I worked the problem.
- I've explained why my answer makes sense.
- I used pictures, symbols, and/or diagrams when they made my explanation clearer.
- My explanation was clear and organized.
- My explanation includes just the right amount of detail not too much or too little.

3. I explained part of the process I used, or I only explained my answer.

- I explained some of my steps in solving the problem.
- Someone might have to add some information for my explanation to be easy to follow.
- Some of the mathematical terms I use make sense and help in my explanation.
- I explained my answer, but not my thinking.
- My explanation started out well, but bogged down in the middle.
- When I used pictures, symbols, and/or diagrams, they were incomplete or only helped my explanation a little bit.

1. I did not explain my thinking or my answer, or I am confused about how my explanation relates to the problem.

- I'm not sure how much detail I need in order to help someone understand what I did.
- I don't know what to write.
- I can't figure out how to get my ideas in order.
- I'm not sure I used math terms correctly.
- My explanation is mostly copying the original problem.
- The pictures, symbols, and/or diagrams I used would not help someone understand what I did.

Figure 4 Analytical trait rubric for mathematical problem solving. Adapted from Central Kitsap School District (2001), with permission from Julie Goldsmith.

Table 1 Analytical trait rubric for oral presentation**Oral presentation criterion 1: Content****5: Strong**

- My presentation had a clear main topic.
- All of the information in my presentation related to and supported my topic.
- The information I included was important to understanding my topic.
- I chose facts, details, anecdotes, and/or examples to make my topic come alive for my audience.

3: Part-way there

- My topic was fairly broad, but the audience could tell where I was headed.
- Most of my details related to and supported my topic, but some might have been off-topic.
- Some of my information was important, but some details might have been too trivial to be included. Maybe I should have left some details out.
- Some of my information may not have been interesting or useful to my audience.

1: Just beginning

- I was not sure what the focus of my presentation was, or I got mixed up and changed topics during my presentation. I think I wandered through a few topics.
- I did not really know how to choose details to share, so I just used whatever came into my mind.
- I forgot to think about what information might be most interesting or useful to my audience.

Oral presentation criterion 2: Organization**5: Strong**

- The opening of my presentation introduced my topic in a way that caught the audience's interest.
- I chose a sequence for the content of my presentation so that it was easy to follow. My audience could easily make a mental outline of the content.
- I used transition words to guide the audience. I do not think anyone got lost listening to me.
- My conclusion wrapped up my topic and left the audience feeling satisfied.

3: Part-way there

- My presentation had a recognizable opening, but it may have been a little plain.
- Most of my ideas were in an order that was easy to follow, but there may have been a place or two where ideas seemed out of place.
- In some places I may have jumped from one idea to the next without helping the audience follow me.
- I had a conclusion. My audience knew when my presentation was over, but I could have done a better job of leaving them with a feeling of satisfaction.

1: Just beginning

- I just plunged into my ideas without setting the audience up to hear about my topic.
- I was not sure what order to put my ideas in, so they came out in a jumble. I think my audience would have had trouble making a mental outline of the content.
- I left out transitions. I did not help the audience follow along with my thoughts.
- When I finished, the audience did not know it was the end. I forgot to make a closing statement.

Continued

Table 1 Continued**Oral presentation criterion 3: Delivery****5: Strong**

- I maintained eye contact with the audience throughout my speech.
- My voice was loud enough for the audience to hear.
- I varied my voice level and intonation to emphasize meaning.
- I articulated clearly so the audience was able to understand every word.
- I spoke at a pace that kept the audience engaged without racing through my speech.
- I avoided repeatedly using filler words between my ideas (e.g., and, uh, um, you know, like, and well).
- I used gestures and movement to enhance the meaning of my words.
- I knew my speech well enough so that I could just glance at my notes to help me remember what to say.
- If I used visual aids or props, they helped make my meaning clearer.

3: Part-way there

- I made eye contact with my audience part of the time. Or, I only made eye contact with a few people in the audience and I forgot to look at everyone.
- My voice was loud enough for the audience to hear part of the time, but it also was too quiet at times.
- I varied my voice level and intonation a few times to emphasize meaning, but I may have spoken in a monotone part of the time, too.
- I articulated clearly some of the time, but some of the time I mumbled.
- I spoke at a fairly good pace, but there were times when I spoke too quickly.
- Sometimes I used filler words between my ideas (e.g., and, uh, um, you know, like, and well).
- My gestures and movement might have been a little stiff or unnatural, but they did not distract the audience from the meaning of my presentation.
- I gave parts of my presentation without having to read my notes, but had to read them quite a bit in places.
- If I used visual aids, they were understandable, but they may not have added much to my meaning.

1: Just beginning

- I had a hard time making eye contact with my audience. I mostly looked up, away, or down.
- My voice was too quiet for everyone to hear me.
- I may have spoken in a monotone, with no variance in intonation. Or I may have tried to vary my voice level and intonation on certain words, but I was not sure which ones to emphasize.
- I mumbled frequently, so the audience had a hard time understanding.
- I had a hard time with the speed of my talking – I either raced or dragged through my presentation.
- I used a lot of filler words between my ideas (e.g., and, uh, um, you know, like, and well).
- My gestures and movement seemed stiff or unnatural, or I moved around so much it distracted the audience from the meaning of my presentation.
- I had to read my notes for most or all of my presentation.
- If I used visual aids, they were confusing. I wasn't sure how to explain them or how to link them to the ideas I was talking about.

Adapted from Arter, J. A. and Chappuis, J. (2006). *Creating and Recognizing Quality Rubrics*, pp. 244–246, Princeton, NJ: Educational Testing Service, with permission from ETS.

Table 2 Holistic rubric for inferences

Score	Criterion
3	Strong inference: A conclusion based on sufficient evidence to be defensible. Or, if there are problems with the evidence, they are described.
2	Inference: A conclusion based on evidence, but not enough evidence to be really sure of the conclusion. Or, there are unnoted problems with the evidence.
1	Wild guess: A conclusion, not a statement of fact, but it is not based on any evidence or the evidence does not support the conclusion. Not an inference: The answer is a statement of fact or a restatement of the problem or issue, not a conclusion based on evidence.

Adapted from Arter, J. (2008) Educational Testing Service. Rubrics Main Handout.

While task-specific scoring may be faster than general scoring, there are several dangers lurking in its use to evaluate products, performance skills, and reasoning. In the kangaroo writing task (Figure 2), for example, there are many ways that a piece might be good. Is it possible that a student will produce a strong response to the kangaroo prompt and yet not fulfill the requirement to enter into the picture imaginatively using devices such as dialog and character names? Similarly, the scoring guide requires the inference that if the work matches the scoring guide, that is, it enters into the picture imaginatively using devices such as dialog and character names, it in fact indicates good writing. Is it possible that a student might fulfill the requirements in the task-specific scoring guide and still not have produced a strong piece of writing? The issue with these considerations revolves around consistency versus accuracy.

Problems with task-specific scoring of reasoning, performance skills, and products are even more dramatic when the purpose is assessment for learning: teacher use of resulting information to plan instruction, student use of information to determine what they already do well, and what needs to be reviewed, or student use of the scoring guide is to learn the nature of quality in general and bring it to bear across tasks. Exactly what in the kangaroo scoring guide will support these uses? The only portions that might assist in these uses are the general portions that can be generalized to the next writing task: sense of drama, imagination, literary devices, and sound conventions.

Compare the kangaroo scoring guide to the 6+1-trait writing rubric in Figure 3. The systematic use of the latter is what will help students to internalize criteria for quality writing and bring them to bear across writing tasks. This is true because a general rubric attempts to directly define the learning target (in this case writing) – no inferences required. This definition gives students and teachers a vocabulary to talk about quality and makes it easier to generalize across assignments.

The problems with task-specific scoring for writing are easily seen; the parallel problem with other

reasoning, performance skill, and product targets, such as math problem solving is more subtle, but equal. Consider this example of task-specific scoring (Arter and Chappuis, 2006: 18): students were shown a picture of a complicated three-dimensional stack of blocks. (Some of the blocks could not be seen because of the two-dimensional rendering of the three-dimensional stack.) The task asked students to answer three questions:

- Part A: How many blocks are in the stack?
- Part B: How many blocks would be found in a similar stack having four sides and a height of six?
- Part C: Write an equation for determining the number of blocks given any value of number of sides (X) and height (Y).

A specific number was given as the answer to Part A. “The answer in the task-specific scoring guide for Part B was: Each side has 15 blocks; there are four sides, $15 \times 4 = 60$.” The specific generalized equation was given for Part C.

The problem is that it’s impossible to tell, from looking at the scoring guide what this item is supposed to assess. Is it problem solving? Communication in math? Spatial reasoning? Algebraic thinking? Something specific to stacking blocks? With task-specific scoring it is impossible to tell. Yet, the inference is being made that correct performance on the task implies that the student is strong at whatever it is that the item is designed to measure. Compare this task-specific scoring guide to the general math problem solving rubric in Figure 4. If the goal is learning what strong problem solving and communication in math looks like so that it can be brought to bear on the next problem, a general rubric is more powerful than one that is task specific.

Students do not enhance their understanding of, for example, quality problem solving, through statements such as, “Each side has 15 blocks; $15 \times 4 = 60$.” They enhance their understanding of quality problem solving through statements like, “The way I worked the problem makes sense and is easy to follow,” and, “I may have shown more than one way to solve the problem,” coupled with examples across tasks that show what is meant.

Based on these considerations, Table 3 shows recommendations for when to use task-specific and general scoring guides. To distinguish between them, the term rubric only is used when referring to general scoring guides.

Having established that task-specific scoring guides reside in the province of extended written response assessments of bodies of knowledge, the rest of this article addresses general rubrics used to assess reasoning, performance skill, and product-learning goals for students.

Holistic versus Analytical Rubrics

General rubrics come in two formats, as described in Table 3: holistic and analytical. Holistic rubrics result in a single overall judgment of quality. Examples are in Table 2 (holistic rubric for inferences), and Table 4

Table 3 Types of scoring guides and when to use each

Type	Description	When to use	Good example of use	Weak example of use
Task-specific scoring guide	A list of specific facts or information to look for in a single task. This results in either assigning points for the presence of specific facts (Figure 1) or determining a level of quality based on the presence of certain features specific to the task (Figure 2).	<ul style="list-style-type: none"> • Can be used to judge student performance only on a single task. • Best used with knowledge targets to identify the pieces of information students are to exhibit in extended written response assessments. • Sometimes used for reasoning, performance skill, and product-learning goals when the goal is speedy scoring and the use is solely summative. 	Figure 1 Carbon cycle. Extended written response assessment of knowledge.	Figure 2 Kangaroo – quality judgments of writing (a product) require a general rubric, especially if the use is instructional.
General holistic rubric	A general description of levels of quality that results in a single overall judgment for a product or performance.	<ul style="list-style-type: none"> • Can be used with any task that measures the same student learning goal. • Best used with reasoning, performance skill, and product-learning goals when there is only a single dimension of quality. • Sometimes used with any complex learning goal if the purpose is to get a single overall summary of student status. 	Table 2 Inferences. This is a reasoning goal, and there is probably only a single dimension of quality.	Table 4 Holistic rubric for informational writing. For instruction, it would be more useful to determine student strengths and weaknesses using an analytical trait rubric.
General analytical trait rubric	A general description of levels of quality along several different important dimensions of a product or performance that results in a separate judgment for each dimension.	<ul style="list-style-type: none"> • Can be used with any task that measures the same target. • Best used with reasoning, performance skill, and product targets when there are several important, distinguishable dimensions of performance. • Especially useful when the purpose is formative. 	<p>Table 1 General analytical trait rubric for oral presentation (a performance skill). Identifying the important dimensions of performance and evaluating them separately for quality is useful, especially if the use is formative.</p> <p>Figure 3 6+1 Trait writing-assessment rubric.</p> <p>Figure 4 Analytical trait rubric for math problem solving (reasoning and communication in math).</p>	

(holistic rubric for writing). Analytical rubrics describe levels of quality along several different important dimensions of a product or performance; this results in separate judgments for each dimension. Examples are in **Table 1** (general analytical trait rubric for oral presentation), **Figure 3** (6+1-trait writing-assessment rubric), and **Figure 4** (analytical trait rubric for math problem solving).

Purpose and the complexity of the learning goal to be assessed determine which is best. Holistic rubrics are best used when the reasoning proficiency, performance skill, or product being assessed is relatively simple and only has a single dimension of quality, as is the case for inferences (**Table 2**). Holistic rubrics are also used with more complex learning goals when the purpose is to make a single overall judgment of current student status – assessment of learning. When the purpose is formative, an analytical rubric for multidimensional learning goals is better because it allows the user to generate a profile of student strengths and weaknesses. A quote from Graves (1983) explains why:

One of the best examples of good teaching I have ever encountered was with a golf professional. On my first lesson, he said, “Here is a bucket of balls . . . hit ‘em.’” A few minutes later he wandered back and quietly said, “Keep hitting them, only this time keep your head down, eye on the ball.” By the next bucket of balls he had introduced one more skill for the day . . . no more. Before a few weeks were out, he had quietly attended to my feet,

grip, shoulder level, and follow through. A few years later I realized with a start that every single one of my problems was visible on the first lesson. If I had attended to all of them that first day, I would probably have missed the ball entirely and resigned in disgust from ever playing golf again (pp 314–315).

During learning it is useful to break a complex performance into manageable parts and practice each separately.

Characteristics of High-Quality Rubrics

To serve their purposes of consistent scoring and defining complex learning outcomes, rubrics need to have certain features, captured in the rubric for rubrics (**Table 5**; Arter and Chappuis, 2006).

For easy reference, we call the two major dimensions of quality in the rubric for rubrics criteria or traits, the lettered subheads under each criterion indicators, and the numbered phrases under each indicator descriptors.

The descriptors under each indicator are not meant to function as a checklist. Not everything has to be present (or missing) for the rubric under consideration to be judged to be at a particular level of quality. Rather, look for the constellation of indicators that best describe the rubric under consideration.

Table 4 Holistic rubric for writing

<i>Excellent</i>	<i>Good</i>	<i>Needs work</i>
1. The paper is clear and focused. It holds the reader's attention. Relevant details enrich the central theme.	1. The writer is beginning to define the topic, even though development is still basic or general.	1. As yet, the paper has no clear sense of purpose or central theme. The reader must make inferences from sketchy or missing details.
2. The organization enhances and showcases the central idea. The order, structure, or presentation of information is compelling and moves the reader through the text.	2. The organizational structure is strong enough to move the reader through the text without too much confusion.	2. The writing lacks a clear sense of direction. Ideas, details, or events seem strung together in a loose or random fashion; there is no identifiable internal structure.
3. The writer speaks directly to the reader in a way that is individual, compelling, and engaging.	3. The writer seems sincere but not fully engaged or involved; the result is pleasant or even personable, but not compelling.	3. The writer seems indifferent, uninvolved, or distanced from the topic.
4. Words convey the intended message in a precise, interesting, and natural way. The words are powerful and engaging. Technical words, when used, are used correctly.	4. The language is functional, even if it lacks much energy. It is easy to figure out the writer's meaning on a general level. Technical words, when used, are sometimes used incorrectly.	4. The writer demonstrates a limited vocabulary or has used vocabulary incorrectly.
5. The writing has an easy flow, rhythm, and cadence. Sentences are well built, with strong and varied structure.	5. The text hums along with a steady beat, but tends to be more pleasant than fluid.	5. Sentences are choppy, incomplete, rambling, or awkward.
6. The writer demonstrates few errors in conventions and may even have used conventions to enhance meaning.	6. Sometimes conventions are handled well and enhance readability; at other times, errors are distracting and impair readability.	6. Errors in spelling, punctuation, capitalization, usage, and grammar repeatedly distract the reader and make the text difficult to read.

Adapted from *6+1 Trait Writing Assessment Scoring Guide*, Northwest Regional Educational Laboratory (1999).

Table 5 Rubric for rubrics

5 – Strong	3 – Medium	1 – Weak
Criterion 1: Coverage/organization		
A. Covers the right content		
1. The content of the rubric represents the best thinking in the field about what it means to perform well on the skill or product under consideration.	1. Much of the content represents the best thinking in the field, but there are a few places that are questionable.	1. You cannot tell what learning target(s) the rubric is intended to assess, or you can guess at the learning targets, but they do not seem important, or content is far removed from current best thinking in the field about what it means to perform well on the skill or product under consideration.
2. The content of the rubric aligns directly with the content standards/learning targets it is intended to assess.	2. Some features do not align well with the content standards/learning targets they are intended to assess.	2. The rubric does not seem to align with the content standards/learning targets it is intended to assess.
3. The content has the ring of truth – your experience as a teacher confirms that the content is truly what you do look for when you evaluate the quality of a student product or performance. In fact, the rubric is insightful; it helps you organize your own thinking about what it means to perform well.	3. Much of the content is relevant, but you can easily think of some important things that have been left out or that have been given short shrift, or it contains an irrelevant criterion or descriptor that might lead to an incorrect conclusion about the quality of student performance.	3. You can think of many important dimensions of a quality performance or product that are not in the rubric, or content focuses on irrelevant features. You find yourself asking, Why assess this? or Why should this count? or Why should students have to do it this way?
B. Criteria are well organized		
1. The rubric is divided into easily understandable criteria as needed. The number of criteria reflects the complexity of the learning target. If a holistic rubric is used, it is because a single criterion adequately describes performance.	1. The number of criteria needs to be adjusted a little: either a single criterion should be made into two criteria, or two criteria should be combined.	1. The rubric is holistic when an analytic one is better suited to the intended use or learning targets to be assessed – or – the rubric is an endless list of everything; there is no organization; the rubric looks like a brainstormed list.
2. The details that are used to describe a criterion go together; you can see how they are facets of the same criterion.	2. Some details that are used to describe a criterion are in the wrong criterion, but most are placed correctly.	2. The rubric seems mixed up – descriptors that go together do not seem to be placed together. Things that are different are put together.
3. The relative emphasis on various features of performance is right – things that are more important are stressed more; things that are less important are stressed less.	3. The emphasis on some criteria or descriptors is either too small or too great; others are all right.	3. The rubric is out of balance – features of more importance are emphasized the same as features of less importance.
4. The criteria are independent. Each important feature that contributes to quality work appears in only one place in the rubric.	4. Although there are instances when the same feature is included in more than one criterion, the criteria structure holds up pretty well.	4. Descriptors of quality work are represented redundantly in more than one criterion to the extent that the criteria are really not covering different things.
C. Number of levels fits targets and uses		
1. The number of levels of quality used in the rating scale makes sense. There are enough levels to be able to show student progress, but not so many levels that it is impossible to distinguish among them.	1. Teachers might find it useful to create more levels to make finer distinctions or to merge levels to suit the rubric's intended use. The number of levels could be attuned easily.	1. The number of levels is not appropriate for the learning target being assessed or the intended use. There are so many levels it would be impossible to readily distinguish among them, or too few to make important distinctions. It would take major work to fix the problems.

Continued

Table 5 Continued**Criterion 2: Clarity****A. Levels defined well**

1. Each score point (level) is defined with indicators and descriptors. A plus: There are examples of student work that illustrate each level of each trait.	1. Only the top level is defined. The other levels are not defined.	1. No levels are defined; the rubric is little more than a list of categories to rate followed by a rating scale.
2. There is enough descriptive detail in the form of concrete indicators, adjectives, and descriptive phrases that allow you to match a student performance to the right score. A plus: If students are to use the rubric, there are student-friendly versions, and/or versions in foreign languages for English language learner (ELL) students. A plus: There is information on rater agreement rates that shows that raters can exactly agree on a score 65% of the time, and within one point 98% of the time.	2. There is some attempt to define terms and include descriptors, but some key ideas are fuzzy in meaning.	2. Wording of the levels, if present, is vague/confusing. You find yourself saying such things as, "I'm confused," or "I don't have any idea what this means." Or, the only way to distinguish levels is with words such as extremely, very, some, little, and none; or completely, fairly well, little, and not at all.
3. If counting the number or frequency of something is included as an indicator, changes in such counts really are indicators of changes in quality.	3. There is some descriptive detail in the form of words, adjectives, and descriptive phrases, but counting the frequency of something or vague quantitative words are also present.	3. Rating is almost totally based on counting the number or frequency of something, even though quality is more important than quantity.
4. Wording is descriptive not evaluative.	4. Wording is mostly descriptive of the work, but there are a few instances of evaluative labels.	4. Wording tends to be evaluative rather than descriptive of the work; e.g., work is mediocre, above average, or clever.

B. Levels parallel

1. The levels of the rubric are parallel in content – if an indicator of quality is discussed in one level, it is discussed in all levels. If the levels are not parallel, there is a good explanation why.	1. The levels are mostly parallel in content, but there are some places where there is an indicator at one level that is not present at the other levels.	1. Levels are not parallel in content and there is no explanation of why, or the explanation does not make sense.
---	---	---

Adapted from Arter, J. A. and Chappuis, J. (2006). *Creating and Recognizing Quality Rubrics*, pp. 183–186, Princeton, NJ: Educational Testing Service, with permission from ETS.

An odd number of levels is used because the middle level represents a balance of strengths and weaknesses. A strong judgment does not necessarily mean that the classroom rubric under consideration is perfect; rather, it means that it would require very little work to get it ready for use. A middle judgment means that some work would be required to make the rubric under consideration usable, but it probably is worth the effort. A weak judgment means that the rubric under consideration needs so much work that it probably is not worth the effort – it is time to find another one or begin from scratch.

In addition, a medium score does not mean average. This is a criterion-referenced scale, not a norm-referenced one. It is meant to describe levels of quality in rubrics, not to compare those currently available. It could be that the typical currently available rubric is closer to weak than to medium.

Although three levels are defined, it is in fact a five-level scale. Think of level 4 as a combination of characteristics

from levels 5 and 3. Likewise, level 2 combines characteristics from levels 3 and 1.

Using the Rubric for Rubrics to Analyze Sample Rubrics for Quality

The following analyses serve two purposes. First, they illustrate the criteria, indicators, and descriptors in the rubric for rubrics. Second, they highlight current issues and considerations about rubrics.

The 6+1 Trait Writing Assessment rubric is strong in all the areas described by the rubric for rubrics. It covers the features of student writing generally thought to be important, it is organized well, the number of levels is appropriate, it attempts to be descriptive and tries to avoid use of vague relative-quantity words, and the levels are strictly parallel. It helps teachers plan instruction, diagnose student strengths and weaknesses, identify students requiring additional assistance, and plan remediation.

It sends a strong and accurate message to students about what high-quality writing looks like.

To illustrate common problems with rubrics, **Table 6** (research report rubric) and **Table 7** (book report rubric) are used.

Rubric for rubrics criterion (trait) 1: Coverage/organization

Covers the right content

While many of the features in the book report rubric in **Table 7** represent important learning outcomes for students, there are some features that do not quite ring true or represent best thinking about what students need to know and be able to do. For example, why does the title page need an illustration (feature 9)? Is it possible to have a good book report without an illustration? Or why is there a requirement for typed, 12-point font, etc.? While this might make it easier for the teacher, it is not an indicator of quality in general. Format is represented by two features: feature 2 (types, font size, length, line spacing) and feature 9 (title page plus illustration). Are there other features of format that are more important for the student to learn?

The book report rubric illustrates the bigger issue of confusion about purposes of rubrics. Is the goal to enable students to get a high grade on an assignment, task, or project, or is the goal to define important complex learning goals for students? If the goal is just to enable students to score well, anything can be put on a rubric – length, type

face, illustrations, and so forth. If the goal is to define important learning outcomes, then not anything goes. In fact, why have a rubric for a book report anyway? Is not the book report just the context for teaching and assessing learning goals such as (1) identifying and summarizing plots, and (2) writing? It would be better to take the requirements for the assignment (length, cover, etc.) out of the rubric and focus instead on defining the complex learning goals that should be the real target of the assignment.

In this regard it is pertinent to ask what message is sent to students by the rubric about what the real learning goals of the work are and where they should focus effort and thought.

The tension between enabling students to score well and defining the important characteristics of a learning outcome can arise when students are involved in developing the criteria by which their work will be judged. Sometimes students include irrelevant criteria. We have to be ready and able to guide students to the important dimensions of work; not anything goes.

Criteria (traits) are well-organized

The book report rubric in **Table 7** could be better organized. Instead of 15 features, might the rubric better communicate what is important if the 15 features were organized into three traits: ideas/content (features 4, 5, 6, 7, 8, and 10; format (features 1, 2, and 9); and conventions (features 11–15). Feature 3, meets the requirements of the task, might be left out entirely because it is repetitive – all the other features specify the requirements of the task. The reorganization might serve to direct thinking about balance. Are ideas/content more important than format and conventions or should they all be weighted the same? The decision might go either way, but it appeared balance was not a consideration at all in the original. The reorganization might also serve to direct thinking about the content of the rubric – the extent to which it represents important learning targets for students.

Number of levels fits targets and purposes

Consider the research report rubric in **Table 6**. The trait of content/organization is worth 50 points. What is the difference between, say, 40 and 41? It is unlikely that teachers could independently be able to assign the same number of points or that students would understand what it takes to earn that extra point. Such rubrics may be used by teachers to make it easier to assign a grade, but they do not promote accuracy or assist with formative interpretations.

Other current issues and considerations about number of levels are these:

1. *Odd or even number of levels.* For formative uses of rubrics, a better consideration is the number of levels that can be usefully distinguished, and how each of the levels is defined. For example, in the rubric for rubrics a 3 is

Table 6 Research report rubric – too many levels

Score	Criterion
50 points	Content/organization: A theme is established and developed with the most pertinent details; content is accurate; technical words, when used, are used correctly; information is organized to easily lead the reader through the ideas; pacing is good – the author takes his/her time on important or confusing points, and speeds up when detail is not necessary; there is an inviting opening; and the ending sums up the ideas.
10 points	Style and voice: The style shows that the writer is interested in the topic and wants the reader to be as well. Sentences are varied in beginnings and lengths and enhance the flow of the work.
20 points	Format: The writer has used the format usual in this type of writing.
10 points	Conventions: Spelling, grammar, punctuation, and paragraphing show very few errors, none of which interfere with the meaning or the style of the report. In fact, conventions are sometimes used purposefully to enhance the meaning of the text.
10 points	References: At least 10 references that are relevant and comprehensive.
_____/100	Total

Table 7 Book report rubric

	<i>Exceeds standard (5 points for each)</i>	<i>Meets standard (4 points for each)</i>	<i>Approaches standard (2 points for each)</i>	<i>Below standard (0 points for each)</i>
1.	Includes the following information: title of the book, author, copyright, publisher, and date	Includes most of the following information: title of the book, author, copyright, publisher, and date	Includes some of the following information: title of the book, author, copyright, publisher, and date	Missing most or all of the following information: title of the book, author, copyright, publisher, and date
2.	Typed, 12 point Times Roman font; two pages; 1.5 spaced	Typed, 12 point Times Roman font; a page and a half; 1.5 spaced	Not typed; one page	Not typed, less than one page
3.	Meets the requirements of the assignment	Meets most of the requirements of the assignment	Meets some of the requirements of the assignment	Does not meet the requirements of the assignment
4.	Information shared shows insightful understanding of the book	Information shared shows adequate understanding of the book	Information shared shows partial understanding of the book	Information shared does not show understanding of the book
5.	Conclusion clearly states your opinion about the book	Conclusion states your opinion about the book	Conclusion is present, but does not state your opinion about the book	Conclusion is missing
6.	Main characters are thoroughly described	Main characters are described	Some main characters are described	Main characters are not described
7.	Setting is clearly identified	Setting is identified	Setting is incompletely identified	Setting is not identified
8.	Plot is summarized completely	Plot is summarized adequately	Plot is partially summarized	Plot is not summarized
9.	Title page plus illustration	Title page plus illustration	Title page plus illustration	Title page plus illustration
10.	Timeline includes 10 or more important events	Timeline includes 7–9 important events	Timeline includes 4–6 important events	Timeline includes three or fewer important events
11.	All spelling is correct	3–5 spelling mistakes	6–10 spelling mistakes	More than 10 spelling mistakes
12.	All punctuation is correct	1–2 punctuation mistakes	3–5 punctuation mistakes	More than 6 punctuation mistakes
13.	All capitalization is correct	1–2 capitalization mistakes	3–4 capitalization mistakes	More than 5 capitalization mistakes
14.	Correct grammar	One grammar mistake	2–3 grammar mistakes	More than 3 grammar mistakes
15.	Correct subject/verb agreement	One subject/verb agreement problem	Two subject/verb agreement problems	Three or more subject/verb agreement problems

Adapted from Arter, J. A. and Chappuis, J. (2006). *Creating and Recognizing Quality Rubrics*, p. 53, Princeton, NJ: Educational Testing Service, with permission from ETS.

defined as a balance of strengths of weaknesses. This is less likely to make a middle score a dumping ground for indecision.

2. *Four levels: exceeds standard, meets standard, almost meets standard, and below standard.* The argument here is that such rating scales make standards-based evaluations and summaries easier. While this might be true for summative uses of rubrics, there are dangers when using rubrics formatively. There is a considerable body of research on the type of feedback to students most likely to produce learning. In general, descriptive feedback is better than evaluative feedback, such as grades. Statements such as below standard are also evaluative. Placing value judgments on how much is good enough too early in the learning process can be counterproductive.

Rubric for rubrics criterion (trait) 2: Clarity **Levels defined well**

One consistent problem with rubrics is the use of vague relative-quantity words like extremely, very, some, and

not much, or almost always, frequently, sometimes, and never. Examples of this are in the book report rubric in **Table 7**. For example, consider the seventh indicator, setting is clearly identified. What is the difference between clearly identified, identified, incompletely identified, and not identified? Even if adults could consistently rate level of identification, would students understand what it takes to clearly identify a setting?

Descriptive detail in a rubric is the opposite of vague quantity words. For example, consider the trait of ideas in the 6+1-trait writing-assessment rubric (**Figure 3**). This rubric does not say that the topic is very clear and focused, somewhat clear and focused, marginally clear and focused, and not focused at all. Rather, it tries to describe what makes writing clear and focused by using phrases like the topic is narrow and manageable, the topic is fairly broad; however, the reader can see where the writer is headed, and the writer is still in search or a topic, is brainstorming, or has not yet decided what the main idea of the piece will be. If rubrics are to

communicate, descriptive words and phrases are necessary. Incorporating the most telling words and phrases into a rubric is a continual process of refinement as users come to more clearly understand what actually does make a performance or product good.

Another common problem relating to the clarity of rubrics is the use of counts to define levels. If one goal of a rubric is to make an essentially subjective judging process as objective as possible, it would seem that counting something would help. The problem with this is that quantity is not always an indicator of quality. For example, it is submitted that three highly relevant and comprehensive references in a research paper are better than ten marginal ones; or in the case of the book report rubric in **Table 7**, under indicator 11, perhaps six spelling mistakes on different words are more of a problem than six spelling errors all on the same word. An important issue is the message sent to students about the nature of quality when counts are used.

Levels parallel

In general, it is desirable to have each level of a rubric describe the same feature. For example, if the quality of the conclusion for a laboratory experiment is described at one level of quality, it would be useful to describe it all levels. All the rubrics illustrated herein are strictly parallel – they are either lined up across the page, or features are numbered or lettered.

There may be cases when levels do not need to be strictly parallel. For example, if the levels of a rubric are thought of as stages in development in becoming competent in some dimension of performance, perhaps these stages are well indicated by different aspects of performance.

Conclusion

Scoring rubrics can be powerful tools for assessment and learning if designed with purpose and the type of learning goal to be assessed in mind. This article has argued for the use of general, analytic rubrics when the use is assessment for learning.

Good assessment-for-learning strategies and examples using rubrics can be found in Stiggins *et al.* (2006, ch. 7); Arter and Chappuis (2006, ch. 6); Arter and McTighe (2001, ch. 6); Spandel (2005); and Kimpton and Harnisch (2005).

Second Language Assessment

L F Bachman, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Second-language testing is concerned with measurement and ethical issues that arise in settings where individuals' proficiency in a language that is not their mother tongue or first language (L1) is being assessed, or where their knowledge and skills are being assessed in a language that is not their L1. Examples of the former include assessments of the second- or foreign-language (L2) proficiency of English-language learners (ELLs) in schools, international students seeking admission to universities in which the language of instruction is for them an L2, individuals seeking professional certification for or employment in positions that require proficiency in an L2, or individuals seeking to emigrate to a country where the dominant language is for them an L2. In such settings, where we need to make inferences about individuals' L2 proficiency, language is both the instrument and object of the assessment. That is, we present individuals with assessment tasks that engage them in L2 use (instrument) so that we can interpret their performance as an indication of their L2 proficiency (object).

Examples of settings in which individuals' knowledge and skills in various domains are assessed in an L2 include assessments of the academic achievement and aptitude of students whose L1 is not the language of instruction, the professional competency of individuals whose L1 is not the language of their intended professional practice or employment, and individuals who intend to emigrate to a country where the dominant language is for them an L2. In such settings, L2 proficiency may be either an ancillary skill that facilitates individuals' demonstration of their knowledge or skills in another area, such as science, mathematics, healthcare, law, welding, or plumbing, or considered part of the construct to be assessed.

The primary measurement issue that arises in both theory and in practice in second-language assessment is understanding and defining the construct to be assessed and understanding the nature of assessment tasks and the interaction between test-takers and these tasks. Ethical issues that arise from these settings include the consequences of and responsibility for assessment use.

Language testing as a field draws on information and knowledge in both applied linguistics and educational measurement. Relevant knowledge and information from applied linguistics include the nature of language as a formal system of signs, for example, sounds, utterances,

letters, words, texts, and the cognitive and social correlates of these signs which give them meaning in situated discourse. Relevant knowledge and information from educational measurement include the nature of theoretical and mathematical models of measurement, and of the practical argumentation and reasoning and empirical methods for supporting the validity of interpretations and the appropriateness and consequences of the uses of assessments.

Measurement Issue: The Construct to be Assessed

Historical Perspective

In the past 50 years, L2 language ability or proficiency has been defined in a number of different ways.

Skills and elements

The first explicitly defined model of language ability for language testing was the skills-and-elements approach that was articulated by Lado (1961) and Carroll (1961, 1968). In their formulations, there was a clear distinction between skills and abilities, on the one hand, and approaches/methods/test types on the other. The skills aspect of this model comprised auditory comprehension, oral production, reading, and writing, while the elements comprised pronunciation, grammatical structure, vocabulary, and cultural meanings.

The skills-and-elements approach was the first in the history of language-testing to explicitly draw upon both current linguistic theory and views of language learning and teaching and psychometrics. This approach was extremely influential, and informed a generation of large-scale assessments of foreign or second language in the United States.

Language ability as unitary

In contrast to the skills-and-elements approach, other language testers have viewed language proficiency as a unitary entity. However, two very distinct views of the nature of that entity have emerged: one as a trait or ability that individuals have, and one as what individuals can do (Upshur, 1979).

Language ability as pragmatic expectancy grammar

Drawing on research into the nature of intelligence, particularly Spearman's (1904) theory of general intelligence,

Oller (1979) proposed what he called the “unitary trait hypothesis”, which stated that language proficiency is essentially a single unitary ability, rather than separate skills and elements. In the most extensive discussion of this research and the theory that underlay it, Oller (1979) identified the general factor from his empirical research as “pragmatic expectancy grammar”, which he defined as “the psychologically real system that governs the use of a language in an individual who knows that language” (Oller, 1979: 6). Oller argued that this ability could best be assessed by integrative assessments, such as the dictation, cloze, oral interview, and written composition.

Language ability as performance: Direct testing/performance assessment

Another view of the construct to be tested emerged in the 1970s, particularly in North America, as a result of an intense interest, in both research and practice, in the testing of oral proficiency. Proponents of this view, who called it “direct testing” (Clark, 1972, 1979) or “performance assessment” (Jones, 1979, 1985; Wesche, 1987), argued that it constituted a major sea change from the skills-and-elements approach. The published discussions of direct testing/performance assessment tended to focus primarily on the nature of the test tasks, which were claimed to mirror, or approximate real-life language use outside of the test itself (Clark, 1975). In defining the construct to be tested, proponents of direct testing/performance assessment referred to real-life language performance which they viewed as the criterion for test tasks (Clark, 1972, 1979). Performance on a direct test was seen essentially as a predictor of the language performance that could be expected of the test-taker in real-life settings.

The most influential practical realization of this approach in practice is the Oral Proficiency Interview (OPI) that originated in the Foreign Service Institute of the US Department of State and that has since been adapted for use by other agencies in the US government, as well as for assessing oral proficiency in foreign- and second-language programs in academic settings (American Council on the Teaching of Foreign Languages, 1983) and in other countries (Wylie and Ingram, 2006). While this approach to assessing oral language proficiency has been criticized from a variety of perspectives in applied linguistics, (Bachman and Savignon, 1986; Kramsch, 1986; Lantolf and Frawley, 1985; Young and He, 1998), the OPI continues to be widely used.

Both Oller’s unitary trait view and the OPI were debated heatedly among language testers and other applied linguists in the 1980’s. Although the former debate drew to a close as more and more research supported a multicomponential view of language ability (Bachman and Palmer, 1982; Carroll, 1983; Oller, 1983; Vollmer and Sang, 1983), concerns with the OPI continue

to the present (O’Connell and Norwood, 2007). The view of language ability as performance reemerged in the 1990s under the label of “task-based performance assessment” (Brown *et al.*, 2002; Norris *et al.*, 1998; Skehan, 2001). This approach draws on research from second-language acquisition and language pedagogy (Skehan, 1996, 1998). Nevertheless, proponents of task-based assessment share with the direct testers the views that the construct to be assessed performance on language-assessment tasks that replicate is real-life tasks, and that the primary use of this performance is to predict performance on future real-life language use tasks.

Language ability as multicomponential, communicative competence

At about the time the debate surrounding the unitary trait hypothesis was drawing to a close, applied linguists in the North America and the UK began exploring a much broader view of language ability, drawing on a wide range of research in functional linguistics, sociolinguistics, discourse analysis, psycholinguistics, and language acquisition as well as developments in communicative syllabus design and communicative language teaching.

One of the earliest, and still most influential, discussions of this broadened view of language ability for language testing was by Canale and Swain (1980). In their article, they adopted the term ‘communicative competence’ to describe the ability that is of interest in both language teaching and testing. They defined communicative competence as “the relationship and interaction between grammatical competence, or knowledge of the rules of grammar, and sociolinguistic competence, or knowledge of the rules of language use” (Canale and Swain, 1980: 6). In addition to grammatical and sociolinguistic competence, Canale and Swain posited a third component which they called strategic competence, and defined it as “verbal and non-verbal communication strategies that may be called into action to compensate for breakdowns in communication due to performance variables or insufficient competence” (Canale and Swain, 1980: 30). Canale and Swain’s view of the construct to be measured was much richer than those that preceded, and initiated a major shift in the way language testers viewed the construct.

Canale and Swain’s paper opened a new avenue of research and debate in language testing, leading to several independently convened symposia being held in the UK (Alderson and Hughes, 1981; Hughes and Porter, 1983) and the US (Palmer *et al.*, 1981; Rivera, 1984) to address issues that had been raised by them in their paper, along with the research that supported a multicomponential view of language proficiency.

Building on Canale and Swain’s work, Bachman (1990) conceived of performance on language tests as a function

of the interaction between an individual's language ability and the characteristics of the test method (Bachman, 1990: 113). To address these issues in both the design and development of language tests and the interpretation and use of assessment results, Bachman proposed two frameworks: (1) communicative language ability and (2) test method facets. Communicative language ability was essentially an extension of the Canale and Swain model, in which their notion of strategic competence was expanded from one that functioned essentially in accommodation and compensation to one that he hypothesized underlies all language use. Bachman saw test method facets as "analogous to the features that characterize the context of situation, or the speech event, as this has been described by linguists" (p. 111), and argued that these could "be seen as restricted or controlled versions of these contextual features that determine the nature of language performance that is expected for a given test or test task" (p. 112).

Bachman's two frameworks were subsequently incorporated into an approach to practical test development by Bachman and Palmer (1996), who renamed 'communicative language ability' simply 'language ability' and 'test method facets task characteristics'. Bachman and Palmer argued that in order for score-based interpretations to generalize beyond the test itself, the characteristics of the assessment tasks needed to correspond to the characteristics of tasks in test-takers' target language use (TLU) domains. They argued that by analyzing the characteristics of tasks in the TLU domain, test developers could use these sets of characteristics as templates for generating assessment tasks that would be representative of tasks in the TLU domain. The framework of task characteristics was thus seen as a way to solve the sampling problem of performance assessment and to thus provide a stronger basis for making inferences to domains beyond the test itself.

Bachman's and Bachman and Palmer's frameworks provided richer descriptions of both the construct and assessment tasks than previous approaches to language testing, but they were not without limitations. Even though their approach views language use in terms of interactions between ability and context as discourse is co-constructed, their frameworks are essentially descriptive and provide little explanation of how ability and context interact with each other in language use. Thus, while this approach may provide practical guidance for the design, development, and use of language tests, it does not solve the issue of how abilities and contexts interact in test-takers' performance.

Current Issues in Defining the Construct

Currently, the dominant view in the field is that language ability consists of a number of interrelated areas, such as

grammatical knowledge, textual knowledge, and pragmatic knowledge, and that these areas of language knowledge are managed by a set of metacognitive strategies that also determine how language ability is realized in language use or the situated negotiation of meaning (Bachman, 1990; Bachman and Palmer, 1996; Chapelle, 1998; Chapelle, 2006). Of all these areas, grammatical and textual knowledge have been the most extensively researched and developed in language testing (Purpura, 2004). The area that has been researched the least, pragmatic knowledge, has recently begun to be investigated extensively. Researchers working essentially within Bachman's (1990) definition of pragmatic competence as knowledge of "the relationships between utterances and the acts or functions that speakers intend to perform through these utterances" (p. 89) and drawing on cross-cultural research in language use have developed prototype assessments for use as instruments in applied linguistics research as well as operational measures of this construct (Hudson *et al.*, 1992, 1995; Roever, 2006; Yamashita, 1996).

Other researchers have challenged this view on a number of counts. Working largely within the area of assessing interactive speaking and drawing on a variety of research literatures outside of language assessment, these researchers have identified a number of problems and lacunae in current conceptualizations of the construct, oral language ability, and how we go about assessing it. These researchers who focus on the nature of the interactions in oral face-to-face language use have argued that the view of language ability solely as a cognitive attribute of language users ignores the essentially social nature of the interactions that take place in discourse. They argue that language ability resides in the contextualized interactions or discursive practices that characterize language use (Chalhoub-Deville, 1995, 2003; Chalhoub-Deville and Deville, 2005; McNamara, 2003; McNamara, 1997; Young, 2000).

In a critical review of this debate Bachman (2007) identifies three different approaches to defining language ability: (1) ability-focused, (2) task-focused, and (3) interaction-focused. He concludes that the theoretical issues raised by these different approaches to defining the construct, language ability, present challenging questions for both empirical research in language testing and practical test design, development, and use. For language testing research, these questions imply the need for a much broader methodological approach, involving both so-called quantitative and qualitative perspectives. For language testing practice, they imply that focus on ability, task, or interaction, to the exclusion of the others, will lead to weaknesses in the assessment itself or to limitations on the uses for which the assessment is appropriate.

A closely related issue is the extent to which language ability includes content knowledge. The effect of test-takers' content knowledge on language test performance

is well documented in the language assessment literature (Alderson and Urquhart, 1985; Clapham, 1996; Douglas and Selinker, 1993; Pappajohn, 1999) and the dominant view has been that this is a source of bias in language tests. (Interestingly, in the research on the assessment of educational achievement, it is the reverse: content knowledge is considered the construct to be assessed, while language ability is typically viewed as a source of bias). An alternative view has been articulated in the area of languages for specific purposes assessment. According to this view, what we want to assess 'is specific purpose language ability' (Douglas, 2000) which is a combination of language ability and background knowledge. While a number of assessments of language for specific purposes have been developed and are being used (e.g., by Australian Federal Government, European Organisation for the Safety of Air Navigation, University of Cambridge ESOL Examinations), there is still considerable debate in the field concerning the theoretical basis for such assessments (Hamp-Lyons and Lumley, 2001).

Recently, the issue of the relationship between language ability and content knowledge in test performance has been the focus of considerable research with respect to assessing the academic achievement of ELLs. On the assumption that the construct to be assessed is knowledge and skills in some specific area such as mathematics or science, a widely held view is that ELLs lack the English proficiency necessary to demonstrate their content knowledge on assessments of academic achievement (Koenig, 2002; Koenig and Bachman, 2004). (Bachman (2002) presents an alternative view, in which the construct to be assessed is something like "the ability to use language to communicate knowledge in an academic discipline"). This view has spurred considerable research into the effects of accommodations – changing aspects of the assessments themselves or in the way they are administered – that are intended to compensate for ELLs' lack of English proficiency (Abedi and Gandara, 2006; Abedi *et al.*, 2004). Although the results of this research are often conflicting and inconclusive (Sireci *et al.*, 2003; Thompson *et al.*, 2002), accommodations for ELLs on assessments of academic achievement continue to be widely used (Rivera *et al.*, 2000).

Ethical Issues in Language Assessment

While research into the nature of language ability and performance on language assessments has been historically and continues to be a major area of focus in language assessment research, this is no longer the sole, or even the dominant, concern of the field. Language testers are investigating the difficult questions about the consequences of assessment use, fairness, and the ethical responsibilities of test developers and users.

Consequences of Assessment Use

Language testers have considered the consequences of assessment use in two domains, that of society at large and language instruction. Viewing language assessment from the perspective of critical social theory, Shohamy (2001) discusses the ways in which language assessments are used to promote unstated objectives aimed at benefiting enfranchised groups in a society. Similarly, McNamara (2001) argues that the very constructs we assess are politically constructed; McNamara and Roever (2006) discuss the societal values that underlie such use and larger sociocultural contexts in which language tests are used. Drawing on moral philosophy, Kunnan (2000a, 2004) has outlined a framework for considering fairness in language assessment. His framework includes several qualities: (1) validity, (2) absence of bias, (3) access, (4), administration, and (5) social consequences. These researchers all argue that greater attention needs to be paid, in both the development of language assessments and in the ways these are used, to the social and political milieu in which language assessment takes place and the consequences of the ways these are used.

Looking at the narrower domain of language instruction, a number of language testing researchers have investigated the impact of language assessments on instruction and instructional processes, referred to in the language testing literature as 'washback' (Alderson and Wall, 1993, 1996; Cheng, 1997; Cheng *et al.*, 2004; Green, 2007; Qi, 2005; Wall and Alderson, 1993). The net result of this research is that washback is not just a simple matter of better assessments producing better instruction. Rather, it consists of a network of complex interactions among all stakeholders in the instructional setting (Hawkey, 2006; Wall, 2005).

Professionalism

Language testers have also grappled with the professionalization of the field and the extent to which language test developers are responsible for the ways in which their tests get used. Davies (1997) and Stansfield (1993) have discussed professional ethics in terms of exemplary practice or creating an ethical milieu for language testing practice. Others have talked about the issues involved in developing a code of professional ethics for language testers throughout the world (Bishop, 2004; Boyd and Davies, 2002). In 2000, the International Language Testing Association adopted a code of ethics.

Justifying Assessment Use

These two strains of concern, the validity of assessment-based interpretations of language ability and ethical issues of assessment use, are coming together in a growing body

of research that investigates both the validity of score interpretations and the consequences of assessment use (papers in Kunnan, 2000b; Reath, 2004). Drawing on argument-based approaches to validation in educational measurement (Kane, 2006; Mislevy *et al.*, 2003), Bachman (2005) describes an assessment use argument (AUA) which he argues can provide the conceptual basis for explicitly linking concerns with validity to those of consequences. Building on this conceptualization, Bachman and Palmer (2010) describe 'assessment' justification as the process of providing a rationale and evidence to justify the use of a particular assessment. Since it is the use of a specific assessment that needs to be justified, justification is inherently local. In other words, the AUA for a particular assessment provides a local theory that makes explicit claims about the roles of consequences, decisions, interpretations, and assessment reports in the assessment, and identifies the evidence that needs to be collected to support these claims. The purpose of an AUA is thus to provide and empirically support a coherent argument that is convincing to stakeholders that using the assessment will help promote the intended beneficial consequences.

The Future: Challenges and Opportunities

Second-language assessment faces two interrelated challenges in the future: bringing together its concerns with issues of validity and use, and addressing the growing need worldwide for the active engagement of language testers in the design, development, and use of practical language assessments for real-world uses.

McNamara (2006) argues that the constructs that underlie real-world language assessments are both socially and politically constructed. From this he concludes, "the political imposition of language testing constructs means that language test validation research will have an impact only to the extent that it is politicized." (p. 38). The challenge will be to move beyond the validation of language ability constructs and the rhetoric of postmodern critical theory. As suggested earlier, one mechanism for explicitly linking the measurement concerns about reliability and validity with the ethical concerns about consequences and professionalism is provided by an AUA such as that proposed by Bachman and Palmer (2010). A conceptual framework provided by an AUA and a critical epistemology that admits a wide range of evidence, from research (qualitative and quantitative) to documentation, regulations, laws, community values, and at the same time critically questions these presents language testers with a daunting challenge. This challenge also presents an opportunity for language testers to bring together their concerns about validity and consequences.

The greatest challenges language assessment as a field faces, however, are in the arenas where language tests are

being used to make decisions about individuals and institutions. Two of these are in the areas of classroom language assessment and assessing foreign languages.

Classroom Assessment

There is a huge demand, worldwide, for greater involvement of individuals with expertise in language testing in the areas of classroom and accountability assessment. Although classroom language assessment is one of the most exciting areas in our field (papers in Broadfoot, 2005; Davison, 2007: 1172; Rea-Dickins, 2000; Rea-Dickins, 2004), this is still not considered mainstream language testing by many. In the past quarter of a century, language testers have been only marginally involved in issues of accountability assessment for K-12 and adult education. This has been and continues to be the case worldwide, where the action in large-scale accountability assessment has been the domain of psychometricians and educators, with language testers providing occasional advice from the periphery. Finally, while the vast majority of published research in language testing over the past half century has focused on learners/users of English as a second or foreign language, there is a growing body of research and experience, again worldwide, in the assessment of languages other than English, as these are being learned both as second and as foreign languages.

The assessment demands of No Child Left Behind (United States Congress, 2001, 2002) in the US have greatly increased the pressure on states to develop more useful assessments both for accountability and in the service of classroom language learning. Similar pressures continue to be seen in other countries as well (Brindley, 1998). Of particular concern to language testers and other applied linguists are issues of assessing the English-language development and academic achievement of ELLs (Hakuta and Beatty, 2000; Koenig, 2002; Solano-Flores and Trumbull, 2003). Similar concerns and issues surround the assessment of ELLs in adult schools (Mislevy and Knowles, 2002; US Department of Education, 2001)

Assessing Foreign-Language Proficiency

Recent initiatives on the part of the US government to increase the nation's capacity in foreign languages are also placing increased demands for useful assessments of foreign languages, particularly the less commonly taught ones (US Department of Defense, 2005; US Department of Education *et al.* 2006). As increasingly larger amounts of government resources at all levels – federal, state, and local – are likely to be going into foreign-language instruction in the coming years, there will most likely be a concomitant need for greater accountability (O'Connell and Norwood, 2007). In K-12 education, there is already

an accountability mechanism in place and it can be expected that as the federal government invests more heavily in foreign language instruction at this level, an accountability mechanism will be required and this will necessitate the development of assessments of foreign-language proficiency that meet the accepted professional standards for validity and impact.

Language testing as a field has grown over the past 30 years in its use of sophisticated statistical and measurement models and ever-refined approaches to naturalistic observation to make advances in understanding the nature of language ability, and will continue to advance in understanding how to deal with the ethical issues of the uses and consequences of language assessments in the real world.

The immediate and long-term prospects for language testing as a field are filled with opportunities and challenges. Turning these opportunities and challenges into accomplishments will depend upon the willingness and capability of language testers to apply the knowledge and skills acquired over the past half a century to the urgent practical assessment needs of our education system, from kindergarten to adult school, and of our society. It will also depend upon our willingness to leave the comfortable confines of the academy and join our colleagues in education and measurement to toil in the fields of practice. It is believed that language testers have a unique combination of knowledge and skills as well as a growing understanding of the issues involved in addressing the validity of interpretations and the consequences of test use. If we can but apply this expertise to the practical problems of assessment in our education systems and society, we are in a position to provide leadership and contribute greatly to making our meritocracy fair and equitable.

Self-adaptive test – An adaptive test in which the examinee is allowed to choose the difficulty category of each administered item.

Self-adaptive tests (SATs) were proposed in the context of psychological and educational measurement as an alternative to computerized adaptive tests (CATs). The purpose of a CAT is to obtain a precise estimate of ability with a small number of items. CATs are efficient tests tailored to a specific examinee. The item difficulty is matched to the examinee's ability. CATs apply more difficult items to more competent individuals, and easier items are applied to those less proficient. The psychometric basis for CAT is item response theory (Hambleton and Swaminathan, 1985), which provides the mathematical justification for this operation mode.

Because in CAT item difficulties roughly match an examinee's ability, the percentage of items passed is only about 50% for any individual, irrespective of ability. Some authors have questioned whether CATs are appropriate from a motivational point of view (Andrich, 1995). As a result, variants of CATs have been proposed to ease examinee's comfort and reduce anxiety. For instance, easy CATs are adaptive tests that match item difficulty to a smaller ability than the estimated one, with the purpose of increasing the proportion of items passed (Lunz and Bergstrom, 1994; Revuelta *et al.*, 2003).

A SAT is an adaptive test in which the examinee is allowed to choose the difficulty category of each administered item (Rocklin and O'Donnell, 1987; Rocklin, 1994; Johnson *et al.*, 1991). The item bank is divided into five or seven difficulty levels. Prior to the administration of each item, the examinee chooses one of the difficulty levels and the computer program selects the most informative items for that group of items based on the most recent ability estimate. In most applications of SAT, previous to the selection of a difficulty level for an incoming item, the computer program provides feedback on the correctness of the last response (Roos *et al.*, 1997; Vispoel, 1998).

The idea behind SAT is that allowing the examinee to play some role in the item-selection process may be beneficial from a motivational point of view. In particular, the possibility of selecting difficulties may be helpful for

reducing anxiety during the test. The consequence would be a purer and more valid estimate of ability, that is, a test score that reflects better the true ability level and that has not been contaminated by anxiety during the test.

Figure 1 depicts the flowchart for a SAT administration session. The test begins with a provisional ability estimate, which may be a value close to the mean population value. Step 2 is specific for SAT and consists of selecting one of the difficulty levels; this step is missing during a CAT. Step 3 consists of selecting an item within the group of items with required difficulty. Item selection is based on the statistical information and the content constraints inherent to adaptive testing. During a CAT, the item bank is not divided into groups of homogeneous difficulty, and the testing algorithm is not subjected to difficulty constraints. The selected item is administered to the examinee and the response is recorded in step 4. Step 5 consists of providing feedback on the correctness of the response; this step is usually missing in CAT. The estimate of ability and the standard error are computed in step 6. The termination criteria involved in step 7 are the test length, standard error of ability, and content constraints. The test ends when the individual has received enough items from any content category and the standard error of the estimated ability is smaller than some arbitrary criterion, such as 0.3.

Item response theory is needed at two points of the flowchart: in step 3, where items are selected partially based on the statistical information that they provide about the estimated ability, and in step 6, where the abilities are estimated on the same measurement scale for individuals that have responded to different items.

Investigations on Anxiety and Comfort

A body of applied psychometric literature has focused on the benefits of SAT for increasing motivation and reducing anxiety during the test. These investigations are based on two hypotheses (Revuelta *et al.*, 2003):

1. *Perceived control hypothesis.* The test is considered a source of stress. Because the stress is reduced when the individual has some control over the aversive situation, the perceived control over the test is the cause of a reduction in anxiety (Wise, 1994).
2. *Perceived performance hypothesis.* Because in SAT the individuals obtain feedback on the number of errors, the selection of difficulty may be used to increase the

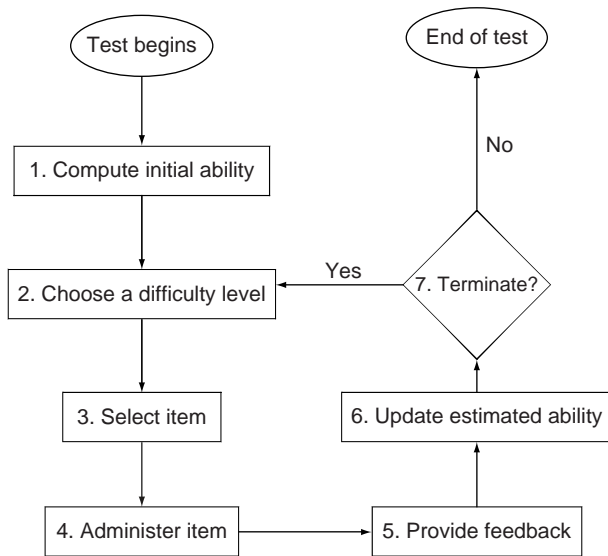

Figure 1 Flowchart describing a SAT.

number of items passed. Anxiety is reduced because difficulties can be adjusted to increase the number of items passed, which is interpreted by the examinee as a better performance (Ponsoda *et al.*, 1999).

The perceived control hypothesis provides an explanation on the effects of SAT that is based on the investigations on anxiety by Averill (1973): the opportunity to modify the aversive stimuli (the test) reduces the stress in comparison to those situations where the control is absent. However, Wise *et al.* (unpublished) showed that not all the individuals who respond to a SAT wish to have that control. If an individual does not desire to control difficulty, SAT may produce an increase of anxiety and a reduction of ability. In summary, SAT would be beneficial only for those individuals with high anxiety and low self-conception on the ability measured by the test (Wise *et al.*, 1994).

The perceived control and the perceived performance hypotheses do not necessarily exclude each other. In fact, the control provided to the examinee is a control of the difficulty levels, which can be adjusted to increase the perceived performance on the test. The perception of control depends also on the instructions given to the examinees. Typically, the instructions indicate that correct responses are weighted by item difficulty to obtain the test score. A high number of correct responses to easy items produce a lower score than a smaller number of correct responses to harder items. In this way, difficulties may be selected to increase the test score, and the control on difficulty may be perceived as an indirect control on the test score or the performance on the test.

The empirical studies have reported some important differences between CAT and SAT and provided support for these hypotheses. In general, SAT yields higher mean

ability estimates and a lower posttest anxiety than CAT (Shermis *et al.*, 2001; Vispoel and Coffman, 1994; Vispoel *et al.*, 1994; Wise *et al.*, 1992; Ponsoda *et al.*, 1997; Rocklin, 1996). Pitkin and Vispoel (2001) conducted a meta-analysis to integrate the different published studies and to gain a better understanding of the differences between CAT and SAT. The result is that estimated ability is higher in SAT, although the estimated effect size is modest (0.11). Moreover, SAT reduces the negative effects of anxiety on test performance, and the standardized effect size for anxiety reduction is 0.18.

The benefits of SAT are not attained without cost; in particular, testing time is longer because the individuals have to spend some time selecting difficulties. Regarding measurement precision, the standard error of ability is higher and reliability is lower than in CAT. Moreover, the instructions given to the examinee are more complex and important in a SAT than in a CAT. If an individual selects difficulty widely apart from the true ability level, the measurement precision would be very low. For these reasons, it is very important that the instructions of the test must very clearly state that the individual should avoid those difficulty levels that do not involve a challenge, that is, those items that are routinely passed or failed. SAT is also very sensitive to the pattern of difficulties, and there is no way to obtain a precise ability estimate if the individuals ignore the instructions.

SAT may also present difficulties related to the development and security of the item pool. Even though most adaptive tests measure a unidimensional ability, they apply some type of control balance of the test content. The item pool is divided into several content groups, and the final test should have a balance number of items from each content category. In SAT, each difficulty level should have a sufficient number of items from each content category because some individuals select all the items from the same difficulty level. Moreover, item exposure control strategies shall be developed specifically for SAT to avoid the occurrence of individuals selecting the same difficulties and receiving the same items, and to obtain a balanced item exposure rate within each difficulty group.

Because of the problems encountered with a pure SAT testing strategy, some hybrid testing strategies have been proposed between CAT and SAT. For example, restricted self-adapted tests (RSAT; Wise *et al.*, 1993) prevent examinees from choosing difficulty levels that differ widely from the most informative one. In an RSAT, the range of choices is restricted to a region around the provisional estimate of ability. Results on RSAT regarding measurement precision and anxiety are more similar to CAT than to SAT (Roos *et al.*, 1998; Plake *et al.*, 1995), and the supposed benefits of SAT are not attained.

Assisted self-adapted testing (ASAT; Hontangas *et al.*, 2004) provides advice to the examinee regarding the difficulty level that best matches the ability estimates, and

yields results similar to CAT. A third variant is the SCAT (self-adaptive supplemented with computerized adaptive test), which acts as a SAT at the beginning of the testing session and as a CAT in the middle and the end of the test (Ponsoda *et al.*, 1997). The idea behind SCAT is that in the first part of a CAT the provisional ability estimate may differ widely from the final one; and the difficulties selected by examinee may be better matched to ability. Finally, the easy SAT recommends the examinee to select easier items than the difficulty level that best matches the ability estimate (Ponsoda *et al.*, 1999).

Investigations on Item-Selection Strategy

The examinee's control over the administration of items gives rise to a number of item-selection strategies that may be related to ability or some other personal characteristics. The item-selection strategy is the association pattern between the response given to an item (pass/fail) and the difficulty selected for the next one. A body of applied research has focused on this problem and has identified two strategies (Hontangas *et al.*, 2000; Johnson *et al.*, 1991; Rocklin, 1989):

1. The rigid strategy is followed by those examinees that select the same difficulty level throughout the test.
2. The flexible strategy consists in selecting a harder level after a correct response and an easier one after an incorrect one.

Figure 2 illustrates the strategies by showing the difficulties selected by two individuals during a 10-item SAT. The item bank is divided into five difficulty levels. The black dots denote the passed items, whereas the white dots are for the failed ones. The dotted line corresponds to an individual who follows the rigid strategy. This individual selects the same difficulty throughout the test, with some minor changes, irrespective of the response to the previous item. The solid line corresponds to an individual who follows the flexible strategy. This individual selects the same difficulty or a higher one after a correct response,

Figure 2 Difficulties selected by two individuals during a SAT session.

and the same difficulty or an easier level after an incorrect response. Then, the flexible strategy consists of searching the more challenging difficulty level, those with a higher uncertainty on the correctness of the response.

The flexible and the rigid strategies can be considered as theoretical patterns for selecting difficulties. In real SAT applications, many individuals exhibit strategies that combine these two or change their strategy throughout the test. For example, the failure-tolerant strategy is followed by those individuals that select the same difficulty level after failing an item and a harder one after a correct response.

Theoretical Investigations on the Statistical Properties of SAT

A theoretical investigation on the statistical properties of SAT was conducted by Revuelta (2004). Bradlow and Thomas (1998) had demonstrated that missing responses are not missing at random data in choice-based examinations (those that permit an examinee to select the items from a designated list). The consequence is that the maximum-likelihood estimate of ability commonly used in item response theory is not valid for this type of test. Conversely, Mislevy and Wu (1996) showed that this problem does not apply to CAT. In SAT, the examinee has more control over the item-selection mechanism in CAT but less than in choice-based examinations. For these reasons, the possibility of estimating ability in SAT remained problematic.

Revuelta (2004) showed that in SAT, the population of examinees is divided into several subpopulations that differ in the item-selection strategy. Moreover, he proposed a latent class model to estimate the number of strategies and identify the strategy followed by each examinee, and applied it to a real data sample. More importantly, this investigation showed that the strategy may be related to ability, which implies that the strategy should be taken into account when estimating abilities.

Consider step 6 of the flowchart depicted in **Figure 1**. Let θ be the ability of the individual and x_i the response given to the i th item. The probability of observing a response pattern $x = (x_1, \dots, x_I)'$ is given by

$$f(x; \theta) = \prod_{i=1}^I f(x_i) b(i), \quad [1]$$

where $b(i)$ represents the probability of selecting item i from the bank and $f(x_i)$ is the probability of the response x_i . In a CAT, $b(i)$ depends on the properties of the item-selection algorithm. The function $f(x_i)$ is computed by using one of the models of item response theory, for example, the one-, two-, or three-parameter logistic models (Hambleton and Swaminathan, 1985). During a CAT, the maximum-likelihood estimate of θ is obtained by maximizing $f(x; \theta)$ with respect to θ .

Consider a population of SAT-taker individuals that is divided into several strategies. Let S be the number of strategies and p_s be the probability of sampling an individual that follows strategy s . The probability of the observed responses is given by

$$g(\mathbf{x}; \theta) = \sum_{s=1}^S p_s \prod_{i=1}^I f(x_i) b_s(i), \quad [2]$$

where $b_s(i)$ is the probability of selecting item i for those individuals that follow strategy s . The probability $g(\mathbf{x}; \theta)$ is a marginal probability function because the strategy followed by the individual is unknown, and the parameters of $b_s(i)$ and p_s are estimated from the data.

The result of the empirical application of the model described in eqn [2] is that there is an association between the strategy and the ability of the individual, and the same strategies are not used for individuals of different ability. In more formal terms, the probability p_s depends on θ . The consequence is that p_s contains information about θ . Therefore, in a SAT the maximum-likelihood estimate of θ is obtained maximizing eqn [2] instead of [1], which implies that the pattern of difficulties is used for estimating ability.

From a purely measurement perspective, this is undesirable because the ability estimate depends not only on the pattern of correct and incorrect responses but also on the item-selection strategy. Moreover, this finding could be exploited by the examinees to obtain a positively biased ability estimate by using the most optimal strategy. For these reasons, SAT appears to be more appropriate for investigating personality characteristics, such as risk-taking behavior or anxiety reduction, than as a tool for obtaining a precise ability estimate.

The theoretical investigations on SAT suggest that the item-selection strategy affects the scores and may be the cause of biases on the ability estimate. The existence and magnitude of these biases have not yet been clearly shown and there is still another unresolved problem: the robustness of the traditional maximum-likelihood estimate to violations of the assumption that the strategy is unrelated to ability. That is, the consequences of estimating ability by using the eqn [1] instead of [2] during a SAT session. Surely, the response would depend on the strength of such a relation, as formalized by the relation between θ and p_s .

Conclusions

The purpose of SAT is to obtain a more valid ability estimate by reducing the effect of anxiety on the test score. Empirical research has shown that not all individuals are highly anxious and benefit from SAT, and that highly anxious individuals show differential tendencies to cope with anxiety and do not necessarily benefit from SAT.

SAT can be viewed as a strategy of test accommodation devoted to some of the individuals that exhibit high-state anxiety related to the testing situation. From this viewpoint, anxiety is considered a disability that prevents the individuals from performing their best during the test. Chapter 10 of the Standards for Educational and Educational Testing, published by the American Psychological Association *et al.* (1999), is devoted to test individuals with disabilities, where the test modifications are designed to accommodate the needs of these individuals. In the face of these standards, there is still a long way to go before SAT can be routinely applied in a real testing scenario.

To apply SAT in a real evaluation, an important concern should be to clearly identify the group of individuals that present this disability. Moreover, the theoretical mechanisms that underlie test anxiety, coping strategy, and ability need to be investigated further, and more empirical evidence should be provided on the properties of SAT scores for groups of individuals with different anxiety and personal characteristics (Rocklin *et al.*, 1995).

Another important unresolved problem is the validity of the SAT scores. Supposedly, SAT may provide a purer measure of ability than CAT because the influence of anxiety is removed and the individuals may perform at his/her best. Research has shown that mean scores are higher for SAT than CAT, although the explanation of this finding in relation with construct validity is still unclear. Moreover, not all the individuals deal with anxiety in the same manner and the benefits of SAT may depend on personal characteristics, even for the population of highly anxious individuals. Thus, it has not yet been established whether this kind of test accommodation is legitimately applied only to the subgroup of highly anxious individuals, to some of them or to any examinee. Finally, if the hypotheses about the underlying mechanisms of SAT are correct, the consequence should be a purer measure of ability and an increased predictive validity. However, this hypothesis is yet to be tested in empirical studies.

Given the current state of research, SAT appears to be a useful tool to investigate stylistic characteristics of the individuals, such as risk-taking behavior or locus of control. SAT can be also applied in low-stakes evaluations such as diagnosing learning difficulty, in which the examinees themselves may wish to obtain a realistic ability estimate. However, the validity of SAT for measuring ability in high-stakes settings constitutes an open problem that requires further investigation.

Glossary

Accountability index – Measure that uses specific rules to combine test scores into a single number or label for use in accountability decisions.

Status measure – Score or aggregate of scores collected at a single point in time.

Successive cohort measure – An index that compares student performance in a school (or grade) in one year to the performance of students in that same school (or grade) in the previous year.

Quasilongitudinal measure – An index that compares the performance of a school's students in a specific grade to the performance of students in the previous grade in the previous year.

Value-added models – Complex statistical models that attempt to isolate the contribution of a teacher or school to a student's achievement.

Score inflation – Gains in scores on high-stakes tests that are larger than the gains in the underlying construct the test is designed to measure.

Test-based accountability (TBA) systems that hold educators accountable for students' scores on standardized achievement tests are prominent in many school systems throughout the world. In the United States, such systems became the cornerstone of federal education policy as a result of the No Child Left Behind Act (NCLB) of 2001, and many states had TBA systems in place for several years prior to NCLB. Most TBA systems report scores for schools or school systems, although some programs are designed to hold individual teachers and principals accountable through pay-for-performance plans in which salary increases or one-time bonuses are awarded on the basis of student test scores.

Large-scale, standardized achievement tests are the central component of these systems. These tests have traditionally served a variety of purposes in education and have been used in both high-stakes and low-stakes contexts. Standardized tests are often used to monitor the education system as a whole, and in many schools they are intended to play an important role providing feedback to help educators make decisions about instruction. High stakes for individual examinees are sometimes associated with tests: scores may be used to make decisions about course assignment, high-school graduation, professional certification, licensure, and other decisions that have

consequences for the person taking the test. The distinguishing characteristic of the TBA systems discussed in this article, as opposed to other ways of using test scores, is the linking of students' scores to consequences for the adults who have responsibility for teaching those students.

This article explores the use of tests in accountability systems. It describes different metrics that have been constructed from test scores for use in TBA, and discusses some of the strengths and limitations associated with each. It also describes a variety of other issues that arise when test results are used to hold individual educators or schools accountable.

Accountability Indices

The use of test scores for teacher or school accountability requires the construction of an aggregate measure, such as an average score for all of the students in a teacher's class or in an entire school. A variety of methods exist for creating these aggregates, or performance indices, but most of them fall into one of several types. This section describes the major types of indices and the relative benefits and limitations of each. For simplicity, the text primarily refers to schools as the units of accountability; however, most of the points are relevant to other units such as classrooms.

Status Measures

Perhaps the most straightforward approach to assigning a single number to a school is to calculate a simple average or other aggregate of scores collected at the same point in time, such as the percentage of students scoring at or above the proficient level from a spring test administration. These are often called status measures to distinguish them from measures based on change or growth. These single-point-in-time measures are typically intended to provide information about the current performance of a school's students or to compare a school's performance against an established target. The calculation of these measures is generally simple, although the need to combine information across different tests, subjects, or grade levels sometimes leads to the adoption of fairly complex rules for constructing these measures. The data demands for most status measures are minimal; for example, they do not require the linking of individual student scores over time, although they do require rules for determining

which students to include in the calculations when students transfer schools midyear. However, the inferences that these measures support are limited. Because they do not adjust for students' prior achievement, they provide limited information to inform inferences about the effectiveness of education a school provides. Their use in TBA systems has sparked intensive debate about the appropriateness of holding schools accountable for students' performance without recognizing the other factors contributing to their achievement.

There are some measurement issues that arise in the calculation of status measures. If scores need to be combined across different grade levels, they need to be placed on a comparable scale. Norm-referenced scores such as normal curve equivalents (NCEs) or percentile ranks are often used for this purpose, and, more recently, the percent-above-cut metric (e.g., the percentage of students scoring at the proficient level or above) has become widespread. Although these types of scales provide a straightforward way to combine results from different grades, they are likely to mask some differences in the meanings of scores across grades. For example, the proficient cut score might not be equally rigorous in every grade. Similar issues arise when combining results across different subjects. Although these measurement issues are important to address, arguably, the most significant drawback of status measures is the absence of adjustment for student characteristics including prior achievement.

Successive Cohort and Quasi-Longitudinal Measures

One way to address the variability in the prior achievement of students served by different schools is to compare the current performance of a school's students with the performance of the students the school served in previous years. An increase in the scores from one year to the next is often interpreted as indicating that a school is improving its effectiveness. This interpretation, however, requires an assumption that the background characteristics of the students, including their prior achievement, remain constant over time. Research on successive cohort measures has shown that substantial year-to-year variability in student characteristics leads to noisy and inaccurate estimates of schools' effectiveness. Another drawback of these measures is that they do not directly measure students' growth in achievement and can provide misleading information about schools' performance. For example, a school that achieves higher-than-average gains in individual students' achievement from the entry year to the exit year, and that does so consistently year after year, would attain a gain of zero on a successive cohort change index. Therefore, these measures cannot support strong inferences about school or teacher effectiveness.

One approach that is sometimes used to address variability in student characteristics across cohorts is to follow an individual cohort over time, such as by comparing the scores of a school's fourth graders with the prior year scores for that school's third graders. These measures, sometimes called quasi-longitudinal change scores, typically require a testing program that uses a vertical scale, which is a scale that links test scores across grades to reflect their increasing difficulty. When a vertical scale is used, differences in scores for consecutive grades can be interpreted as indicating the amount of achievement growth attained over the course of the year, although there are a number of psychometric challenges associated with creating valid vertical scales.

Quasi-longitudinal measures address some of the sampling and attribution problems that are inherent in successive cohort measures, but they are not immune from them, especially when student mobility is high. Both successive-cohort and quasi-longitudinal measures are appealing because of they are relatively simple to calculate and, like status measures, do not require data systems that follow individual students over time. However, their inability to provide information about individual student gains makes them less appropriate for inclusion in TBA systems that impose high stakes.

Growth or Value-Added Measures

Approaches that follow individual students over time are generally called growth models or measures. They include simple change-score models, in which each student's prior-year score is subtracted from that student's current-year score and the change scores for all students in a school are aggregated to produce a school-wide measure. They also include more complex, value-added measures. All of them have the advantage of directly examining individual students' test-score growth over time rather than relying on group averages of single-point-in-time measures. Several categories of growth measures are discussed briefly here.

Average gain score

The simplest growth measure is an average of individual-student gain scores that involves subtracting a student's prior-year score from his or her current-year score. This measure is easy to calculate and straightforward to explain to stakeholders. However, gain scores have some properties that make them less than ideal for use in TBA systems. They are often correlated with student background characteristics; simply subtracting out prior achievement does not adequately control for student background. They rely on an assumption of linearity in the test-score scale, which may not be warranted. In addition, students with missing data in either year are

excluded, and these scores can only be calculated when there is a vertical or developmental scale on the test.

A modification of the simple gain score is an average residual. This measure involves fitting a simple linear model that regresses current-year score on prior-year score, calculating the residual from this model for each student, and obtaining the average of these residuals for the whole class or school. This approach may be modified to include other covariates, such as student background characteristics. Like the simple gain score, this type of index is relatively transparent and easy to implement, but it may be affected by measurement error, which can limit its ability to remove the effects of student background variables from the estimated effects. Moreover, it cannot be used for students with a missing score in the prior year.

Value tables

When the achievement test is scored according to performance levels (e.g., basic, proficient, and advanced) and when there is a desire for transparency, the value table approach may be desirable. Value tables assign points based on students' movement across performance levels. The set of rules embodied in the table is applied to each student, and the points for students are aggregated to the appropriate level (teacher or school). A simple example is provided in **Figure 1**.

Figure 1 illustrates how value tables can be used to communicate priorities and create incentives to focus educators' behaviors. Schools receive points when students move from their current performance level to a higher level, and they receive more points for students who move more than one level. They also receive more points for moves at the lower end of the achievement distribution than at the higher end, a rule that might be designed to promote extra focus on low-achieving students. Schools receive points for keeping students at their current level only when those students are already scoring proficient or above. This table could be altered in a variety of ways, such as by assigning negative values to moves from one level to a lower level or assigning a small number of positive points for students who fall from advanced to proficient to allow for regression to the mean due to measurement error in the test.

As noted above, value tables may be desirable in situations for which transparency is particularly important,

Year 1 achievement level	Year 2 achievement level			
	1	2	3	4
1 – Below basic	0	150	225	300
2 – Basic	0	0	125	200
3 – Proficient	0	0	75	150
4 – Advanced	0	0	0	75

Figure 1 Sample value table.

such as when test scores are used to determine individual teachers' salaries or bonuses. They also provide a way for the designers of the TBA system to communicate their priorities and assign rewards or penalties in a way that is consistent with those priorities. However, value tables have some drawbacks. Like the gain scores discussed above, they only include students who have scores at both relevant time points. Moreover, the rules for assigning points, no matter how carefully considered, are essentially arbitrary and there is typically little effort to explore the sensitivity of decisions to the specific numbers used. Limited empirical studies of the estimators have shown that they can be sensitive to student background characteristics and are unlikely to fully remove the confounding effects of these variables from performance measures. Because value tables rely on performance levels, information about changes within levels is lost, and the measures are affected by other technical issues that arise in the context of standards-based reporting of scores.

Random-effects models

This class of models includes a variety of approaches to modeling the joint distribution of test scores for each student. One example is the layered model used at one time by the Tennessee Value-Added Assessment System (TVAAS), one of the first and most prominent value-added models used in the United States. These models address many of the shortcomings of the other approaches discussed in this section. They allow students who have incomplete test-score data to be included. Also, some of these models can be used with a variety of test-score scales, unlike the gain score models which require a vertical scale. Extensive research has been conducted to explore the properties of these models in the context of estimating teacher effects, and has shown that if enough scores are included for each student (the minimum number is generally considered to be three), they can remove most of the effects of individual student characteristics from estimates of teacher performance. One of the key criteria is that the multiple measures from students are linked with different teachers and that there are no isolated groups of teachers with any students in common. These conditions are less likely to hold for schools than for teachers, and thus the desirable properties of these models maybe less likely to apply to estimates of school performance. The models can be extended in a number of ways, such as by incorporating terms that allow teacher or school effects to diminish over time. Significant drawbacks of this class of models are their complexity and lack of transparency.

Student fixed-effects models

Finally, student fixed effects may be included in models as a way to address confounding that results from individual student characteristics. The dependent variable in these

models is often a gain score, but a single test score may also be used. The model used in estimating school or teacher effects includes an indicator variable (or fixed effect) for each individual student in the data as well as indicators for teachers or schools. By including students fixed effects in the model, the school effects are estimated by variations in outcomes within students, so that persistent effects of individual students do not contribute to the estimated performance measures. Consequently, only students who switch schools contribute to estimates of school effects that are not grade- or year-specific. This restriction of the sample to students who switch schools can greatly reduce the data available for estimating school performance and has been cited as one of the limitations of fixed-effects methods. These models are also challenging to implement on a large scale, are not transparent, and typically require vertically scaled scores.

Challenges in using growth models for TBA

All of the models discussed in this section have clear advantages over the status and cohort-based measures presented earlier. The more-complex models tend to support more valid inferences about teacher or school contributions to achievement than do the simpler models, although no model completely isolates these effects in all cases. Moreover, for some accountability purposes, the need for transparency might lead to a decision to use a less-complex model; trade-offs between transparency and validity must be considered.

All of these measures require longitudinally linked, student-level data, with multiple measures per student and with links between the student's test score and the appropriate unit of accountability (teacher or school). Even when the basic infrastructure is in place to support the collection of this type of data, there are challenges associated with ensuring its accuracy. Determining which teacher or school should receive attribution for a particular score is especially difficult when students move or when more than one school or teacher provide instruction in a particular subject. Clear and consistent rules must be developed to deal with these problems, and applying these rules can be time consuming and expensive. Those responsible for designing TBA systems must decide whether these costs are justified by the quality of the resulting information.

Measurement Issues Raised by Test Use in School Accountability

Regardless of the specific model used, policies that hold schools or educators accountable for student test scores raise a number of issues that need to be considered and addressed. The accountability index is only as good as the

testing program that underlies it, and existing large-scale testing systems face several challenges that are likely to affect their validity. This section does not provide a comprehensive discussion of these issues, but briefly discusses some of the more salient ones.

Test Preparation and Score Inflation

The research on high-stakes testing points to two interrelated concerns that arise when consequences are related to test scores. First, scores tend to become inflated, which means that they overstate the actual level of achievement the test score is intended to represent. This inflation probably occurs in large part as a result of the second finding, which is that teachers and other educators often respond to high-stakes tests by increasing their focus on tested material and decreasing their focus on material not included in the test. Teachers, for example, have responded by reallocating instructional time from non-tested subjects to tested subjects and from nontested topics to tested topics within a subject area. Teachers also tend to focus more on specific item formats and styles, and on test-preparation activities. The use of performance levels in accountability systems has been associated with an increased emphasis on students who are performing near the cut point. Although less common, cheating and other clearly negative responses can also occur. Many of these responses may be mitigated through the design of TBA systems – for example, by including a variety of item formats, considering gains at all points in the score distribution, and by instituting security measures that reduce the likelihood of narrow test preparation or cheating.

Inclusion of All Students

TBA systems are usually intended to include accurate measures of performance for all students served by a school or teacher. A number of policy decisions around inclusion need to be made, such as how to treat students who attend a school for only a portion of the year. Perhaps the most challenging issues, however, pertain to students with disabilities and students whose first language is different from the language in which the test is written. Many TBA systems have explicit policies addressing the inclusion of these groups. For instance, rules may specify the percentage of students with disabilities who may be excluded from regular testing and given alternative assessments or the number of years in which a student must have received instruction in the tested language to be included in testing.

The validity of the entire TBA system will be affected by the validity of scores for students in these groups. Accommodations or modifications to testing are sometimes

made to enhance test validity, but some research suggests that these changes often lead to inaccurate inferences about student achievement.

Alignment

The theory of action behind many of today's TBA systems is that published content standards will communicate the goals students are expected to achieve, and the tests will accurately measure student attainment of these standards. In addition, there is generally an assumption that schools will adopt curriculum programs that provide students with opportunities to learn the material embodied in the tests and standards. This theory requires that tests, standards, and curriculum be aligned with one another. A number of approaches to measuring alignment have been developed, and most jurisdictions that adopt TBA systems conduct an alignment analysis. The methods for evaluating alignment are imperfect; however, in many cases, they have shown that while each test item may be found to be aligned with one or more standards, the tests often fail to capture the breadth and depth that the standards were intended to convey. Higher order reasoning and problem solving are especially likely to be neglected, perhaps in part because of the difficulty of developing test items that tap these skills and that can be administered and scored in a cost-effective way. Aligning tests with curriculum is even more challenging, especially when schools or districts have latitude over the curriculum they adopt and when there is extensive local variation in curriculum.

Reporting in Terms of Performance Levels

The final issue addressed here stems from the nature of reporting that is often used in accountability systems. TBA systems are frequently built on the assumption that all students should be able to achieve a specific level of performance, and that tests should be scored in a way that clearly communicates what knowledge and skills the student has demonstrated. In many cases, these considerations have led to decisions to report according to performance levels such as basic, proficient, and advanced. Each level is associated with a specific cut score on a test. NCLB, for example, requires states to report the percentage of students exceeding the proficient threshold. States must also develop other levels such as basic and advanced, but accountability decisions are based exclusively on whether or not students score at or above proficient.

The use of performance levels is intended to promote better communication, but there is little evidence that most stakeholders truly understand what it means to be classified as proficient or advanced. Moreover, in the United States, where states under NCLB have been permitted to set their own cut scores, the meaning of proficient varies widely across states. Several methods have

been developed for setting these cut scores, but all of them rely heavily on professional judgment, and different methods often result in different cut scores.

Moreover, because these types of scores only capture differences in performance when those differences cross one of the thresholds, they can provide misleading information about student performance. Many of the categories cover a broad range of test scores; a student scoring at the high end of the proficient range may be more similar to an advanced student than to a student scoring at the low end of that category. The use of performance levels is especially problematic for the interpretation of test score gains or group differences – whether the gap between two racial/ethnic groups increases, decreases, or remains constant over time, for example, sometimes depends on where the cut score is set. These drawbacks suggest that caution is warranted when interpreting results based on performance levels.

Summary

Scores on student achievement tests are frequently used to hold educators accountable. The use of test scores in this way assumes that those scores provide reasonably valid information about the quality of education teachers or other school staff provide. A number of methods for creating accountability measures from test scores were described, and differences in the extent to which they support valid inferences about school or teacher effectiveness were discussed. All of the methods presented above, however, are subject to measurement issues that are inherent in large-scale achievement testing. Some of these were discussed in the previous section, but this is by no means a comprehensive list. The use of test scores in accountability systems must be accompanied by careful considerations of threats to validity, and by efforts to minimize those threats to the extent possible.

Many of the concerns raised earlier can be mitigated, although probably not eliminated completely, through careful design of TBA systems. Several sets of guidelines for appropriate test use have been published; the best known is probably the *Standards for Educational and Psychological Testing* published in 1999 by the American Educational Research Association, the American Psychological Association, and the National Council on Measurement in Education. Although the standards do not focus exclusively on accountability testing, many of the guidelines included in that document are relevant. Perhaps the most important advice found in this document is that a single test score should not be used to make high-stakes decisions about individuals. The meaning of this seems fairly obvious in the case of tests with stakes for individual students (though even in that case the implications are widely debated); however, it also pertains to accountability decisions that rest on an aggregate score. The standard implies the need for a

compensatory system, in which low scores on one measure can be offset by good performance on other criteria, but that has not always been followed. Providing examinees with multiple opportunities to take the test (or equivalent forms of it) is consistent with the standards but is not generally considered sufficient to meet the requirement for multiple measures.

The use of tests in accountability systems should be subjected to ongoing monitoring that documents the responses of stakeholders to the system. Whether TBA leads to desirable or undesirable responses will depend in large part on the extent to which educators support the system and believe that it provides accurate information about their efforts and effectiveness. Future developments in value-added methodology and in assessment design will lead to new policies and practices surrounding TBA.

Introduction

Test development or test construction refers to the science and art of planning, preparing, administering, scoring, statistically analyzing, and reporting results of tests. This article emphasizes a systematic process used to develop tests in order to maximize validity evidence for scores resulting from those tests.

The point of view of this article is large-scale, high-stakes cognitive testing, scored using classical measurement theory (CMT), which also provides an adequate model for most classroom tests. The selected-response test item format, exemplified by the prototypic multiple-choice item, is an excellent format for testing student cognitive achievement at most levels of schooling and at all levels of the cognitive taxonomy. The 12-step process model is also useful for other testing formats, including performance-type tests using item formats such as the constructed-response form, simulations, structured oral examinations, and all other blended or combination formats.

This test development process model applies equally well to nearly all types of cognitive tests, including those intended to measure achievement or ability, tests used for academic or job placement, tests intended to diagnose learner's strengths and limitations, tests intended to provide learners with formative feedback on progress as well as a final summative measure of cognitive achievement in a domain, and occupational-type tests used to credentialize individuals for a profession or occupation.

The emphasis on some steps will depend on the exact purpose of the test being developed. Some steps or tasks may be subsumed into other tasks or dismissed as unnecessary for a particular testing situation. This process model, summarized in **Table 1**, may be reordered or reorganized, given special requirements for the proposed test, but most tasks will be required to be carried out for most tests, whatever format is used.

Process Model: 12 Steps for Effective Test Construction

This model emphasizes documenting validity evidence for test score data. All test scores require validity evidence to support or refute intended interpretations. In general, the higher the stakes or consequences associated with test scores, the more the sources of scientific validity evidence

required. However, multiple sources of scientific validity evidence are desirable for all test score data.

Step 1: Overall Test Plan

The first planning stage is important since many decisions made at the outset will have an ultimate impact on the quality of the test and the validity evidence for scores resulting from the test.

A clear statement of the proposed purpose of the test scores is critical to the validity of test scores. This statement of purpose determines the hypothesized construct intended to be measured. All validity documentation will seek to refute or support this hypothesis concerning the construct thought to be measured.

The purpose statement may be as simple and narrow as: "...to measure student achievement on the content of instructional objectives in biochemistry, units 2 to 4." Or, as comprehensive as: "...to measure the summative cognitive achievement, across all subspecialties of internal medicine, of physicians in post-graduate medical training in internal medicine, year 2." The statement of clear intent or purpose for using test scores is essential to guide all development activities and suggest sources of validity evidence that will be needed. The test's purpose statement and hypothesized construct, if clearly stated, will assist test developers throughout the cycle in determining which process steps are most essential, when each step must be accomplished, the logical order of the steps, what level of sophistication is required, how the process might best be documented, and so on.

This first planning stage requires agreed-upon timelines, especially for group test development projects, as well as role and task designations. If there is a fixed deadline for test administration, working back from that date will help provide a realistic timeline for accomplishing all the essential tasks.

The complexity of the proposed test and the consequences of the resulting test scores will generally determine the length of the test development timeline, the number and qualifications of staff or personnel required, and so on. Large-scale, high-stakes test development projects often take 1–2 years to complete and require the input of staff with many different capabilities – subject matter experts (SMEs), test development specialists, test editors, psychometricians, production specialists, information technology specialists, and so on. Classroom-type tests, on the other hand, are usually developed by a

Table 1 Twelve-step process model for test development

Steps	Example test-development tasks
1. Complete plan	Systematic plan to guide all other test-development activities: clear statement of test's purpose and definition of the construct; desired test-score interpretations or inferences; planned validity evidence; rationale for test format(s); psychometric model; timelines; security; quality control plan
2. Definition of content	Exact sampling plan relating items to domain; rational or empirical foundation; major source of content-related validity evidence
3. Test specifications	Content operationally defined and specifically related to Step 2; documents content definition; provides content-related validity evidence for score inferences to domain
4. Developing items	Creation of effective test stimuli or item formats; principles of effective item writing; item writer training; content and editorial review to reduce bias
5. Test design and assembly	Designing and operationalizing test forms; item or prompt selection; operational sampling by planned blueprint; pretesting, item tryout
6. Producing test forms	Publishing or producing tests; security, validity, quality control issues
7. Administration	Validity issues concerned with standardization; fairness issues; proctoring, security, timing issues
8. Response scoring	Validity issues; psychometric model; quality control; key validation; item analysis
9. Establishing passing scores	Establishing defensible cut or passing scores; relative vs. absolute methods; validity issues; comparability of standards and constancy of score scale
10. Reporting test results	Validity issues: accuracy, quality control; timely; misuse issues
11. Item banking	Effective item banking; security; flexibility
12. Documentation – technical report	Process documentation: thorough, detailed documentation for validity evidence

teacher or a small group of instructors, with far fewer resources and time but smaller-scale test projects also benefit from an overall planning step.

Quality control issues should also be addressed with a comprehensive plan for assuring accuracy and quality at every stage of test development. The ultimate success of all test development processes is determined by the quality and quantity of the validity evidence for the test scores. This first comprehensive planning step helps assure a successful outcome.

Step 2: Definition of Content

Test content is the single most important feature for most tests, especially achievement tests. Content-related validity evidence is an important type of validity evidence required for achievement tests of all kinds. The manner in which the content to test is determined is key to this type of validity evidence.

Many different methods are used to delineate the content for tests. Generally, these methods use empirical, rational, or a combination of empirical and rational methods.

For many high-stakes tests, such as most credentialing examinations, empirical techniques, generally referred to as practice analysis, task analysis, or job analysis, are used to establish the appropriate content to sample in the test, which in turn serves as a major foundation for content-related validity. These empirical procedures typically employ survey research methods to systematically

sample the opinions of qualified individuals who are knowledgeable about the content domain. After empirical data are collected and analyzed, content-expert decision makers use the results of these studies to formulate an exact sampling plan that reflects the relative importance of various content areas and their criticality for safe or competent practice in the discipline.

Empirical and rational methods are combined to delineate test content for some tests. For example, accountability tests (state-wide assessments), which may be used to evaluate student progress in mastery of essential learning objectives or skills and to evaluate school success, often define content through complex methods using both empirical data from stakeholders (students, parents, teachers, administrators) and rational methods from SMEs in order to arrive at group consensus judgments about the appropriate content to test.

Rational content-defining methods are used for almost all lower-stakes tests. These methods require judgments by SMEs as to the appropriate content to sample and the relative emphasis of the content for measurement of the construct of interest given the purpose of the test. For most classroom achievement tests, content decisions are made by the teacher or instructors, based on the instructional objectives, the teaching/learning experiences, and subjective judgments about the relative importance of topics and content. At minimum, such rational content-defining methods should strive to be unbiased and yield test content that fairly represents instruction and student learning expectations.

The process of content definition is fundamental to test validity. The construct of interest begins to be operationalized through systematic efforts to delineate the exact content domain or universe. The ultimate success of the test as a measure of the construct depends greatly on the soundness of the methods used to define content.

Step 3: Test Specifications and Blueprint

This step specifies all the essential details of the proposed test and all the processes to be used to develop that test. This test-specifications step guides the remaining test-development steps and provides essential documentation and rationale as validity evidence. One important component of this step is to outline the sampling plan which serves as a blueprint or detailed guide for test developers to assure a one-to-one correspondence of the test stimuli or items to the total content domain, universe, or population.

Test stimuli, items, or performance prompts are samples – theoretically random samples from an infinite number of all possible stimuli – used to make inferences to the population or total domain of content. Examinee performance on the particular test items or performance prompts of any given test is of interest primarily to provide a scientifically sound basis for inference to the whole content domain. Thus, the logical basis for these inferences – and a fundamental aspect of validity evidence – relies on the reasonableness of the sampling plan for items and item content.

Test blueprint

The test blueprint operationalizes a sampling plan and ensures that the test is a representative, reasonable, and fair sample of the content domain. Many different procedures can be used to develop this blueprint or sampling plan. For achievement tests, especially classroom tests, a simple matrix of item content by cognitive level may be sufficient. This matrix crosses content topics or areas (to whatever level of specificity desired), with cognitive process levels (such as recall or recognition of facts; application of facts, concepts, and principles; problem solving and other higher-order cognitive processes) and specifies the proportion of items in each cell of the matrix. This type of blueprint is typically prepared by the instructors, based on subjective but informed and rational judgment, and forms the basis for item or prompt development. Blueprinting of content ensures systematic, comprehensive, and representative sampling of the domain, at cognitive levels judged to be appropriate, and functionally aligns the test with instruction. Fair, unbiased, and reasonable blueprinting of content provides a major source of content-related validity evidence, especially when independently verified after the test has been developed.

Large-scale test development programs may use more sophisticated and more complex methods to blueprint the test content and relate the content of test items to the domain. At minimum, test blueprints or other types of exact sampling plans for high-stakes tests require some consensus of representative groups of SMEs.

Test specifications

Every important detail of the test must be specified, together with a rationale for all critical choices. For example, for a cognitive achievement test, what item formats (constructed-response, selected-response, both) will be used? What is the rationale? If selected-response items are to be used, what type (multiple-choice, matching, extended matching, multiple true–false, and so on). Why? How many items will be used on the test and what is the justification for the number of items? Who will create the test items? What is the rationale for the selection of the item or prompt writers? What training will the item or prompt writers receive? How will the test be administered (performance, paper-pencil, oral, computer-based)? What is the rationale?

Each of these 12 steps of effective test development has many individual decision points, each with a myriad of details to be decided. Each test development choice-point is an opportunity to enhance or lessen validity evidence.

Step 4: Item or Prompt Development

Creating effective test items or performance prompts is a challenging task. Writing effective items or prompts is a major test-development task, requiring application of principles based on many years of research; this task also requires specific training, practice, experience, and feedback.

The principles of writing effective selected-response items, summarized here, are well documented in the research literature. Most of these principles may apply to creating performance prompts as well.

Principles of effective items

Well-written and effective selected-response items have the following characteristics. Items focus on a single important idea, concept, or principle asking a specific question at a cognitive level that is aligned to the instructional activities of the learners. Item wording is unambiguous and well edited for content accuracy, language clarity, and style. The stem or lead-in of the item contains most of the information and both the stem and the answer options are worded positively, avoiding negative words. A direct question is usually best. Trick questions and questions dealing with trivial information should be avoided.

The answer options should contain one and only one correct or best answer to the stem question, and most experts must agree that this is the best or most correct answer. Answer options should be homogeneous in content such that all options represent the same general class. Effective selected-response items use as many total options as necessary, but three options (one correct and two plausible incorrect) are usually sufficient. All incorrect answer options must be plausible such that some uninformed examinees choose these distractors. Avoid using *all-of-the-above* and *none-of-the-above* answer options, as well as specific determiner words such as always, never, and all, which clue an incorrect answer choice. There should be no grammatical cues to the correct answer.

Some common item writing problems: Item flaws

Some item writers attempt to test too much material in a single item. Usually, an item that focuses clearly on a single idea works better than an item that is overly complex in its form. Generally, the straightforward single-best answer multiple-choice item works best, so that complex formats – such as formats that require multiple answers or complex answer choices using combinations of options – should be avoided. Open-ended, nonfocused item stems such as, *which of the following statements is true (or not true)?* are usually followed by a set of answer options that require the examinee to answer true or false to each separate option. While the multiple true–false item form is a legitimate format in which each option is separately scored as true or false, it is not effective to use this form for multiple-choice items with one correct or best answer.

Specialized training of item writers, with practice and constructive feedback, is often lacking. Instructors at all levels of teaching frequently lack the specialized training, experience, and practice needed to become effective item writers. Furthermore, teachers often lack sufficient time to prepare effective test items and lack the resources of larger-scale testing programs to carry out the content and editorial reviews which tend to greatly improve the overall quality of newly created test stimuli.

Quality control and security controls for items must be maintained throughout the item-writing stage. Content and editorial review and rewriting is an important means to improve the quality and effectiveness of test items.

Step 5: Test Design and Assembly and Step 6: Producing Test Forms

For most classroom tests, assembling the items into a final form of the test is somewhat trivial. For large-scale tests, with complex multiple-form designs, which may be computer delivered, the final assembly step is far more complex and fraught with quality control challenges. For

all types of written tests, there are validity issues associated with test design, assembly, and production. For classroom-type tests, producing test forms is straightforward, usually involving simple reproduction methods under the direct control of the instructor. For high-stakes, large-scale test programs, production of printed or computer-based tests can be extremely complex.

Quality control of the final test product is the most important issue at these steps. The design of the test and the items selected for the final form of the test must be a representative sample of the content so that these particular items can generalize to the domain of interest.

Pretesting or item tryout is a concern at the test design and assembly step. Large-scale tests typically imbed newly created items on final test forms in order to evaluate the statistical performance of new items. A variety of pretest or tryout designs may be used, but in all cases pretested items should comprise a relatively small proportion of the total test. Classroom tests generally cannot pretest items because of logistic and security issues, so all newly created test materials must be evaluated for effectiveness at the first test use, making key validation (see Step 8) all the more critical.

For high-stakes tests, security issues abound at this stage of development since extremely secure test items or performance prompts may be out of the direct control of the test developers for the first time in the test-development cycle. Any compromise of quality or security at this stage can spoil the entire test-development effort by invalidating some or all of the test scores. Careful documentation of the chain of security must be maintained for high-stakes tests, including secure transport or shipping of all materials to and from production sources or the security controls for computer-based tests.

If there are production-type errors or problems, such that the final test is difficult or impossible to read or use, the validity of the scores resulting from the test may be compromised. Thus, production issues are validity issues.

Step 7: Test Administration

Administration represents the culmination of all test-development steps up to this point. The items or prompts developed to sample the domain are presented as stimuli to examinees in such a way as to control or standardize as many extraneous variables as possible.

Major validity concerns about test administration revolve around security and standardization issues such as:

- proctoring for standard test administration conditions;
- reduction or elimination of test irregularities, such as cheating;
- timing issues such that all examinees have identical amounts of time; and

- security of all test materials before, during, and after the test.

Lax, insecure, or unstandardized test-administration conditions can invalidate score interpretations for some or all examinees and spoil all the test-development work.

Step 8: Response Scoring

Scoring test responses is the starting point for many psychometric concerns and validity issues. CMT models are used for most classroom-type tests. Item response theory (IRT) models are applied to many large-scale tests. The choice of psychometric model has some impact on test development, but this impact may be minor except for specific test design and data collection methods. Whatever psychometric model is used for scoring, examinee responses are compared to the scoring key and typically awarded one point if the response agrees exactly with the scoring key (or rubric) and zero points if the response does not match. Other scoring systems can be used, but right–wrong (0, 1) scoring is the most parsimonious and the starting point for almost all scoring methods.

Item analysis

Item analysis is a process of counting examinee responses to test items and compiling statistical data on the number of examinees who answer the item correctly in order to evaluate the difficulty and the discrimination of the test item. Item discrimination refers to how sharply the item differentiates between examinees who obtain high scores on the test and those who have low scores on the test and is usually estimated as a correlation between the item score and the total test score.

The purpose of item analysis is to evaluate the performance or functioning of test items or prompts. Such data can be used for several purposes including the improvement of future tests and the enhancement of test validity evidence through the elimination of poorly performing test items. Item analysis data can be compiled for all types of tests, including performance tests.

Item analysis data is also used to evaluate the patterns of responses to the correct and incorrect options of the item. Option item analysis permits the evaluation of the functioning of both correct and incorrect options.

For most achievement tests, the ideal selected-response test item will be of middle or medium difficulty (about 55–75% correct) since such an item provides maximum information about examinee achievement. Also, ideal items will sharply discriminate high- and low-scoring examinees, having high positive-correlation coefficients with the total score on the test.

Key validation

For test development, one of the major uses of item analysis is for key validation of test items prior to their final scoring. Key validation refers to the process of performing a preliminary item analysis on tests in order to evaluate the performance of test items prior to final scoring. Key validation allows the test developer to eliminate items that are problematic and may be invalid before students receive final scores on the test. Key validation is especially valuable for tests with many newly written items which have not been pretested.

Step 9: Establishing Passing Standards

Many tests require assignment of a pass or fail status from the test scores or some other classification system, such as grades. All methods used to establish pass or fail cut scores on tests require judgment and are therefore somewhat arbitrary and subjective. Passing scores answer the question: How much is enough to know in order to be classified as passing the test? All passing scores represent policy decisions, but should be informed by unbiased expert judgments about the content tested.

There are three major methods commonly used to establish passing scores on tests: normative, absolute, or combination methods (**Table 2**). Normative passing score methods use the relative ranking of examinee scores to determine the cut score or grade to be assigned. In normative methods, the relative location of the examinee's score in the distribution of scores is the key feature. Absolute methods use the judgment of experts concerning the subject-matter content of the test items to establish the passing score. Combination methods have some normative and some absolute characteristics.

Absolute passing score methods are widely used, especially for high-stakes tests. Such methods emphasize examinee competency and directly address the issue of what the examinee knows or can do. The normative methods, in their pure form, address only the issue of relative standing on whatever is measured by the test, not what content has been mastered.

Table 2 Examples of passing score methods

<i>Method</i>	<i>Judgment</i>	<i>General type</i>
Angoff	Items	Absolute, item centered
Ebel	Items and relevance	Absolute, item centered
Hofstee	Test	Blended: normative/absolute
Contrasting groups	Examinee performance	Examinee centered
Borderline group	Examinee performance	Examinee centered

For large-scale tests using absolute passing scores, statistical equating of test scores across different forms or administrations of the test is usually required to maintain the identical meaning or interpretation of the passing score. Most tests are slightly harder or easier across forms or administrations. Equating levels these slight differences in difficulty and maintains the constancy of the score scale over time so that the passing score has the identical interpretation.

For many classroom-type achievement tests, passing scores or grading scales are determined administratively by policy outside the direct control of the teacher or instructor. Ideally, these policy decisions are based on some types of informed, unbiased judgments concerning the content tested, the nature and quality of the instruction and the tests, and the actual achievement of the students.

Step 10: Reporting Test Results

For many classroom tests, reporting the results of tests is straightforward. Feedback on student performance may be limited to a total test score, with information on the grade or passing status associated with the score. Feedback that is instructionally useful may be an important feature of classroom achievement test score reporting. For high-stakes tests, the reporting of test results may be more complex and detailed.

Generally, the reporting of all types of test scores should be accurate, timely, clear, and meaningful to examinees and other users of the information, and, if possible, should provide specific useful feedback on performance strengths and limitations. If diagnostic-type feedback is provided, the sample of items or behavior upon which subscale performance is based must be sufficiently large to be reliable. Some indicant of the errors of measurement inherent in the scores should be provided.

The score report should clarify legitimate uses of scores and indicate what constitutes a misuse of scores on the test.

Step 11: Item Banking

Item banking refers to the process of filing or storing test items or prompts, together with identifying performance information about them, such that such test materials can be reused on future tests. Security, usability, and flexibility of item-classification systems are key elements of a successful item-banking system. For classroom-type tests, item banking may consist of a secure paper-filing system or secure computer files containing the test materials and minimal identification and item/prompt performance information.

Large-scale testing programs usually require sophisticated computer-based item-banking systems, which maintain large numbers of test items, together with many identification and performance variables about the item. Such systems allow maximum flexibility in storing and retrieving test items/prompts to meet all the content requirements and item-characteristic requirements specified by the testing plan and specific blueprint.

Desirable item banking characteristics include:

- security;
- ease of operation – both input of text and data and output of items/prompts;
- flexibility – the ability to change classification systems and details;
- strong data manipulation capabilities; and
- ability to use multiple item characteristics to sort and select items/prompts

Step 12: Summary Documentation – Technical Report

Step 12 is a summary step, both for all the previous test-construction processes and this article. Documentation of validity evidence is important for all tests. For high-stakes tests, validity evidence should be clearly and completely documented in a written technical report. Some examples of technical report content, organized around the 12-steps of test development include:

- purpose of the test and clear statement of how scores will be interpreted;
- how test content was determined;
- how those who prepared test stimuli were selected;
 - training, experience, demographics if relevant;
- how security was maintained throughout the test-development cycle;
- rationale for method of administration: paper-pencil or computer-based;
- complete information on test scoring;
 - rationale for psychometric model
 - statistics summarizing test results: mean difficulty, discrimination, passing rates
 - item-analysis results
 - information on pretesting
- documentation on equating methods used, if any; and
- documentation on the methods used and the results of any standard setting study

Test development, as process and methodology, consists of multiple well-defined steps or processes. In this article, the test-development process has been outlined in 12 major steps, all of which are generally required for nearly all tests. Test validity evidence is the key organizing principle for each of these steps.

Test Translation and Adaptation

A Allalouf and P Hanani, National Institute for Testing and Evaluation, Jerusalem, Israel

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Test adaptations have become common in recent years for a variety of reasons. There have been an increasing number of international studies that deal with cross-national, cross-cultural, and cross-lingual comparisons of attitudes, traits, abilities, and educational achievements, for example, the Third International Mathematics and Science Study (TIMSS), which has been translated into 45 languages for use in 30 countries. There is a growing demand for adapted tests for use in selection and certification. In addition, there is a need for cross-lingual and cross-cultural personality and intelligence measures (e.g., the widely used Wechsler test that has been adapted and normed in many languages and countries). As a rule, tests should be administered in the examinee's native language, unless the aim is to test foreign- or second-language proficiency. If a valid and reliable test exists in one language, and there is a need for the same test in other languages, translating and adapting the original test makes good sense. The term test adaptation is preferable to test translation, as it includes all the activities needed to ensure that the intended meaning is retained across languages (Geisinger, 1994). The adaptation process should follow a detailed guide, which usually prescribes a series of consecutive stages such as double-translation, forward and backward translation, and independent reviews, so that the end result is in natural and fluent language. There should be a high degree of similarity in terms of psychometric characteristics between the translated items and the original items to ensure fairness in the measurement process. A fair and reliable comparison of test performance among examinees from different linguistic backgrounds is possible if several steps (i.e., differential item functioning (DIF) analysis between the different languages versions) are taken after the test is administered. These steps will enable score comparisons between the different language groups.

The Adaptation Process

Preparing a test that is constructed in one language and culture for use in a second language and culture requires an adaptation process that takes into account the linguistic and cultural differences between speakers of the two different languages. This process – sometimes referred to as transadaptation (Zucker *et al.*, 2005) – consists of accurately translating those items in the source language which can be adequately rendered in the target (translated) language,

and changing other items which, in simple translation, could lead to linguistically, culturally, or psychometrically inappropriate measurement. The translation and adaptation process should follow specified steps (see Hambleton and Patsula, 1999; Hambleton, 2005; Maxwell, 1996):

1. *Ensuring construct equivalence.* Persons familiar with both languages and cultures must agree that the same measured construct (i.e., content domain, attribute, etc.) exists both in the source language and culture and in the target language and culture.
2. *Determining the adaptation design.* There are two main standard designs used in producing an adaptation: forward-and-backward-translation and forward-only translation.

With the forward-and-backward-translation design, one or more translators adapt a test from the source language to the target language. If the translation is done by a number of translators (working independently), they meet to resolve differences in their translations and produce a single version. Other translators then take the agreed-upon version of the test and adapt it back to the source language. Again, this results in several versions which are merged into a single final version. The original and back-translated versions of the test are then compared and judged with regard to their equivalence (see step 5). This procedure focuses mainly on the source-language version. There is a rather low probability of detecting errors through this procedure, as the back translator may be able to produce a good translation into the source language, even if the original translation was poorly done and resulted in a nonequivalent target-language version of the test.

With the forward-only-translation design, the test is adapted from the source language to the target language by one or more translators with different areas of expertise or from different cultural backgrounds, who work independently. The different versions of the translation are then merged into a single version. The advantage of the double-(or multiple-)translation procedure is that a high degree of equivalence of source and target languages is obtained as all the translators involved focus on both the source and target versions. Another type of forward translation is one in which two parallel source versions are produced in two different languages, and then two independent translations (one from each source language) are produced and merged into a single version in the target language. This design was implemented by the Programme for International Student Assessment

(PISA) International Coordination Centre (Grisay, 2003; Grisay *et al.*, 2006). The advantage of this procedure is that it avoids giving too much importance to cultural forms and linguistic characteristics that are tied to one specific source language.

3. *Building the adaptation team.* The team should include translators and reviewers who are fluent in both languages, familiar with both cultures, and who have some knowledge of both the test's subject matter and principles of test development. A team is preferable to a single translator, as it offers a variety of approaches and perspectives, and thus ensures that the right decisions will be made and a good adaptation produced.
4. *Initial translation and adaptation.* Translators should follow guidelines aimed at ensuring that:
 - a. the cultural context of the item is familiar to all examinees who will take the test in the target language;
 - b. none of the items is provocative or offensive in its adapted version;
 - c. the conceptual equivalent of a word or phrase is kept;
 - d. the essential meaning of the item does not change;
 - e. the difficulty level of the translated item is equivalent to that of the source language;
 - f. the language used is natural and fluent; and
 - g. measurement units, seasons, places, animals, monetary currency, etc. are equally familiar to all examinees.
5. *Reviewing.* After the target language version is completed, additional reviewing is needed. It is important that the reviewers are from different backgrounds and countries of origin, since special attention must be given to different dialects or nuances of a language (e.g., the many dialects of Arabic; British as opposed to American English; and Spanish spoken in Argentina as opposed to Spain). It is recommended that the reviewers first check the adapted version of the test without looking at the source version, to see whether the items stand on their own merits. Only then should the adapted version be compared to the original, with special attention given to the quality of the adaptation. Reviewers note their comments and suggest alternatives. A panel of experts which includes the translator, experts in the subject matter, and experts in test development discuss the comments and revise the adapted version. A helpful step in reviewing is asking reviewers to answer the question in the adapted version. If they give a wrong answer, it may indicate that the adaptation is flawed, thereby indicating a need for revision of the item.
6. *Conducting field tests.* The review of the adapted version of a test should involve a number of translators and reviewers to ensure that most of the problems in the adapted version will be identified and fixed. Nevertheless, some problems go unnoticed until test items are field tested. Item revisions are made where necessary.

7. *Constructing the test final version and documenting the adaptation process.* The final target-language version of the test should be the result of all the above-mentioned steps, in accordance with the required test content and difficulty specifications. All stages in the test adaptation process should be documented – including reviewer comments and the changes made.

Achieving Equivalency

Once the test has been constructed and administered, a three-step procedure should be implemented to ensure a high degree of similarity between the scores of the adapted version and those of the source-language version: (1) detecting construct bias by checking that the dimensional structure of the test versions is equivalent, (2) detecting item bias by applying DIF analysis, and (3) linking the scores of the source- and target-language test versions.

1. *Detecting construct bias – dimensionality assessment.* The purpose of this analysis is to determine whether the construct measured exists in all groups, and if so, whether it has been measured in the same manner in all groups. The goal, in other words, is to examine whether the total score calculated for each test version represents the same construct in each language group. Dimensionality assessment can be done using factor analysis, weighted multidimensional scaling, and other methods (Sireci and Allalouf, 2003; Georgas *et al.*, 2003).
2. *Detecting item bias.* According to the commonly accepted definition of DIF, an item functions differently across groups when examinees of equal ability but from different groups (in this case, different language groups) are not equally likely to respond correctly to that item. When DIF is detected, the next step is usually to investigate the reasons for it, so as to determine whether the DIF item is also biased against one of the language groups. A comprehensive distinction between the two terms, DIF and bias, was made by Zieky (1993):

It is important to realize that DIF is *not* a synonym for bias. . . judgment is required to determine whether or not the difference in difficulty shown by the DIF index is *unfairly* related to group membership. The judgment of fairness is based on whether or not the difference in difficulty is believed to be related to the construct being measured (p. 340).

DIF detection can take place before test administration, using a judging-type procedure (Hambleton and Jones, 1995), but is usually carried out statistically, using empirical data, after the test versions have been administered. Among the main methods employed for this purpose are: delta plot/transformed item difficulty (TID) technique, Mantel–Hanszel, logistic regression,

the item response theory (IRT)-based test, and the simultaneous item bias test (SIBTEST); each method has its advantages (see Holland and Wainer, 1993).

Findings from DIF studies. Generally, translated items tend to vary in terms of the degree of DIF detected. Angoff and Cook (1988) analyzed the equivalence between the Scholastic Assessment Tests (SAT, used for admission to higher education institutions in the USA), and its Spanish-language counterpart, the *Prueba de Aptitud Académica* (PAA). They found that verbal items containing a large amount of text have lower DIF than items containing a small amount of text – where every word is critical and every translation problem has a considerable impact on item characteristics. For example, reading comprehension items have lower DIF than verbal analogies. Conversely, no DIF is expected in nonverbal items such as math or figural items, as noted by Gafni and Melamed (1991). Some studies have listed the possible causes for DIF existing across test versions in different languages. For example, Allalouf *et al.* (1999) studied the translation from Hebrew into Russian of the verbal reasoning domain of the Psychometric Entrance Test (PET, which is used for admission to universities in Israel). They found that DIF is likely to occur if there are differences between source and target language in: (i) word difficulty, (ii) item format, (iii) cultural relevance, and (iv) content.

Implications of DIF studies. Test constructors and translators should be made aware of the results of such studies, and take them into account when adapting a test from one language to another. Such caution will help them to avoid translating items that may have a cultural bias, to seek target-language words of comparable difficulty, to preserve the original item format, and to avoid using content that gives an advantage to one of the language groups.

3. Scoring and linking

Scoring. If the DIF analysis reveals that the psychometric characteristics of certain items have been altered by the translation, these items should not be used for scoring both test versions (source and target). This will make the source and target versions more similar psychometrically, and their scores more comparable.

Before the DIF items are omitted, they should be examined carefully for bias by experts in the subject area, since in very rare cases, as was pointed out by Ellis (1989), there may be real differences in the way a certain language group performs on specific test items – differences rooted in experience, knowledge, or culture. These differences may be considered relevant, and in such cases, the DIF items are not to be omitted from the scoring process.

Linking. An adapted test can be linked to the source-language test even if some items in the target language function differently from the source-language

items. This linking can be achieved by using only the non-DIF translated items as common items (anchor). However, this should be done carefully since deleting too many DIF items can result in an anchor that is too short for equating (see Sireci, 1997).

Perspectives for the Future

In a thought-provoking paper titled ‘Comparing the incomparable’, Wainer (1999) discusses a comparison between groups who took different language versions of a test. In particular, he looks at cases in which there is little overlap in content between the test versions. In such cases, Wainer claims, a fair comparison is actually impossible. Professional test adaptation should avoid such situations. Indeed, sometimes certain test items in one source language cannot be adapted into another language due to irreconcilable cultural or lingual differences. In these cases, some items should be developed in the target language directly. Advances in test adaptation procedures and methodology – based on a large number of studies, including very recent research (e.g., International Test Commission, 2006) – have also helped create new and updated test adaptation standards that take into account new linguistic quality-control methods. Software tools for translation and translation-quality assessment will definitely play an important role in the near future – initially as a rough tool for human translators and later as a more sophisticated aid.

Testing Creativity

M A Runco, California State University, Fullerton, Fullerton, CA, USA; Norwegian School of Economics and Business Administration, Bergen, Norway

© 2010 Elsevier Ltd. All rights reserved.

The study of creativity has become highly objective and scientific over the past 25 years. This increased objectivity has resulted in part from improvements in testing and measurement. These improvements, along with a dramatic increase in the scientific interest in creativity, has been motivated by the nature of creativity: It has innumerable benefits, including those suggested by correlations with various indications of psychological and physical health, and in education, as an objective that can lead to skills (e.g., adaptability, flexible, and original problem solving) that transfer easily to the natural environment. Then there are the benefits for society as a whole. Creativity fuels technological and social progress and evolution. Creativity is associated with discovery, invention, and innovation. It has replaced knowledge and information as the most important commodity for contemporary society and the future.

The fulfillment of creative potential and the enhancement of creative talent, both depend on accurate measurement. The accurate assessment of creative potential and talent is, however, challenging to say the least. Creativity presents several unique measurement problems. There is, for example, no one universally accepted definition of creativity. This has led to a plethora of different kinds of tests and assessments, some of which do not agree with one another. In traditional psychometric terms, the lack of one accepted definition also undermines the construct validity of creativity tests. This is the label given to the interpretation of test results as indicative of a trait, skill, or capacity – in the present case creative talent. As is the case in many definitions of validity, the definition is often formulated as a question. Validity addresses the question, “Are you measuring what you think you are measuring?” The more specific question specifically addressing construct validation is, “Which construct is explained by the test scores?”

The concept of construct validation was broadened in 1999 such that, when possible and directly relevant, information in addition to test scores is taken into account. In fact, the 1999 Standards for Educational and Psychological Testing (APA, 1999) broadened the definitions of all forms of validity. Specifics from particular test questions and content are now to be taken into account, in addition to test scores, for example, and validity decisions are now focused more on the interpretation of scores than on the test scores themselves. It has even been suggested that validity should be treated as a global and unitary concept, which takes what was formerly separated into

construct, content, and criterion-related validities, all into account at once when making psychometric decisions. Clearly, psychometric theory has shifted such that the inferences drawn from tests are the most important and the test scores themselves only one source of information.

Measuring Originality

There is wide agreement on one aspect of creativity, namely originality. Yet, while originality is necessary for creativity, it is by itself not sufficient. Truly creative actions and products also require some sort of effectiveness, fit, appropriateness, or value. Creative things are, at a minimum, both original and fitting. The originality requirement makes measurement especially difficult because it implies that an examinee’s responses on a test may be the most creative when they are unique, novel, unusual, and contrary to norms. In other words, original and therefore creative things are dissimilar to what has come before. Instead of fitting into norms, then, original and creative responses and answers to test questions are uncommon or even unique. This obviously is dramatically different from a test which assesses whether or not an examinee knows what are supposed to be the correct answers. One breakthrough in the field of creativity testing took place when originality was operationalized in terms of statistical infrequency, rarity, or falling outside norms. In this fashion, originality can be measured.

Tests as Samples of Behavior

There are a large number of creativity tests. None of them is perfect, though of course the same thing could be said of just about any test. Assessments and tests are, after all, samples of behavior, and as such they are limited. The more accurate tests have content validity; they provide the most representative samples of behavior, ability, or aptitude. The better the sample, the better is the test. For creativity, the difficulty is that a large range of processes may be relevant. Creativity is typically defined as a syndrome, or complex, for this reason. Most tests focus on one part of the creativity complex (e.g., personality or cognitive capacity), or at most a small set of traits or capacities. They do not, then, sample the range of relevant skills and traits. Not surprisingly, the predictive validity of these tests is moderate at best.

A second difficulty is that creative behavior is typically intrinsically motivated. Interest comes from within the individual rather than from rewards, incentives, bonuses, or other extrinsic factors. Both intrinsic and extrinsic motives can sometimes play a role in creative performances, but the former is typically much more important than the latter. In fact, extrinsic factors can actually inhibit creative performance. They are sometimes distractions and frequently pull the individual's attention away from the tasks and direct that attention towards expectations, schedules, or the reward itself. Sometimes intrinsic motivation diminishes when extrinsic factors are presented to the individual. When this happens, creativity tends to suffer. All of this creates problems for measurement because tests, and their rationale and the feedback provided by the scores, are all extrinsic. Thus an individual can be highly creative when following his or her own intrinsic interests, but the examiner will not uncover that talent because the test is not an intrinsically motivated activity.

Divergent Thinking Tests

Divergent thinking tests are probably the most commonly used estimate of the potential for creative thinking. They can be used to measure originality and can be used in such a way that intrinsic interests are tapped. These are the tests alluded to earlier that take advantage of the rarity of original and creative responses, answers, solutions, and ideas. They are characterized by open-ended questions, which allow an examinee to produce numerous ideas. This is one of the most obvious ways that tests of divergent thinking differ from intelligence tests (IQ tests) and most academic tests. Those tests rely on convergent thinking; there is one or very few correct or conventional answers. The question, "where do we get turpentine" is convergent and typical of IQ tests. (Points are awarded for the answer "a fir tree" but not for any other answer, including "a hardware store".) The question, "in what ways can a brick be used" allows divergent thinking. Many responses can be given. That is a question for the alternative uses test of divergent thinking. Other questions ask about uses for a shoe or coat hanger. The instances test, asks the individual to list things that move on wheels, strong things, or things which are square. The similarities test asks how a grocery store and restaurant are alike, or how a potato and carrot are alike. There are also visual or figural tests, which ask the examinees to list their ideas concerning what an abstract line drawing could represent.

Performance on these tests is usually statistically independent of performance on tests of convergent thinking. The implication is quite significant: If schools rely on tests of convergent thinking, which most do, they will not identify students with notable potential for original

problem-solving and creative talent. Also quite significant is the point that the independence of divergent and convergent thinking seems to depend on the testing environment. There is clear independence when divergent thinking tests are administered in permissive testing environments (which emphasize through test instructions that the students can list multiple ideas and need not worry about spelling, grades, or time limits) but some correlation between divergent and convergent thinking in more traditional testing ones (where there may be time limits and clear expectations for remembering correct answers or factual information). Permissive testing environments minimize the impact of extrinsic constraint and allow intrinsic involvement by the students.

Divergent thinking tests have been modified since they were first developed, and some of the newer tests are designed specifically to allow intrinsic interests. There are, for example, realistic tests of divergent thinking that ask about situations which students might actually encounter in the natural environment. One of these asks students to list possible solutions to a problem of forgotten homework or getting in to trouble by sitting next to a loud uncooperative peer. Other tests allow problem-finding, problem-identification, and problem-generation. These represent processes which have been associated with actual creative performance many times over. In fact, it has been proposed that the quality of a solution depends upon the quality of a problem. Therefore individuals must first find a good problem or they will not find good and creative solutions. Problem-generation tasks present questions such as, "Can you list problems which might be faced by students at your school?" Another is, "List as many problems as you can that might arise between you and your peers." As is the case with all estimates of divergent thinking, these allow multiple ideas and solutions.

The directions given with such tasks will depend on the age of the examinees. Otherwise a verbal bias might keep a creative individual from understanding the task well enough to perform at his or her true level of ability. And that is one goal of testing: to minimize measurement error and thereby obtain scores that are indicative of true ability or true capacity. Recall here the idea in the 1999 Standards for Educational and Psychological Testing that the objective of good testing is to draw useful, accurate, and appropriate inferences.

Tests of divergent thinking have been used with nearly all age groups. Even preschool children can be tested, though not with paper-and-pencil measures. They can be given a tangible stimulus, such as a plastic object, and asked to list all of the ways it can be used or all of the things it might be. Their responses are recorded and, if necessary, transcribed for scoring. Students of all ages can also be tested easily, as can special adult populations (e.g., entrepreneurs) or individuals in late adulthood. Divergent thinking tests are not the final answer in creativity-testing,

but they do have a broad application. They are best viewed as estimates of the potential for creative thinking. They are certainly not synonymous with, nor do they guarantee, actual creative performance.

Creativity, Problem Solving, and Bias

This brings us to another issue in creativity-testing. It involves a relationship between creativity and problem-solving. Divergent thinking tests assume that creativity can be estimated by asking individuals to find and solve problems. Yet, not all creativity involves problem-solving. Some creativity involves self-expression and some is proactive rather than reactive (i.e., a response to a problem).

Then there is the problem of experiential bias. This is a concern with realistic tests. Their realism may make these tests more intrinsically interesting than the more artificial tests, and individuals tend to give more ideas to realistic tests than the other ones. Unfortunately, realistic tests elicit relatively low originality scores. This is probably because of the same kind of experiential bias which plagues IQ testing. With an experiential bias, individuals who have particular experiences rely on their memory of those experiences instead of, or perhaps more often than, using their imagination and generating ideas anew. In an IQ test, for example, an individual might be asked how far Honolulu is from Los Angeles. If the examinee has made that particular trip, he or she may remember how far it was and know the answer. But what if the same examinee, with the same level of intelligence, has not made that trip? Of course, questions like this draw heavily from long-term memory, but that is just another way of saying that there is an experiential bias; it might also be called a memory bias. It is a potential problem for construct validity. However, there is another perspective, a rebuttal which notes that individuals must be intelligent in order to benefit from experience.

All divergent thinking tests are scored for ideational fluency and ideational originality. The first of these is operationally defined as the number of ideas produced. The second is defined in terms of the number of unique or original ideas produced. Occasionally, ideas are judged subjectively for their originality, but of course this introduces the issue of interjudge or interrater reliability. Divergent thinking tests are sometimes scored for ideational flexibility, which represents the number of categories or themes in an individual's ideational pool. There is a fair amount of overlap among these three indicators, but this can be statistically controlled using regression techniques if predictions are being calculated using correlational statistics, or ratio scores might be used. These take fluency or originality and divide by an individual's fluency. The resulting ratio score controls for an individual's productivity. This is especially important because

chances are that the more ideas an individual produces, the more likely it is that he or she will be flexible and find unique or unusual ideas.

The theory of remote associates also justifies ratio scores. It suggests that the best ideas are remote. According to this theory, humans generate ideas along with change, one idea leading to the next, and then to the next. The first ideas we tend to think of are the most obvious, and original and unusual ideas are only found later. They are remote associates. Of course ratio scores have some statistical problems. In particular, ratio scores are often unreliable. They are also hypothetical because they hide an individual's actual ideation. In other words, an individual who produces two ideas, one of which is highly original, will have the same ratio scores as an individual who produces 20 ideas, ten of which are original.

Occasionally, only fluency is used with divergent thinking tests, but this is probably inappropriate given what has been said earlier about originality being the necessary component of creativity. It is probably best to use a profile that includes fluency, originality, and flexibility for any examinee. Other indices have been used, including elaboration and appropriateness. These are not nearly as well understood as fluency, originality, and flexibility, nor as often used. They do have particular applications.

Domain-Specific Assessments

Creativity potential and talents are sometimes assessed within domains, such as art, music, mathematics, and so on. This is an attractive option, given the corpus of research showing that eminent creators tend to work within particular domains and the research, often with students, that they tend to have quite specific creative interests. This can be done in two ways. First, a checklist of activities and accomplishments can be administered. These list different activities within domains and ask the respondent how often they have been involved in each (e.g., painting pictures, taking photographs, and using mathematics in an original way to solve a problem). These checklists often sample several domains, and include a section asking the respondent to briefly describe his or her most impressive project. Although the essay format of this description requires determination of interrater reliability, it does allow a qualitative score to complement the quantitative score provided by the checklist. Checklists such as these may best be viewed as criteria rather than as predictors of creativity since they look back at previous activities and achievements.

A second domain-specific assessment method involves actual creative products. Examinees can be asked to write a poem, for example, to assess linguistic or poetic creativity. They might also be asked to construct a simple collage. Of course, products such as these require an evaluation by

judges, so once again the issue of interrater reliability arises. The consensual assessment technique, developed by Teresa Amabile, is often used with products and tends to have highly reliable ratings. It relies on appropriate judges (who are experts in the domain in question) who each examine and rate products on originality, technical skill, and creativity. Importantly, the assumption is that appropriate judges know what to look for and therefore are not given any definition of creativity.

Personality and Biographical Indicators

Personality tests are sometimes used as estimates of creative talent. Even the MMPI now has a creativity scale; a creative personality scale has long been used as part of the California Psychological Inventory. Several creative personality scales have been developed for the 300-item Adjective Check List. Other tests of personality, including those focused on the Big Five, are sometimes used in creativity research. Of particular relevance within the context of the Big Five is the Openness scale. One advantage of most of these personality assessments is that they can take into account both indicative traits (e.g., openness to experience), which support creative efforts, as well as the contraindicated traits (e.g., conformity), which make creative performance unlikely.

Admittedly, personality assessments are probably not the most impressive estimates of creative talent, in part because the important characteristics vary from creative domain to domain. Additionally, the State X Trait interaction, which characterizes so much of personality psychology, is an issue, the crux of which is that traits vary from situation or context to situation (the state). Therefore, an individual may show the relevant traits in one context, but not in another. For this reason, predictions from personality tests are limited. Of course, personality assessment is one useful source of information. As a matter of fact, this may be the best way to approach the measurement of creativity: recognize that it is a complex syndrome and multifaceted, and therefore, avoid relying on any one assessment.

Biographical measures of creative potential are usually developed by identifying the common background variables of unambiguously creative individuals, and then asking other individuals (on a paper-and-pencil measure) if they have had similar experiences. The Biographical Inventory of Creativity, for example, asks individuals if they had imaginary friends as children, or if their parents took them to museums and other cultural activities. These sorts of things may be relevant; highly creative individuals often do have imaginary friends as children and their parents typically do expose them to diverse cultural activities. The limitation is probably obvious: not all creative people may have the same backgrounds. Additionally, an individual may have an ideal background for creativity but

not be interested in expending the effort to be creative. When this is the case, someone with a creative personality or creative background may not behave or perform in a creative fashion. In psychometric terms, any index of creative personality or background is in this particular situation unlikely to have acceptable predictive validity.

Ratings by Parents, Teachers, or Supervisors

Sometimes it is useful to obtain ratings from parents, teachers, or supervisors. The rationale for this approach is that these groups often have a great deal of information about the individual being rated. The raters may also be more objective than the person himself/herself. Self-reports are open to memory, honesty, and socially desirable responding errors. Of course, raters may not be perfectly objective. Parents, for example, may have a slanted perspective and ratings could easily suffer from halo effects or similar biases. In this example, a halo effect may occur when parents' feelings about their child influence all ratings, across the board. Even if the child is not often original, the parents may think so highly of the child that they give a high rating to originality – and everything else. This may explain why ratings given by parents and teachers do not agree all that much. This is not to say that teachers are entirely objective. They seem to look mostly at characteristics that fit well with the context of a classroom (e.g., being polite and considerate), which makes perfect sense given that they may have 20, 30, or even more children to monitor at any one time.

The Criterion Problem

One of the longstanding difficulties in the area of creativity-testing is referred to as the criterion problem. This is a huge problem because tests must have criterion-related validity. They should, for example, be able to predict certain criteria (those positively related to the construct in question) but also be unrelated, or perhaps negatively related, to constructs, which should be independent. As an example of the latter, which is discriminant validity, creativity test scores should not be strongly related to traditional intelligence and the IQ. If they are strongly related, it is likely that the creativity test is merely testing traditional intelligence.

There are no widely accepted criteria of creative potential and creative talent. As a matter of fact, there is a kind of circularity here because if there was a widely accepted criterion of creative performance, it might be used instead as a predictor! That line of reasoning does not apply to one kind of criteria, namely those that are unambiguous, such as the actual creative performances of

established creators (e.g., Nobel laureates or award-winning artists). Some measures start by selecting a particular domain and then identifying individuals who are performing at a very high level and are ambiguously creative within this domain. Their backgrounds may then be examined with the hope that predictors can be identified and used to select up-and-coming creative persons. There is, however, yet another kind of sampling concern with this method. If this kind of methodology is used to find a predictor of creative talent, only mature and fulfilled potential will be measured. In other words, the predictors used in the biographical or other predictive measures will only reflect that which was important for individuals who have everything going for them and already perform at a highly creative level. What predicts their performance may not help us to identify individuals who are merely potentially creative. There is a big difference between mere potential and actual manifest performance. For this reason, measures developed with this kind of retrospective method may not be useful when working with children or in gifted and talented educational programs. In both of those cases, the interest may be a measure of creative potential rather than creative productivity.

Conclusions

Not surprisingly, several psychometricians have concluded that creative thinking must be used by examiners when attempting to develop creativity tests or attempting to

measure creative talent and creative potential. Standard measurement techniques often do not apply to creativity. It poses several unique challenges for psychometricians, especially because originality is necessary but not sufficient and thus norms cannot be used as they are with other tests.

As is the case with all good scientific work, it is best to start with a sound theory. In the case of creativity, this means accepting the notion that it is a syndrome or complex and that no one measure captures all kinds of performance (e.g., all domains). It is probably best to triangulate and employ more than one measure. Even then, the intrinsic interests of examinees must be taken into account, as should the idea that individuals who have manifest creative talents may have something that differs from what we see in individuals who have mere potential and need encouragement for its fulfillment. As a matter of fact, it is these individuals with potential in need of fulfillment who probably will benefit the most from accurate testing.

Testing in History

S Wineburg and B Fogo, Stanford University, Stanford, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

In 1917, the year the United States went to war, history erupted onto the pages of the American Psychological Association's *Journal of Educational Psychology* (Bell, 1917). J. Carleton Bell – the *Journal's* managing editor and professor at the Brooklyn Training School for Teachers – began his tenure with an editorial entitled 'The historic sense'. Bell claimed that the study of history provided an opportunity for thinking and reflection – qualities lacking in many classrooms.

In a companion article, Bell and his colleague, David F. McCollum, presented the first empirical report of achievement testing in history. The authors put forth five ways in which the elusive historic sense might be defined:

1. The ability to understand present events in light of the past.
2. The ability to sift through the documentary record – newspaper articles, hearsay, partisan attacks, contemporary accounts – and construct "from this confused tangle a straight forward and probable account" of what happened, a goal they pointed out of many "able and earnest college teachers of history" (Bell and McCollum, 1917).
3. The ability to appreciate a historical narrative.
4. "Reflective and discriminating replies to 'thought questions' on a given historical situation" (Bell and McCollum, 1917).
5. The ability to answer factual questions about historical personalities and events.

The authors conceded that this fifth aspect was "the narrowest, and in the estimation of some writers, the least important type of historical ability" (Bell and McCollum, 1917). At the same time, they acknowledged it was this aspect that was "most readily tested." In a move that would seal the fate of achievement testing in history in North America for much of the twentieth century, Bell and McCollum elected the path of the "most readily tested." Of their five possibilities only one – the ability to answer factual questions – was chosen for study. While perhaps the first instance, this was not the last in which ease of measurement – not priority of subject matter understanding – determined the shape and contour of an achievement test in history.

Bell and McCollum administered their test to 1500 Texas students in 1915–16. The overall score at the elementary level was a dismal 16%. In high school – following a year of history instruction – students scored a shabby

33%, and, in college – following then a third exposure to history – scores barely approached the halfway mark (49%). The authors concluded that studying history in school led only to "a small, irregular increase in the scores with increasing academic age." Bell and McCollum blamed the educational system and its charges: "Surely a grade of 33 in 100 on the simplest and most obvious facts of American history is not a record in which any high school can take pride" (Bell and McCollum, 1917).

By the next world war, hand-wringing about students' historical benightedness had moved from the back pages of the *Journal of Educational Psychology* to the front pages of the *New York Times*. "Ignorance of U.S. History Shown by College Freshmen" trumpeted the headline on 4 April 1943 – a day when the main story reported that Patton's troops had overrun Field Marshal Erwin Rommel at El Guettar. Providing support for Allan Nevins's claim that "young people are all too ignorant of American history" (*New York Times Magazine*, May 3, 1942), the survey showed that a scant 6% of the 7000 college freshman could identify the 13 original colonies. Often, students were simply confused. Abraham Lincoln "emaciated the slaves" and, as first president, was father of the Constitution. A *Times* editorial excoriated these "appallingly ignorant" youth. "Either the college freshman, recently out of high school, were poorly prepared on the secondary level," surmised *Times* reporter Benjamin Fine, "or they had forgotten what they learned about United States history" (*New York Times*, 4 April 1943). In either case, the survey revealed a "vast fund of misinformation on many basic facts" among American youth (Fine, 1943).

Hand-wringing over students' lack of historical knowledge resurfaced in time for the US bicentennial celebration in 1976. With the aid of the Educational Testing Service (ETS), the *Times* tested nearly 2000 freshmen on 194 college campuses. On 2 May 1976, the results rained on the bicentennial parade: "*Times* Test Shows knowledge of American History Limited." Of the test's 42 multiple-choice questions, students averaged 21 correct – a failing score of 50%.

Results from the 1987 and 1994 administrations of the National Assessment of Educational Progress (NAEP; known informally in the US as the nation's report card) have shown little deviation from these earlier trends (Ravitch and Finn, 1987; NAEP, 1996). The 2001 NAEP administration serves as a case in point. In its wake came the same stale headlines: "High School Seniors Flunk History," (Fletcher, 2002; *Washington Post*, May 9,

2002); “Kids Get ‘Abysmal’ Grade in History: High School Seniors Don’t Know Basics,” *USA Today* (2002) (May 10–12, 2002); the same refrains of cultural decline (“a nation of historical nitwits” wagged the Greensboro [North Carolina] *News and Record*, 13 May 2002); the same holier-than-thou indictments of today’s youth (“dumb as rocks” hissed Lee Bockhorn in the *Weekly Standard*, 13 May 2002); and the same boy-who-cried-wolf predictions of impending doom (“when the United States is at war and under terrorist threat” young people’s lack of knowledge is particularly dangerous, according to *Palm Beach Post*, 10 May 2002). Scores on the 2001 test – significant in that they came after a decade of the Standards Movement – were virtually identical to their predecessors. Six in ten seniors “lack even a basic understanding of American history,” wrote the *Washington Post* – results that NAEP officials castigated variously as “awful,” “unacceptable,” and “abysmal” (reported in *USA Today*, 10–12 May 2002).

Pointing to the 2001 NAEP results, the Albert Shanker Institute claimed in their blue-ribbon report that “something has gone awry . . . We now have convincing evidence that our students are woefully ignorant of who we are as Americans,” indifferent to “the common good” and “disconnected from American history” (Albert Shanker Institute, 2003, emphasis added). All told, such trends among youth point to a perilous “loosening from our heritage” (Albert Shanker Institute, 2003).

One wonders what evidence this committee now possessed that had not been gathering moss since 1917 when Bell and McCollum hand-tallied 1500 student test-sheets. Explanations of today’s low scores wither when applied to results from 1917 – history’s apex as a subject in the school curriculum. No one can accuse those Texas teachers of teaching process over content or serving up a tepid social studies curriculum to bored students – the National Council for the Social Studies did not even exist at the time. Instead of being poorly trained and laboring under harsh conditions with scant public support, these Texas pedagogs were among the most educated members of their communities and commanded wide respect.

There is something almost comic in the ritual display of young people’s historical ignorance – a phenomenon not unique to the US, with abundant parallels in Canada, Great Britain, Australia, Israel, and many other nations. Each generation feels compelled to wag its finger at its youth, all the while forgetting that only a few years back it too was the target of adult scorn. Indeed, Dale Whittington has shown that when results from the early part of the twentieth century are put side by side with the most recent tests, US students do about as well as their parents, grandparents, and great-grandparents (Whittington, 1991). That is a remarkable finding when we compare current near-universal enrolments of today with the elitist composition of the high school in their teens and early 20s.

Young people’s knowledge hovers with amazing consistency around the 40–50% mark despite radical changes in the demographics of test-takers across the centuries.

Instead of rehearsing the ritual of giving kids a test only to find out that they do not know what adults think they should know, we might, instead, raise basic questions about the ability of 17- and 18-year-olds to memorize and retain volumes of discrete, decontextualized factual information – the stuff which, since 1917, has largely defined the substance of achievement testing in history in the US. With the exception of the Advanced Placement examination – geared to a small proportion of college-bound students – multiple-choice tests have dominated large-scale achievement testing in history, despite the fact that written expression – the arrangement of facts into narrative and argument – is at the heart of the historical process.

What happened to the once-prized historical essay? To some extent, it fell victim to a psychometric culture that privileged exactness and objectivity of scoring over deep reflection on the nature of thinking and achievement in the discipline (cf., Stake, 2007). Consider a 1930 study by F. R. Gorman and D. S. Morgan, who argued that having students write essays in history produced “as much harm as it does good.”

The study was conducted in three US history classrooms. These classes – all taught by the same teacher – were assigned different amounts of written homework. Class I was assigned three units, Class II one unit, and Class III none at all. Indeed, Class III did best on the factual outcome measure (181 points vs. 175 for Class I), but the authors failed to account for the wide disparity in the entering achievement levels among students. Moreover, the researchers’ homework assignments often looked more like directions for busy work than for composing thoughtful written responses (e.g., “List Lincoln’s cabinet with the offices held by each”; “List the states which seceded in order, with the dates of secession”). When Gorman and Morgan (1930) concluded that “the popularity of written work with teachers may result from a confusion of busy work with valid learning procedures,” one wonders where the confusion truly lay: with muddled teachers or with zealous researchers determined to demonstrate the ineffectiveness of written assignments?

Advances in psychometrics fueled the movement toward objective testing, as did the spirit of Taylorism that swept American schools between the world wars (Callahan, 1962). However, it would be wrong to see the focus on objective testing as a movement restricted to education and advances in psychometrics. The fact-based image of historical knowledge fit cozily with prevailing views of knowledge in the discipline of history in the 1920s and 1930s. As educational psychologists worked to produce reliable and objective history scales, university historians tried to extricate themselves from their humanistic roots

in order to emerge as scientists who would, as the saying went, “cross an ocean to verify a comma” (Novick, 1988). This doggedly factualist approach – as Peter Novick argued in *That Noble Dream* (1988) – helped distinguish professional historians from their amateur colleagues – a distinction necessary if history was to become a full-fledged member of the academic community. It is no coincidence, then, that, at nearly the same time, Sackett (1919) was presenting his refinement of a world history scale in the pages of the *Journal of Educational Psychology* – a scale that would “nearly eliminate the subjective factor in grading history,” (p. 348), the *American Historical Review’s* editorial policy was being formulated to exclude from its pages “matters of opinion” in favor of “matters of fact capable of determination one way or another” (cited in Novick, 1988).

The Standards Movement

Forms of testing that focused on low-level knowledge and discrete facts were supposed to become obsolete with the advent of standards – a movement that, according to one of its founders, Mark Tucker, would bring us back to asking the most fundamental questions with regard to what students should learn (Tucker and Coddling, 2002). The new goal was not to shake out a grade, to invent items that discriminated among students, but to establish a set of core understandings that all students should attain. In the remainder of our article, we provide an overview of what has happened to the grand promise of standards – and the changes they were supposed to effect on achievement testing – in the most populous state in the union, California.

Indeed, it was in California that the first standards in history/social science were adopted. They originated in the *History–Social Science Framework for California Public Schools*, passed by the State Board of Education in 1987. The *Framework* initiated a new era in state-mandated history–social studies curriculum. It departed from traditional social studies curricula by presenting the study of chronological history in order to develop literacy across the social sciences, to promote civic values, and to nurture critical thinking. The *Framework* increased the amount of history in the elementary grades and mandated sequences of American history for grades 5, 8, and 11 and world history in grades 6, 7, and 10. It was more than twice the size of the state’s previous social science framework and consisted primarily of course descriptions for each grade level – narrative summaries detailing the different units, themes, events, people, and skills covered during the year. As noted in the *Framework’s* preface, these guidelines were designed to help align course content with textbooks, instructional materials, staff development, and testing throughout the state.

In 1998, as a result of national and state legislation calling for the creation of content standards and assessments in core academic subjects, the California Department of Education adopted the *History–Social Science Content Standards for California Public Schools*. As Delaine Eastin, state superintendent of Instruction, and Yvonne Larsen, president of the State Board of Education, explained on page iv: these standards aligned with the *Framework* and “explicitly” defined “the content that students need to acquire at each grade level from kindergarten to 12th grade” (California State Department of Education, 2001). The content standards supplemented the *Framework’s* course descriptions with hundreds of specific historical skills and items. For example, in the 7th grade, students would, in accordance to standard 7.6.8:

Understand the importance of the Catholic church as a political, intellectual, and aesthetic institution (e.g., founding of universities, political and spiritual roles of the clergy, creation of monastic and mendicant religious orders, preservation of the Latin language and religious texts, St. Thomas Aquinas’s synthesis of classical philosophy with Christian theology, and the concept of “natural law”). (California State Department of Education, 1998: 30)

In a nod to local control, the Department of Education stressed that: “The standards include many exemplary lists of historical figures that could be studied. These examples are illustrative. They do not suggest that all of the figures mentioned are required for study, nor do they exclude the study of additional figures that may be relevant to the standards” (California State Department of Education, 1998: vi).

In addition to specifying historical content, the standards also defined analysis skills for students to develop across grade levels. These standards were divided into three categories: Chronological and Spatial Thinking, Research, Evidence, and Point of View, and Historical Interpretation, and split into three levels: 12 analysis standards for grades K–3, 14 for grades 6–8, and 14 for grades 10–12. In 2001, the State Board of Education integrated the content and analysis standards into the *History–Social Science Framework*.

As part of the Standardized Testing and Reporting (STAR) Program implemented in 1998, the California Department of Education initially used the national, norm-referenced Stanford 9 tests to assess the history–social science knowledge of the state’s 9th, 10th, and 11th graders. In the spring of 2001, the Department began introducing the California Standards Tests (CSTs) for history–social science, developed by the Educational Testing Service (ETS) and aligned specifically with the *Framework’s* content and analysis standards. At present, students take these exams at the end of 8th, 10th, and 11th grades. The 8th-grade exam consists of 75 multiple-choice questions covering the standards for grades 6–8,

while the 10th- and 11th-grade tests each include 60 multiple-choice questions to assess the 10th- and 11th-grade standards, respectively. These tests are relatively low stakes. They do not figure into a school's accreditation or a student's graduation status; however, their results are published and do account for approximately 10–15% of a school's Academic Performance Index (API) – a state measure of school progress that is tied to certain rewards and consequences.

The CSTs exemplify many shortcomings of relying exclusively upon multiple-choice tests to measure student historical knowledge. For example, their alignment with the state's history standards is questionable. All of the items on the CSTs relate to specific standards, yet few of the questions begin to capture the breadth of each standard's historical content. In 2005, for example, content standard 6.7.8 – “Discuss the legacies of Roman art and architecture, technology and science, literature, language, and law” (California State Department of Education, 1998: 26) – was measured by the following question:

The origins of checks and balances in the United States can be traced to:

- a. the French Republic
- b. the Roman Republic
- c. the Greek Aristocracy
- d. the Aztec Empire. (California State Department of Education, 2007a: 18)

Furthermore, where the vast majority of the content standards call for students to analyze, explain, understand, discuss, describe, and examine, most of the test questions push students to do little more than recognize and associate. For example, consider content standard 11.5.2:

Analyze the international and domestic events, interests and philosophies that prompted attacks on civil liberties, including the Palmer Raids, Marcus Garvey's “back-to-Africa” movement, the Ku Klux Klan, and immigration quotas and the responses of organizations such as the American Civil Liberties Union, the National Association for the Advancement of Colored People, and the Anti-Defamation League to those attacks. (California State Department of Education, 1998: 49)

Compare this standard with a test-item used to measure student knowledge of it on the 11th-grade CST in 2003:

Marcus Garvey's program in the 1920s emphasized:

- a. vocational training
- b. a back-to-Africa movement
- c. integration into mainstream society
- d. separate-but-equal doctrines. (California State Department of Education, 2007c: 14)

Such examples illustrate the pitfalls of using multiple-choice test questions to assess the complex thinking

processes called for by California's history standards. This tenuous alignment is perhaps most evident in how the CSTs measure the *Framework's* analysis skills standards.

In 2004, analysis skill HR4 (Grade 10) – “Students construct and test hypothesis; collect, evaluate, and employ information from multiple primary and secondary sources; and apply it in oral and written presentations” (California State Department of Education, 1998: 40) – was assessed on the 10th-grade test with the following multiple-choice item:

The streets were hot and dusty on the summer day. Stokers emerged from low underground doorways into factory yards, and sat on steps, on posts, and palings, wiping swarthy visages, and contemplating coals. The whole team seemed to frying in oil. There was the stifling smell of hot oil everywhere.

–Charles Dickens, *Hard Times*, 1854

The historical era most likely referred to in this quotation is the:

- a. Industrial Revolution
- b. Great Awakening
- c. French Revolution
- d. Enlightenment. (California State Department of Education, 2007b: 11)

These questions – like many others on the CSTs – appear to suffer from two sources of invalidity defined by Messick (1995): “construct under-representation” and “construct irrelevant variance.” Where the former features an assessment that “fails to include important dimensions or facets of a construct,” the latter describes test-items that are too general and may measure something other than the target skill or understanding. Both sources of invalidity increase the likelihood of false positives where students are deemed proficient on standards that they may not begin to comprehend.

Beyond the skill mismatch and content under-representation of individual test-questions and standards, other alignment and validity issues characterize the problematic relationship between the CSTs and the *History–Social Science Framework*. Many of the questions on the CSTs feature the historical figures and events that the *History–Social Science Content Standards* claimed were merely “illus-trative” of what teachers might choose to focus on when teaching the standards. For example, in 2006, the 11th-grade test measured content standard 11.7.3 – “Identify the role and sacrifices of individual American soldiers, as well as the unique contributions of the special fighting forces (e.g., the Tuskegee Airmen, the 442nd regimental Combat team, the Navajo Code Talkers)” (California State Department of Education, 1988: 50) – with this question:

During World War II, what was the primary duty of the Navajo Code Talkers?

- a. interpreting confiscated German battle plans
- b. transmitting secret messages to U.S. forces during combat
- c. translating confidential Japanese communications
- d. informing the press about the number of Allied war casualties. (California State Department of Education, 2007c: 16)

Such questions make the history standards far less suggestive and much more prescriptive. They hold teachers and students accountable for the hundreds of figures, groups, events, and phenomena included in the standards and increase the pressure to cover wide expanses of history in short periods of time – a dilemma that approaches the absurd in the case of the 8th-grade test which – by covering the 6th, 7th and 8th-grade standards – measures student knowledge of history from the Paleolithic era to World War I. In so doing, the CSTs run the risk of reducing California's *History–Social Science Framework* to little more than a long list of historical facts for memorization. In this sense, little has changed in the 100 years between Bell and McCollum's test and the 2007 administration of California's STAR test. Then, as now, the real losers are the students.

None of the Above

The dilemmas we face today in assessing young people's knowledge differ little from earlier efforts. Few historians would argue that large-scale multiple-choice tests capture the range of meanings we attribute to the historic sense. Indeed, we continue to use these tests, and will do so in the future, not because they are historically sound or because they predict future engagement with historical study. They endure for the simple reason that they can be read by machines that produce easy-to-read graphs and bar charts. These tests comfort us with the illusion of systematicity – not to mention that scoring them costs a lot less than the alternatives.

A century of achievement testing has taught us time and again that light-rail excursions through mounds of factual information may be entertaining, but such dizzying tours leave few traces in memory. The human mind demands pattern and form, and both are built up slowly and require repeated passes – with each pass going deeper and probing further. If we want young people to know more history, we need to draw on a concept from medicine: triage. As the University of Tennessee's Wilfred McClay (cited in Albert Shanker Institute, 2003) explains,

Memory is most powerful when it is purposeful and *selective*. It requires a grid, a pattern of organization, a structure within which facts arrange themselves in a particular way, and thereby take on significance. Above all, it requires that we possess stories and narratives that link facts in ways that are both meaningful and truthful, and

provide a principle of selection – a way of knowing what facts are worth attending to We remember those things that fit a template of meaning, and point to a larger whole. We fail to retain the details that, like wandering orphans, have no connection to anything of abiding concern The design of our courses and curricula must be an exercise in *triage*, in making hard choices about what gets thrown out of the story, so that the essentials can survive We need to be willing to identify those things that every . . . student needs to know and insist upon them . . . while paring away vigorously at the rest.

Mechanical testing tempts us with the false promise of efficiency – a lure that whispers that there is an easier, less costly, more scientific way. However, the truth is that the blackening of circles prepares students only to blacken more circles in the future. The future belongs to those who know how to think, how to write, how to analyze, and how to critique. When those responsible for writing our history achievement tests realize this, perhaps achievement will truly take place.

Validity

R L Linn, University of Colorado at Boulder, Ouray, CO, USA

© 2010 Elsevier Ltd. All rights reserved.

Validity is the most important consideration in the evaluation of the interpretations of educational assessment results and the uses that are made of those results. Although references are often made to the validity of an assessment, it should be understood that it is the uses, interpretations, and claims about assessment results that are validated.

Validity is a matter of degree rather than an all-or-none characteristic and the degree of validity varies from one interpretation or use to another. One use of assessment results may have a high level of validity, while another use could have modest validity, and a third use might have little or no validity. For example, an assessment might be a relatively good predictor of grades in college and thus yield predictions that have good validity; however, the same assessment might have little validity as a measure of student learning in high school. Another assessment might be a highly valid measure of the content covered in a course, yet have inadequate validity for determining whether or not students should graduate from high school. Thus, it is inappropriate to say that an assessment is valid or invalid. Instead, validity should be evaluated for the particular uses and interpretations that are made of the results; and judgments must be made to determine whether the degree of validity is adequate for a particular purpose.

Guidance on the conduct of a validation program is available from several sources. Perhaps the most notable of these is the *Standards for Educational and Psychological Measurement* (American Educational Research Association *et al.*, 1999) jointly developed by the American Educational Research Association, the American Psychological Association, and the National Council on Measurement in Education, hereafter referred to as the *Test Standards* (The three associations responsible for the *Test Standards* recently decided that it is time to revise the *Test Standards* once again and have appointed Barbara Plake and Laurens Wise as co-chairs of the revision committee. Although the revision will introduce changes and new ideas, the conceptualization of validity has evolved gradually from one edition of the *Test Standards* to the next. Hence, it seems unlikely that the revised *Test Standards* will make fundamental changes in the conceptualization of validity.) Several revisions of the *Test Standards* have been published over the last half century. Each revision of the *Test Standards* provides a statement of a broad professional consensus regarding expectations for the evaluation of the adequacy of interpretations of assessments under a wide range of uses at the time a given edition of the *Test Standards* was published.

Evolution of Conceptualizations of Validity

As can be seen either by reviewing the various editions of the *Test Standards* or by an analysis of the writing of leading measurement experts and validity theorists in major publications such as the four editions of *Educational Measurement*, the concept of validity has evolved over time. Until the early 1950s, validity was generally equated either with the relationship of test scores to an external criterion measure or with the degree to which a test measured what it was intended to measure. Correlations between test scores and criterion measures were used to support the first of these interpretations of validity. Analyses of the content covered by the test in relationship to the content domain that the test was intended to measure were used for the second interpretation.

The two notions of validity that were prevalent in the early 1950s were referred to as predictive validity and content validity. More recent conceptualizations of validity have rejected the notion of different types of validity and, instead, have espoused a unified approach to validity that distinguishes different categories of evidence that are relevant to reaching an overall evaluation of validity of particular interpretations and uses of assessment results.

An expanded view of validity was articulated in the first edition of the *Test Standards* which were then called *Technical Recommendations for Psychological Tests and Diagnostic Techniques* (American Psychological Association, 1954). These recommendations still referred to types of validity, but went beyond the two types of predictive and content. Four types of validity – content, concurrent, predictive, and construct – were described in the *Technical Recommendations for Psychological Tests and Diagnostic Techniques*. Concurrent validity was only a slight variation of the prevailing predictive validity which distinguished between correlations of a test with a criterion measure where the latter measure was obtained at nearly the same time rather than at some later point in time and, subsequently, concurrent and predictive validity got subsumed under the heading criterion-related validity. Content validity also represented a perspective on validity that was familiar at that time, particularly with regard to educational achievement tests. Construct validity, on the other hand, was a relatively new idea when introduced in the 1954 *Technical Recommendations for Psychological Tests and Diagnostic Techniques*. Notions of construct validity that were introduced in the *Technical Recommendations*

were elaborated more fully by the following year in a classic article by Cronbach and Meehl (1955), both of whom were members, with Cronbach as chair, of the committee that developed the *Technical Recommendations for Psychological Tests and Diagnostic Techniques*.

The work by Cronbach and Meehl (1955) had a lasting impact on subsequent thinking about and discussions of validity. Although construct validity was initially thought to be more relevant to the assessment of psychological characteristics, such as anxiety or extroversion, than to the assessment of educational achievement, it gradually came to be widely accepted as relevant to assessments of educational achievement. The acceptance of construct validity came about, in part, because leading measurement theorists continued to promote the concept of construct validity (see, e.g., Cronbach, 1971) and, in part, because they illustrated how it could be made more practical and how construct validity considerations necessarily entered into an evaluation of the uses and interpretations of any assessment. Cronbach's (1971) emphasis on the validation of interpretations of assessment results laid the foundation for more of a unitary view of validity and the subordination of content-related and criterion-related evidence to a construct validity perspective.

By the time the fourth edition of the *Test Standards* (American Educational Research Association *et al.*, 1985) was published, this view of validity had become dominant. "The concept [of validity] refers to the appropriateness, meaningfulness, and usefulness of the specific inferences that are made from test scores. Test validation is the process of accumulating evidence to support each inference" (American Educational Research Association *et al.*, 1985: 9). Shortly after the publication of the 1985 *Test Standards*, however, Messick (1989) argued that the *Test Standards* had not gone far enough in moving toward a unified view of validity in which notions of construct validation were paramount.

Messick's (1989) chapter began with the following definition. "Validity is an integrated evaluative judgment of the degree to which empirical evidence and theoretical rationales support the **adequacy and appropriateness of inferences and actions** based on test scores or other modes of assessment" (Messick, 1989: 13, emphasis in original). Messick elaborated his definition of validity in a two-by-two table corresponding to the adequacy/appropriateness and inferences/actions distinctions of the definition. The rows of the table distinguished two types of support for validity claims – the evidential basis and the consequential basis that are used to support claims of adequacy and appropriateness. The two columns of the table distinguished between interpretations of assessment results (e.g., 55% of the fourth-grade students are proficient in mathematics) and uses of results (e.g., award of a high school diploma). Although uses generally related to interpretations, implicitly

if not explicitly, the uses involve actions of some type whereas interpretations may not.

Contemporary Conceptualizations of Validity

The chapter on validity in the 1999 *Test Standards* continued the trend apparent in the earlier *Test Standards* and in the chapters on validity in the second and third editions of *Educational Measurement*. The discussion of validity in the *Test Standards* begins with a concise definition of validity. "Validity refers to the degree to which evidence and theory support the interpretations of test scores entailed in the uses of tests. Validity is, therefore, the most fundamental consideration in developing and evaluating tests" (American Educational Research Association *et al.*, 1999: 9). Identifying the types of evidence that are most relevant to evaluating interpretations and uses of an assessment logically depends on the proposed uses and interpretations of the assessment results. Thus, it is important to begin with "an explicit statement of the proposed interpretation of test scores, along with a rationale for the relevance of the proposed interpretation to the proposed use" (American Educational Research Association *et al.*, 1999: 9). The 1999 *Test Standards* do not identify different types of validity. Rather they conceive of validity as a unitary concept, but acknowledge that several types of evidence may be germane to the development of a coherent validity argument.

Kane's (2006) chapter on validity in the most recent edition of *Educational Measurement* presents a conceptualization of validity that builds upon the evaluative approach that was articulated by Messick (1989) and in the 1999 *Test Standards*. Kane conceptualized validation as the process of developing two types of argument that he calls the interpretive argument and the validation argument. The "interpretive argument specifies the proposed interpretations and uses of test results by laying out a network of inferences and assumptions leading from the observed performances to the conclusions and decisions based on the performances" (Kane, 2006: 23). The evaluation of the interpretive argument is called the validation argument. The validation argument brings evidence and logical analysis together for the purpose of evaluating the claims and propositions of the interpretive argument.

A systematic analysis of the various uses, interpretations, and claims that are made about assessment results is needed to develop a comprehensive validation program for an assessment. An interpretive argument needs to be developed for each interpretation and the uses entailed in a particular interpretation. Kane (2006) proposes that interpretive arguments be judged in terms of their clarity, coherence, and plausibility. The interpretive argument

can be used to guide the collection of evidence relevant to the particular interpretations, and claims used to support uses of the assessment results, and that evidence needs to be accumulated and organized into relevant validity arguments (Kane, 2006).

Validity Evidence

The 1999 *Test Standards* identify five major “sources of evidence that might be used in evaluating a proposed interpretation of test scores for particular purposes” (American Educational Research Association *et al.*, 1999: 11). These are:

1. evidence based on test content,
2. evidence based on response processes,
3. evidence based on internal structure,
4. evidence based on relations to other variables, and
5. evidence based on consequences of testing.

Evidence Based on Content

An important source of validity evidence is based on the content of an assessment. It begins with the definition of the construct to be measured and the specification of the content for the assessment. Logical analyses and empirical evidence regarding the alignment of the assessment with the content domain that the assessment is intended to measure can provide critical support for a validity argument. Judgments regarding the content of the assessment and its relationship to the content specifications made by independent experts can buttress a validity argument. Experts can also be useful in evaluating the relationship of both the content specifications and the content of the assessment to the construct.

Although content-based evidence is valuable, it rarely, if ever, provides a sufficient basis for a validity argument. Content-based evidence addresses questions of content representativeness and relevance, but does not address questions about assessment scores or the interpretation of those scores. Thus, in most cases, content-based evidence will play only a limited role in the overall validity argument (Kane, 2006: 19).

Evidence Based on Response Processes

Interpretations of assessment results often involve inferences about the mental processes that individuals use when responding to an assessment. For example, an assessment may be interpreted as a measure of a person’s reasoning or problem-solving skills. An issue is the degree to which such interpretations are valid. One approach to obtaining evidence about response processes is to question respondents to assessments about the strategies they used to respond to problems posed by the assessment.

Think-aloud protocols are also used as a means of obtaining evidence about the nature of the response processes during the assessment.

Evidence Based on Internal Structure

Internal analyses can provide evidence of the degree to which the internal structure of the assessment is consistent with proposed interpretations. If several distinct components comprise the construct, then an internal analysis should provide evidence that those components can be distinguished and that they can be combined in ways that are consistent with the hypothesized construct. For example, a mathematics assessment might be intended to measure number sense, algebraic operations, measurement concepts, and geometric relations. An internal analysis that provided evidence that those four dimensions could be reliably distinguished would support the validity of the intended interpretation of the assessment scores. On the other hand, an internal analysis of an assessment of reading that was conceived of as measure of a single dimension should provide evidence of a single major dimension with a high level of internal consistency.

Evidence Based on Relations to Other Variables

Correlations with criterion measures that an assessment is intended to predict are obviously relevant to an evaluation of the validity of an assessment. If an assessment is intended to predict the success in college, for example, then correlations with the grades that students earn in college as well as other measures of success in college provide direct evidence regarding the degree to which the assessment is functioning as intended. However, relations to criterion measures are not the only relations that are relevant.

Relations to other measures of the construct that an assessment is intended to measure provide convergent evidence that supports the validity of the assessment. Relations to measures that are designed to measure different constructs are also relevant. For example, finding that scores on an assessment of mathematical reasoning have higher correlations with other measures of mathematical skills and reasoning than with measures of reading would provide both convergent and divergent evidence of validity.

Evidence Based on Consequences of Testing

The *Test Standards* address the issue of consequences in validation of interpretations and uses of assessment results. After noting that assessments are “commonly administered in the expectation that some benefit will be realized from the intended use of the scores” the *Test Standards* go on to conclude that a “fundamental purpose of validation is to indicate whether these specific benefits are likely to

be realized” (1999: 16). The role of consequences as in the validation has been a source of controversy among measurement experts for a number of years.

Although the inclusion of consequences as part of validation is controversial, Kane (2006: 54) has recently noted there is, in fact, nothing new about giving attention to consequences in investigations of validity. What is relatively new is the salience of the topic and the breadth of the reach that is no longer limited to immediate intended outcomes (e.g., students perform better in classes following the use of a placement test). The inclusion of broader social consequences and the inclusion of unintended as well as intended consequences led to objections by some measurement experts.

The objections that some measurement experts have to the inclusion of consequences in the evaluation of validity have more to do with the question of whether consequences should be a part of validity than they do with the question of whether or not consequences are relevant to an evaluation of a use or interpretation of assessment results. There is broad consensus regarding the importance of investigations of consequences as part of the overall evaluation of particular interpretations and uses of assessment results; however, some authors have maintained that such an evaluation is outside the scope of validity.

Intended consequences of educational assessments often include such outcomes as improved teacher and student motivation and improved student achievement. The collection of evidence regarding such intended consequences of a use of an assessment may involve the use of teacher and student questions, observations, interviews, and/or historical records of student achievement. It is important to look for plausible unintended consequences, such as increased teacher stress and increased student dropout, as well as intended consequences.

An Alternate View

Although the conceptualization of validity articulated in the *Test Standards* represents the prevailing view among measurement experts, there is no universal agreement. As was already mentioned, there is disagreement among experts about the treatment of consequences of the uses of assessment results. A few measurement experts also object to the notion that it is the particular uses and interpretations of assessment results that are validated, rather than the assessment itself.

The November 2007 issue of *Educational Researcher* featured an article by Lissitz and Samuelsen (2007) that proposed an alternative conceptualization of validity that departs in radical ways from the view espoused in the last two editions of the *Test Standards* and in the chapters on validity in the last three editions of *Educational Measurement* by Cronbach (1971), Messick (1989), and Kane (2006).

Lissitz and Samuelsen argue that content considerations are the core of validity. Rejecting the idea that validity depends on the uses and interpretations of assessment results, they argue that validity is (1) a property of an assessment and (2) is determined by evidence related to internal characteristics of content, reliability, and latent processes. Relationships to other variables and considerations of the consequences of assessment uses and interpretations are seen as relevant to an evaluation of the assessment; however, Lissitz and Samuelsen believe that such external considerations are outside the realm of validity.

The Lissitz and Samuelsen article is useful for calling attention to the importance of content, response process, and internal structure considerations; however, as is clear from the analyses by five well-known measurement specialists who wrote responses to that article, considerations of content, response processes, and internal structure do not provide a sufficient basis for evaluating the validity of assessments. Evidence based on content, response processes, and internal structure that are emphasized by Lissitz and Samuelson is clearly important, but the meaning, and hence the interpretation, of assessment results requires a more unified approach to validity that includes the consideration of constructs and relationships to other variables. Validity is best thought of as dependent upon the uses and interpretations of assessment results rather than as a property of the assessment independent of the uses that made be the results or the ways in which assessment results may be interpreted.

Summary

Validity is the foremost consideration in the evaluation of the uses and interpretations of assessment results. It is the interpretations and uses that are validated rather than the assessment itself. Validation begins with the identification of the intended interpretations and uses of assessment results. The identified interpretations can be used to develop interpretive arguments that guide the accumulation of evidence needed to support those interpretations. The evidence can then be organized into a coherent and persuasive validity argument that supports the interpretations and uses of assessment results.

A variety of types of evidence may be relevant to the development of a coherent and comprehensive validity argument. Evidence based on content, on response processes, the internal structure of the assessment, the relation of assessment scores to other measures, and the consequences of assessment uses are all potentially relevant to the development of a validity argument. The most relevant mix of types of evidence depends on the interpretations and uses that are made of assessment results.

Validity of Achievement Gains on High-Stakes Tests

D Koretz, Harvard Graduate School of Education, Cambridge, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Audit test – A second test used to validate gains on a high-stakes test.

Focal test – The high-stakes test scores on which are compared to the audit.

Score inflation – An increase in scores larger than warranted by real improvements in the domain measured.

Target of inference – The set of skills and knowledge about which a test-based inference is made.

VIHS – Validity of inferences under high-stakes conditions.

- Scores on high-stakes tests often – but not always – become inflated.
- The inflation of scores is sometimes very large and rapid.
- Score inflation does not require concrete sanctions or rewards for test scores.
- Inflation is highly variable across schools, and we have as yet little evidence relating its severity to characteristics of schools, students, or test-based accountability programs.

One of the most important elements of education policy today is the growing use of achievement tests to monitor the performance of schools and hold educators accountable. This use of tests has been a cornerstone of education policy in the US and England for some time and is now the focus of reform efforts in numerous other countries.

These uses of tests raise two critically important questions. How valid are inferences about performance when students or educators are pressurized to raise scores on a particular test? How can we evaluate the validity of these inferences? Research to date suggests that scores on tests used for this purpose can become seriously inflated – that is, they can increase markedly more than actual gains in student learning warrant. Addressing this possibility raises difficult theoretical and methodological issues.

Terminology is used inconsistently in the literature addressing these issues. In this article, the term high-stakes testing refers to any testing program that creates strong pressure to raise scores on a particular test, regardless of whether educators or students face concrete sanctions or rewards attached to scores. Test preparation is used to refer to any methods, either desirable or undesirable, designed to prepare students for a particular test.

Evidence of the Problem

A modest number of studies in the United States have addressed the validity of gains in scores on high-stakes tests. The results of these studies are consistent and suggest the following conclusions:

The extant studies of this issue all examine the generalizability of gains. Scores on a test are used to support inferences about students' mastery of a domain or target of inference (Koretz and Hamilton, 2006). If performance on the high-stakes test (often called the focal test) generalizes to the larger domain, it should also generalize to other, lower stakes tests, often called audit tests, provided that the focal and audit tests are intended to support inferences about a similar target. Note that this logic does not require that the audit test be a superior measure in any sense when first used. Rather, it requires only that the focal and audit are intended to support similar inferences about achievement. If high stakes lead to inflation of scores on the focal test, the audit test will become a better gauge of achievement as a result, but this is not a function of the initial quality of the measures.

Evaluations of the testing program Kentucky Instructional Results Information System (KIRIS) implemented in Kentucky during the 1990s illustrate the sometimes dramatic failure of generalization of gains on high-stakes tests. The KIRIS program established targets for score increases for every school, provided financial rewards for schools that substantially exceeded their targets, and set sanctions for those that fell short. This case is a particularly useful example because the state designed the frameworks for its reading and mathematics tests to be consistent with the frameworks for the National Assessment of Educational Progress (NAEP), a periodic, low-stakes assessment administered on a sample basis to nationally and state-representative samples of students. This consistency of frameworks implies a similarity in intended inferences and makes the NAEP a clearly appropriate audit measure for the KIRIS tests.

Immediately upon implementation of the high-stakes testing program, KIRIS scores began rising very rapidly, but scores of Kentucky's students on the NAEP assessment did not keep pace. During the first 2 years of the

program, fourth-grade reading scores on KIRIS increased a staggering three-fourths of a standard deviation. (By way of comparison, the decline in test scores during the 1960s and 1970s that helped generate enthusiasm for test-based accountability in the US was typically about 0.03–0.04 standard deviation per year; Koretz, 1986.) During this same period, the scores of Kentucky's fourth-grade students on the NAEP reading assessment did not increase at all (Table 1; see also Hambleton *et al.*, 1995). The pattern in mathematics was a bit less extreme: very large gains on the state test, accompanied by gains on the NAEP that were roughly one-fourth as large (e.g., Table 2; see Koretz and Barron, 1998). For similar findings from other testing programs that entailed concrete sanctions, see Jacob (2005) and Klein *et al.* (2000).

An earlier study by Koretz *et al.* (1991) provided evidence that score inflation does not require concrete sanctions. This study examined the generalizability of performance in a large, urban district in which teachers and principals were pressured to raise scores on a norm-referenced, multiple-choice achievement test but in which there were no concrete sanctions or rewards for either teachers or students. By current US standards, one might call this a moderate-stakes testing program. In the mid-1980s, the district switched from one test to a very similar competing product, and performance dropped markedly. In third-grade mathematics, for example, mean performance dropped by approximately half an academic year (Figure 1). Four years later, mathematics performance on the new test had returned to its previous, high level. The researchers then administered the old test to a random sample of classrooms. While performance on the new test had climbed half an academic year, performance on the old test had declined by a like amount. In effect, teachers were substituting mastery of the details of one test for mastery of details of the other.

Table 1 Gains on high-stakes test Kentucky Instructional Results Information System (KIRIS) and audit test National Assessment of Educational Progress (NAEP) in Kentucky, 1992–1994, fourth-grade reading

	KIRIS	NAEP
Gain in scale scores	18.8	–1
Standardized gain	0.76	–0.03
Average annual divergence (SD)		0.40

Table 2 Gains on high-stakes test (KIRIS) and audit test (NAEP) in Kentucky, 1992–1996, eighth-grade mathematics

	KIRIS	NAEP
Gain in scale scores	23.7	4
Standardized gain	0.52	0.13
Ratio, KIRIS to NAEP		4.10
Average annual divergence (SD)		0.10

Inadequacy of Traditional Validation

Testing with serious consequences for individuals has a very long history. For example, the imperial examination system in China was instituted more than 1400 years ago (Niu, 2007), and matriculation examinations with serious consequences for students, such as the abitur in German Länder and the baccalaureate in France, became widespread in Europe during the nineteenth century. While the large-scale use of tests to monitor the effectiveness of schools or educational systems is new in many contexts, this function of testing is also not entirely novel, dating back at least to the 1840s in the United States, when a test was implemented for this purpose in Boston (Resnick, 1982).

It has long been recognized that high-stakes uses of tests might induce behaviors that undermine validity. For example, E. F. Lindquist, one of the most influential figures in the development of standardized achievement testing, wrote more than half a century ago:

The widespread and continued use of a test [that is a proxy for an unattainable measure of criterion behaviors] will, in itself, tend to reduce the correlation between the test series and the criterion series for the population involved. Because of the nature and potency of the rewards and penalties associated in actual practice with high and low achievement test scores of students, the behavior measured by a widely used test tends in itself to become the real objective of instruction, to the neglect of the (different) behavior with which the ultimate objective is concerned (Lindquist, 1951: 152–153).

The undermining of outcome measures by behavioral responses to measurement is by no means limited to educational testing. It is often labeled Campbell's law in the social sciences: "The more any quantitative social indicator is used for social decision-making, the more subject it will be to corruption pressures" (Campbell, 1979).

Figure 1 Performance on a moderate-stakes test and an audit test in third-grade mathematics.

Nonetheless, much of the core work of psychometrics, including test design, the development of analytic methods (such as procedures for linking), and empirical validation have proceeded until very recently without much consideration of this problem (Koretz, 2008). Of particular importance here is the inadequacy of traditional approaches to validation for evaluating the validity of inferences under high-stakes conditions (VIHS).

There are several reasons why traditional approaches to validation are insufficient to evaluate VIHS (see Koretz and Hamilton, 2006). With the exception of predictive validity evidence, conventional empirical validity evidence is cross-sectional and primarily correlational and is therefore insensitive to both changes over time and differences in mean levels of performance. This is not problematic when three conditions are met: the location of the scale is arbitrary, there is no reason to expect bias in mean scores, and inferences are cross-sectional. For example, validity evidence of this sort is not problematic when using a low-stakes diagnostic test to determine the normative level of a student's performance. However, these characteristics of traditional validation are critically important when evaluating VIHS. First, many of the most important inferences in high-stakes testing programs are about change over time. Moreover, a key validity question when stakes are high is the possibility of artifactual elevation of scores from inappropriate test preparation, and this bias can arise both in trends (exaggerated improvement from prior years) and in cross-sectional inferences (e.g., upwardly biased estimates of achievement relative to performance standards). Correlations, which are calculated from deviations from means, are insensitive to this bias. This was shown concretely in an evaluation of Kentucky's KIRIS testing program. Scores of high-school students on the state's KIRIS tests were compared to their scores on the ACT college-admissions test. In mathematics, the mean KIRIS score increased by about 0.7 standard deviation in 3 years, while the mean score on the ACT declined trivially. Nonetheless, the student-level and school-level correlations between the two tests remained quite stable over this period (Koretz and Barron, 1998).

Many of the empirical methods traditionally used for validation rest on the implicit assumption of stability in the relationships between the tested sample of material and the broader domain from which it is sampled. Achievement tests are created by defining the domain, creating a blueprint for the test, and then sampling the domain according to the blueprint. The resulting sample of content and skills is intended to represent the larger domain, much as the sample drawn for a political poll is intended to represent the larger electorate. Traditional validation methods are intended to evaluate the adequacy of the tested sample as a representation of the domain. However, as Lindquist (1951) warned, once the test becomes known, there is pressure to focus instruction on the tested sample

rather than the domain of skills and knowledge it is supposed to represent. This undermines the representativeness of the tested sample and causes performance on the tested sample to improve more rapidly than mastery of the domain it should represent. That is, it inflates scores. Traditional approaches to validation do not address this problem. They are well suited to evaluating the initial representativeness of the tested sample, but as typically applied, they are not sufficient to evaluate erosion of that representativeness over time.

Due to the tacit assumption of the stability of the relationship between tested and untested parts of the domain, traditional approaches to evaluation largely ignore behavioral responses to testing. Leaving aside cheating and failures to follow administrative and scoring procedures, behaviors by teachers or students that improve performance on the tested sample are assumed to improve mastery of the domain. This assumption becomes progressively less tenable as increasing stakes intensify the incentive to focus unduly on the particulars of the tested sample rather than on the broader domain the test is intended to represent. The challenge of establishing VIHS is to differentiate the meaningful, generalizable improvements from test-specific gains resulting from high stakes.

A Framework for Evaluating VIHS

Koretz *et al.* (2001) suggested a framework for conceptualizing the problem of VIHS (see also Koretz and Hamilton, 2006). It differs from a traditional view of test construction and validation in several respects – in particular, by highlighting incidental aspects of test construction and omissions from tests, both of which can be keys to score inflation.

A test can be viewed as a sample of performance elements, an intentionally general term that refers to all of the components of a test that influence performance on it. Some of these elements are substantive in that they are related to the intended inference. However, in building a test, it is also necessary to sample nonsubstantive elements that are not directly related to the intended inference. Choice of format is often, although not always, a nonsubstantive choice in this sense. Deciding whether the domain of algebra relevant to a given test includes factoring quadratics is a substantive decision; deciding whether to represent factoring with multiple-choice items is generally not. Other aspects of presentation and response requirements may also be largely or entirely nonsubstantive. Traditional test construction focuses primarily on the sampling of substantive elements, and traditional validation does even more so.

Performance elements are conceptually distinct, but they need not be empirically independent, particularly

in cross section. However, they should be treated as separate if differences among them are relevant to the inference and if they have the potential to vary independently over time. For example, even though algebra and geometry elements are usually highly correlated in cross section, it is straightforward to make them change somewhat independently over time – say, by teaching only algebra and not geometry.

The influence of each performance element on the test score is called its effective test weight. More formally, the test weight is the partial derivative of scores with respect to the performance element. These weights are partly a function of deliberate choices, such as decisions about the proportion of items allocated to a given topic and the discrimination of items selected for use. However, weights also can also be partly unintentional, and even nonsubstantive elements can have considerable weights. For example, a test author may repeat certain styles of presentation or fine details of content without a substantive rationale for doing so, and students' proficiency with these details will then have an appreciable impact on scores.

Which elements should be considered substantive depends on the inference based on scores. Consider the classic example of failure of generalizability offered by Shepard:

When students were asked [on the state's test] to add decimals in vertical format, the state percent passing was 86 percent. In horizontal format for identically difficult decimals, the percent passing was 46 percent. For subtraction of decimals in the two formats the passing rates were 78 percent and 30 percent, respectively (Shepard, 1988: 4).

If one purpose of the test is to compare students' relative mastery of vertical and horizontal formats, this aspect of presentation would be a substantive performance element. However, if the intent is simply to assess competence in addition and subtraction of decimals, the format difference would not be substantive, and if the test author had used only the vertical format, the result would have been a biased estimate of competence.

Scores are used to support inferences about a target of inference. The target of inference is another collection of performance elements, typically a bundle of knowledge and skills. The relative importance of an element to the inference is its inference weight. Inference weights are typically poorly specified. In the case of achievement testing, the target typically comprises a much larger set of performance elements than those sampled for construction of the test. Elements from the target that are not tested by a particular assessment are called implicit elements.

This can be represented as two vectors of weighted performance elements, where π_i represents a performance element, λ_i represents the effective test weight of that element, and ω_i represents its inference weight (Figure 2).

Test	Inference
$\lambda_1 \pi_1$	$\omega_1 \pi_1$
$\lambda_2 \pi_2$	$\omega_2 \pi_2$
\vdots	\vdots
$\lambda_j \pi_j$	$\omega_j \pi_j$
<hr/>	
$0 \cdot \pi_{j+1}$	$\omega_{j+1} \pi_{j+1}$
$0 \cdot \pi_{j+2}$	$\omega_{j+2} \pi_{j+2}$
\vdots	\vdots
$0 \cdot \pi_k$	$\omega_k \pi_k$
<hr/>	
$\lambda_{k+1} \pi_{k+1}$	$0 \cdot \pi_{k+1}$
$\lambda_{k+2} \pi_{k+2}$	$0 \cdot \pi_{k+2}$
\vdots	\vdots
$\lambda_n \pi_n$	$0 \cdot \pi_n$

Figure 2 Schematic of a test and a target of inference.

The top section in Figure 2 represents performance elements that are substantively important for the inference and are represented on the test. Both their test weights and their inference weights are therefore nonzero, although these two sets of weights need not be similar. The middle section, starting with π_{j+1} and ending with π_k , has implicit elements: elements that are important for the inference but are not represented on the test. In the case of most large-scale assessments, this second set is very large because a small sample of test items must represent a large domain of achievement. The final section, beginning with π_{k+1} , comprises performance elements represented on the test but not important for the inference. Many nonsubstantive elements fall into this section.

Validity can then be seen as the extent to which changes on the tested set of performance elements, as weighted by the test, justify inferences about changes on the target of inference, as weighted by users' inferences.

Behavioral Responses to Testing and VIHS

In a traditional framework that assumes low stakes, the impact of the large set of implicit elements can be minor, assuming that the tested elements are a representative sample of the entire domain. If the domain is truly unidimensional, the effects of the omissions are simple measurement error, and the tested sample need not be very large to keep this error reasonable in size. If the domain is modestly multidimensional, the impact of implicit elements is still likely to be modest because of the high cross-sectional correlation among related subdomains under low-stakes conditions.

In contrast, under high-stakes conditions, the impact of incomplete sampling can be very large. Behavioral

responses to testing can make the tested sample unrepresentative of the domain and can undermine the correlations among tested and untested parts of the domain. This can happen in several ways.

As teachers, principals, or students begin to learn what is and is not tested, they can shift instructional resources, such as class time, to focus on the tested elements at the expense of the untested. This entails shifting instructional resources from the elements in the middle of **Figure 2** to elements in the top section. As those in the middle section have nonzero inference weights, this process undermines the ability of performance on the tested sample to represent the target of inference. This is the process about which Lindquist warned years ago. Koretz *et al.* (2001) refer to this process as within-subject reallocation.

Educators and students can also reallocate resources between tested and untested domains – for example, cutting back on music and science, if they are not tested, to free up more time for mathematics and reading. This sort of between-subjects reallocation may be either desirable or not, but it is generally not a matter of VIHS. For example, suppose that a school serving low-performing students responds to a testing program that measures on mathematics and reading by eliminating science instruction in the fourth grade to allow an increase in instructional time in mathematics and reading. Suppose also that mathematics and reading test scores increase as a result. One might argue that the loss of science instruction is an undesirable outcome, or one might argue that mathematics and reading are so essential to the students' later well-being that this is a reasonable price to pay. However, in neither case does this shift in resources necessarily imply anything about the validity of inferences about improved proficiency in mathematics and reading.

Educators and students can also target their efforts on the third region in **Figure 2**, the elements that are given appreciable weight on the test but are not important to the inferences based on scores. Many of these are nonsubstantive elements, such as item format and other modes of presentation. An example is teaching students to use process of elimination to solve problems presented in multiple-choice format, which can produce gains in performance that appear only on multiple-choice tests. When these responses focus on nonsubstantive elements, Koretz *et al.* (2001) refer to them as nonsubstantive coaching. These too can generate increases on the tested vector that are larger than are warranted by increases on the target.

Yet another type of behavioral response that can inflate scores takes advantage of unimportant, sometimes unintentional, substantive details of the focal test. Koretz *et al.* (2001) refer to instruction that targets these details of the test as substantive coaching. One can think of the substantive sampling required for construction of a test as having multiple stages, although they need not be distinct in practice. For example, a state's standards or curriculum

framework may first specify that students should have familiarity with the properties of common polygons and then may add detail, such as this from the Massachusetts mathematics framework for grades 5 and 6:

Students engage in problem solving, communicating, reasoning, connecting, and representing as they: Identify polygons based on their properties, including types of interior angles, perpendicular or parallel sides, and congruence of sides, e.g., squares, rectangles, rhombuses, parallelograms, trapezoids, and isosceles, equilateral, and right triangles (Massachusetts Department of Education, 2000: 42).

Constructing a test, however, requires even further sampling. Which polygons should be represented? Should the test include only regular ones, with six or fewer sides? Irregular but symmetrical polygons? Asymmetrical ones? Should the items require calculation of areas and perimeters? Estimation? Discussion of the relationship between the number of sides and the magnitude of internal angles?

Thus, there can be layers of increasingly fine-grained sampling from within a broad substantive element, eventually reaching the point at which the choices are no longer important for the inference. One could label the finest level of detail relevant to the target as a conceptual element. Often, these conceptual elements can be tapped by a number of more finely grained measurable elements, both substantive and nonsubstantive. This is illustrated in **Figure 3**, which displays the first element in **Figure 2**, π_1 , as encompassing six smaller elements, two represented on the test and the target, three represented in the target but not the test, and one represented in the test but not the target.

If the choices among these fine-grained elements are repeated over time, they too provide an opportunity to tailor instruction to the specifics of the tested sample and to undermine its representation of the target of inference. For example, a Princeton Review publication marketed to prepare students for one state's mathematics assessment notes that "one triangle rule that is often tested [on the state's test] is the *third side* rule: the sum of every two sides of a triangle must be greater than the third side" (Rubinstein, 2000: 52). There is nothing unreasonable about selecting this particular measurable element for inclusion, but its recurrent use – in lieu of other measurable elements

Test	Inference
$\lambda_{11}\pi_{11}$	$\omega_{11}\pi_{11}$
$\lambda_{12}\pi_{12}$	$\omega_{12}\pi_{12}$
$0\cdot\pi_{13}$	$\omega_{13}\pi_{13}$
$0\cdot\pi_{14}$	$\omega_{14}\pi_{14}$
$0\cdot\pi_{15}$	$\omega_{15}\pi_{15}$
$\lambda_{16}\pi_{16}$	$0\cdot\pi_{16}$

Figure 3 Schematic of a single conceptual element, π_1 .

representing the same concept – provides an opportunity for substantive coaching and score inflation.

Finally, educators and students can simply cheat. Whatever the method of cheating chosen—for example, revealing items in advance, modifying answers after the testing period, etc. – the result is necessarily score inflation.

New Directions for Research, Evaluation, and Test Design

It is clear that the validity of inferences about proficiency based on tests used for high-stakes purposes cannot be taken for granted, even after careful validation using traditional methods. To be sure, the sparse research to date does not indicate that score inflation is inevitable. Despite the pervasiveness of test-based accountability in the US, trends on some state tests have been reasonably consistent with those on NAEP (Ho and Haertel, 2006), and research has not clarified the factors – possibly, characteristics of students, schools, test, or accountability programs – that predict the degree of inflation. Nonetheless, the extant research does suggest that this problem is not rare. Moreover, extant research indicates that score inflation can be both rapid and severe, in some instances dwarfing biases one might expect from other sources more commonly addressed in traditional validation studies.

These findings suggest the need for more widespread and routine investigation of VIHS. However, the field has only begun exploring how this investigation should be done. The obvious choice used in most studies to date is to compare trends on focal and audit tests, and this should be done when it is practical. However, this is only feasible when there is a suitable audit test in place – one that is administered to a representative sample or on a census basis in the right grades in the same years, that is intended to support similar inferences, and that can be assumed to be relatively free of inflation itself. A suitable audit measure is often lacking, and in such cases, the burden of evaluating VIHS would greatly increase because it would require either administering an additional audit test or adding an audit component to an ongoing operational assessment.

Moreover, while a simple comparison of trends on focal and audit tests is sufficient to identify instances in which large disparities in trends suggest score inflation, it is a blunt tool. Modest disparities in trends may arise even in the absence of any inflation if the focal and audit tests are designed to support somewhat different inferences. Note, however, that differences between tests are only relevant in this context to the extent that they imply different targets of inference; performance gains, if meaningful, should generalize across substantively irrelevant details of test construction (Koretz, 2007). Differences in intended inferences could bias estimates of score inflation

in either direction (Koretz and Barron, 1998). Moreover, if the focal and audit test happen to share unnecessary particulars – such as substantively irrelevant aspects of presentation or substantively unimportant details of content – there is a chance that inflation generated by behavioral responses to the focal test may contaminate the audit test as well, leading to an underestimate of score inflation. Therefore, simple comparisons of trends may be insufficient to detect modest score inflation, and they are not sufficient for estimating precisely the mix of real gains and inflation when both occur.

The limitations of simple comparisons with extant audit tests pose a design challenge: the need for better and less burdensome audit measures. Ideally, an audit test should be designed to maximize similarities in the intended inferences while minimizing unnecessary similarities in the particulars of test design. In several respects, adding an audit component to an ongoing focal test might be superior to administering an independent audit test. It would remove motivational differences, lessen disruption, and most likely cost less. This might be done, for example, by adding a matrix-sampled block of audit items to the focal test. However, as yet there has been little discussion of these design issues and no empirical evaluation of alternative approaches to this problem.

The crudeness of simple comparisons between focal and audit tests also poses an analytical challenge: the need for analytical methods to be better able to distinguish between meaningful gains and score inflation when they co-occur. Differential item functioning (DIF) analysis might be adapted for this purpose (Koretz and McCaffrey, 2005). One approach might be to categorize items in a manner relevant to VIHS – for example, items that have familiar particulars and audit items that have fewer – and then use DIF analysis to compare performance gains on the sets. One might also do the reverse: use DIF analysis to identify clusters of items showing unusually small or large performance changes and then examine their characteristics *post hoc*. However, these analytical challenges have so far received very little attention.

The challenge to validity posed by high-stakes uses of tests has been recognized since the early days of the science of achievement testing, but to date, it has garnered relatively little attention. Ongoing changes in the uses of large-scale achievement tests have made this issue increasingly important, and recent research has shown the severity of the resulting threats to validity. However, empirical evaluation of VIHS remains rare, and the measurement field still faces the challenge of finding more effective and less burdensome ways of conducting the needed validation.

The Meaning of Educational Indicators

Recent years have witnessed an explosion of interest in educational indicators (Bryk and Hermanson, 1993). This topic has been the focus of a number of reports, papers, study commissions, and national and state panels (e.g., Fitz-Gibbon, 1996; Gray and Wilcox, 1994; Nuttall, 1994; OECD, 1995; Salganik, 1994; Seltzer *et al.*, 2003; Smith, 1988). Most commonly, an educational indicator is expected either to assess or even to be related to a desired outcome of the education system. In this article, we try to clarify the meaning of educational indicators by taking into account the variety of indicators used by several organizations such as the Organization for Economic Cooperation and Development (OECD), the US Department of Education, and the National Science Foundation. The most basic and elementary definitions contend that indicators should describe key aspects of schooling (Selden, 1994).

This definition implies that indicators are statistics that are expected to provide information about significant features of an educational system. For example, indicators often describe how students perform on a national test, what is being taught, or how much is being spent on education (OECD, 1995). Others note that for a statistic to be an indicator, there must be a standard against which it can be judged. For example, comparisons over time offer dates as reference points; comparison among institutions or nations have built-in reference points as well. However, many indicators require more than one reference point. For example, a decline in scores of a national test over a number of years tells us more than a simple statement of the magnitude of the decline. With the addition of reference points, indicators may become more meaningful, more precise, and more useful.

Other researchers claim that indicators should act as vital signs regarding the health of the educational system (e.g., Nuttall, 1994; Oakes, 1989). There are two aspects embedded in this conceptualization. First, by serving as the vital signs, indicators permit the monitoring of education which is typically understood as an ongoing activity. Second, by providing an assessment of the health of a system, indicators provide a basis for making value judgments. Value judgments can be understood as overall assessments that are rather subjective, for there exist no definitive guideposts to determine the health of a system.

Other definitions go even a step further by invoking a policy criterion. Specifically, it is claimed that a statistic

can be considered an indicator only if it is policy relevant (Shavelson *et al.*, 1989). This definition implies that policy-makers want to know what policy levers they can pull in order to improve performance. Thus, this definition provides an instrumental usage of indicators (Bryk and Hermanson, 1993).

In this section, five characteristics of educational indicators have been identified. As a generic synthesis of the available definitions, we support that educational indicators are statistics that describe key aspects of schooling which permit the evaluation and monitoring of schools, teachers, programs, and students. From these activities, value judgments of the health of an educational system or parts of it can be derived and policy-relevant information which contributes to the improvement of the effectiveness of the system should emerge. This definition implies that educational indicators should provide information about the quality of education associated with the effectiveness and efficiency of the system or parts of it such as teachers, schools, and educational regions. However, although many educational indicators are used in research, practice, and policy, their ability to provide valid information about the quality of education could be questioned.

In this article, it is not only argued that validation of educational indicators is needed but it is also claimed that our definition of indicators implies that the validation process should mainly be concerned with the extent to which information provided by an indicator is able to demonstrate effects of the factors addressed upon outcomes of schooling. For example, when we treat the amount of teachers with a certified degree as an indicator, we may assume that subject and/or pedagogical knowledge is important for the quality of teaching and is related to student outcomes. However, unless we demonstrate through either empirical studies and/or quantitative syntheses of studies that there is a relationship between the degree awarded and student outcomes, this indicator cannot help policymakers take decisions on how to improve the effectiveness of the educational system. Such an approach may produce fewer indicators but may help policymakers have a clear understanding on how each of them affects achievement standards.

Since our proposed methodology for testing the validity of prospective indicators places a lot of emphasis on the impact of indicators upon student outcomes of schooling, we clarify below how we conceptualize quality of education. It is supported that ultimately, the criterion

for success in education is the attainment of the aims, goals, and objectives of the educational system. Since schools are places where primarily learning takes place, the objectives of education are primarily student-learning outcomes. These can be found in the cognitive domain and also in other areas such as the affective, the social, and the esthetic domains. It is recognized that student learning in noncognitive areas is determined overwhelmingly by other actors in the society whereas the cognitive domain is determined less by other social agents. This implies that schools have a specific role in the cognitive domain and that consequently, objectives in this area are crucial for the educational system in general. Moreover, achievement of cognitive outcomes determines to some extent achievement in other domains, like motivation and well-being (Knuver and Brandsma, 1993). However, this does not mean that education should be restricted to cognitive objectives since only a partial relationship exists between achievement of cognitive and noncognitive domains (Kyriakides, 2005). Moreover, schools may act as social agents and, being a part of society, they can also contribute partially to these areas. They can provide a social and esthetic environment in which social behavior and esthetic attitudes can be developed. Therefore, schools and teachers should be supported in such a way that objectives are reached and educational quality becomes a fact. In this context, research can offer insight into which indicators contribute to student results and help policymakers take decisions on how to improve educational standards.

The Validation of Indicators: A Proposed Methodology

In the first section of this article, the importance of investigating the impact of indicators upon achievement of both cognitive and noncognitive aims of schooling has been stressed. In this section, suggestions on building a methodology for testing different types of validities of prospective indicators are provided:

1. *Demonstrate the relation of prospective indicators with student achievement gains.* Our first suggestion is concerned with the importance of investigating the impact of prospective indicators on student-achievement gains. This approach implies that fair indicators of school performance need to measure the contribution of teaching to progress made by students at school (Fitz-Gibbon, 1996). The use of value-added approach is attributed to the fact that variations in the final test results of schools reflect partly the educational attainment of students when they enter the school (Kyriakides, 2002). Therefore, information gathered from value-added assessment is more valid in exploring the effectiveness of an educational system or parts of it (e.g., school units).
2. *Search for educational indicators which operate at different levels.* The last point associated with the advantages of using multilevel approaches to identify the effect of indicators on student-achievement gains reveals that we could generate educational indicators which operate at different levels. However, it cannot be claimed that any factor associated with student achievement should be treated as an educational indicator. For example, school-admittance policy may be found to be related with student achievement but this factor refers mainly to the input of the school since the existence of an admittance policy has a direct and strong effect on the prior knowledge of students entering the school. Therefore, the school-admittance policy cannot be treated as an educational indicator since it does not reveal how the functioning of schools can contribute to student-achievement gains. On the other hand, an educational indicator could be generated based on the fact that empirical studies reveal that opportunity to learn at student level is associated with student achievement (Creemers and Kyriakides, 2008). Such a finding reveals that schools could take actions to improve opportunity to learn. Therefore, to generate a relevant educational indicator we need

The use of multilevel analysis to search for the impact of each prospective indicator upon student achievement gains is also recommended. This is due to the fact that multilevel analysis explicitly models the manner in which students are grouped within classes or schools and, therefore, has several advantages in relation to our attempt to search for the impact of an indicator on student-achievement gains. First, multilevel analysis takes into account the existence of hierarchically structured data and the variability associated with each level. One may draw erroneous conclusions if any of these sources of variability is ignored (Opdenakker and Van Damme, 2000). Second, multilevel analysis provides a means of partitioning the outcome variable's variance into different levels (within and between units). Third, it yields better-calibrated estimates for the variance of standard errors (Goldstein, 2003). Fourth, it offers a single framework that combines the information within and across units to produce more accurate explanations and outcomes. Finally, clustering information provides correct standard-error confidence intervals and significance tests, which are more conservative than the traditional ones that are obtained simply by ignoring the presence of clustering (Snijders and Bosker, 1999). By allowing the use of covariates measured at any of the levels of a hierarchy, we can explore the extent to which the differences in average-achievement results between schools can be accounted for by factors related either to the school, to class, or to student characteristics (i.e., to specific prospective indicators).

to demonstrate through empirical studies that this indicator contributes in increasing opportunity to learn at student level and due to that, student achievement is also increased.

3. *Search for both direct and indirect effects of each prospective indicator on student achievement.* Given that an indicator is expected to help policymakers take decisions on how to improve the effectiveness of the educational system, it is considered important not only to provide information associated with an indicator but also to help policymakers and other stakeholders understand whether, how, and why an indicator is associated with student-achievement gains. In order to achieve this aim, we should search for both direct and indirect effects of each indicator on student achievement. For example, some context-level and school-level indicators may influence the teaching and learning situation which is associated with student achievement and thereby such indicators may have indirect effect on student achievement. Searching for both direct and indirect effects of educational indicators upon student achievement helps policymakers take decisions on how to design intervention programs to improve effectiveness by making sure that changes in the functioning of an indicator will affect intermediate variables and due to that student achievement could be improved. For example, a reform program aiming at the reduction of the class size may not have any effect on student achievement unless it is designed in such a way to help teachers improve their teaching practice (e.g., increase teacher–student and/or student–student interactions). Similarly, providing resources for learning could improve teaching if it is designed in a way to help the teachers and the school to provide more learning opportunities to students or to contribute in the professional development of teachers. Thus, our suggestion for searching for both direct and indirect effects of educational indicators on student achievement has as its ultimate aim to help policymakers understand how and why an indicator is associated with achievement.
4. *Find out whether there are nonlinear relations between indicators and student achievement.* In order to expand our understanding of the impact of an indicator on student achievement, we should also find out whether a nonlinear relation between an indicator and achievement exists. This argument is supported by the fact that meta-analyses of the effect of some effectiveness factors upon student achievement revealed that although they have been perceived as factors affecting teacher or school effectiveness and/or have been used as educational indicators, the research evidence is problematic. For example, teacher subject knowledge is widely perceived as a factor affecting teacher effectiveness (Scriven, 1994) but teachers' subject knowledge,

regardless of how it is measured, has rarely correlated strongly with student achievement (Darling-Hammond, 2000). The explanation may be, as Monk (1994) reported, that the relationship is nonlinear: a minimal level of knowledge is necessary for teachers to be effective, but beyond a certain point, a negative or no relation may occur. Similar findings have been reported for the impact of classroom emotional climate and teacher management upon effectiveness. A negative emotional climate usually shows negative correlations, but a neutral climate is at least as supportive as a warm climate.

Our suggestion to search for nonlinear relations does not only imply that more complex statistical techniques should be used in analyzing data concerned with the relation of an indicator and student achievement but also that the optimal points of the functioning of an indicator should be identified (Creemers and Kyriakides, 2008). In the case of education, we give emphasis to the existence of inverted-U curvilinear relations since such relations reveal that there is an optimal point for the function of a specific factor. After the optimal point, a negative relation with achievement exists, and thereby the identification of the optimal point has important implications for improving educational practice. Obviously, other nonlinear relations might exist. In case that there is more than one optimal point, the question can be raised about the efficiency of application of a certain factor after the first optimal point.

5. *Search for relations between indicators which operate at the same level.* There is also a need to carefully examine the relationships between the various indicators which were found to be related with student achievement and operate at the same level. The identification of relations between indicators may reveal a grouping of factors that make teachers and schools effective. Therefore, providing policymakers with information on how educational indicators operating at the same level are related to each other may generate a more comprehensive picture of the effective characteristics of education. As a consequence, comprehensive strategies for improving effectiveness could be developed (Creemers and Kyriakides, 2006). The results of a study attempting to test the validity of Walberg's (1984) educational productivity model reveal more complex indirect relationships between factors affecting student learning (Reynolds and Walberg, 1990) and provide some support to our suggestion to search for relations between indicators.
6. *Find out whether each indicator is generic or differential.* Although educational indicators are sometimes treated as generic in nature, their impact on different groups of students/teachers/schools may vary. Therefore, a critical question for each prospective indicator is associated with the extent to which it can be treated

as generic or differential. Although we could use different dimensions to investigate whether an indicator is differential (see Campbell *et al.*, 2004), we give more emphasis to the extent to which indicators are able to explain variation on student achievement across countries. This is attributed to the fact that the educational debates that are currently in evidence in many societies concerning the appropriate means of raising educational standards are often based upon simplistic transplants of knowledge from one educational system to another by making use of information gathered by educational indicators held by different countries without any detailed acknowledgment in the educational-policy debate as to the possible context specificity of the apparently effective policies in the original societies utilizing them.

Such an approach in testing the validity of educational indicators reveals the importance of conducting comparative studies in order to understand much more about why some indicators explain effectiveness across countries while others do not. For example, variables associated with inputs such as money spent in education may be associated with the improvement of effectiveness in some countries but not in others. This variation in what works is likely to in its turn generate a need for more sensitive theoretical explanations than those at present on offer, since the variation by national contexts forces the development of more context-specific explanations of how indicators can be used by policymakers to improve practice. Therefore, there is a need to identify effectiveness factors that are present in different educational contexts and generate relevant generic educational indicators. Moreover, factors that are unique to specific countries as well as factors that operate differently in different educational settings should be highlighted.

Beyond conducting comparative studies to find out whether a prospective indicator is generic, meta-analyses of national studies could be undertaken. Using multilevel approaches we can analyze the observed effects of each study and the sources of variances among the findings emerging from different studies (Raudenbush and Bryk, 1985). Therefore, differences in reported effect sizes of an indicator on student achievement can be modeled as a function of study characteristics such as the differences in the countries where the study was conducted or the type of outcomes used to measure student achievement. As a consequence, the extent to which an indicator has a differential effect could be identified.

7. *Investigate the interpretive validity of each prospective indicator.* Traditional conceptualizations of validity treated validity in terms of three distinct facets, or evidential areas: (1) construct validity, (2) criterion validity, and (3) content validity. Each of these facets remains important for contemporary testing. Moreover, all of them involve

scientific generalization. However, contemporary discussion of test validity emphasizes that validity does not refer to a property of a test; rather it refers to the meaningfulness and appropriateness derived from test scores (American Educational Research Association *et al.*, 1999). Although Popham (1997) argued for a limited definition of validity and treated validation as an objective, scientific concern, separate from disputes over the consequences of testing, Linn (1997) and Shepard (1997) favored a broader conception of validity which would include the consequences of test use and the descriptive interpretation of test scores. An emphasis on content and criterion-related questions as well as the strong program of construct validity (Cronbach, 1988) may lead us to underestimate the importance of issues dealing with the consequences of using an educational indicator. However, in real-world applications, we want the desirable consequences of using an indicator or any other instrument to be more important than its negative consequences. Therefore, teachers and policymakers, as end users of educational indicators, should contribute a distinctive perspective on validity of indicators, referred to as inferential validity (Kyriakides, 2004). This implies that the validation of a prospective educational indicator should be concerned not only with demonstrating that it has an effect on student achievement but also with finding out whether statistical figures associated with an indicator are clear and informative to different stakeholders and help them take decisions on how to improve educational practice. Survey studies looking at the perceptions of different stakeholders about the meaning of each indicator and on how each indicator can be used to improve educational effectiveness should be conducted. In addition, results of experimental/evaluation studies concerned with the use of prospective indicators to improve the effectiveness of an educational system or parts of it could help us test the inferential validity of an indicator.

Conclusions: The Main Features of the Proposed Methodology

The proposed methodology for testing the validity of prospective indicators attempts to give answers to three basic questions. First, our attempt to search for relations between an indicator and student-achievement gains reveals whether an indicator is important in predicting the quality of education in relation to student-learning outcomes. Second, beyond demonstrating that an indicator is associated with student achievement, it is considered important to explain why the indicator is able to predict the quality of education. This question reveals the role that educational research and theories associated with educational effectiveness can play in generating and testing the validity of indicators. Unless theoretical explanations of

the impact of indicators are given, neither can their construct validity be tested, nor can the use of information gathered from each indicator to improve policymaking be ensured. In this article, it was claimed that in order to provide a clear answer to this question, we should search for both direct and indirect effects of each indicator on student achievement. We should also find out whether linear or nonlinear relations between indicators and student achievement exist and whether each indicator is generic or differential. Finally, relations among indicators operating at the same level could be identified in order to help us establish comprehensive strategies for improving effectiveness.

The third question raised here is concerned with the actions that teachers and policymakers take as a consequence of the information provided by an indicator. Since indicators are expected to help schools, policymakers, and other stakeholders to design action plans for improving the quality of the system at different levels, it is argued that we should find out how information emerging from an educational indicator is used.

It is finally pointed out that the proposed methodology for testing the validity of prospective indicators does not imply that a specific sequence in providing answers to the above three questions is more desirable than others. It is possible that empirical results providing answers to the first question may help us establish a theoretical explanation of the impact of a prospective indicator and thereby give answers to the second question. We may also initially provide answers to the second question by developing or using specific theories on how some prospective indicators are associated with student achievement and then generate evidence to test these theories and demonstrate the relation of these indicators with student achievement. The latter approach is in line with the typical way used to test the construct validity of measurement instruments but the possibility of using this approach is mainly based on the extent to which educational research can provide us with strong theories explaining why some teachers/schools/systems are more effective than others. Finally, we should consider the possibility that initially studies looking on how schools or systems make use of evaluation data to improve their practice provide answers to the third question and at a later stage we may conduct research to answer the first two questions concerned with the construct validity of indicators.

Establishing Criteria for Valid Indicators in Education

Throughout the literature on educational indicators, scholars provide lists of criteria for choosing indicators. The single most frequently cited criterion is in regards to the technical quality of the data including the issues

of reliability and validity (Blank, 1993; Nuttall, 1994; Shavelson *et al.*, 1989; Smith, 1988). However, our attempt to provide suggestions on testing the validity of each prospective indicator implies that valid educational indicators should meet the following five criteria. First, our emphasis to testing the interpretive validity of each prospective indicator implies that a valid indicator should be informative to the public and help policymakers and other stakeholders develop strategies to improve educational standards. It is easy enough to spot an educational indicator, though interpreting it accurately is often more difficult and thereby emphasis on testing the interpretive validity of indicators is given in this article. It is apparent, as Selden (1994) observed, that defining educational indicators and indicator systems lies principally in determining how they are used. Different uses of indicators offer different forms of control over educational systems but we give more emphasis to the extent to which indicators help policymakers and other stakeholders develop an evidence-based approach to improve quality of education.

Another important criterion of a valid indicator that emerged from our methodology of testing the validity of indicators is concerned with the extent to which empirical support to the ability of an indicator to influence quality of education has been provided. For this reason, we emphasize the importance of demonstrating that an indicator has an impact (direct or indirect) upon student-achievement gains.

Third, beyond the empirical support, an indicator should also get theoretical support that helps policymakers and other stakeholders understand how and why an indicator is associated with achievement (Benjamin, 1996). With this criterion we are facing with the challenge of developing theoretical models illustrating why some teachers/schools/educational systems are more effective than others. Although at the moment there is no single agreed-upon model of educational effectiveness, it has to be acknowledged that during the last 10 years, attempts to generate comprehensive models of educational effectiveness have been made (e.g., Creemers, 1994; Scheerens, 1992; Stringfield and Slavin, 1992) and some empirical support to the validity of these models has been provided (e.g., de Jong *et al.*, 2004; Kyriakides, 2005). Moreover, a dynamic model of educational effectiveness addressing some of the major weaknesses of the current models has been recently developed (Kyriakides, 2008). By making use of these models we may generate valid indicators which are not only informative to policymakers but are supported both empirically and theoretically as well.

A fourth criterion for valid educational indicators is that they are not only policy relevant but they also include aspects that can be manipulated by policies or programs (Nuttall, 1994; Shavelson *et al.*, 1989; Smith, 1988; Visscher, 2001). This implies that indicators should not only refer to input variables especially since part of

the improvement of modeling educational effectiveness is the development of models which give more emphasis to process rather than simply to input and output variables.

Finally, it was argued that we should find out whether an indicator is generic or whether it has a differential impact on achievement. Making clear whether an indicator is generic helps policymakers make better use of the results of comparative studies to improve effectiveness. In addition, information emerging from differential indicators could be useful for establishing reform policies on providing equal opportunities and helping schools and teachers reduce unjustifiable differences in outcomes of schooling (Campbell *et al.*, 2004).

Implications for Policy and Research

The last section of this article is concerned with implications of generating valid indicators for policy and educational research. Although policymakers have their own agenda which is not necessarily fully determined by empirical facts, in view of rational decision making, policymakers are expected to take into account empirical validated knowledge about the political issues at stake. Therefore, the development of valid indicators may help policymakers develop an evidence-based approach for building educational policy. Moreover, the understanding of the impact of an indicator on student achievement is essential not only for the content of a reform policy associated with this indicator but also with the process of disseminating a reform policy. As a consequence, the proposed methodology for testing the validity of prospective indicators is expected to provide information concerned with whether, how, and why an indicator is associated with student achievement. Specifically, our understanding of effective education could be expanded if we answer questions associated with the impact of an indicator on student achievement such as whether it has direct and/or indirect impact on student achievement and on whether its relation with outcomes is linear or nonlinear. Essential for improving educational practice is also to find out whether indicators operating at the same level are not only related to student outcomes but are also related to each other. Finally, finding out whether an indicator is generic or differential may help policymakers understand that results achieved in one country cannot be replicated in another country by a simplistic transplant of some factors, which seem to be imported without any detailed knowledge of possible contextual factors that might explain how factors that work in one country may be ineffective in another country. What is needed is not borrowing policies but generating valid generic and differential educational indicators which reveal those characteristics of the educational systems that explain variation in achievement within and across countries.

Such an approach may allow us to build an evidence-based approach in introducing reform policies.

The proposed methodology for testing the validity of educational indicators has implications for conducting studies which could generate evidence about the relation of each indicator with student-achievement gains. We also draw suggestions on conducting quantitative syntheses to test the validity of prospective indicators especially since meta-analyses help us find out whether an indicator has any differential impact. Therefore, the proposed methodology has significant implications for conducting systematic research which can help us develop the theoretical framework of educational effectiveness. But the proposed methodology does not have implications only for conducting studies concerned with the validity of prospective indicators. Generating valid indicators may also have significant implications for redesigning comparative studies such as those conducted by the International Education Association (IEA) and the OECD. Secondary analyses of Trends in International Mathematics and Science Study (TIMSS) and Programme for International Student Assessment (PISA) studies revealed that although a large number of variables at student, classroom, and school level were taken into account, these variables were able to explain only a small percentage of student-achievement variance (Kyriakides, 2006). It could be assumed that if the instruments of these studies had provided more information concerned with valid indicators, more variance would have been explained. This holds true especially at the country level, since variables associated with different educational policies that may affect the school or teacher level were absent. Therefore, the establishment of valid educational indicators could contribute to extending the scope of IEA and OECD studies and at the same time could aid in developing a better understanding of education by which all countries participating in these studies would benefit.

AD 1088: Ancient Globalization

With the benefit of a millennium of hindsight, it appears ironical the University of Bologna came into being offering trade in secular expertise, including the *ius gentium*, the Roman law of peoples. These legal principles were useful in advancing the incipient right of nations, and defending nation-states against the predatory claims of their contemporary rivals, the transnational polities of Empire and Church. Bologna's self-narration (Czarniawska, 1997) today revolves around its special historic claim as *Alma Mater Studiorum*, the oldest continuously operating degree-awarding autonomous institution (Rüegg, 2003), not a college of scholars but a teaching institution independent of state power and religious authority (Huff, 2003: 179; Makdisi, 1981). Its origins demonstrate the truism that knowledge (its creation and transfer) and the skilled competence that knowledge generates are intimately tied to power. Although the social effects of such knowledge–power links are usually indirect and long term, they can be world changing.

The mother university emerged from scholarly effort to assemble and disseminate extranational authoritative knowledge. An ironical outcome was to promote national institutions and even nationality itself. Today, the name Bologna is a code word for procedures and structures in support of global higher education, returning it to its extranational origins. This is appropriate rather than ironical, since from its inception, organized higher learning has been international in content and aspiration. It is

fitting too that the *Constitutio Habita* of 1158, Bologna's academic constitution (1155, according to Rüegg, 2003: 12), enshrines scholastic privilege, later venerated as the documentary origin of academic freedom (Watson, 2005: 373) in the struggle between the Pope and the Holy Roman Empire. This too became international, when on 18 September 1988, 430 university rectors signed the *Magna Charta Universitatum*, marking the 900th anniversary of the university's foundation.

All institutions engage in storytelling to solidify their constituents and define their distinctiveness (Gabriel, 2000; Boje, 2001). Bologna's self-narration tells a story of universalism, principles of institutional autonomy, and academic freedom – a narrative that is today widely endorsed.

The training imparted at Bologna during the eleventh and twelfth centuries arose because new markets emerged (incipient nations and institutions) demanding skilled competence in law and legal rhetoric. Universities today, both Western and non-Western, are enmeshed in rapidly integrating markets for competence as they supply these markets with skills. Universities also reinforce the existence of these markets and their reliance on universities. These markets, then as now, transcend boundaries of nation and culture, though most are still grounded in national traditions and all are marked by stratifications of power and inequalities of wealth.

Bologna's quest for origins (D'Epiro and Pinkowish, 2001), despite serving nationalist claims, is largely confirmable (Rüegg, 2003). In AD 1088 (AD 1087, according to Huff, 2003) a certain Irnerius (and Pepo) commences

teaching Emperor Justinian's sixth-century codification of Roman law, the *Corpus Iuris Civilis*, recently discovered at Pisa (Malagola, 1888). It is a confirmation of the irony that Irnerius' original academic activity was simply to gloss the ancient text, underscoring the indispensability of literate practices to all scholarly activity (Lo Bianco, 2004) while inadvertently adding value.

Lay students arrive in the city from many lands contracting to purchase this glossed knowledge. They organize themselves into collectivities, noncitizen guilds, or Learning Nations comprising Hungarians, Greeks, North Africans, Arabs, Franks, Germans, Iberians, etc. These became the locomotive of the educational economy, since students "had all the power . . . and dominated the masters" (Kerr, 2001: 16, 145; Rüegg, 2003: 12). The Learning Nations serve many purposes: they enhance the purchasing power of students, impose lecturer diligence, require regular timetables, and provide rent control and other practical support.

In 1888, in the aftermath of Italy's national independence, a festival of studies was organised at Bologna to celebrate its eighth centennial (UniBo, 2008) as the mother of universities. The late nineteenth century, an era of internationalism marked by European imperial expansion, jars with the festival's theme of cooperative internationalism. However, while universities inevitably reflect their cultural and national setting, an internationalist impulse runs deep. Knowledge cannot easily be confined within bounded geopolitical spaces, and the technical skill and philosophical reflection that universities produce stimulates cross-border markets for their exchange. The marketplace for competence is international because technical efficiency and substantive reflection are endlessly mutable, applicable, and exchangeable.

Islam's earliest institutions of learning, *madrāsas*, and higher education alike, were dispersed internationally, yet gathered around a shared textual tradition and modes of interpretation, all essentially forms of religious scholarship, but teaching and scholarship were also applied to science and law (Makdisi, 1981; Talabani, 1996; Daun and Arjmand, 2005). In diverse ways, universalism is found in all regions of the world, during all ages and across all civilizations (Hopkins, 2002), even in light of persistent arguments for the intellectual and moral roots of globalization, as distinct from economic and pragmatic ones, originating in European struggles (Headley, 2007). Today, the characteristic mode of higher education universalism applies an early 1800s' German conception of a research university adapted by American-inspired organizational and teaching models.

A shared medium of instruction (MOI) and standardized literacy are indispensable for the possibility of international education, even when the language concerned does not retain a home base in any nation.

Latin functioned in this way for some 14 centuries after Rome, making possible a Republic of Letters (McNeely and Wolverton, 2008); "almost unaffected by political and economic collapse" (Ostler, 2007: 18). This place-less Republic permitted elites to communicate and forge bonds of identity as "a community of scientists and scholars" (Ostler, 2007: 280). Today's Latin, on a historically unprecedented scale, is English, and perhaps because it does retain several home bases, English facilitates both the rise of international education and invests it with dilemmas, issues, and problems. It is important to note that it is not general spoken English that performs this facilitative function, but a range of identifiable registers of literate and persuasive academic English. To retain its privileged position, this kind of English is buttressed by a veritable industry of certification, assessment, and codification practices.

These practices are self-replicating and work to standardize, codify, and disseminate a teaching and written standard in scientific English discourse. Contemporary globalization is fueled by such communication practices making possible "the widening, deepening and speeding up of world wide interconnectedness" (Held *et al.*, 1999: 2). Since the *Lingua Mundi* has not supplanted other languages of scholarship and science, these share the communicative load involved in research, publication, teaching, explanation, and dissemination. Some might ultimately pose a threat to the privileges and domination accorded to scientific English. The precedent of Latin is instructive; ancillary scholarly languages initially shared a minor, mostly spoken, role in academic communication with Latin, then expanded to share literate functions with Latin, and then under impulses of nationalism and pedagogical effectiveness rose to challenge and eventually displace Latin altogether. National vernaculars achieved this only after modeling their rhetorical and literary practices on Latin's example, and therefore today, in specialized vocabulary and modes of reasoning, perversely assure it some kind of permanence.

AD 1999: Contemporary Globalization

The education reform commonly known as the Bologna Declaration was signed on 19 June 1999 by 29 European countries aiming to establish a European Higher Education Area by 2010. Naming new semantic fields, codifying names, standardizing codes, and disseminating their use are all indicators of emergent fields. These processes permit calibration and standardization; comparable nomenclature accompanies degree simplification, permitting standard divisions between forms and levels of study, standard degree requirements, and a standard grading scale with common transcript. In its implementation, Bologna

generates greater administrative coherence and procedural operations. The self-conscious aim is continent-wide comparability.

The expanding number of signatories, 45 at the time of writing, has meant that Bologna standardization has produced catalytic effects beyond its zones of application. Although ostensibly a move for administrative uniformity, Bologna will engender slow-acting but important long-term cultural consequences. One example is the European Credit Accumulation and Transfer System, leading to conversion from longer to shorter first degrees. More commonly designated bachelor graduates will facilitate masters-level expansion as the 3-year regime replaces most 5-year first degrees. Shorter duration first-degree standardization will accelerate study abroad, reduce first-degree government costs, and make master programs the major international study option.

Structural changes such as these fertilize the graduate education market, student behaviors, and study patterns, and make institutional dynamism more likely. In turn, these developments stimulate further adoption of English to attract nondomestic enrolments. More European countries are likely to offer price-based competition for international students in disciplines unconnected to local cultural or linguistic study, for example, English-medium business, technology, and science programs.

From their inception, universities have been the key global institution, far outlasting practically all other ancient institutions – functioning in a shared language, enrolling international students, engaging international academics, and disseminating knowledge beyond national borders. According to Altbach (2004), all universities today, other than Cairo's ancient Al-Azhar, originate from the European medieval university, with non-Western countries having European models "imposed on them by colonial masters. Even those countries not colonized by Western powers – such as Japan, Thailand, Ethiopia . . . – adopted the Western academic model . . . even where, as in China, well-established indigenous academic traditions already existed." (p. 4).

The 1999 *Magna Charta Universitatum*, now available in 47 languages, attracts increasing Asian, American, and African adherents, with signatories now totaling 579 (IPPT, 2008; UniBo, 2008) in 78 countries. It originated in the medieval recognition of rights to unhindered travel to study or teach; but fidelity to its principles of freedom and autonomy appears to be independent of setting and time.

Universalism in higher education therefore, has many sources and modalities: secular and religious, geographic and civilizational, technical and economic, and both imposed and voluntary. The modalities include cooperative charters of principle, competitive ranking of prestige, colonization and domination, and trade in commodified language and certified study (Tan and Rubdy, 2008).

Globalization and *Lingua Mundi*

A recent study by Cha and Ham (2008) documents historic patterns of foreign-language study. During 1875–99, only 6% of secondary-school curricula worldwide nominated English as the first foreign language, increasing to 70% of primary and 80% of secondary curricula by 1990–2000. In Asia, English was represented in only 33% of primary curricula during 1945–69, growing to 83% in primary and 100% for secondary by 2005. By 2006, practically all instances in which foreign languages were employed to teach mainstream subject matter in Asian universities involved English. Recent growth in English is mostly independent of whether countries were British colonies or under American political influence, leading the authors to argue that English is no longer a foreign language, but rather a kind of foundational knowledge, or basic skill used for globalization. Supporting such claims are projections of English use as well as learning, particularly those made by Graddol (2006) who claims that English students and users might in a period of only two decades equal a third, or even half, the world's population.

The diverse sources of demand for English produce innumerable local cultural and political meanings and effects. Global English defies temptations to depict its role in today's world according to a simple binary choice between imperial instrument and unproblematical asset. Concern often arises about English when it replaces teaching-through national languages, even in countries with long-standing national scientific-education traditions, for example, the Netherlands and Sweden. Recent debates about teaching in English had unpredictable effects, pushing policymakers to retreat from multilingual policies concerned about long-term vitality of Swedish as a result of exposure to globalization (Boyd, 2007: 175). This is also true in China, where obligatory English alongside Putonghua results in a tri-lingual and tri-literate burden on non-Han minority populations (Feng, 2007).

Human capital theorizations dominate education policies practically everywhere, and English-delivered instruction reflects and helps to strengthen a distinctive marketplace for competence, certification, and exchange. Internationally compared degrees, international universities, and student mobility are not exclusive to English, but it is the most consistent element in such arrangements. Representing English as a basic skill has the effect of reducing its foreignness and even of representing English as purely an instrument of communication, or a postidentity language (Lo Bianco, 2005). These labels and ways of talking about English are the discursive accompaniment to its material attractiveness as a commodity (Lo Bianco, 2007b; Tan and Rubdy, 2008).

The nature of this commodity is decreasingly Anglo-American and increasing number of Asian institutions

position themselves as suppliers of general English and increasingly for specialized education through English. For some observers, a single global society (Cha and Ham, 2008) follows in the wake of English-mediated mass education with its standardized qualifications, increasingly portable form, and traded in an interlinked marketplace of skills. Perhaps, this is premature given the recency of domination by English as demonstrated in the Cha and Ham data; however, what is clear is the expanding number of extranational communities of communication founded in professional identities and facilitated by English-knowing bilingualism. These are evident in professional associations, professional conferences, and in the academic work and professional conversations that sustain these communities of communication. As these communities are elites within their own societies, this association of English as a medium is making possible horizontal linkages, that is, of elites across national boundaries, associates knowing English with social stratification and inequality.

As the medium of most international scientific literature and the most disseminated journals, both in print and electronic form, English clearly dominates the conversations of academic life. Access to its elevated registers is therefore, for individuals and institutions, a predictor of advantage, such as when competitive promotions rely on reputable publication in approved journals. English capability is increasingly associated with reward systems in higher education as reputation is a critical ingredient of systemic advancement. The reality is, however, that access to English, especially in developing countries, is distributed according to preexisting social, ethnic, and geographic divisions. Schooling, much less higher education, cannot adequately compensate for inherited advantages in access to the powerful written and spoken styles of English, which are often informally acquired in family and affinity networks that socialize privileged groups in cultural capital (Bourdieu, 2005). Education systems which favor English-delivered instruction, therefore compound existing inequalities for minority and poor populations who are precluded by prevailing social structures from acquiring prestigious forms of English.

The effort to reproduce and conform to the norms of academic life which prevail in Anglophone settings requires institutions and societies more generally to make adjustments that go beyond what occurs in universities alone, impacting deeply on social networks and relationships. Additionally, Altbach (2004) notes several ways in which English constitutes advantages for American and British authors and institutions, such as the cost of English-language databases, products and resources, direct experience in editing and housing scholarly journals, and procedural advantages in peer review and academic writing. Higher education institutions in developing

countries find access to this array of advantage systems, through which critical information is negotiated and reputations forged, cost-prohibitive. Restrictions on ownership and usage, such as stringent copyright procedures, entrench existing hierarchies of control and quality and quantity of access.

However, there are other and more subtle cultural and ideological questions which arise, such as command of persuasive argument styles inherent in particular disciplines and their surrounding traditions of academic life (Lo Bianco, 2004). As the reasoning and rhetorical practices valued in the Anglophone tradition are associated with privilege and success within societies, indigenous versions of these practices can be displaced or challenged. While it is true that languages contain low ideology and relatively culture-free transactional styles, higher-order functions of language are hardly neutral. An important recent exploration of this is Wierzbicka's (2006) study of the persisting layers of culture in English. In this work, Wierzbicka finds semantic bias within the grammatical core and discursive styles of English contributing a significant installment in what is a long debate about how language and thought intersect. At the very least, this work serves to render problematic the often naive assumption that any language can be rapidly removed from its historic and contextual origins and shorn of traces of these, as occurs when English is considered a totally neutral tool of communication, an instrument without imprint of history and culture.

Formal university rankings represent a clear example of the language-prestige hierarchy. In the 2006 edition of the Shanghai Jiao Tong Index (SJTI), 19 of the world's 20 top-ranked universities were American or British and 66% of the top 100 were located in English-language settings. In his analysis of the SJTI, Marginson (2007a) argues that such rankings "... favour universities ... from English language nations because English is the language of research (non English language work is published less and cited less); and universities from the large US system as Americans tend to cite Americans" (p. 133).

Reflecting on this palpable advantage bias, Van Parijs (2007: 85) proposes a kind of native-speaker tax on Anglophones, payable to English learners to defray the costs of acquisition. Van Parijs calculates the subsidies involved, concluding that Chinese people would receive €32.20 per capita from the Anglo population; French speakers would be granted a €24.24 subsidy; and Danes would each receive €23.76. While Coulmas (2007) adopts a more accommodating stance he also acknowledges the extra burden imposed on non-native users of English but implies a possible future shift when he has an interlocutor in simulated conversation on scientific publishing conclude: "I registered for an intensive Chinese course yesterday" (p. 13).

Gigantic Peripheries

China, along with India, constitutes what Altbach (1998) has called gigantic peripheries to American and English-centered contemporary globalization. Since 1998, they remain gigantic but have moved close to the center of where knowledge and human capital economic power intersect. In very different ways, Chinese and Indian education systems reveal immense penetration by English.

In 2001, the Chinese Ministry of Education issued a stipulation that universities should provide 5–10% of undergraduate instruction in foreign languages (Pan, 2007), leading to considerable growth of English–Chinese bilingual teaching, and expanded the scope of English teaching at other levels (MinEd, 2001). An evaluation of these initiatives at East China University of Science and Technology in Shanghai found predictable problems of implementation and uneven readiness, but by 2006 bilingual education was flourishing; producing results superior to traditional English teaching (Pan, 2007: 212).

In such environments, English has two principal roles, as MOI and as object of instruction for English majors. Exploring this accelerating globalization in Chinese higher education, Chang (2006) also looks at adjustments to national English language policy.

Documenting a surge of use of English as MOI, Chang's study identifies the ripple caused into the basic university-training models, in revisions to the national curriculum and in textbook design and content. No fewer than six new training models had emerged: English major plus courses in other specialisms, English major plus an orientation toward other disciplines, English major plus a minor, a major plus English language, English language plus another foreign language, and dual degree – BA degree of English language and literature plus another BA degree.

It is unlikely that such an array of English-centered program designs and training models producing composite-type graduates, can be quarantined within English training or language departments in universities. Instead, it is more likely to cause organization adjustments throughout education, as what English training is, becomes meshed with basic academic preparation in a growing number of academic disciplines. English and Chinese will share the communicative load in some programs, such as collaborative degree programs discussed by Pan (2007) which are conducted in English with components of Chinese-language facilitation or support to enhance learning or to overcome predictable gaps. In other settings, such as Malaysia, which have a more established local history of English, there is growing use of English-only (Altbach, 2004; Kaur, 2004) or English-dominant programs.

The transnational status of institutions extends such intra-institutional changes brought about by English

medium education. In a dramatic display of such developments, *Science Magazine* recently proclaimed that Chinese universities are now the top feeders for US doctoral programs. Reporting research showing that Tsinghua and Peking Universities “have topped the list of undergraduate schools whose graduates go on to earn a doctorate from an American university” (Mervis, 2008: 185) the story underscores the transnational dimension of contemporary higher education, the facilitative function of English, and the extent of mobility.

This integrated and global marketplace fosters trade in expertise with practically instantaneous exchange of information. The two prestigious Chinese institutions beat the University of California, Berkeley, to third place with Seoul University next. This cross-border transfer and burgeoning interdependence between US and Chinese higher education is accompanied by massive Chinese investment in high-scale research capability and increasing attraction to large numbers of in-bound students and academic staff in Chinese-language programs.

Small Peripheries

More asymmetrical is the relationship between globalized education products, processes, and certification, and small societies. Cambodia, with its history of multiple colonization and dependency, is an instructive and disturbing case. Exemplifying this is the case of the Royal University of Phnom Penh, founded on 13 January 1960 (Man and Luong Chan, 2002), incidentally a signatory to the *Magna Charta Universitatum*.

Cambodian language policy (Clayton, 2002) has been buffeted by colonization, immersion in global markets, and now by the influence of development assistance, often with linguistically tied programs. Influencing the communicative patterns of Cambodian society are strategic, cultural, ideological, and economic interests from outside, intertwined with domestic interests, and the choices that result from their interaction on questions of MOI, minority-language rights and foreign-language preferences. All these points are in evidence in the recent history of one institution. Since its inception, the Royal University of Phnom Penh (originally Khmer Royal, then Phnom Penh University), taught mostly in French during the 1960s, underwent gradual Khmerization during the 1970s, conserving some use of French, but was closed due to political upheaval and violence between 1975 and 1978. During the 1980s, teaching was initially in Russian, later Vietnamese was added, and still later Khmer was included. In the late 1980s and early 1990s, first French then English were used alongside Khmer. From the early 2000s, teaching has been mainly in Khmer but with booming interest in English and

residual use of French, often promoted as a condition of assistance (Man and Luong Chan, 2002; Clayton, 2006).

Despite the obvious disruptive effects of such changes, MOI policy is often taken to be a straightforward question of cost and efficiency. In this unproblematic depiction, a country or a single institution would simply calculate the costs of different language choices and opt for the cheapest and most feasible alternative. Informing the calculation of cost would be the availability of academic literature in the different language choices, the expense and feasibility of translation, and the availability and training costs of lecturers. Opposition to such efficiency-based reasoning is often represented as backward-looking nationalism or sentimentality. However, reducing MOI choices entirely to such a binary between cost and sentiment, or technical efficiency versus national-language ideologies, is crude, obscuring some very complex issues and problems, which extensive documentation of MOI policies reveal. Not least among these complicating factors are the potentially corrosive effects on the internal efficiency and vitality of national languages when they are excluded from high-level scientific discourses. Affecting people, rather than languages, are the ways in which MOI policies preferring foreign over local languages compound inequalities already faced by minority or disadvantaged groups. Neither of these arguments relates to sentiment, but to the practical effects, on people and on their languages, of favoring external or foreign languages over local ones.

In the light of this, it is not surprising that Tollefson and Tsui's (2004) survey of Asian experiences with MOI policy leads them to argue that there are always agendas involved in choosing a language of instruction, that these agendas align with particular interests, and are subject to change over time in response to shifting economic and political circumstances. We can see these shifts clearly in the case of Sri Lanka (Ceylon), Malaysia, and Singapore. In the postcolonial context of the mid-1950s, these countries all ejected English from their education systems for reasons of national reconstruction, nationalism, or local administrative consolidation; however, by the early 2000s all three had reinserted English both as an object of instruction and as MOI. In some cases, English has been restricted to teaching only some disciplines, especially science, mathematics, technology, and business studies, while in others it was used more widely (Lo Bianco, 2007a). In the mid-1950s, when English was evicted from education, there were protests in its defense, and today when English has been either fully or partially restored as a teaching as well as a taught language, there are varying levels of concern and agitation against its new status.

Kaur's (2004) examination of the Malaysian case isolates the contribution of higher education bifurcation to undermining Malaysia's previous ability to resist the

incursions of English. Bifurcation refers to reforms permitting English-medium private universities to operate alongside Malay-medium public universities. These were the catalysts provoking a wider dismantling of the Malay-only MOI stance, eventually also in schools. Mon-lingual Malay-educated majority-population interests were made vulnerable by the marketplace advantages of English-knowing bilinguals, and in 2009, there continues to be vigorous debate about both the efficacy and desirability of using English to teach mainstream subjects and the ripple effects onto different ethnic and social groups. The public/private divide highlights how the asymmetrical acquisition of English compounds internal social stratification. A related situation typifies Sri Lanka (Lo Bianco, forthcoming) where language learning aligns with social opportunity, ethnic and racial backgrounds, geography, and social class.

Language planning in universities at a time of rapid and profound globalization can only be properly examined as choices situated within preexisting sociopolitical contexts, reflecting divergent interests and agendas as much as opening up new opportunities in emergent markets. Tollefson and Tsui (2004) rightly identify sociopolitical processes as key drivers of MOI choices, rather than unproblematical technical assessments of costs in delivery of content, or access to scientific literature. Even when cost and efficiency considerations predominate, debates about language policy cannot be credibly separated from inherited historical arrangements. Both the discourse, which accompanies MOI policy and the agendas various interests advance are underscored by Tsui's analysis of Hong Kong, in which she argues that MOI is:

... shaped by an interaction between political, social and economic forces. . . among these agendas, it is always the political agenda that takes priority. Other agendas. . . come to the fore only if they converge with the political agenda. Yet it is always these [other] agendas that will be used as public justification for policy making. (Tsui, 2004: 113)

Conclusion

Globalization transforms universities directly making research-based higher education, like finance services, a sensitive and exposed sector (Marginson, 2007b). Critical to national economic positioning, cultural production, and international communication, higher education achieves its capability through intense and endemic globalization. Knowledge-intensive sectors, industries and services, are aggregated around and within universities, making them large business corporations organizing the collection of knowledge and its dissemination in publishing, seminars, conferences, and applications of various

kinds. These interactions bring to the surface an intense connection between English and technical knowledge and help make the language itself a commodity (Tan and Rubdy, 2008) traded in its distinctive marketplaces.

Although positioned in national states, knowledge economies are interlinked across national boundaries, and are organized by these global relations. Opportunities for mobility and employment opened up by English are not as well distributed and organized as is often supposed. English does not just mediate access to knowledge and skills, but is a substantial component of knowledge and skills. Languages and their associated literacies impose their own hierarchies and can compound endemic inequalities even when they offer new opportunities and prospects.

The contemporary era of global education recalls its ancient precedents because it underscores the nonconfineability of knowledge and the internationalist impulse of the university. Education systems both celebrate and defend academic freedom and institutional autonomy and accommodate peripheries, whether gigantic or small, to norms that privilege arrangements set by the dominant centers of education. These patterns are linked to economic privilege and power, and align closely with the world's current language regime. While current language arrangements might not be assured or permanent, their entrenched power contains elements, which are self-fulfilling and which are deeply rooted in systems of reward, ranking, and comparison.

On the positive side, language-based globalization also promotes multiple channels of communication and increasingly uses technologies based on multiple literacies, combining digital, electronic, and visual with the print literacies of the past. These potentially expand the range of individuals and social groups able to participate in and benefit from higher education. No education will be immune from such epoch-making changes and even the most technical subjects and fields of research will have to deal with audiences, which are multicultural and highly mobile and communication technologies that threaten to disrupt the very basis of written literacy (Crossman, 2004). Scientific literate communication is as ancient as the institutions which rely on it, and its future forms appear to be as dynamic as their contemporary functions. As all such changes are located within endemically unequal arrangements, the ancient globalization of institutions sheds light on patterns that too often we imagine are unique in time.

Glossary

Constructive alignment – The alignment of teaching and assessment to the intended learning outcomes.

Engineering education research – An academic discipline engaged in scholarly enquiries into the principles, methodologies, and practices in engineering education.

Graduate attributes – A set of individually assessable outcomes that are indicative of the graduate's competencies.

Professional competencies – A set of knowledge, skills, and attitudes which a practicing professional should possess and be able to demonstrate in a holistic manner.

Student learning outcomes – What a student should know or be able to do as the result of a learning experience.

Student mobility – The ability of students to study or work after graduation across national boundaries.

Substantial equivalence – A principle used in establishing the mutual recognition of qualifications by focusing on a set of graduate attributes that are necessary for entry to the profession, rather than mandating identical content and outcomes.

Washington Accord – An international agreement which recognizes the accredited engineering degree programs of its signatories and recommends that graduates from these programs be recognized as being prepared to practice engineering at the entry level.

Introduction

Globalization of Higher Education

The higher education sector worldwide has seen many significant changes in recent years. The evolution from elite to mass education has led to a much larger student population and, along with it, a more diverse student body in terms of age, gender, academic, and cultural backgrounds. There are also more modes of delivery and different types of learning experiences, many of which are made possible by the advent of technology. Along with an increasing demand of accountability for public funds

spent on higher education, universities everywhere are under pressure to manage these changes in an efficient and effective way.

At the same time, employers worldwide are placing new demands on university graduates. The inevitable progress of globalization has changed the ways companies operate and the attributes they look for in new hires. In order to compete internationally in a knowledge economy, multinational companies will need to be more agile and adaptive. They want to build a workforce of people who can work productively in a multidisciplinary and cross-cultural environment and are willing to recruit from all over the world.

An important consequence of globalization then is the increasing mobility of students entering and graduating from universities. In Globalization 3.0, a term coined by Friedman (2006), individuals of high mobility can choose to study, work, collaborate, and compete anywhere in the world. Many universities have taken advantage of this development to expand their international student population by recruiting globally. University graduates also enjoy a much wider choice of geographical locations in which they can pursue their career paths. With the diminishing importance of national boundaries, there is a need for international norms and standards by which academic qualifications from different countries can be meaningfully compared. Furthermore, with the emphasis on lifelong learning, an international framework for capturing learning experiences beyond formal education is necessary.

Globalization of Engineering Education

The engineering profession, in terms of its practice, research, and education, has always had a global presence. In fact, engineers have contributed to globalization through technological advances in areas such as communication, energy, environment, logistics, materials, and biotechnology. Engineering companies are often multinational, operating in multiple sites and employing engineers worldwide.

Ironically, despite the contributions engineers have made to the well-being of modern society, engineering as a profession is becoming less attractive to young people, especially in developed countries. An engineering education is often perceived to be narrow, boring, and demanding. It is thus incumbent on engineering schools to come up with innovative curricula that, as put by Vest (2006), arouse engineering students' passion, curiosity, engagement, and

dreams, and thereby prepare them better to face the exciting opportunities in engineering and related disciplines. Furthermore, these graduates will need to have a set of attributes, which can be benchmarked internationally, to ensure their global mobility. The Washington Accord is an international effort to this end, by encouraging institutions that offer engineering degree programs to focus on student learning outcomes in an accreditation process that leads to mutual recognition.

Washington Accord

History

The Washington Accord was an agreement signed in 1989 by six engineering education accreditation bodies. These bodies, having examined the accreditation processes, policies, and procedures in their respective countries, concluded that they are comparable. The original six signatories therefore recognize the substantial equivalence of their engineering degree programs in satisfying the academic requirements for the practice of engineering at the entry level of the profession.

It should be noted that the agreement covers only accredited educational qualification but not professional registration, which rests with individual countries or regions. However, each signatory will encourage the licensing body in its own country or region to accept the substantial equivalence of engineering education programs accredited by other signatories.

The administration of the Accord is supported by a secretariat and the signatories meet biennially. In order to become a signatory, an applicant must be nominated by two of the existing signatories and supported by at least two-thirds of the existing signatories. A successful applicant will be given a provisional status and a prescribed period during which the applicant must demonstrate that it has an accreditation system that is comparable to those of the existing signatories. The change from a provisional status to a full signatory will require the unanimous approval of the existing signatories.

Table 1 shows the founding, other, and provisional signatories of the Washington Accord. In recent years many countries or regions have expressed an interest in joining the Washington Accord and, as part of that process, developing accreditation systems for engineering degree programs.

Related International Partnerships

Based on the principle of substantial equivalence established in the Washington Accord, the Sydney Accord and the Dublin Accord came into being in 2001 and 2002 to recognize accredited qualifications for engineering technologists and engineering technicians, respectively.

Table 2 summarizes the founding and provisional signatories of these two accords.

Another system for a common recognition of accredited engineering degree programs for entry to the profession is the European Network for Accreditation of Engineering Education (EUR-ACE), which established framework standards for comparing educational qualifications in the European Higher Education Area.

The Engineers Mobility Forum agreement and the Asia Pacific Economic Cooperation (APEC) Engineer agreement have been introduced to promote the mutual recognition of professional competence in engineering, both using the International Professional Engineers Register. There are also many international engineering organizations, such as World Federation of Engineering Organizations (WFEO), European Federation of National Engineering Associations (FEANI), and Pan American Federation of Engineering Associates (UPADI), for the sharing of good practices in global engineering activities.

Graduate Attributes and Professional Competencies

Graduate attributes are a set of statements of what graduates from an engineering degree program are able to do

Table 1 Signatories of the Washington Accord

Founding signatories (1989)	Australia, Canada, Ireland, New Zealand, United Kingdom, and United States	
Other signatories	Hong Kong China (1995), South Africa (1999), Japan (2005), Singapore (2006), Chinese Taipei (2007), Korea (2007), and Malaysia (2009)	
Provisional signatories	Germany (2003), India (2007), Russia (2007), and Sri Lanka (2007)	

Table 2 Signatories of the Sydney Accord and Dublin Accord

	<i>Sydney Accord originally signed in 2001</i>	<i>Dublin Accord (originally signed in 2002)</i>
Founding signatories	Australia, Canada, Hong Kong China, Ireland, New Zealand, South Africa, and United Kingdom	Canada, Ireland, South Africa, and United Kingdom
Other signatories	United States	
Provisional signatories		New Zealand (2006) and United States (2007)

and form the basis of outcome-based accreditation criteria. These statements should be clear, succinct, and assessable. The graduate attributes in the Washington Accord, Sydney Accord, and Dublin Accord are all defined in 13 areas: academic education, knowledge of engineering sciences, problem analysis, design/development of solutions, investigation, modern tool usage, individual and teamwork, communication, the engineer and society, ethics, environment and sustainability, project management and finance, and lifelong learning.

For consistency and ease of comparison, a common stem is used in the three accords for each attribute, with the characteristics of engineers, engineering technologists, and engineering technicians differentiated by range information. For example, the common stem for individual and teamwork is: function effectively as an individual, and as a member . . . ; the range information is:

- Engineer: or leader in diverse teams and in multidisciplinary settings.
- Engineering technologist: or leader in diverse technical teams.
- Engineering technician: in diverse technical teams.

There are no differentiating characteristics in three of the 13 attributes (ethics, environment and sustainability, and lifelong learning).

Whereas graduate attributes are meant for academic accreditation, professional competencies are for professional registration. As such, professional competencies define a set of knowledge, skills, and attitudes which a practicing engineer should possess and be able to demonstrate in a holistic manner. The overall performance standard is defined in terms of 13 areas: comprehend and apply universal knowledge, comprehend and apply local knowledge, problem analysis, design and development of solutions, evaluation, responsibility for decisions, manage engineering activities, ethics, protection of society, communication, lifelong learning, judgment, and legal and regulatory. Again, stem and range information are used to differentiate the professional competencies of engineers, engineering technologists, and engineering technicians. For example, the common stem for problem analysis is: define, investigate/clarify/state, and analyze; the range information is:

- Engineer: complex problems.
- Engineering technologist: broadly defined problems.
- Engineering technician: well-defined problems.

There are no differentiating characteristics in four of the 13 areas (ethics, communication, lifelong learning, and legal and regulatory).

Graduate attributes and professional competencies provide a common language for the comparison of educational and professional systems in different parts of the world. In the spirit of substantial equivalence, graduate attributes should not be rigidly interpreted, but instead should be

viewed as an indication of the expected outcomes of an engineering degree program worthy of accreditation.

Impact of the Washington Accord on Engineering Education

Outcome-Based Accreditation

The conceptual framework of outcome-based education is to start with clear intended learning outcomes, then to use the most appropriate curriculum, pedagogy, and assessment to ensure that students succeed in achieving such outcomes. Simply put, a learning outcome is what a person should know or be able to do as a result of a learning experience; it should state clearly the conditions under which a learner can do a particular task and the expected level of performance.

Learning outcomes can be classified into three categories: knowledge, skills, and affective (or attitudinal) outcomes. According to the taxonomy proposed by Ewell (1984), knowledge outcomes include breadth of knowledge and depth of knowledge (in a specific discipline); skills outcomes include general competencies and professional/occupational skills; and affective outcomes include personal goals and aspirations, general attitudes, values, and satisfaction, attitudes toward self, and attitude toward others.

At a time when traditional educational processes have become more diverse in terms of the input and process variables, learning outcomes provide a common language by which graduates from different programs can be meaningfully compared. For this reason many accreditation systems that have an international presence have adopted an outcome-based approach in recent years. The idea is not to ensure identical learning outcomes across national boundaries but, in the spirit of substantial equivalence, spell out clearly what graduates from an accredited program should be able to do for entry to the profession.

In outcome-based accreditation, the focus is on program-level learning outcomes. It is important that these outcomes are (1) consistent with the mission of the program and that of the university, (2) determined based on inputs from all relevant stakeholders, and (3) defined by appropriate performance indicators. The evaluation of the program can then be made by reliable criteria and benchmarks, with an emphasis on providing specific feedback for improvement purposes. The essence of outcome-based accreditation is a commitment to continuous quality improvement based on credible evidence.

A Case Study: ABET, Inc

Engineering and technology programs in the United States are accredited by ABET, Inc. In response to growing concerns that ABET accreditations for engineering degree programs were too bureaucratic and not conducive to educational innovations, ABET introduced in the mid-1990s

Engineering Criteria (EC) 2000. The key focus of EC 2000 is to measure the outcomes of engineering degree programs, in terms of what graduates can actually do.

The EC 2000 has eight components, with criterion 3 being program outcomes and assessment. Criterion 3 states that engineering degree programs must demonstrate that their graduates have the following capabilities:

1. An ability to apply knowledge of mathematics, science, and engineering approaches to the discipline.
2. An ability to design and conduct experiments and analyze and interpret data.
3. An ability to design a system, component, or process to meet desired needs.
4. An ability to function on multidisciplinary teams.
5. An ability to identify, formulate, and solve engineering problems.
6. An understanding of professional and ethical responsibility.
7. An ability to communicate effectively.
8. The broad education necessary to understand the impact of engineering solutions in a societal context.
9. A recognition of the need for an ability to engage in lifelong learning.
10. A knowledge of contemporary issues.
11. An ability to use the techniques, skills, and modern engineering tools necessary for engineering practice.

Every engineering degree program in the United States has now gone through the EC 2000 process and a vast majority of programs have been accredited. A study of the impact of EC 2000 (Lattuca *et al.*, 2006) showed that the new accreditation criteria had led to a positive, and sometimes substantive, impact on engineering programs, student experiences, and student learning. In particular, these researchers noticed a greater emphasis on professional skills and active learning after EC 2000. Their data showed that engineering students who graduated in 2004 differed significantly from their predecessors in eight of ten experiences inside and outside the classroom. Furthermore, there was a slight rise in the knowledge and skills in science, mathematics, and engineering, despite the focus on professional skills. The researchers also reported higher levels of faculty support for continuous improvement, notwithstanding a mixed emphasis on teaching in the faculty reward structure. Results of this study provided the most comprehensive evidence thus far for the effectiveness of an outcome-based approach in accreditation.

Impact on Curriculum, Pedagogy, and Assessment

Curriculum

Many capabilities in EC 2000's criteria 3a–3k for the accreditation of engineering degree programs are related to traditional values related to liberal education. This means

an engineering degree program needs to place increasing emphasis on skills and affective outcomes. At the same time, EC 2000 stipulates the following curriculum requirements in engineering degree programs: (1) 1 year of university-level mathematics and basic sciences, (2) 1.5 years of engineering topics, and (3) humanities and social studies. It also makes explicit the requirement of a major design experience that not only draws on professional knowledge and skills acquired from coursework, but also incorporates engineering standards and realistic constraints.

The need to strike a balance between professional preparation and liberal education in engineering degree programs is not unique to ABET and, in fact, is common to all signatories in the Washington Accord as is evident in the descriptors for the 13 graduate attributes. In order to meet this challenge, engineering educators have developed innovative approaches in curriculum design, pedagogy, and assessment. In curriculum design, there has been a shift from a compartmentalized approach to a holistic approach, resulting in integration in the following areas:

- Integration of different disciplines (e.g., a multidisciplinary approach to problem solving).
- Integration of theory and practice (e.g., incorporating more real-world examples in the curriculum; creating internships and cooperative programs).
- Integration of professional skills across the curriculum (e.g., teamwork, communication).
- Integration of curricular and co-curricular learning (e.g., service learning).

As an illustration of the first integration (of different disciplines), many engineering schools have introduced curricula aimed at combining technology and management. Instead of the traditional model of engineers pursuing MBA degrees, now engineering students can choose from a wide range of options such as minor in business, major, double major, dual degree, or BS/MS combined degree in technology and management. The intent is to produce graduates who will become managers and leaders in technological companies.

One important curriculum issue is the global competence of engineering graduates. As Lohmann (2003) observed, there are three common elements that require attention: foreign language proficiency and cultural acclimation, discipline-related study abroad, and professional experience in an international setting. Besides offering language and intercultural training, many engineering schools in recent years have increased the number of international students and exchange students. A curriculum needs to offer the flexibility for students to explore meaningful international experiences, be they academic or professional.

Pedagogy

The best-designed curriculum will not work unless its implementation is supported by appropriate learning and

teaching activities and assessment approaches. The consistency among learning outcomes, pedagogy, and assessment is known as constructive alignment (Biggs and Tang, 2007), which is essential in outcome-based education.

The major shift in pedagogy is from a teaching perspective to a learning perspective, drawing from research on how people learn. Even though many engineering courses are still taught in a classroom setting, more active learning approaches such as problem-based learning and collaborative learning have been introduced. These approaches engage students to take more responsibility for their learning, usually by working in teams to solve problems. Problem-based learning (PBL), in particular, has been adopted widely by engineering educators; an entire curriculum based on PBL has been offered by Aalborg University since 1974.

Technology has also led to many pedagogical innovations, including content creation and dissemination, asynchronous learning and teaching, learning management systems, and social networking via the World Wide Web. It is now possible for students from all over the world to work on a team project via web conferencing, thus making it easier to inject international experiences into the curriculum.

The adoption of innovative pedagogies requires a systemic effort on faculty development. Universities worldwide are incorporating pedagogy training as part of the orientation of new faculty. For serving faculty, support for teaching is usually provided in three different formats:

1. short courses or workshops on specific topics;
2. learning communities which enable teachers to share their experiences; and
3. formal training programs leading to certification or qualification.

Some European countries are requiring their university teachers to be formally certified or qualified. As discussed further below, everywhere in the world engineering educators are increasingly engaged in a scholarly discussion of learning and teaching matters, guided by the latest findings in engineering education research.

Assessment

Assessment has always been the most challenging aspect in the outcomes–pedagogy–assessment alignment. With a shift in focus from knowledge outcomes to skills and affective outcomes, engineering educators have responded by developing new assessment strategies (Olds *et al.*, 2005; Shuman *et al.*, 2005). In particular, assessment practices have evolved from the assessment of learning, to assessment for learning, then to assessment as learning.

In assessment of learning, the emphasis is on finding out what a student has learned. Typical assessment tools include examinations, term papers, reports, presentations, etc. The assessment usually leads to a grade, based on norm-referencing (drawing a curve) or criterion-referencing (using a set of criteria).

In assessment for learning, the emphasis is on using assessment to facilitate learning. Students are given clear expectations of the intended learning outcomes and their roles in managing their learning. Then students are given appropriate learning activities, along with specific and timely feedback for improvement throughout the learning process. The assessment is often formative rather than summative in nature, in that, it does not involve a grade.

In assessment as learning, students are actively engaged in the assessment process to the extent that they assess their own work and the work of their peers. Assessment becomes a key feature of learning in this approach. When students are aware of the criteria upon which their performances will be assessed, they usually do a conscientious evaluation of their own and others' performances. Learning portfolios (including e-portfolios) can be an effective tool for capturing this type of self-learning and assessment.

It appears that whereas knowledge outcomes can be reasonably assessed with conventional tools, skills and affective outcomes are best assessed with an integrative approach that collects a body of evidence from different perspectives (self, peers, teachers). Furthermore, an overall assessment strategy should be developed to facilitate learning and not just to grade. At its best, assessment serves three important purposes: (1) to promote the intended learning outcomes, (2) to produce credible evidence of having attained those outcomes, and (3) to help students become self-regulated learners in the process.

Increasingly, universities worldwide are under pressure to produce assessment results that demonstrate not only student achievement, but also institutional effectiveness in its educational delivery. So even though learning-oriented assessments demand a lot of human and financial resources, it is incumbent upon engineering educators to develop coherent and effective assessment methodologies. Both ABET and the Assessment of Learning Outcomes in Engineering (ALOE) Working Group in the United Kingdom have provided useful assessment resources. The Council for Higher Education Accreditation (CHEA) Award for Institutional Progress in Student Learning Outcomes, first introduced in 2006, has identified institutions in the United States that are exemplary in addressing student learning outcomes (Eaton, 2008).

Engineering Education Research

Inherent in an outcome-based approach is a commitment to continuous improvement based on credible evidence. In order to obtain such evidence, engineering educators have to address many complex yet fundamental questions on learning and teaching. Education reforms can no longer be piecemeal and empirical, but need to be supported by a holistic and research-based framework. An important consequence of implementing outcome-based accreditation in engineering degree programs then is the emergence of engineering education as a discipline.

The American Society for Engineering Education (ASEE) launched in 2006 an initiative titled Advancing the Scholarship of Engineering Education (ASEE, 2006). Its intent is to transform engineering education through educational scholarship to better prepare graduates for the twenty-first century. This initiative has since led to a project funded by the National Science Foundation, the main purpose of which is to provide a blueprint for and initiation of actions to rapidly transform engineering education (ASEE, 2008). A special report was also published in 2006 in the *Journal of Engineering Education* (Special Report, 2006) to summarize the research agenda for engineering education. To address the questions of what content (knowledge and skills in context) future engineers must possess; how the said content is being learned; and how learning of the content should be assessed, five research areas have been identified as follows:

1. Engineering epistemologies – research on what constitutes engineering thinking and knowledge within social contexts now and into the future.
2. Engineering learning mechanisms – research on engineering learners' developing knowledge and competencies in context.
3. Engineering learning systems – research on the instructional culture, institutional infrastructure, and epistemology of engineering educators.
4. Engineering diversity and inclusiveness – research on how diverse human talents contribute solutions to the social and global challenges and relevance of our profession.
5. Engineering assessment – research on, and the development of, assessment methods, instruments, and metrics to inform engineering education practice and learning.

Even though the above initiatives are in the United States, similar developments in engineering education research are taking place worldwide. In 2007, an International Conference on Research in Engineering Education (ICREE) was held for the first time; it was renamed as the Research in Engineering Education Symposium (REES) in 2008. These events brought together a global community of scholars to share their works and to discuss future research directions in engineering education.

Summary

Globalization has redefined the meaning of international competitiveness. For companies, it means the ability to operate anywhere in the world and be able to attract talent from everywhere. For individuals, it means the ability to choose the company and location to work for. For universities, it means the ability to attract international faculty and students, to build global alliances in

education and research, and to produce graduates that are highly sought after both locally and overseas.

This increasing mobility of people calls for international standards by which academic qualifications can be meaningfully assessed and compared. The Washington Accord is one such example in defining the attributes engineering graduates should possess for entry into professional practice. The descriptions of graduate attributes usher in an outcome-based approach in accreditation, which is increasingly adopted in other professional fields. Furthermore, in the spirit of facilitating lifelong learning, an outcome-based approach has also been used in the drafting of qualifications frameworks (e.g., the European Qualification Framework), for which diverse learning experiences need to be properly recognized.

The essence of an outcome-based approach in accreditation is its focus on student learning and achievement. By examining critically what a student should be able to do after a learning experience and how best to make that happen, engineering educators have introduced innovations in curriculum design, pedagogy, and assessment. Above all, the move toward making learning explicit has built a culture of collecting research-based evidence. This in turn, has led to the emergence of engineering education research as a discipline, one that brings people together to have a scholarly discourse on how best to improve engineering education and, in turn, engineering practice.

The Washington Accord serves as an excellent example of how the evolution of an accreditation system in response to global trends can positively impact educational delivery. Quality assurance itself, of course, is a continuous process for improvement, and the system should continue to evolve and improve based on partnerships among the stakeholders.

HIGHER EDUCATION

Higher Education: An Overview

P Scott, Kingston University, Kingston upon Thames, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The development of modern higher education has been one of the most profound but least celebrated social revolutions of the past half-century. The development of much more extensive, and also more open, systems of higher education was not only the culmination of a long educational revolution which began in the nineteenth century when national systems of elementary education first emerged in Europe and North America, it also empowered, and reflected, a more far-reaching revolution in occupational structures, individual identities, gender relations, and even lifestyles. The impact of higher education on society, the economy, and culture continues to increase. In his work on clever cities the American scholar Richard Florida has ably described the nexus of creative freedom, social fluidity, and economic dynamism characteristic of the most dynamic twenty-first-century societies – and which can be substantially linked to the development of mass higher education. No single phenomenon perhaps has done more to determine the feel (or, in a more profound sense, the ethos) of contemporary society than the presence within them of millions of citizens who have experienced higher education. No single phenomenon has had a greater influence on the life-chances of individuals. No single phenomenon has had a greater impact on the economy through science and technology and also through the diffusion (and redefinition) of expertise. In retrospect, the creation of mass higher education systems may come to be seen as the greatest, and best, achievement of the twentieth century – overshadowing its more obvious legacies of genocide, war, and social conflict – and the best hope for the twenty-first century.

Moreover the development of contemporary higher education systems has been a global phenomenon – in two different senses. First, it has been global in its reach.

The expansion (and diversification) of higher education has not been confined to the so-called “West” – the north Atlantic world of the United States/Canada and Western Europe, with its outliers in the Antipodes. It has had an equal, if not greater, impact in the Middle East, South and East Asia, Latin America, and even Africa despite the difficulties that the continent has encountered. Only two regions were initially less affected by the development of mass higher education systems – Central and Eastern Europe, and the People’s Republic of China, where more restricted systems persisted until the last decade of the twentieth century. Second, the development of modern higher education systems has been intimately linked with the phenomenon of globalization. These systems have been shaped by globalization as the increasing flows of students across national frontiers testify – and as the ideologies and practices of global capitalism have eroded older statist conceptions of higher education as a public space insulated to some degree from the pressures of the market. But the same systems have also been vital contributors to globalization through the pivotal role played by universities in the emergence of virtual/global scientific communities and their more diffuse role in the development of global cultures embodied in mass graduate populations.

This overview is divided into two main sections bracketed between this brief introduction and a concluding summary:

1. The first section looks back. It examines in turn (a) the development of mass higher education systems since the 1960s; (b) the major policy drivers for this massification (and different policy responses to it); and (c) the various conceptualizations of this phenomenon.
2. The second section looks forward. It considers three major clusters of characteristics of contemporary

higher education systems: (a) their relationship with the economy; (b) interactions between higher education and politics and society; and (c) linkages with wider issues of identity and culture.

Looking Back

The Development of Mass Higher Education

The most significant phenomenon associated with the development of higher education has been expansion – of the number of students enrolled and also of the number of institutions. In 1900, it was estimated there were fewer than 500 000 students enrolled in higher education in the entire world, a tiny fraction of 1% of the relevant age group. By the end of the twentieth century, according to UNESCO, there were more than 100 million university and college students, one-in-five of young adults. In absolute terms, therefore, higher education expanded by more than 200 times, and in real terms by more than 20 times, during the century. In most developed countries, typically more than half of the young adults are now enrolled in higher education (although definitions of higher/tertiary education remain fluid, which make precise trans-national comparisons difficult). But expansion has not been confined to developed countries. Algeria now has more students than the entire world at the beginning of the twentieth century. Although participation levels are not the same – there are approximately 350 students per 10 000 people in developed countries compared with only 45 per 10 000 in sub-Saharan Africa (in most other regions the figures vary between 200 (Asia) and 250 (central and south America)) – the pattern of expansion has been remarkably similar, consistent and accelerating growth.

In most developed countries, the development of different levels of education was a sequential process beginning with primary education, then moving on to secondary education, and culminating with higher education. In the United Kingdom, for example, more than two generations separated the establishment of universal primary education in 1870 from the creation of compulsory secondary education in 1944, followed less than a generation later by the rapid expansion of higher education in the 1960s. In many developing countries, in contrast, the development of various levels of education has been a near-concurrent process, with expanded higher education systems being created almost in step with the growth of universally (or widely) available primary and secondary education (a phenomenon which has been criticized by the World Bank concerned about skill imbalances and graduate unemployment). With the (hopefully temporary) exception of sub-Saharan Africa, there appears to be a worldwide process of leveling-up in higher education enrolments.

The expansion of higher education, therefore, is a pervasive phenomenon, an expression of the *longue durée* of modern society rather than of transient political or economic circumstances. The number of university and college students continued to increase throughout the twentieth century, despite revolutions and world wars. Expansion also took place in a wide range of countries with different social structures, political and economic systems, and cultural traditions. The differences in growth rates that can be observed are best regarded as secondary phenomena. Decolonization in Asia and Africa clearly encouraged the more rapid expansion of higher education, but on foundations laid down during the colonial era. In Central and Eastern Europe, during the Communist period, growth rates lagged behind those in Western Europe, but still broadly followed the same pattern (and then accelerated rapidly after 1989). Clearly emancipatory episodes, such as the decline and fall of colonial and Communist empires, have played a role in stimulating the growth of higher education – as has the development of more comprehensive democratic cultures in Western societies; there were intimate links between higher education expansion and the New Left during the 1960s, as there have been more recently between expansion of new social movements, notably feminism. Also, changes in occupational structures and definitions of expertise have generated new demands for skills which only higher education can meet.

The expansion in the number of institutions has been equally remarkable. The great majority of universities and colleges has been established since 1900, and the majority since 1960. After the medieval period and nineteenth century in Europe, the past 50 years has been the third great age of university foundations, this time on a global scale. Typically, this growth in the number of institutions has taken two forms – the establishment of brand-new institutions; and the promotion of existing technical and professional schools:

1. The establishment of new campuses of the University of California at Santa Cruz, Santa Barbara, and San Diego in the 1960s was a good example of the first form of growth in the number of institutions – as was the near-contemporaneous creation of new universities in the United Kingdom (also sometimes called the Shakespearean universities because of the cities in which they were established or the names they chose – York, Lancaster, Warwick, Essex, Sussex, and so on). In most developed countries, similar new universities were established between the 1950s and 1980s, with teaching and residential accommodation and research facilities grouped together on (often expensively) designed campuses rather than sprawling incoherently across cities; animated by similar values, the integration of teaching and research and a holistic vision of

higher education combining traditional disciplinary and radical interdisciplinary elements; organized according to similar principles, essentially those of the so-called academic guild; and funded discreetly but generously by the burgeoning welfare state. Existing universities were heavily influenced by this model, as they attempted to create academic precincts out of the urban clutter they had inherited and adopted the academic and organizational values of the newly established universities. Since the 1990s, new institutional types have emerged, notably in Central and Eastern Europe, and South and East Asia where the number of private higher education institutions based on corporate (and managerial) rather than academic (and collegial) principles has rapidly increased. In a similar way, these new institutions have influenced the behavior of existing universities.

2. The second form of growth in the number of higher education institutions displayed a less-consistent pattern. In broad terms, as the educational and so-called administrative scope of higher education systems was extended (and, indeed, the very idea of systems of higher education comprising more than traditional universities came to be accepted), the effect was to re-designate institutions variously labeled technical, professional, or extended-secondary as part of these new systems. Two approaches were taken (which are discussed in greater detail in the next section). The first was simply to re-categorize as part of higher education, existing institutions such as the *Fachhochschulen* in Germany, now usually described in English as universities of applied science. The second was a more deliberate attempt to create larger non-university institutions through a process of mergers to act as a counter-weight to the traditional universities. The best example was perhaps the establishment of the polytechnics in England and Wales, although similar approaches were also taken in Australia and the Netherlands. These institutions placed greater emphasis on professional formation and applied research and less on providing a holistic higher education and undertaking traditional academic research – at any rate, initially. Distinctions between different institutional types – whether traditional universities already established by the middle of the twentieth century, new universities established between 1950 and 1980, polytechnic-like institutions created through restructuring processes, or unadorned higher vocational/professional schools – tended to be eroded as all institutions have gravitated toward a more instrumental and corporate model.

Policies, Structures and Funding

To summarize the evolution of higher education policies across several decades and many countries, developed and

developing, is clearly a difficult task. However, a small number of pervasive trends can be identified:

- the shifting balance between policies reflecting push factors, predominantly the result of deeper social change, and pull factors, predominantly reflecting the needs of the economy as identified by governments, as the major driver of higher education policy;
- the establishment of better-articulated binary systems of higher education under state direction followed by greater, but more customized, differentiation of institutional missions in response to the emergence of quasi-markets in higher education; and
- a parallel drift from predominantly state funding of universities and colleges to more mixed-funding regimes in which students, and other users of academic services, are expected to make more substantial contributions.

Push and pull

During the second-half of the twentieth century, and up to the present, the main engine of higher education expansion has been increasing demand from potential students, even if the extra resources required to fund that expansion have often been justified by governments in terms of the need to develop a more highly skilled (and increasingly graduate) workforce. Certainly, in developed countries, the growing number of qualified secondary school leavers has been the major factor in increasing participation in higher education, while attempts to steer this growing demand into subjects regarded as more important for economic development (often reduced, misleadingly, to the so-called STEM subjects – science, technology, engineering, and mathematics) have produced disappointing results. In the UK, for example, the two periods of most rapid higher education growth can be attributed to wider changes in educational policy which had the effect of increasing the pool of available candidates – in the late 1960s following the introduction of comprehensive secondary schools; and in the late 1980s and early 1990s following the introduction of a common system of secondary school examinations. Similar reforms in other countries had the same effects. In that sense, it is fair to say that push factors have predominated over pull factors, market forces (or, more accurately, social and cultural pressures) over workforce planning.

However, this conclusion must be qualified in two respects. The first is that student demand has become increasingly heterogeneous. Until the 1960s, in Europe (earlier in the United States and later in many developing countries), student demand was largely an expression of the aspirations of young adults, predominantly male and from comparatively privileged social backgrounds already possessing considerable cultural capital. These aspirations

could readily be translated into traditional patterns of higher education provision. Today student demand is an expression of the aspirations of much more diverse social groups – women (the revolution in gender relations inspired by feminism has been a major factor in the development of nearly all higher education systems) and older adults (shifting career patterns and new occupational structures have combined with notions of higher education as an agent of socio-cultural credentialization as well individual enlightenment/enjoyment to promote ideas of lifelong learning), as well as students from less-privileged social backgrounds and minority cultures (reflecting the strengthening emphasis, in many developed countries at any rate, on equal opportunities). These much more diverse, and even conflicting, aspirations have proved to be more difficult to translate into stable patterns of higher education provision.

The second respect in which this conclusion must be qualified is that there has been a trend for both push and pull factors to strengthen in recent years – the former because access to higher education has become more crucial as a determinant of middle-class culture as older class, gender, and ethnic determinants have become less decisive (or as a means of transcending these older determinants, which helps to explain the rapid expansion of higher education in some developing countries even in the face of significant levels of graduate under/unemployment); the latter because in post-industrial society knowledge resources, whether in the form of highly skilled technical experts or of research and innovation capacities, are regarded as increasingly crucial for economic success. As a result governments have placed more emphasis on the instrumentality of higher education, urging universities to forego traditional academic priorities and to work more closely with business and industry. They have also redoubled their efforts to steer higher education, establishing special programs to promote STEM subjects or employer engagement. This shriller rhetoric has tended to mask the underlying driver of higher education development, social change as mediated through student demand.

Systems and markets

The second pervasive trend has been structural reform, as the number of higher education institutions has increased and organized systems of higher education have been established. Structural reform has taken two main forms:

1. The first has been the creation of well-articulated systems in which institutions are assigned clearly defined roles, usually arranged in a hierarchy with explicit arrangements for student progression between tiers. The best examples remain the state systems in many individual US states, with the California Master Plan as an archetype, but they have been emulated in

many other countries with different social systems. The Chinese pattern of key universities, both at national and provincial levels, is another example of a planned stratified system. These systems are both open – in the sense that they typically embrace the totality of post-secondary education and encourage student progression – and planned, in the sense that they restrict masters and doctoral programs (and, by extension, research) to top-tier institutions.

2. The second has been the, often more chaotic, development of binary systems which preserve the distinction between academic (or scientific) and professional higher education. The best example was in England and Wales where polytechnics were established in the 1970s; current examples include the distinction between universities and *Fachhochschulen* in Germany. Typically, the development of binary systems has passed through various phases – starting with an initial recognition that higher education was more than universities and leading to efforts to articulate alternative, more vocational, forms of higher education. Binary systems were emancipatory initially, because they enabled new groups of students (and new disciplines and professions) to access higher education (albeit on subordinate terms). More recently, while struggling to contain academic drift, they have tended to be perceived as educationally rigid and socially restrictive.

Both stratified and binary systems have adapted in different ways to the strengthening of the market in higher education. Stratified systems, on the Master Plan model, have made it easier to identify, and to sustain, major research universities – the top universities which feature in global league tables – but at the cost perhaps of restricting the adaptability and responsiveness of non-elite institutions. Binary systems, in contrast, have made such identification and sustenance more difficult because of their inbuilt reluctance to discriminate between traditional universities and their failure to contain academic drift. But their categorization of institutions in terms of broad educational mission rather than by means of tight administrative classification has perhaps made it easier for individual institutions to respond to market opportunities, especially when binary systems have tended to fray (or, as in Australia and the UK, be superseded by unified but differentiated systems).

However, both stratified and binary systems are ideal types. There are many different variants which may even appear to have more in common with systems of the other type than others systems of their own type. For example, some apparently binary systems have more than two sectors while some stratified systems have become more permeable. Also both ideal types have been subverted by three factors:

1. The first, and more familiar, is the impact of private institutions which has been analyzed by Philip Altbach

and David Levy. Although in the United States the most visible part of the private sector has played a relatively stable, and elite, role, the past two decades have seen the rapid proliferation of more dynamic, but also much more populist, private universities and colleges – for example, in Central and Eastern Europe and in India (often concentrating on subjects such as business and management and information technology). The influence of the private sector has been compounded by the semi-privatization of key elements within publicly regulated institutions.

2. The second factor is globalization. Even in the less intense form of internationalization, this factor enabled institutions to escape from their nationally designated roles in either stratified or binary systems. For example, higher professional schools in the Netherlands have used international partnerships to allow them to engage in activities formally reserved for traditional universities in the Dutch system. The impact of full-blooded globalization on higher education systems is likely to be similar to its impact on economic systems. It has even been argued that the days of national higher education systems are numbered.
3. The third factor is the emergence of regional groupings. The best example is the European Higher Education Area (EHEA) established as a result of the Bologna process which has led to increasing coordination of structures and policies across more than 20 European countries. But universities themselves, especially research universities, have taken the initiative and formed trans-national associations, for example Universitas 21.

Funding and fees

The third pervasive trend has been the, still unresolved, debate about how mass higher education systems should be funded – by the state through taxation, the individual through fees, or by some combination of the two (and other income sources such as endowments or user payments). The standard assumptions, strongly promoted by the World Bank and more tentatively supported by the OECD, have been that it is no longer possible to rely on state funding and that students therefore must make an increasing contribution to the cost of their higher education. Fee regimes have been progressively introduced into some higher education systems which were previously funded almost entirely by the state – beginning with Australia where the Higher Education Contribution Scheme (HECS) was introduced in the mid-1980s, followed by the UK between 1998 and 2004. Tuition fees have also been introduced in the Netherlands and, provisionally because the legal basis for charging fees remains unclear, and in some German *Länder*. At the same time, the low-fee regimes that prevailed in many US state

systems between the 1950s and 1980s have been progressively replaced by moderate-fee regimes, while American private universities have substantially raised their fees. Charging for tuition has also been adopted by several African countries to ensure minimum funding levels for their universities. Only in Nordic and Mediterranean Europe, the Middle East, and Latin America has the introduction of student fees been successfully resisted. The progressive introduction of student fees appears to amount to a global, and inescapable, trend.

However, this noisy debate about fees needs to be seen within a wider context – in two important senses:

1. First, charging tuition fees has been simply one element, and not the most important element, in both the funding of higher education institutions and financial support for individual students. In the case of institutional funding, questions have been raised about the extent to which charging more for tuition might have skewed university and college priorities because it has encouraged students to adopt a more pronounced consumerist mentality – for example, toward student services and away from basic research. There is some evidence this has happened in both US private and state universities which have increased fees substantially. In the case of student support, many other factors apart from tuition fees have had to be taken into account – including the availability of loans (or grants) to cover living expenses, other social benefits for which students have been eligible, and the impact of tax regimes (in particular, the scope for off-setting the cost of loan repayments against tax liabilities). It is also important to recognize that fee regimes have differed substantially in their details. Some have been variants of a graduate tax – for example, when the state has provided subsidized loans for students to pay their fees. In practice, there have been very few examples of pure-fee regimes in public higher education systems which require students to pay the fees either out of their (or family) resources or to take out commercial loans.
2. Second, the debate about fees has often served as a proxy for other important debates. One debate concerned the overall resourcing of higher education (whether those resources were provided by individuals in their roles as taxpayers, fee-payers, or consumers, was a secondary question). The issues included whether universities and colleges have been receiving an adequate share of national GDPs, and the extent to which they should have been expected to take advantage of new learning technologies, and to exploit global economies of scale in research, to improve their efficiency. Another important debate has been about access – what proportion of the population should be educated to higher education level, and on what terms?

Some advocates of fees have seen charging for tuition as a rationing device, to restrict access to the truly worthy and motivated (and, in a few cases, simply to restrict access). Others have justified charging fees in terms of social equity, because by abolishing indiscriminate subsidies to the more privileged (the effect, they argue, of funding higher education through taxes because tax systems have become less progressive since the waning of the welfare state), it has become possible to target financial support on students who are in genuine need. A third, and more ideological, debate has been about the marketization of higher education. Advocates have often regarded the introduction of fees as the first stage in a much wider process of modernization (in a domestic context) and liberalization (in an international context).

Theories of Higher Education Development

Until the middle of the twentieth century, little was written about higher education from a sociological or economic perspective. Before the advent of mass higher education, the bulk of scholarly writing about universities was historical or philosophical in orientation – or merely rhetorical. Nor did mainstream sociologists or economists devote much attention to higher education as a field of enquiry. Only in exceptional circumstances, for example, the Nazi period in Germany and its aftermath, were urgent questions about the role of universities in society seriously explored. As a result, higher education remained a largely under-theorized domain before the 1960s. It was the development of mass higher education systems in this and subsequent decades that encouraged the more systematic development of theories of higher education development. First, the establishment of new universities, often on eye-catching campuses which gave them a high public (and political) profile, demanded a more sophisticated articulation of their rationale – and, in particular, whether this rationale was different from that for the existing, more traditional, universities. Second, the extension of higher education systems to embrace non-university institutions also encouraged more systematic reflection on the purposes of these wider systems – and, in the case of binary systems, whether these institutions were intended to represent a new paradigm of higher education.

Two broad bodies of theory have developed which can be, approximately but not exactly, related chronologically to different phases in the development of mass higher education. The first was broadly functionalist in approach. A pioneering work by Talcott Parsons on the American university set the tone, a strand that continued in the work of younger colleagues such as Neil Smelser. But the most frequently quoted conceptualization was that developed by Martin Trow in the late 1960s and 1970s. He offered a three-stage evolutionary model – beginning with elite

higher education dominated by traditional universities and characterized by restricted access (with up to 10% of the relevant age group enrolled); moving on to mass higher education with much higher levels of participation (up to 40% of the age group) and with a greater variety of institutional types; and culminating in universal higher education embracing, in effect, the whole of post-secondary education. Two comments were made about Trow's typology – first, that it could be seen as a theoretical analogy of the three-tier structure of Californian higher education institutionalized in that state's Master Plan; second, that it appeared almost to be an endogenous theory in which wider social-economic (and scientific/cultural) change was either absent or treated as a given (as was ideology, despite the contemporary emergence of the New Left). The latter deficit was remedied to some extent through the work of a fourth American scholar, Burton Clark, on the connections between the academic system, that is, higher education and research, and the social, political, cultural, and other major systems of modern society.

It is not perhaps an accident that in this first phase, from 1960 until the mid-1980s, much of the theorizing about higher education development originated in the United States. America had been first to experience mass higher education; and the expansion of higher education was seen as closely related to the development of the post-war welfare state. But in the second phase, since the mid-1980s, two new factors have been encountered which tended to invalidate some of the assumptions prominent in these theories. First, the actual development of higher education systems, as empirically observed, appeared to have diverged in key respects from this theoretical path. For example, although most developed countries now enrol more than 50% of the age group in higher education (and, therefore, in Trow's typology, had reached the universal phase), these systems do not appear typically to exhibit the characteristics of universal systems which had been predicted. One reason for this divergence is that the knowledge societies which emerged in the first decade of the twenty-first century have not followed the model of post-industrialism imagined by Daniel Bell and others, a quarter of a century ago. Instead of developing into techno-rational and emancipatory forms, they display more disturbing characteristics, combining emotive ephemerality with control and surveillance.

Second, the rationalistic/positivistic styles that characterized intellectual life in the third-quarter of the twentieth century have been challenged by new ideas. These ideas have been extremely heterogeneous (indeed, this heterogeneity has been their defining characteristic). They have ranged from post-structuralism which later broadened out into more radical expressions of post-modernism; through new definitions of authoritative

knowledge which revived older notions of social constructivism and/or emphasized the contextualization of scientific production, the proliferation of knowledgeable actors, and the reflexivity of scientific exchanges; to more accessible accounts of risk, globalization, and markets as generators of chronic uncertainties. At the same time, new ideas in political science and organization theory have called into question the stability and predictability of the higher education landscape. As a result, higher education has come to be seen as terrain that, both academically and organizationally, is volatile and contested, turbulent, and unpredictable.

The shift from systems to markets in the organization of higher education, therefore, has been mirrored in a similar shift in theories of higher education development, from the linear to the reflexive and from the simple to the complex. Examples include Ron Barnett's work. This second broad body of theory also emphasizes the increasingly intense, but also unstable and transgressive, exchanges between the academic system and other systems. Although more intellectually stimulating, this body of work may be of less immediate help to policymakers and institutional leaders than the theoretical accounts it displaced. However, alongside these meta-theoretical accounts of higher education development, a second strand of academic work has emerged that combines empirical research evidence with more detailed theory – for example, in economics and psychology. Sophisticated rate-of-return analyses have been developed, stimulated to a large extent by the debate about fees and markets in higher education. Theoretically well-informed studies of student learning have also proliferated. This second strand of theoretical work has been much more relevant to the development of public policy; indeed, its direct relevance has occasionally raised questions about degrees of critical distance (if not its scientific objectivity).

Looking Forward

Few people are expecting higher education to expand as fast in the next century as it expanded in the past century. As participation rates currently exceed 50% in most developed countries, even near-universal levels of participation would require substantially less than a doubling in the size of most higher education systems. Also, in many developed countries, the number of young adults, still higher education's core constituency, will decline in the years leading up to 2025 – although, there will be significant differences between socioeconomic and ethnic groups and the overall size of the population will continue to increase because of longer life spans (which could have a significant impact on those higher education systems that adopt a genuinely lifelong learning orientation). Demographic trends beyond 2025, of course, are only

projections subject to revision. It is also important to note that migration patterns could have an important effect on population profiles even before that date. Nevertheless, the consensus is that, in developed countries at any rate, the scope for rapid quantitative expansion is limited. In many developed countries, the scope is greater. But even here, substantial progress has already been made toward developing mass higher education systems with relatively high levels of participation, and predictions suggest that global population levels will stabilize as a result of changes in fertility by the end of the century.

However, the past century has also witnessed a fundamental transformation in both the scale and the purposes of higher education. This mirrored an equally fundamental transformation in wider society – the national state was transformed into the welfare state which is now evolving into the so-called market state; the industrial economy based on manufacturing has been succeeded first by a services economy (with a large public, or social, sector) which is now being subsumed into the post-industrial knowledge-based economy, elite culture has been supplemented by a mass culture, and individual lives have been transformed by affluence (or, more pejoratively, *affluenza*), radical shifts in gender relations, and (not least) participation in mass education. The dominant consensus is that social and economic change will accelerate as the twenty-first century advances. So, even if the scope for quantitative change in higher education systems is limited, the scope for qualitative change could be unbounded.

Higher Education and the Knowledge Economy

Of the three relationships which are discussed in this section, the key one is seen as the relationship between higher education and the knowledge economy. In the eyes of most politicians and other policymakers, and also of an increasing number of university leaders (although not so many of their academic colleagues), this relationship is seen as central to the case for continuing public investment in higher education (and also the primary justification for private investment by individuals when they are paying fees). However, even if the dominance of this relationship is accepted, the implications for universities are far from clear. The central argument is that higher education has become the powerhouse of the new knowledge economy, producing not only highly skilled graduates but also the primary research which powers this new economy. But there are counter-arguments:

1. The first is that the knowledge economy is not as novel as is often supposed. Symbolic knowledge of all kinds has always been crucial to the working of human societies; what is new is the explosion of technical knowledge (and especially of technical processes for data management). It can be argued that the role of the university in

creating symbolic knowledge was (and is) at least as great as its role in producing technical knowledge – a role which can be undertaken by other knowledge organizations. In other words, Apple or Google are the leading institutions of the twenty-first-century knowledge economy, not Harvard or Oxford.

2. The second counter-argument is that in the knowledge economy/society, all organizations have to be suffused with knowledge – by active producers as much as by passive consumers of knowledge. Many of the most successful private-sector organizations value not only the technical knowledge most relevant to their operations, the intellectual property which they generate, and the technical experts they employ, but also the entire knowledge resources represented by their wider workforces; this explains the increasing emphasis on organizational development. These organizations often regard the nurturing of these wider knowledge resources as crucial in terms of securing competitive advantage. The implications of such thinking for universities are far-reaching. Instead of being privileged primary producers in the new knowledge economy, they must work with other knowledge producers in collaborative networks.

There are four main ways in which universities contribute to the knowledge economy: (1) as primary producers of basic research which can be translated into commercially valuable or socially useful goods and services; (2) as agents through which this translation process can take place, by means of technology transfer, knowledge management, and other entrepreneurial activities; (3) as producers of skilled people, from future researchers through a mass graduate workforce to skilled technicians; and (4) as agents of socialization whereby large numbers of young adults can be inducted into optimistic rationalizing ideologies – science, democracy, national development, perhaps the free market. It is often assumed that the first is the special responsibility of research universities (an unproblematic category in the US, but a more contentious – and politically divisive – one in many other countries). The second is seen as the special responsibility of regional universities (or other higher education institutions) with more direct experience of engagement with business and industry, and local communities. The third is assumed to be the responsibility of all institutions – but segmented by level, that is, future researchers are most appropriately trained in research universities, while technician education is the primary responsibility of higher vocational schools. The fourth is similarly the responsibility of all, but the reproduction of elites is still regarded as the quasi-monopolistic responsibility of leading universities.

But this apparently neat categorization of responsibilities may become increasingly difficult to sustain. There

are likely to be two flash-points. The first will be over the future funding of research. In the past two decades, research assessment systems have proliferated – often with the explicit intention of concentrating this funding in a smaller number of research-intensive universities (although in the process of their operation these systems have often, unwittingly, revealed how widely distributed high-quality research has become in mass higher education systems). Efforts have also been made in some countries to encourage regional universities to concentrate on (in the terminology adopted in the UK) third leg activities – in other words, applied and translational research, technology transfer, and other forms of dissemination. But both have produced disappointing results – as well as significant political friction. The main reason is that, in the context of mass higher education and of a pervasive knowledge economy, it no longer makes sense to regard the generation of knowledge as a restricted activity. Instead, it has become a reflexive rather than a linear process, with multiple actors rather than primary producers. Fundamental discoveries can be made in near-market, or socially embedded, environments (just as would-be applied research can be undertaken in academic environments as Michael Gibbons and his colleagues have discussed in two recent books). In other words, not only the boundaries between research-intensive universities and other higher education institutions have become more permeable, the frontiers between the academic and the economic systems have also been transcended within a broader system of innovation.

The second flash-point is likely to be over the differentiation of institutional missions within mass systems, often coded for maintaining (or re-imposing) a more categorical hierarchy of institutions rather than a recognition of the need for all institutions to diversify to respond to a widening variety of social and market demands. But the dynamics of the new knowledge economy, with its proliferation of symbolic and expert knowledge(s), hard and soft forms of knowledge, tend to subvert and frustrate all attempts to produce a clear taxonomy of institutions. As a result, many universities, whether research intensive or socially engaged, have had to extend their missions to embrace new roles and activities. It is this incorporation of once-peripheral activities into the core that has characterized the development of most higher education institutions, more so in systems that have abandoned traditional distinctions between universities and higher professional education and less so in systems which have continued to be more stratified or segmented. This phenomenon of mission stretch, rather than so-called academic drift, is likely to become more significant in coming years. This may place more emphasis on the resourcefulness of institutional leaders and managers and less on the resilience of systems.

Higher Education and Political Economy

The development of twenty-first-century societies has also transformed the links between higher education and the wider political and social environment. It is argued that a fundamental shift has taken place in the dominant social form – from the state (and, especially, in the second-half of the last century, the welfare state) to the market (and, increasingly as the twenty-first century unfolds, the global market). In practice, this broad assessment needs to be qualified in a number of ways. First, the state has not withered away; despite the popularity of political rhetoric about the need for a small state, in practice, the state is as pervasive as ever. Second, markets and globalization are hardly new phenomena; from its birth, the university, as its name suggests, was imagined as transcending national frontiers, and global trading empires have existed for at least half a millennium. However, the shift from state to market may still serve as a good enough narrative, a metaphor which captures a key characteristic of twenty-first-century society.

This shift is often aligned with another transition – from modernity to post-modernity. As a narrative, the welfare state, with its Enlightenment values and its Weberian practices, displayed many of the features associated with modernity – progress defined in normative as well as materialist terms, regularity (even standardization), and scientific objectivity. The market, also as a grand narrative, displays many of the features associated with post-modernity – a moral fluidity, volatility, and subjectivity (but also, it is argued, creativity and innovation). However, there are two ways of thinking about the shifting balance between the state and the market. The first is a literal interpretation which suggests that the state is in actual decline; and, therefore, that many of its responsibilities (e.g., for providing higher education) must now be shouldered by the market. The second is a more nuanced account which suggests that both the state and the market are being infiltrated by new values, which can be labeled a “post-modern.” The state is behaving increasingly as an entrepreneurial agent, the prime responsibilities of which are not only to create the conditions for economic growth but also to create quasi-markets in the public sector, through a combination of privatization and the so-called new public management. The market now is not only characterized by new (and outlandish) trading instruments, notably in financial services, but also by the intersections between the state and the market. These extensive borderlands of regulation and privatization are becoming both more complex and more significant – and arguably the key sector of advanced twenty-first-century political economies.

The implications for higher education of this shift from the state to the market are potentially far reaching:

1. If a literal interpretation is preferred, it may imply that the educationally liberal and socially progressive orientation, and academic (or scientific) values, of the twentieth-century university are likely to become less powerful. The post-War university was clearly closely aligned with the welfare state – not only quantitatively, in the sense that the expansion (and diversification) of higher education systems after 1945, and especially after 1960, was seen as the culmination of long social and educational revolutions that reached back into the nineteenth century, but also qualitatively, in the sense that critical intellectual values were seen as at the heart of the modern university experience (in parallel with the liberal/social-democratic values that suffused post-War European societies, even when ruled by conservative governments). Maybe in the twenty-first century, this will change – both the governance of universities, where academic guilds and state bureaucracies will be superseded by more entrepreneurial models, and the funding of both students and institutions, where fees (and other quasi-market mechanisms) will replace state grants. Both trends appear already to be well established.
2. However, if the second more-nuanced interpretation of the shift from state to market is interpreted in more metaphorical terms, a rather different future for universities may emerge:
 - First, the state may retain, and even strengthen, its control over higher education. There are few signs that the state is even prepared to reduce its detailed operational control over universities. Instead, this control is being exercised in different ways – no longer through traditional administrative regimes, which in practice gave universities considerable room for tactical (and strategic) maneuver, but instead, through increasingly elaborate accountability regimes, from which there is no escape. The cult of targets is already a dominant feature of the new audit state as discussed in books by Michael Power and Marilyn Strathern. The state has also reinvented itself as a contractor with quasi-autonomous (but, in practice, heavily regulated) universities as providers of academic goods and services, the skills of graduates and the outputs of research. For example, in England and Wales, politicians talk in terms of “something for something” – in other words, the government will provide increased funding for universities only in return for specified deliverables. This heightened state intervention is justified by a new discourse that emphasizes the competitiveness of the global knowledge economy.
 - Second, markets too are changing. The production of goods and services, organized through corporate bureaucracies, is no longer the dominant form in the post-modern markets that flourish in many developed countries; these markets are instead characterized by new patterns of behavior, both ultra-creative

in terms of the generation of novelty (including the invention of ever-more complex and inventive financial instruments) and also ultra-volatile (and ephemeral) because of the instantaneities of modern information and communication technologies. Classical capitalism of the industrial age, or even of the social markets that flourished in the era of the welfare state, might have offered an alternative model for the organization of higher education systems to the dominant state-control model; they possessed their own patterns of stability and regularity. But it is more difficult to imagine how the hyper-capitalism of the twenty-first century can provide such an alternative model. In practice, higher education systems are likely to be stranded in the state-market borderlands of targets and regulation that are the second (and perhaps less dynamic) form of twenty-first-century political economy.

Higher Education and Identity and Culture

The third set of relationships is between higher education and wider sociocultural issues – of identity, for individuals; and culture, for society at large. In terms of the *longue durée* of human civilization these relationships are potentially the most significant; but they are also the most difficult to describe. There have been comparatively few studies of the impact of the expansion of higher education on the cultural characteristics of contemporary societies, their ethos, although empirical studies have demonstrated that graduates live longer, enjoy better health, participate more in the political process, and have other positive attributes. Developed countries now possess mass graduate populations where once they only contained small university elites, a change of historical significance in terms of democratic culture and economic capacity. However, the impact of mass higher education has often been regarded as an essentially secondary phenomenon, a subordinate element within much larger transformations such as the erosion of traditional elites, the decline of class-based politics, and revolutions in family structures and gender roles.

However, it is possible to argue that the expansion of higher education over the past half-century has been a phenomenon of primary significance. The impact of expansion has been felt in two distinct ways:

1. The first is familiar. There has been a rapid increase in the number and proportion of highly skilled jobs, for which academic and professional credentials are often required, to keep pace with changes in the occupational structure of the knowledge economy. But it may be a mistake to concentrate exclusively on traditional forms

of scientific, technical, and expert credentialization. In post-modern societies, not only has the number of occupations that require university-level qualifications increased – for example, nurses and other healthcare workers as well as doctors, or policemen as well as lawyers. More subtle and diffuse, but equally significant, forms of social credentialization may also have been at work.

2. This social credentialization is the second way in which mass participation in higher education has had an impact on twenty-first-century societies. Two or more generations of expansion have not only created mass graduate workforces servicing the needs of a knowledge economy; they have also generated a graduate culture, which may be the twenty-first-century equivalent of the bourgeois culture of the nineteenth and twentieth centuries. Today, it is impossible to be middle class, the dominant social class in most advanced societies, without some experience of higher education. However, this assertion must be qualified in two ways:

- First, there are powerful links between the narrower credentializing, or entrepreneurial, functions of higher education and its wider role in the development of a graduate culture. This relationship between business success, particularly in the newer creative industries, and the rich social and cultural milieus which are characteristic of cities with large student and graduate populations, provides an important link between expert and social forms of credentialization. It may also revive, and reinforce, the argument about the links between modernity and modernization, between economic development and a socially progressive culture.
- Second, the graduate culture of the twenty-first century is different from the bourgeois culture of the nineteenth and twentieth centuries. Access to higher education may continue to be socially inequitable (and, in particular, access to elite universities). But contemporary graduate culture is much more open – to women (which is why feminism and mass access to higher education are so closely aligned) and to ethnic and religious minorities. This culture is also more dependent on higher levels of formal education (and the cultural breadth that is associated with experience of higher education). It is not entirely implausible to link the solidity of democratic institutions in post-War Europe, and also the liberalism of most European societies, to the advance of higher education.

However, there may be other dimensions of post-modern societies which relate less well to higher education. It is true that traditional, and fixed, social identities

based on class and gender (and also national affiliations) have gradually been eroded – and even superseded – by newer, more open, and more fluid, social identities based on a combination of expertise (the credentializing functions of universities) and on enlightenment (their wider educational, and civilizing, potentialities). But other, even more novel, forms of identity are also emerging – for example, identities that are based on patterns of consumption and lifestyle choices, which are volatile and ambiguous; or on ethno-religious categories which may be equally contrived, post-modern constructions despite their fundamentalist labels. Higher education's links to these (quintessentially) post-modern identities are much less straightforward. Universities certainly play a key role in the socialization of those who are most able to experiment with new social identities by expressing distinctive lifestyle choices (as well as giving them the credentials which provide them with the economic resources to make such choices). It is also true that higher education systems play a key role in socializing ethnic and religious minorities, so they have some responsibility for (and leverage over) any anti-socialization tendencies among these communities. But in both cases, the influence of higher education is muted.

Conclusion

In this article, the development of modern higher education systems has been discussed mainly in terms of its broader relationship with society, the economy, politics, and culture. This could lead to the conclusion that the emergence of mass higher education is essentially a social phenomenon, the outcome of the shaping of higher education by these larger social and economic forces. Higher education, to a certain extent, itself is an active agent, because the expansion of the system has transformed it into a social force in its own right. But this would be a misleading conclusion in two different senses. First, higher education has always had a powerful social presence. In some respects, the elite universities of the past were even more influential social agents with a crucial role in the reproduction of political and administrative elites, which was more important than their responsibilities for the socialization of cultural elites or the training of scientists, scholars, and researchers until well into the twentieth century. The erosion of elites, and the parallel problematizing of technical and professional expertise, has complicated the links between mass higher education and wider society – which may now be more pervasive but are also more diffuse.

Second, it is important to emphasize that higher education is an academic system. It is shaped as much by the internal dynamics of academic disciplines as it is by external social and economic forces. There is an inside story as well as an outside story. Admittedly, teaching and

research, the two main expressions of academic disciplines, are shaped by social forces (but they also shape them); many disciplines, in particular, professional and applied disciplines, are themselves socially (and economically) as well as cognitively constituted; and in a knowledge society, researching and learning are no longer so clearly constrained within disciplinary boundaries (or even within the boundaries of specialized knowledge organizations) but instead, have become socially distributed activities. But, it remains true that it is impossible to write about higher education without taking into account what Martin Trow called its private life of academic enquiry.

There is no space in this article to attempt to sketch out the academic landscape. But a major force in shaping higher education over the past century has been the emergence of new disciplines – their ceaseless re-configuration as specialties have come and gone – and the decline and fall of old disciplines. The transformation of the humanities from aspects of civilized discourse into a taxonomy of expert subjects, the uneasy cohabitation of basic scientific enquiry with techno-science, the efforts to build (and then defend) a critical base in the social sciences – these were only the most colorful threads within a finely woven academic narrative. It is difficult to predict the major intellectual and scientific developments that will shape the continuing private life of higher education in the twenty-first century: more radical forms of inter-disciplinary enquiry in the humanities and social sciences perhaps; in the natural sciences, the explosive potential of the development of remarkable new experimental technologies; in some more applied fields, the attenuation of the distinctively academic sphere within a wider knowledge enterprise without clear organizational boundaries. But, if exact prediction is impossible, two ambitions are not only possible but essential. The first is to assert the continuing importance of intellectual values that are normatively as well as cognitively grounded within mass higher education systems; these values are more not less essential in mass systems than they were in the elite systems of the past (Fallis, 2007). The second, more fancifully, is to let the imagination roam – to conjure up these new academic landscapes. In considering the future of higher education, this is just as important as predicting new social forms – the knowledge economy, post-modern society, or the market state. Together, they will shape that future.

Glossary

Development center – A structured series of activities aimed at bringing about greater self-awareness of leadership strengths and areas for improvement. Such activities include: 360° diagnostics, simulated interactions, and in-tray activity.

Myers Briggs type indicator (MBTI) – A personality instrument, based on Jungian theory, which suggests that individuals have innate psychological or mental dispositions.

Introduction

The position of department chair is one of leadership, charged with the challenges of developing the department's future and of building faculty vitality. As we move into the new millennium, we face a time of major change ... changing student clientele, disintegrating college curricula, growing technological changes, and shifting attitudes and practices of faculty represent some of the many forces currently shaping higher education ... Anticipating your changing environments, developing a future-oriented statement of department mission, and providing leadership to unify department activity toward a 'planned' future is the mark of effective academic leaders ... The time of 'amateur administration' where professors temporarily step into the administrative role

of department chair has lost its effectiveness. The call for leadership is real. Department chairs are critical to the future of the college, department, and faculty (Gmelch and Miskin, 1993: 1–2).

The above quote, written over a decade ago, stills holds true, and holds true for the range of academic management and leadership roles in higher education (HE). Focusing on the role of head of department, or, department chairs, or heads of school (these three terms will be used interchangeably, as representing a key strategic academic management post in HE, in the section which follows), is to focus on what is recognized as one of the most crucial roles in the university (Ramsden, 1998; Shattock, 2003). Without heads of departments who are effective leaders and managers, there is a greatly reduced chance of the university vision and strategy becoming a reality, as they are a key factor in terms of creating an appropriate environment in which the academic endeavor can thrive (Ramsden, 1998; Gibbs *et al.*, 2007). It is really only over the past one to two decades that the cruciality of this role has been properly recognized, and measures taken to first, more accurately articulate just what this role entails, and, second, offer support in terms of development and training in preparation for this role.

As Benoit and Graham (2005) note:

Most academic chairs starting out today will find their role much more complex than they would have just a decade ago. Chairs are involved in a wide variety of tasks, including defining the strategic missions of their units, curriculum planning, performance reviews, fiscal oversight, and advocating for and representing their departments

to the university at large and to external constituents. Academic chairs need skills different from those that originally attracted them to the independent life of the scholar. No one explains their new role to them, and most new chairs learn through personal experiences and by watching what other chairs do (p. 1).

Given the recognition that the head of department role is both crucial and complex, this section sets out to explore current thinking on, first, the range of factors that have led to the increasing complexity of the role; second, the contractual obligations of the role to include its key components and recruitment issues; third, expectations for delivery of the role and appropriate support; fourth, training and development for the role; and, finally, issues for the future.

The Growth of Complexity of the Role of Head of Department/School

In the UK, post the Jarrett Report (1985), the need for better management of higher education (HE) was highlighted. Greater accountability came about with the advent of the quality-assurance agency, the introduction of the research-assessment exercise, the funding councils, and the professional and statutory bodies. Department heads have been delegated more and more responsibilities and accountabilities with respect to various operations and functions (Shattock, 2003). Similar trends have taken place globally (Ramsden, 1998). Indeed, globally, even more performance measures have now to be taken into account (Cuthbert, 2002) for example, leagues tables (Shanghai and Jiao Tong), student surveys, and funders' more rigorous approach to performance assessment. Alongside a reduction in the unit of resource, overall financial health is assessed, in order to categorize higher education institutions (HEIs) according to perceived risk of failure. The business of leadership in HEIs is increasingly in the spotlight as institutions first, engage in global competition for limited resources – most particularly the student market; second, endeavor to respond to the rapidity of technological development and its impact on all aspects of a university's operations; third, address the so-called commodification of knowledge (Bargh *et al.*, 2000); and fourth, explore alternative means of funding further to the state reduction in the unit of resource. Heads of department need to be not only highly effective managers to respond to these drivers, but also entrepreneurial in their thinking in terms of taking their vision forward to ensure survival, sustainability, and global positioning of their departments. No longer is the role of head of department one of steward, or caretaker because to maintain the *status quo*, or stand still, is no longer an option. As Ramsden (1998) notes:

Higher Education is going through a revolution ... The future success of our universities depends on academics' capacity to respond energetically to change. To help academics face new and uncertain demands, we need an entirely different approach to their management and leadership" (Introduction).

So, alongside all the above developments has been an evolving realization that the role of the head of department requires both leadership and management capabilities – not something that many academics are assisted in developing over the course of their academic careers as noted by Benoit and Graham (2005) earlier. As Stevenson and Howlett (2007) state about the appointment of heads of school in the chartered universities of the UK:

Historically, ... leaders were selected 'papally' using soundings from school/faculty members and a nomination system where appointments were often made without interviews" (p. 114).

There now exists recognition that to take such a lax approach to the appointment of a key leadership and management role within an institution is to risk alienating and losing key staff who are crucial to the realization of universities' missions (Murray, 1999; Stevenson and Howlett, 2007). Heads of departments are increasingly required to navigate a complex and turbulent environment, in order to ensure their staff are provided with the best possible environment in which to deliver teaching and research (Gibbs *et al.*, 2007). Attempts to codify such a role are explored more in the section which follows.

The Contractual Obligations of the Role

Further to the realization among researchers globally that the role of head of department was becoming increasingly complex (Gmelch and MIskin, 1993; Shattock, 2003; Benoit and Graham, 2005), there has been a concurrent move to unpack and articulate what exactly the role entails. Once this was established, HEIs have been in a better position to design job descriptions that not only articulated the various requirements, responsibilities, and accountabilities, but provided a conceptual framework for those contemplating taking on such a role. Among early studies was Tucker's (1993) edition of *Chairing the Academic Department* which cataloged 54 different duties. Carroll and Gmelch (1994) undertook a study of US department chairs to focus on roles and duties, articulating ten priority duties (see **Table 1**).

Dyer and Miller (1999) suggest that the investigation of department chairs in the US has tended to focus on their "roles and responsibilities, needed skills, and challenges and coping strategies" (p. 20). Murray (1999), in her article, 'Department chairs call for leadership training,' refers to

Table 1 Ten priority duties of US department chairs

1. Recruit and select faculty
2. Represent the department to administration
3. Evaluate faculty performance
4. Evaluate faculty research and publication
5. Maintain conducive work climate
6. Manage departmental resources
7. Encourage professional development efforts of faculty
8. Develop and initiate long-range departmental goals
9. Provide informal faculty leadership
10. Remain current with academic discipline

From Carroll, J. and Gmelch, W. (1994). Department chairs' perceptions of the relative importance of their duties. *Journal for Higher Education Management* 10, 51.

many studies, to include that of Joseph Steinmetz, chair of psychology at Indiana University. Steinmetz's view is that "good scientists don't necessarily make good chairs... People with management experience, however, often do" (p. 3). He suggests that aspiring chairs should be provided with different departmental responsibilities to bring about awareness of and the development of managerial skills.

Knight and Trowler (2001), further to their extensive research into the role of departmental head, offer the following quotation from one of their US interviewees, illustrating the benefits of engaging in various roles outwith the department prior to taking on a head of department role:

Before becoming chair, I served in leadership positions in the faculty senate. I was viewed as a voice of reason in many situations and as someone who was not afraid to take an unpopular position on an issue, in other words, couldn't be bullied into submission. This has given me substantial credibility with the upper level administration. I also developed very strategic alliances with the business community. They are big supporters of me and the upper level administrators are reluctant to cross me. When they have, the business community has rallied to my position. These trump cards are used VERY sparingly, though. In fact, it was only needed once in the last four years. Skills that help: good reputation in previous on campus leadership spots... ability to set up key alliances with influential contributors... sense of humor that can be used to diffuse difficult situations" (p. 143).

Stevenson and Howlett (2007) offer a heads-of-school framework (see **Table 2**), which identifies and unpacks six behaviors required of the role:

1. working at the strategic level,
2. leadership,
3. credibility,
4. communicating with others,
5. working with people, and
6. embracing change (p. 121).

A host of studies now exist which have generated broadly similar lists (Bareham, 2004; Benoit and Graham,

2005; Aziz *et al.*, 2005; Creswell *et al.*, 1990). How not to put off potential heads of department with these long lists of responsibilities and behaviors required for the role is considered in the next subsection.

Expectations of Staff and Post Holder with Respect to the Role

A number of studies have analyzed the various aspects of the head of department role which today underpin many in-house leadership development programs. However, fewer studies have examined the transition required to make an effective head of department and what will be required in terms of change of self-concept and ways of working. Deem (2007) and Henkel (2000, 2002) have explored the notion of academic identities. Deem (2007) refers to career-track routes, reluctant managers, and good-citizen routes to academic management. Henkel (2000) is more concerned with the reprofessionalization of academics in the midst of the growing complexity of the environment which HE inhabits, which she sees as requiring a re-articulation of core values. Gmelch and Miskin (1993) go beneath the surface of these concepts, unpacking just what is entailed in terms of the transition into an academic management position.

Gmelch and Miskin's (1993) nine transitions that individuals face when moving from a faculty position to that of a department chair still hold good today (see **Table 3**), articulating the transition as being from:

- solitary to social,
- focused to fragmented,
- autonomy to accountability,
- manuscripts to memoranda,
- private to public,
- professing to persuading,
- stability to mobility,
- client to custodian, and
- austerity to prosperity (pp. 11 – 12).

An issue identified in a number of studies focuses on an expectations disconnect between what an incumbent head of department expects of the role, and what they actually experience – often leading to either great stress or an inability to make the professional transition required of the post. This notion is explored in Achtenberg's (2004) article, Look before you leap: Transitions from faculty to administration, which offers itself as a useful summary of how becoming a chair will change your life, with the suggestion that it should be read at the stage when a career move to head of department is being contemplated.

Once in the role, a number of studies suggest that the anxiety and stress can be all consuming. Murray (1999), calling for universities to bolster their guidance of chairs by offering leadership training, quotes a chair of a psychology

Table 2 University of Newcastle: Heads-of-school framework

<i>Behavior</i>	<i>Indicators</i>
Working at strategic level	Sees the big picture and thinks strategically. Is able to manage complex problems and issues. <ul style="list-style-type: none"> • Able to articulate strategic vision for organization • Identifies opportunities for enhancing reputation, kudos, and financial security of organization • Identifies appropriate structures for making strategic vision a reality • Comfortable working with complexities • Can apply numerical problem-solving skills
Leadership	Takes control to ensure that objectives are met. <ul style="list-style-type: none"> • Provides clear direction to others • Delegates tasks to others without relinquishing control and responsibility • Is comfortable with conflict and prepared to confront individuals who stand in the way of organizational achievements • Acts decisively
Credibility	Inspires the trust and confidence of others by the way they handle themselves and others. <ul style="list-style-type: none"> • Energizes others • Possesses insight; particularly into the needs and motivations of others • Self-confident in manner and able to take unpopular decisions • Is straightforward, open, and fair in dealings with others • Motivated to set individual interests aside and work hard for future success of organization
Communicating with others	Communicates with colleagues effectively. Is able to persuade and influence others. <ul style="list-style-type: none"> • Listens to the views and opinions of others • Disseminates key messages to others • Is able to influence by persuasive and articulate communications • Responds to communications from others in clear, appropriate, and timely fashion
Working with people	Exceptional interpersonal skills. <ul style="list-style-type: none"> • Able to relate well to all types of people • Able to alter style depending on people or situation • Behaves with diplomacy • Interested in others and motivated by helping them to feel valued and to succeed • Motivates others so that they wish to contribute
Embraces change	Recognizes the need for change and is forward looking. Promotes the benefits of change to others. <ul style="list-style-type: none"> • Is proactive in ideas generation • Accepts the reality and requirements of change • Uses initiative and presents new ideas and approaches • Is able to achieve change at individual and organizational level • Is supportive of others during change
Planning and organizing	Manages time and resources by prioritizing and organizing effectively. <ul style="list-style-type: none"> • Effective at organizing and managing heavy workload • Anticipates future demands for staff, information, etc. • Identifies quickly what is important and prioritizes and acts accordingly
Management of pressure	Copes with criticism and the demands of the job. <ul style="list-style-type: none"> • Is able to separate him/herself from the job in hand so that negative feedback does not become overwhelming • Able to bounce back in the face of setbacks • Driven to succeed even when problems seem intractable • Remains positive and optimistic when going gets tough

From Stevenson, T. and Howlett, L. (2007). The leadership succession challenge for higher education: A pilot of leadership development centres at Newcastle University. In Marshall, S. (ed.) *Strategic Leadership of Change in HE: What's New?* pp 114–128. London: Routledge Taylor Francis.

department at a university in Indiana: “The worry was pervasive At lunch, in the shower, at home, with my family. It kept me up at night” (p. 1) but he does go on to say that it would not have been so hard if the university had introduced him to what to expect: “I wasn’t prepared for the stress . . . Training would have helped” (p. 1).

Studies of the characteristics of effective chairs are numerous. There are a good number that examine characteristics of a specific discipline areas, for example, chairs of business schools (Bolton, 1996; Bareham, 2004; Bellamy

et al., 2003; Clott and Fjortoft, 2000); others examine characteristics of chairs within a certain institution (Aziz *et al.*, 2005; Meredith and Wunsch, 1991; Lindholm, 2003), and there are those that generate more generic typologies as highlighted throughout this section.

Creswell *et al.* (1990) undertook a qualitative survey of 200 US department chairs who had been identified as excelling in the role as chair. They identified 15 factors as contributing to this excellence as articulated in **Table 4.**

Table 3 Transitions to leadership

1. *From solitary to social.* College professors typically work alone on research, teaching preparation, and projects. Now, as chair, your responsibility forces you to work with and through others. For example, department goals cannot be achieved alone; they must be achieved in concert with your faculty.
2. *From focused to fragmented.* While professors must have long, uninterrupted periods to work on scholarly pursuits, your work as department chair, like other management positions, is characterized by brevity, variety, and fragmentation.
3. *From autonomy to accountability.* Professors generally enjoy control over their time and the feeling of autonomy over activity and movement in their working environment. As you move from your role of professor to administrator, you tend to lose this sense of autonomy and become accountable to upper administration and the faculty for your time and accessibility in the office, as well as for your actions and activities.
4. *From manuscripts to memoranda.* The scholar and researcher labors over a manuscript for a long period of time. Before finding printer's ink, the work goes through many revisions and critiques. As department chair, you quickly must learn the art of persuasion and precision through memos. Thus, chairs report less stress from manuscripts and more from completing paperwork on time.
5. *From private to public.* The professor may block out long periods of time for scholarly work, but as chair you have an obligation to be accessible throughout the day to the many publics you serve. In essence, you move from the privilege of a closed door to the obligation of an open-door policy.
6. *From professing to persuading.* In the academic profession, the professor disseminates information in a manner that will meet the learning objectives of others. As you turn from professor into chair, you profess less and practice more the art of persuasion and compromise.
7. *From stability to mobility.* While always growing and exploring new concepts and ideas, faculty generally experience movement within the stability of their discipline and circle of professional associations. As a chair, you also attempt to retain your professional identity but must become mobile within the university structure. In order to be at the cutting edge of educational reform and to implement needed programmatic changes within, you must be more mobile, visible, and political.
8. *From client to custodian.* In relation to university resources, the professor is a client, requesting and expecting resources to be available to conduct research, classes, and service activities. As chair, you represent the custodian and dispenser of resources and are responsible for the maintenance of the physical setting as well as providing material and monetary resources.
9. *From austerity to prosperity.* While in actuality the pay differential between professor and chair may not be significant, the perception of more control over departmental resources creates the illusion of greater prosperity as chair.

From Gmelch, W. and Miskin, V. (1993). Understanding the challenges of department chairs. In *Leadership Skills for Department Chairs*, pp 11–12. Bolton, MA: Anker.

Table 4 Fifteen factors contributing to chair excellence, according to Creswell *et al.* (1990)

1. Learn about their roles and responsibilities in both the department and institution;
2. Create a balance between professional and personal lives;
3. Prepare for their professional futures;
4. Establish a collective department vision or focus;
5. Develop faculty ownership of the vision;
6. Initiate changes slowly (as a caution against making changes too soon after taking over);
7. Allocate resources of time, information, and assignment to encourage the vision;
8. Monitor progress in realizing the vision;
9. Create a climate open to the flow of ideas to build trust;
10. Listen to the needs and interests of academic staff;
11. Helps academic staff set professional goals;
12. Ensure academic staff receive feedback;
13. Provide representation of academic staff to colleagues and senior administrators;
14. Serve as a role model and mentor;
15. Encourage and support faculty.

From Creswell, J., Wheeler, D., Seagren, A., Eg, N., and Beyer, K. (1990). *The Academic Chairperson's Handbook* Lincoln, NE: University of Nebraska Press.

Benoit and Graham's (2005) study of successful chairs revealed that there were three types of experiences which were felt to be both rewarding and satisfying: obtaining resources for the department, implementing their vision, and creating a positive environment. Lorange's (1988)

study identifies strategic vision as crucial to departments, depicting it as a "rallying point in its strive (sic) to create academic value" (p. 301).

Hecht *et al.* (1999) identified a number of attributes which made for head of department effectiveness, to include being seen as a person with integrity, capable of politicking on behalf of the department, and ensuring adequate marketing of the achievements of the department. Similarly, trust and integrity issues were found to be important in a US study conducted by Murray and Stauffacher (2001). In Moses and Roe's (1990) study of Australian heads of department, however, trust and integrity were less prominent.

Harris *et al.* (2004) conducted a study of leadership effectiveness of heads of department across five US research universities. Their conclusions included a consideration of what made for effective leadership behavior from differing perspectives and identified five factors, not differing significantly from other typologies other than articulating the requirement for an ethical approach (see **Table 5**).

Additionally, they noted that praising staff for good performance, being seen as someone who keeps promises, and acting as a role model for others were deemed to be important.

Stevenson and Howlett (2007) undertook a series of interviews with key senior staff at the University of Newcastle in the UK, which generated eleven specific leadership needs (see **Table 6**). Their findings resonate well with factors raised in other studies, but a distinct need

Table 5 Effective leadership behavior

1. An ethical approach whereby people are treated with respect;
2. Effective communication;
3. Developing a shared vision – particularly in connection with the development of teaching programs and of curricula – in conjunction with others in the department;
4. Networking with the central administration and other departments on behalf of the department;
5. Empowerment of academic staff.

From Harris, J., Martin, B., and Agnew, W. (2004). The characteristics, behaviours and training of effective educational/leadership chairs. In Thompson, D. and Crampton, F. (eds). *The Changing Face(s) of Educational Leadership: UCEA at the Crossroads*. Kansas City, MO.

Table 6 Specific leadership needs

1. Financial/budget awareness
2. Planning and organizing to achieve goals
3. Handling conflict
4. Delegating and letting go
5. Managing and prioritizing an increasing workload
6. Thinking more broadly about faculty/university/sector issues
7. Strategic visioning skills
8. Assertiveness with challenging colleagues
9. Leading others through change
10. Decision making to make progress
11. Staying focused and positive in the face of challenge and pressure (p. 124).

identified in their study was “staying focussed and positive in the face of challenge and pressure” (p. 124).

There is evidence to suggest that this wealth of research as explored in this section has helped to inform the sort of training and development now offered for heads of department (Hecht *et al.*, 1999; Stevenson and Howlett, 2007; Murray, 1999; Rhodes, 2007), despite Bargh *et al.*'s suggestion that:

... an adequate theory of management and/or leadership in academic has yet to be developed, and needs to be firmly grounded in the specific features of the HE sector” (Bargh *et al.*, 2000: 162).

Training and Development for the Role

In response to the concern about preparing academics in a better manner for a possible future role as head of department, the notion of development centers has been introduced in the UK – a notion imported from other areas of the public sector most notably the National Health Service and State Schools, and blue-chip companies such as the Royal Bank of Scotland and Bayer. The aim of development centers is to help both organizations and individuals alike determine (further to the deployment of assessment-center technology), diagnose, and formulate an appropriate personal-development plan

for prospective heads. The purpose of this plan is to assist the individual move toward the realization of his/her leadership potential. Stevenson and Howlett's (2007) account of the setting up of a development center at the University of Newcastle in the UK was further to the university's concern to develop a pool of potential heads of school. Such an initiative had the added benefit of assisting certain ambitious individuals realize, prior to putting themselves forward for the heads-of-school role, that such a role was not actually one that they were either comfortable with or capable of undertaking. As Stevenson and Howlett (2007) note, “investing early can prevent expensive mistakes in the Heads of School appointment process” (p. 125).

Many research studies explore the range of support for heads of department, suggesting various tactics that they have identified as working, in terms of better preparing and supporting heads of department. For example, Murray (1999) considered a range of training options, which included co-opting potential leaders onto various department and university committees, filling administrative roles, or directing various activities. This technique (referred to by Steinmetz in Murray's 1999 article quoted at the beginning of this section) of what constitutes an induction is used quite extensively for prospective heads of department in UK HEIs. However, for individuals to gain maximum benefit from such opportunities, it is suggested that training and development be run in parallel (Rhodes, 2007). An exploration of what research studies suggest effective training and development might look like as what follows.

Little empirical research has focused on the process of determining the training and development needs of heads of department. Two such recent studies, however, provide a useful starting point. The first, undertaken by Aziz *et al.* (2005) in the USA, revealed four key primarily cognitive areas: (1) budgets and funding, (2) academic staff issues, (3) legal issues, and, finally, (4) professional development. A UK study conducted by Ramsden (2006) sought to explore the benefits sought from a heads of department program, identifying six primarily affective areas: (1) self-knowledge, (2) environment knowledge, (3) style/reflection, (4) learning new techniques, (5) sharing experiences, and (6) gaining confidence.

Wolverton *et al.* (2005), identifying a similar set of complex needs for chairs and prospective chairs at the University of Nevada, subsequently designed a developmental program of seven 3-h sessions over 1 year, based on:

- conceptual understanding (tools and techniques to improve performance);
- skill development (communication-related issues); and
- reflective practice (journal based on Myers Briggs Type Indicator diagnostics and small group discussions).

Increasingly, leadership development for academic managers is seen as a cognitive process, moving into the

affective domain, as opposed to solely a training process. As Weick (2001) notes, leadership development is partly about sense making which comes through a journey of self-discovery, understanding, and reflecting on relationships with others, and an awareness of the environment.

Few studies reveal development programs which attempt to develop both the competences as well as the competencies for the role. McLeod and Jennings (1990) have documented a course they ran for International Business Machines (IBM) (UK) which addressed the latter, suggesting effective development programs including:

Gestalt work, personal construct theory, guided affective imagery, Chinese philosophy, psychosynthesis, and using the right –hand side of the brain” (p. 69).

The incorporation of a number of these approaches is now used in the programs offered by the Leadership Foundation for Higher Education in the UK, with the program for heads of department (or those aspiring to such a role) including:

- knowledge, understanding, and skill development;
- case-study analysis;
- self-awareness diagnostics;
- personal construct theory;
- mythodrama; and
- reflective practice.

Rhodes (2007), writing about developing leaders at the University of Chester in the UK, refers to the view that the most effective learning for managers takes place in the workplace. He developed a three-phase in-house program (see **Table 7**) at the University of Chester which moved from the concrete to the abstract conceptualization of the requirements of the role. The third phase:

developed and adapted to take account of the rapidly growing trend towards more personal forms of learning support: mentoring, coaching, 360 degree feedback, secondments, and directed learning relevant to the working context” (p. 69) (**Table 8**).

Despite all the support that can be offered to heads of department in the form of training and development, the

stress of the job remains a major concern (Sarros *et al.*, 1997: 284). Juggling the constant stream of administrative work with that of leading, teaching, and research and scholarship, flags up a growing problem with prioritization and time management. Despite the growth in complexity, and the constant juggling act to ensure attendance to the range of areas requiring an input (e.g., strategic visioning and planning, teaching, curriculum development, research leadership, monitoring resources, and supporting staff), a significant number of committed academics view the role of head of department as offering an opportunity to make a difference. So, what further research remains to be done to better prepare and support heads of department of the future?

Issues for the Future

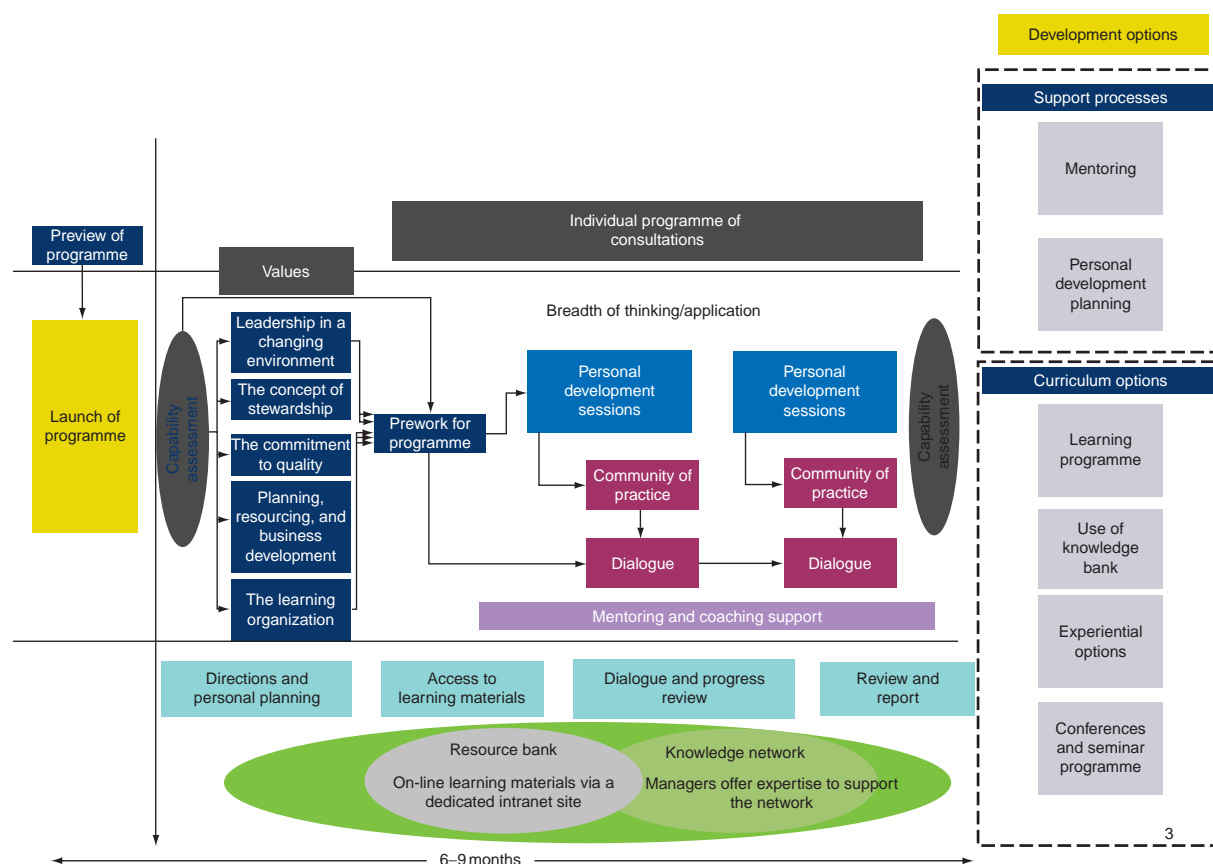

Increasingly, it is recognized that higher education should be more outward looking in terms of seeking and sharing best practices, to include scanning initiatives globally and cross-sectorally. As the world of higher education becomes more competitive, with recognition that knowledge workers are HEI's most important asset, modernizing issues such as those below need to be addressed.

There appear to be three key issues facing HEIs looking to prepare and support heads of department in a better manner. First, despite studies such as Stevenson and Howlett's (2007), there are few studies of effective interventions to help address the issue of succession planning in terms of encouraging academic staff to view this key leadership and management role as a credible career pathway. Exploring talent management and succession planning in other sectors may provide some clues as to what might be trialed and hopefully formally critiqued via publication. The second area that still appears to cause concern in terms of heads of department is their recruitment and the appointment process. Having a pool of credible and well-motivated potential heads of department would be the ideal; however, the harsh reality in the UK is that often soundings have to be taken as to who might be prepared to put themselves forward for the role and, hopefully, not only be a good role model for the rest of the department, but be sufficiently strategic, entrepreneurial, and business minded to be able to take the department forward. As a result, the appointment procedure, most particularly in the chartered universities of the UK, does not always appear as transparent as it should, nor as open as it could be, if an advertisement were placed with a diverse pool of applicants, able to be drawn from, to come forward for formal interview. Finally, despite a host of diversity and equality initiatives, the lack of females and ethnic minorities in these roles remains an issue – certainly in the UK. More studies of initiatives in these three areas would undoubtedly provide some insights as

Table 7 The University of Chester management development program

Phase 1	Generic management development: e.g., strategic management, organizational effectiveness
Phase 2	Action learning sets: to promote the alignment of individuals in support of corporate objectives
Phase 3	Role modeling effective leadership: an emphasis on leadership behaviors

Introduction: Framing the Focus of Enquiry

Organization, Roles and Context

In some countries and some centuries the idea of leading and managing a university when linked to the responsibilities of a president and his or her senior management team might be regarded as something of an oxymoron. There are several reasons for this. The first concerns conceptions of the university as an organization. Traditional conceptions of the university as a community of scholars, collegial institution, or organized anarchy suggest different expectations of leadership and the role of leaders from those associated with concepts of the university as a business or entrepreneurial venture. The second reason is associated with the nature of a president's role. Election to this position as first among equals suggests a different view of how the leadership role is conceived and executed from a situation in which the role is filled through internal or external selection and appointment to the top rank in a hierarchy. A third reason is linked to the term, management, and the role of the senior management team in leading and managing the university. Use of this terminology locates our topic broadly in the latter half of the twentieth and early twenty-first century and positions it in relation to the political, economic, and social contexts of that era. This period, then, defines the parameters of our enquiry.

Diversity of Perspectives

The variables identified above, namely, the university as an organization, the locus and source of authority for university leadership, and the context and time in which leadership occurs are important in framing how leadership is conceived, organized, and delivered. These variables are all reflected in the analytical framework adopted by Bargh and colleagues in their empirical and theoretical study of University Leadership in the UK and in the 5-year study of Institutional Leadership Project (ILP) conducted by Birnbaum and colleagues in the US. Another important variable is the national focus of studies – as Bargh and colleagues recognize and explore – there remain organizational and cultural differences in the

role of rector of a continental European university, president of a university in the USA, and vice chancellors in UK. The interplay between processes of leadership and management within institutions and the wider national and political context within which universities operate also features in many studies from different parts of the world. These studies provide an opportunity to examine the changing practices, as well as the structures and balances of power between the state and the institution.

There is diversity, as well, between universities of different types, historical origin, and legal and financial status within countries. Such factors also impinge on expectations and analyses of the task of leading and managing universities. To quote Madeline Green, a US scholar of institutional leadership, “With more than three thousand institutions. . . Diversity is the hallmark of the American system. Just as there is no recipe for institutional effectiveness, there is no single model of leadership. And definitions of effectiveness and of leadership requirements inevitably change over time.”

Leading and Managing the University

The literature associated with leading and managing the university can be separated, in part, from the literature associated with the role of president and the nature and responsibilities of a senior management team. The unit of enquiry in the first of these domains is the institution and, in the second, the focus is on individual actors. However, there are also studies that bridge the gap by examining actual or potential links between an institution and its performance and the profiles of leaders.

Within the domain of leading and managing the university, terminology again comes into play. In some studies, leadership is a dominant concept embracing management; in other cases, managing is the primary focus, but embracing leadership. In continental European studies, the broader term, governance, is widely used to include the role of rectors and boards within university decision-making processes. Some studies also specifically disaggregate concepts of leadership and governance or leadership and management as well as the associated roles and responsibilities of each domain. In other cases, the discussion is of shared responsibilities for leadership

between governors or trustees and presidents. Such different approaches facilitate an examination of the dynamics of relationships between actors and the critical interdependencies of leadership, governance, management and administration, and indeed, politics, in the running of an institution.

An important topic in the corporate literature is the link between leadership and organizational performance. A recent literature review in the UK has examined research on leadership and institutional effectiveness in higher education and has found a dearth of rigorous empirical work. The most important studies identified are included below.

University Presidents

The nature of the presidential role and the factors that impinge both on expectations surrounding the role and the way the role is exercised clearly offer a rich vein for research. UK and Australian studies, for example, focus on the individuals occupying or seeking presidential roles and examine their profiles, career paths, and remuneration. These studies shed light on sustained or divergent trends over time, the social and disciplinary profiles of incumbents, the characteristics and capabilities sought for the role, rewards, and recruitment and selection processes. A number of hypotheses are posited or tested in these studies including the relationship between disciplinary and professional backgrounds and social and academic status, as well as the power and influence of presidents within the university or with external constituencies such as government, funding bodies, and sponsors. Other studies in this territory explore barriers to entry, such as gender or ethnicity, and examine strategies for development and recruitment that seek to eliminate or reduce barriers. The development routes and learning opportunities offered to or taken by individuals provide another field for research linked to entry to the role of president or member of the senior management team. The lens is also turned on leadership style and approach in studies that concentrate on how the role of leader and management team is exercised in practice.

Senior Management Teams

The amount of published work on senior (or top) management teams in higher education is limited. In the USA, Bensimon and Neumann provide the most comprehensive analysis based on several focused dialogs with 15 presidents of US higher education institutions. Gioia and Thomas undertook an extensive study of how senior management teams make sense of important issues that affect strategic change in modern universities. More recent studies have emerged in the UK: Jarzabkowski and Wilson provide insights into how one senior team formulated and implemented strategy at the University of

Warwick, tracking the process of strategy formulation through the interplay of various structures within the institution. In a later article, Jarzabkowski extends the analysis to three UK institutions: Warwick, the London School of Economics (LSE), and Oxford Brookes University, exploring some of the micro-practices of strategy. Further work in the UK by Taylor explores the relationship between the overall organizational structure and institutional leadership through a case-study analysis of four UK institutions (all research-led premier league institutions) that had undergone major institutional level restructuring in recent years. Most recently, another UK-based empirical study is investigating the challenges and changes associated with the composition of top management team structures in higher education institutions. This research identifies changes in roles and responsibilities and examples of good practice, or good processes, within institutions in the public and private sectors of higher education.

Types of Literature

The types of available literature in relation to our topic are wide ranging, which include field research of various kinds, scholarly reflections and analyses, personal accounts, policy reports, and media articles. Both quantitative and qualitative approaches are represented in the research studies and research is undertaken in a variety of disciplinary fields as part of the general social science and management literature and the specific literature relating to studies in higher education. On the positive side, there is a rich array of knowledge and insights available. On the negative side, however, there is an absence of recognized and cumulative approach to knowledge generation and many studies lack rigor either in terms of theoretical underpinnings or methodological soundness. There is also an imbalance between normative studies and reflective accounts built on practice and experience, and theoretical and investigative research, with fewer studies in the second category.

Focus of the Enquiry

In the next section, we focus more deeply on two main areas: the roles and responsibilities of presidents in leading and managing the university and senior management teams in order to identify findings, concepts, and issues arising before concluding with suggestions concerning future avenues for research. A few key texts are sampled. These have been chosen for their empirical base, practical insights, and their connections to the wider leadership literature so as to give an indication of the types of study available and their value for different purposes and audiences.

Leading Universities: The Role and Responsibilities of Presidents

Two empirical studies of presidential leadership undertaken in the last 40 years stand out because of the breadth of methods used, the range of data collected, the theoretical perspectives presented, and the new knowledge and insights achieved from the research. The first was undertaken in the US over a 5-year period from 1988 to 1992 (the ILP); the second was undertaken in the UK over a 2-year period. An earlier and smaller-scale empirical study in the UK by Bargh and colleagues has also influenced both the practice of leadership and leadership development in the UK and Europe. In the US, the work of Green and Green as well as of McDade has had similar impact.

The US ILP is important for several reasons. First, the authors examined theories of leadership from outside higher education and tested them in the context of universities. Second, they adopted an approach to studying leadership that was closely linked to universities as organizations. By combining the two perspectives, the researchers were able to offer an integrated conceptual approach to strategy formulation and execution that made sense of the complexity of an institution in its particular context and the stage of development. Building on initial work on the cybernetics of academic organization, the project concluded with Birnbaum's analysis of success and failure in the college presidency.

This project is one of the few higher education research studies that attempt to tackle the difficult question of how leadership effectiveness can be depicted and evaluated. Birnbaum and his colleagues drew on the three criteria defined by Cameron, namely, goal achievement, resource acquisition, and smooth internal functioning, to arrive at a definition of good leadership in academic institutions based around constituent support. The studies conducted by Birnbaum and his colleagues are collectively valuable in emphasizing the importance of context for the exercise of leadership and in placing presidential leadership within a wider framework of institutional players, culture, and history that places limits on the influence of a single individual. The individual studies undertaken within the project are equally important. They focus on different stages of the presidential role, sampling new and experienced presidents. The social and cognitive processes that shape the symbolic and substantive aspects of leadership and how presidents learned their job and assess their effectiveness are further themes. The researchers also explored leadership and follower-ship as well as leadership, culture, and change. Each of these avenues of enquiry is represented in the wider literature on leadership, beyond higher education.

The UK study by Bargh and colleagues is significant for different reasons. First, the research achieves greater depth and more comprehensive coverage than many other

studies by combining several types of data. The biographical data are longitudinal, examining the changing career experiences and backgrounds of vice chancellors for the period 1960–97. A total of 341 cases were collected in two linked databases. The study also includes comparative international data from four countries: the UK, US, Sweden, and the Netherlands. These data comprised a literature review examining executive leadership in the US and Europe and three questionnaire surveys of university presidents, yielding more than 100 usable responses. The third element of the research – aimed at getting a more grounded view of the day-to-day work of vice chancellors – involved institutional case studies. These were based on semi-structured interviews in ten institutions (covering vice chancellors and other members of staff and governors) as well as nonparticipant observation of three further vice chancellors at work over a period of 2–3 weeks in their institutions.

A second reason to value this work is that it focuses on the rhetoric and the reality of a historical transition in the role of institutional leaders – from academic to managerial leadership. This transition is still in progress in many countries as they experience governance reforms that reflect continuing change in the relationship between higher education and the state. Bargh and colleagues demonstrate that the assumed trajectory from one form and style of academic and collegial leadership to managerial and corporate leadership is not so clear-cut. This is partly because of the diversity of institutional missions, histories, and cultures and partly because the transitional state encompasses both forms, as represented in new titles of vice chancellor and chief executive. The evidence drawn from their comparative research suggests that the British and European leaders and, to a lesser extent, their US counterparts shared common experiences. Each in different ways were coping with a complex and often conflicting set of pressures including the “the contradictions of free-market rhetoric, the apparent retreat of the state from planning and the competing demands of corporate control versus creativity and entrepreneurship.” The authors conclude that the role relies on a set of implicit and negotiated powers that align more readily with political organizations and processes than overtly commercial and corporate ones.

The study examines university leadership in detail, tracing the evolution of the role from 1945 in five successive periods, all of which are closely connected to the prevailing sequential political contexts of consolidation, growth and innovation, as well as crisis and challenge. Through the empirical data and analysis, the authors highlight the impact of this context on the changing structures of universities as well as the internal and external role of their leaders. External accountability features particularly strongly as part of the new demands of the role.

This includes traditional representational functions as well as managing and redefining the boundaries of the institution with government and an array of new agencies set up to assess, guide, or support the internal functions of the institution. External accountability also encompasses relationships with the governing body. Since the research was completed, the role of the governing body has become more prominent, and the range of business at board level heavier, more complex, and demanding. This is also true of the range of external partnerships and collaborative ventures with which universities engage, from business and the community to international consortia. The external role of the vice chancellor or president is increasing in most countries, and the balance of time spent on internal and external roles remains a preoccupation for institutional leaders. However, Bargh and co-workers found much variation in practice with no agreement among their respondents about the appropriate balance at any one time.

The study provides valuable insight into the internal role of vice chancellor. Classic leadership responsibilities are examined including developing the mission, strategy building and strategic planning, creating structures in support of strategy, and balancing continuity and change in relation to the values of the organization. The vice chancellor's role in academic leadership is also analyzed. This is seen as central to strategy and mission and, in a modern university, involves managing the interface between governors and senior academic colleagues. The unique features of the vice chancellor's role are described as combining academic and symbolic leadership with managerial expertise. Further fine-grained detail is provided of how the social practice of leadership is exercised. There are clear parallels here to the earlier US study – both sets of researchers, drawing on their data – that emphasize the need to think of university leadership in terms of the language and metaphors of complex political systems, “rather than engineering and simple linear models of command and control.”

The comparative data collected in the Bargh study highlight further points of convergence. For presidents, rectors, and vice chancellors there are shared preoccupations: with strategy, with finding appropriate mechanisms to link control with entrepreneurship and competitive advantage, and in dealing with the consequences of dwindling state resources for higher education. However, beyond being subject to similar environmental forces, there remains great diversity of leadership style and behavior reflecting both situation-specific agendas as well as the individuality of the incumbent. To provide a further check on similarities, differences, and possible convergence in presidential roles and responsibilities, we need to look outside Europe, North America, and Australasia. Transforming and transition countries are an important source of data. Cloete and co-workers provide

an overview of the contexts and challenges facing South African institutional leaders, particularly those in historically disadvantaged institutions (HDIs). Some presidential roles are the same: developing mission, strategic planning, mobilizing support, increasing efficiency, and financial planning and management. However, the contexts are significantly different in terms of resources, political, social, and economic challenges, leading in a strongly unionized environment and dealing simultaneously with a variety of crises.

Further useful contributions from this region have focused on the role of South African vice chancellors in institutional transformation. Bell explores an African perspective on transformational or transformative leadership through interviews with ten vice chancellors of HDIs. No commonality of perspective on leadership, or an African style of leadership, emerged. Instead, Bell's study highlights several conflicts that illustrate the tensions experienced in moving from scholarly notions of leadership (Scott's donnish phase of governance) to a managerial phase with strong expectations of democracy built into it. Kulati's study is also about tensions; this time between reliance on governance transformation at the structural level while neglecting the role of institutional leadership in shaping change. He too explores the shifting balance between collegial and managerial forms of leadership, arguing the case for transformative leadership that facilitates effective institutional management in the context of a professional culture that eschews being. At the end of his paper, Kulati raises important questions for further research, namely, the agency versus structure tension and the personality versus environmental fit challenge. In other words, to what extent are individual leaders and their senior teams critical to achieving success in challenging times?

Senior Management Teams

Both the studies cited above not only consider the role, style, and impact of individual leaders in leading and managing the university but also the part played by senior staff in the collective process of leadership. Other studies also contribute to the picture: Gardiner surveyed a small focused sample of presidents to explore their role in team building and the characteristics of an effective presidential team. Middlehurst takes a wider view of group dimensions of leadership by examining the contribution of senior administrators, lay officers, and committees, as well as senior management groups, describing the interactions, relationships, and dimensions of symbolic, stylistic, and substantive institutional leadership as a complex drama. Major studies of senior management teams in higher education are, however, more limited than studies of presidents. Two are selected: the first arose from the ILP in the US and examines teams and teamwork as part

of leadership, whereas the second is a UK-based study recently completed by Woodfield and Kennie.

Bensimon and Neuman report the difficulties of language (e.g. “a team is not always a team”) and summarize the advantages and disadvantages of teamwork. The authors also offer valuable insights into how presidents do or do not make use of their teams. They find that effective team builders construe the work of their teams in terms of three functions: utilitarian, expressive, and cognitive. The first is formal and task oriented, assisting the president in achieving a sense of rationality and control over institutional functioning. The second is social and integrative, reinforcing a sense of connectedness between individuals involved in joint ventures. The third involves sense-making with the purpose of enabling the group to behave as a creative or corrective system able to see problems from multiple perspectives, to question and challenge. Bensimon and Neumann differentiate between real teams that focus on all three dimensions and illusory teams that focus only on the utilitarian function. They note that the key difference between the two is how the team thinks together and again offer a useful conceptualization of eight thinking roles for a presidential team. These include five core roles, namely definer, analyst, interpreter, critic, and synthesizer, as well as three roles that support the core, disparity monitor, task monitor, and emotional monitor. Understanding and balancing different roles is an important contributor to effectiveness in teams’ thinking, learning, and acting together. The authors suggest that while they observed the process of team learning at the micro-level, it was likely also to be reflected in the wider organization. These insights locate this study in relation to wider research on the learning organization and also to the burgeoning field of shared leadership and distributed leadership.

Woodfield and Kennie’s study of top team structures is similarly empirically based and practically orientated toward helping institutional leaders and their teams analyze their role and performance. Two conceptual frameworks have been created from evidence drawn across the UK sector. The authors relate these frameworks to the range of functions that top teams typically undertake and suggest their suitability for different institutional contexts. From their desk research and interviews (to be supplemented by questionnaire data), the researchers highlight key issues related to the formation and operation of top teams that are likely to impinge on their operational effectiveness. These include:

1. clarifying the criteria for membership of the top team;
2. understanding the meaning of team work in a top team;
3. deciding on the focus of top team activities and functions;
4. outlining agreed working practices;
5. dealing with conflicts and competing priorities;

6. evaluating both personal and team effectiveness;
7. relationship building and interaction;
8. reviewing succession planning, training, and development; and
9. providing relevant support and resources for top team activities.

The findings from the UK study are already beginning to identify not only different modes of team operation but also the range of challenges that top teams face in different types of institutions. The research also provides further evidence of tension, transition, and the need for alignment in the ways that universities are led and managed through a variety of formal and informal structures and groupings.

Future Research

There are many gaps and avenues for further work in the general territory covered above. First, the higher education literature is more limited in range and scope than the corporate literature on chief executive leadership and the operations of senior teams. Equally, bespoke research in higher education would benefit from wider and deeper comparisons with other sectors, by including interdisciplinary perspectives and by examining institutions as organizations. The dynamics of change, transition, and transformation (as well as continuity) could usefully be examined more fully, both in terms of stages of organizational and historical development and from the perspective of different cultures and traditions.

At a macro-level, the interplay between university leadership and the wider political, economic, and social system are worth exploring as institutions and their leaders are drawn more deeply into the rhetoric and reality surrounding the role of universities in developing or transforming societies. However, micro-level treatment of this agenda is also needed for a deeper understanding of the part played not only by the president and his or her team, but also by other leaders, including professional managers, senior academic managers and professors, and teachers and researchers. While the career routes of presidents continue to be charted and examined, the wider career and developmental experiences of members of senior teams are not so well researched. In this context, the particular experiences of those leaders who move into and out of higher education should be explored. At the individual level – and at the level of structural and cultural processes – there remains a pressing need to research the experiences of would-be or could-be leaders, including women and ethnic minorities; Eveline’s recent work is a welcome contribution in this territory.

There are also disconnects that require bridging. There is a gap between: (1) theory and practice, (2) policy

interests and the agendas of researchers, (3) macro- and micro-level studies, and (4) empirical and normative literature. There are also fruitful areas for combining investigation and evidence, for example, between the world of practitioners and consultants working in higher education. Ultimately perhaps, research should reflect the landscape in which the subjects operate and make their contribution to the development of higher education; it should more fully examine the interplay between academic, symbolic, managerial, and societal terrains.

Glossary

Adaptive university – An adaptive university is an institution that needs to work with its environment in order to thrive and survive and is able to respond flexibly. Structures and processes of adaptation involve a committed and supporting leadership. Differentiation of structure is an important prerequisite for adaptation.

Administration – Administration is one of three distinct features (i.e., governance, leadership, and administration) of higher education management and refers to the operational side of running an institution, that is, the structures and processes by which decisions are planned, organized, and controlled.

Board – College or university boards represent very important stakeholders of the individual institution who can range from business managers, politicians, professors to international experts. Board members tend to come from outside the institution and tend to be accountable to the ministry of local government as well as trustees of the institution.

Entrepreneurial university – A university that acts in a more market-oriented way and is run by committed leaders who act based on a coherent strategy and who integrate different constituencies.

Governance – Governance is one of three distinct features (i.e., governance, leadership, and administration) of higher education management and refers to the structure and process of decision making.

Idiosyncratic nature of HE¹ – The idiosyncratic nature of higher education includes ambiguous goals, multiple constituencies, unclear technologies, the pivotal role of experts in the organization, and the environmental vulnerability of colleges or universities.

Leadership – Leadership is one of three distinct features (i.e., governance, leadership, and administration) of higher education management and implies the role of top-level positions taking responsibility for the overall institution.

New public management – New public management is a leading principle in higher education management and dominant in Europe due to the large number of European public institutions. It emphasizes competition, hierarchical and

professional management, and output funding (Schimank, 2005).

Performance contracts – Performance contracts are contracts that were developed as a management tool which define service levels and performance, including indicators such as research productivity or number of entering students or graduates.

Professionalization of HE – Professionalization of university management emphasizes the fact that colleges and universities need to be managed by higher education experts rather than by lay faculty members. Know-how such as leadership, human resource development, financial control and marketing, as well as conflict management are necessary for professional HE managers.

Institutions of higher education have experienced a period of change and transformation since the early 1990s. Colleges and universities have been confronted with an ever-increasing competitive environment. As a response, market mechanisms have intensified and institutions of higher education have been expected to become even more efficient and effective. With this, issues concerning the management of colleges and universities are a critical element in the success of institutions.

Management can be defined as the structures and processes of leadership, governance, and administration. When thinking about management, it is important to keep the idiosyncratic nature of higher education institutions in mind (Baldridge *et al.*, 1977; Clark, 1983; Weick, 1976). Colleges and universities are known for their ambiguous goals, multiple constituencies, unclear technologies, the pivotal role of experts in the organization (i.e., professors), and their environmental vulnerability. Models describing this specific nature range from organized anarchy (Cohen and March, 1974), loosely coupled systems (Weick, 1976) collegial, bureaucratic, and political approaches (Birnbaum, 1989) to adhocracy (Mintzberg, 1979). Management has to take these characteristics into account in order to be successful. Questions of shared governance, the role of leadership, and the shift from bureaucratic compliance to professional management often arise.

Across the continents, higher education management developed new approaches to make colleges and universities more efficient and effective. In Europe, new public management has been used to introduce institutional autonomy and accountability (Schimank, 2005; Shattock, 2003).

¹ higher education.

In the US, increased marketization led to the commercialization of management with special emphasis on revenue generation and professional administrators (Bok, 2003; Rhoades, 1998; Slaughter and Leslie, 1997). In Asia, most of these models were copied and related to the idiosyncratic situation of the respective country (Kennedy, 2003). Australia followed most of the Anglo-Saxon tradition with an increased market-driven approach (Marginson and Considine, 2000).

Key Management Issues

The management of higher education involves three distinct features: governance, leadership, and administration. Governance refers to the structure and processes of decision making. Leadership implies the role of top-level positions taking responsibility for the overall institution. Administration refers to the operational side of running an institution, that is, the structures and processes by which decisions are planned, organized, and controlled (Sporn, 1999).

Governance

One major issue of higher education management refers to governance and decision making inside the institution. Going back to the work of the renowned higher education researcher Burton Clark (1983), three levels constitute the governance structure of systems and institutions alike. Clark refers to this phenomenon as the triangle of coordination. In a nutshell, the levels include the overall system, the institution, and the academic community. Depending on the power and strength of any given level, three coordination styles can be differentiated: state authority, market, and academic oligarchy. Accordingly, certain rules apply to governance depending on the character of the system. They could be rules and regulations, mechanisms of supply and demand, or peer pressure. Accordingly, Clark positioned different countries and their higher education system within the triangle. For example, the US turned out to be market oriented while Italy was basically governed by professors (academic oligarchy). Former Russia (USSR) as well as Sweden and France were defined as a state-controlled system.

With the rise of neo-liberal policies globally focusing on effectiveness and accountability, institutional autonomy empowered central administration and leadership (i.e., rectors, presidents, and vice chancellors of institutions, and deans and heads of institutes or departments). External stakeholders (as board members) started to play an important role in governance representing general societal interests (Birnbaum, 2000; Maassen, 2000; Slaughter and Leslie, 1997). Overall, market mechanisms of supply and demand changed the notion of higher education from

a social system to an industry with important implications for institutional governance (Gumport, 2000).

Governance structures define the role of institutional leaders, academic faculty senates, individual faculty, central administration, and external stakeholders. Leaders in colleges and universities have an ever-increasing importance as they are responsible for the overall success of the institution. They are accountable to an external board. The power of the faculty senate has often been reduced to either a consultancy function (e.g., US, the Netherlands) or to a concentration on issues of academic nature, that is, teaching and research (e.g., many European countries; De Boer, 2001).

A stakeholder approach in higher education governance is most visible through external boards at colleges and universities (e.g., US: board of regents, board of trustees; Europe: university boards, board of trustees). Board members represent very important stakeholders of the individual institution who can range from business managers, to politicians, professors to international experts. The board members come from outside the institution and tend to be accountable to the ministry or local governments as well as trustees of the institution. Appointments to such boards are an important and sometimes contested issue. They can range from purely ministerial to a combination of institutional and governmental nominations (Gumport and Pusser, 1999). Boards in that sense have an important external control and linkage function with the external institutional environment.

Another important form of governance structures are executive boards. They often consist of the top leadership team, that is, rector and vice-rectors, dean and associate deans, or presidents, provost, and vice presidents. They make decisions at the highest level of the institution. Members are often appointed by the board of trustees. There is a functional divide with responsibilities ranging from research to international affairs and board members decide, for example, upon research funds allocation, promotion procedures, and general infrastructure.

The senate is the third element of institutional governance. At this level, major areas for decision making concern the core function of universities in teaching and research. Members can include all faculty members or a subset as delegates of different fields or schools. In the Anglo-Saxon model, senates have mostly advisory function and consist of professors and/or academics with faculty-rank only. The continental European model sees the senate as a decision-making body with membership of all groups, that is, representatives from the group of faculty, students, and administration (Weiler, 2005).

Leadership

The leadership of colleges and universities has been strengthened over the last decades in most higher education

systems. The rector, president or chancellor as well as the vice rectors and deans are the ones running the institution at the top. They are supported by an administrative structure which is also moving from a bureaucratic to a managerial model (Birnbaum, 2000; Mora, 2001).

Institutional leaders have been established as the key figures and major players within the steering of colleges and universities. Their role can be compared with that of a chief executive officer (CEO) or head of the board of directors. Responsibilities encompass the planning and implementing of all major areas ranging from budget and space to teaching and research. He or she is accountable for the success or failure of the institution. The president would often be responsible for external relations and fundraising while a provost would lead the academic side of the enterprise. Leaders are no longer necessarily hired from the faculty of the specific institution. Comprehensive searches are run to find candidates with adequate qualifications. Still in order to guarantee credibility, some academic/faculty background or an equivalent expertise like management of a research center is necessary.

Leadership structures have to combine responsibility and accountability (Weiler, 1998). In many countries, the management practice has been to divide strategic and operational issues. The consequence has been that committees decided (sometimes without the necessary background information, data, or preparation) on issues for which they then have not been held accountable. For example, a senate could decide on the introduction of a new study program without the necessary budget plan. With accountable forms of leadership in place, institutions of higher education define responsibilities based on the specific areas of expertise. Hence, a senate would look at curricula and quality-control issues, whereas a leadership team would fund programs and provide necessary infrastructure.

The leadership level at colleges and universities includes a whole set of growing positions. Vice rectors, deans, and program directors take over certain areas ranging from finance, research and teaching, and international relations to undergraduate and graduate programs. Candidates are often found within the faculty of the institution. For full-time positions, special financial incentives are necessary to attract the right individuals. Deans and vice rectors are normally members of the leadership team with their budgets and areas of responsibility. Often they function as an important liaison between the faculty and the administration. Trust between groups and identification with institutional goals seems to be one of the most important success factors in today's colleges and universities. From European universities, it can be learnt that a faculty-dominated administration or top-level leadership team can help the institution to thrive and overcome major obstacles (Rhoades and Sporn, 2002a; Sporn, 1995).

In the US, administration is sometimes twice as large as the faculty. With this, it is a pivotal task of university leaders to pay close attention to the integration of academic and administrative cultures (Clark, 1997; Dill, 1982; Sporn, 1996).

Administration

The management of colleges and universities is defined as the structures and processes by which decisions are implemented. In a sense, structures imply the role of administration, and processes mean instruments and tools of management. Looking back over the last 25 years reveals that a tremendous change occurred within colleges and universities. In the 1970s, European universities and colleges were based on a bureaucratic model of management with a divided organizational structure, that is, a state bureaucracy at individual institutions responsible for compliance with legal requirements and an academic guild providing the core performance in teaching and research. Following this period, a collegial form of management evolved. This type can be characterized as institutional management and administration firmly rooted in the faculty. Professors have taken over major administrative positions for running the institution in this manner. With the rise of a new policy in higher education, more market pressure, and the call for professionalism, a managerial approach to administration developed. This referred to the use and adoption of private industry tools such as performance indicators, personnel development, and standard reporting. Another major trend can be observed toward more entrepreneurial forms of management. Here institutional leadership sets up certain incentive structures to create opportunities for individual members of the faculty to create new ways of income and generally doing business. Hence, accountability and responsibility for most activities are decentralized. The top-level management solely provides an infrastructure and controls for results (Clark, 2004; Shattock, 2000, 2003; Sporn, 1999).

Problems of management arise from the dualism of controls (Birnbaum, 1989) at most colleges and universities. Compared to business firms, universities have two parallel systems based on very different goals. While the faculty is mainly concerned with the pursuit and dissemination of knowledge, administration has to aim at efficiency and effectiveness of the whole institution. This tension increases with resource scarcity and uncertainty (Cohen and March, 1974). As mentioned earlier, a shift of authority from faculty to administration can be observed.

In a more competitive environment of scarce resources, clarity and agreement on the organizational mission are considered a fundamental basis of success. Higher education management responds by developing a mission, establishing strategic plans, and defining common objectives.

However, with the complexity of academic and administrative goals and little agreement on priorities and measures of goal achievement, it is hard to develop coherent and consistent mission statements. Teaching, research, and service – the dominant three overall goals in higher education – are too broad to serve as starting points for mission statements. Higher education institutions could be managed more effectively if their missions were clarified but this has proven to be difficult to do in larger and more complex organizations. Hence, administration and management have to learn to function within the context of conflicting objectives (Birnbaum, 1989; Kezar and Eckel, 2002).

Yet another problem of higher education management is the distribution of institutional power. Organizations such as colleges and universities rely on expert power (i.e., faculty). Professors are less motivated by salary incentives than by internalized principles of academic freedom and ethical behavior, and by exchange with colleagues with similar values. Hence, faculty behavior cannot be managed successfully by business firm standards. Administration needs to find ways to address this issue by responding to the intrinsic motivation of faculty through recognition, involvement, and respect.

Overview of Management Approaches

Taken together, governance, leadership, and administration form the management in and of higher education. As many authors have noted, a changing environment of colleges and universities has called for a change in management approaches. Given the rising skepticism of society with its institutions, legitimacy and accountability of higher education have become prominent issues (Gumport, 2000). Accordingly, different approaches emerged which are outlined as follows: new public management, strategic management, and professionalization of university management. Their application differs depending on institutional type – especially regarding public and private colleges and universities.

In Europe with its dominance of public institutions, new public management and management by objectives based on performance contracts are leading principles in higher education management. This is tightly connected to the notion of performance funding. New public management emphasizes, for example, competition, hierarchical and professional management, and output funding (Schimank, 2005). Competition between and within institutions based on the principles of supply and demand (in the form of proposals and negotiations for funding) has been introduced in order to spur quality. Management had to respond by becoming more business-like with clear reporting lines and experienced managers involved (and not faculty members). Funding has been based on transparent target goals. In many countries, contracts

were developed as a management tool which defined service levels and performance, including certain indicators ranging from research productivity or number of entering students to graduates.

Ex-post steering is a distinct element of new public management. Institutions can be evaluated regarding their input they are able to process or the output they produce with any given resources. Trends show that output orientation gains importance at colleges and universities. Colleges and universities need to demonstrate the number of graduates, patents, publications, and services to the community in order to receive funding and respect. A key challenge is the definition of indicators. Faculty members believe mostly in the concept of peer review for an objective evaluation of their performance in teaching and research. They find it hard to accept other forms of feedback such as student ratings, rankings by journals, or government indicators. Professors rely more on referred journal articles, citation indexes, or groups of peers visiting their classes. A clear conceptual framework should be part of the total quality management of higher education institutions which takes these differences into consideration (Dill, 1993; Rhoades and Sporn, 2002b).

Strategic management emphasizes the role of the environment and the types of changes which affect colleges and universities. The major goal of strategic management is to keep institutions successful in a changing environment based on flexible and adaptive structures together with a clear strategy. As Shattock (2000, 2003) pointed out successful strategic management needs to take a couple of elements into consideration: competition, opportunism, income generation and cost cutting, relevance, excellence, and reputation. Environments for higher education have turned into competitive markets for talent. Institutions have to be able to assess opportunities and turn them into entrepreneurial activities, thereby providing the basis for acquiring additional funds. At the same time, costs need to be understood and reduced wherever possible. Programs are offered on this market with the understanding to provide value for clients. This should enhance institutional reputation and overall excellence.

The professionalization of university management emphasizes the fact that colleges and universities need to be managed by trained experts rather than lay faculty members. The US has seen a long tradition of university and college managers. Only presidents and provost often need to have some faculty background. Many institutional leaders come to the job ill-prepared and with wrong assumptions. Necessary experience and know-how include, for example, leadership, human resource development, financial control and marketing, as well as conflict management. Academic training programs in higher education management, competitive salaries, and international searches are standard instruments to increase the professional management of colleges and universities. With this, managers

become powerful players who use instruments of business to run the institution. Conflicts arise as values between academic and administrative staff clash. A new compromise seems to be underway where faculty concentrates on teaching and research whereas managers handle the administration of the institution (Rhoades and Sporn, 2002b).

Concluding Perspectives

There are different concepts which have been coined by higher education researchers to describe trends for education management. Although they have been developed in the late 1990s, they still seem to be valid: the learning university, the adaptive university, and the entrepreneurial university.

The model of a learning university resonates with the core function of universities, that is, teaching and research, and applies the concept of organizational learning to institutions of higher education. The underlying principles regarding the learning universities are twofold. On the one hand, the university must provide an atmosphere where student learning can be enhanced. On the other hand, universities as learning organizations have to restructure in order to better react flexibly and proactively to a dynamically changing environment. Some factors play a critical role for university management (Senge, 2000): line managers as promoters, academic units as change agents, university leaders learning from private industry, self-organized restructuring, faculty involvement, and internal networks. The learning approach enables higher education managers to take a fresh look at the structures and processes of innovation. Accordingly, university management needs to develop structures which enhance learning by allowing the building of internal and external networks, by providing sufficient data on performance and environmental trends, and by finding innovative forms of collaboration between faculty and administration.

The adaptive university is based on the assumption that institutions need to work with their environment in order to survive and thrive. Structures and processes of adaptation involve a leadership which is committed and has a supportive role, that is, providing resources to initiatives and to projects initiated by the core units (i.e., academic institutes and departments). Management should be professional, and shared governance involving both faculty and administration should be in place. Differentiation of structure is an important prerequisite for adaptation. In order to respond flexibly, different units can help to respond to a diverse set of external demands. Clear goals will then provide sufficient direction of all university activities. An entrepreneurial culture can prepare the grounds for a climate where individual projects get rewarded and institutional interests (and finances) are protected (Sporn, 1999). Especially the value system and

the institutional culture need to reinforce adaptation. The orientation toward change, risk-taking, and flexibility is an important prerequisite for successful adaptation (De Zilwa, 2007; Kezar and Eckel, 2002).

The entrepreneurial university acts in a more market-oriented higher education system. An entrepreneurial university management is run by committed leaders who act based on a coherent strategy and who integrate different constituencies. Linkages with outside organizations and groups help to reach across traditional institutional boundaries. Differentiated funding based on public spending as well as corporate and private giving enhance the independence of the institution and increase the number of initiatives. The academic units need to be integrated and respected for their role as the core providers of teaching and research. A common value system should be in place which reconciles managerial groups and academics. A culture which supports change will form the basis of the entrepreneurial university (Clark, 1998). From an international perspective, Clark continued his work around the globe to conclude with the concept of the self-reliant university, that is, an institution operating in a highly competitive market and achieving success through tailor-made solutions and collegial entrepreneurialism. As he points out: "The mantra for reform becomes: complex universities operating in complex environments require complex differentiated solutions. One hundred universities require 100 solutions." (Clark, 2004: 183)

The management of and in higher education is a complex task. The nature of colleges and universities, the right balance of leadership, governance and administration, and the use of management instruments need to be chosen with great care in order to fit with the very nature of the institution. Once a culture of trust and respect has been established, higher education institutions can succeed and thrive in an environment which has become increasingly turbulent and competitive.

Managerialism and Collegialism in Higher Education Institutions

M Shattock, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

New public management (NPM) reforms have been a characteristic of most developed countries in an effort to contain the rising costs of public services, although Pollitt and Boukaert suggest that the intensity has been greater in countries where governments comprise single-party majorities, such as in the UK, Australia, Canada, and New Zealand, than in countries where coalition or more consensual governments operate, such as in Finland, the Netherlands, or Germany (Pollitt and Boukaert, 2000); it is generally agreed that the stimulus for many countries was the Thatcher revolution in the UK. The impact of NPM or the new managerialism, as it is sometimes called, on the public services has created a new orthodoxy which governments have sought to reflect in the management of higher education. *The Report of the Steering Committee on Efficiency Studies in Universities* (the Jarratt Report) (CVCP, 1985) which was prompted and funded by the UK government and the Lambert Report (HMSO, 2003) funded by HM Treasury, as well as the *Higher Education Management Review* (the Hoare Report) (AGPS, 1995) in Australia are all examples of governments seeking to transfer reforming styles of management used elsewhere in the public services into the universities.

Managerialism as an Ideology?

Some scholars argue that new managerialism should be seen in ideological terms. Tapper writing about the governance of higher education sees the creation of the UK funding council system as:

part of a much broader range of thinking about the control of social policy in Britain in the light of economic failure and political ineptitude. (Tapper, 2006)

Deem and Brehony (2005) looking at new managerialism at the institutional level see it “very clearly as an ideological rather than a technical reform” and quote as evidence manager academics who “assert their right to manage both academics and other staff, thus suggesting that as a social group, such manager academics are very interested indeed in maintaining relationships of power and domination.” However, not all scholars would go this far. Kogan and Hanney (2000) define managerialism as:

the shift in power from senior academics and their departments to the central institution and the dominance of systems over academic values. (Kogan and Hanney, 2000)

However, they make it clear that this partly came about “from institutions’ need to meet new demands from fewer resources.” Marginson and Considine, writing of the parallel Australian scene paint a similar picture:

Those senior executives controlling the future of universities have both more power and less room to manoeuvre than before, while those dependent on them for leadership have fewer alternative means to define their futures than previously was the case. (Marginson and Considine, 2000a)

They define the enterprise university as having “strong executive control,” “a distinctly corporate character” where academic bodies have been “supplemented (and sometimes supplanted) by vice-chancellors’ advisory committees and private ‘shadow’ university structures,” and as operating in a situation where underfunding drives “a pseudo-market in fee incomes, soft budget allocations for specific purposes and contested earnings for new enrolments and research grants” and where some market elements, for example, the recruitment of overseas students, are driven by openly commercial motives (Marginson and Considine, 2000b). These characteristics derive very largely from the imposition of government (Dawkins)-led reforms, which imposed institutional mergers and marketization on universities involving a much more rapid institutional adjustment than was faced in the UK. However, the processes they list are internationally recognizable and have also been described as the growth of academic capitalism (Slaughter and Leslie, 1997) or of university entrepreneurialism (Clark, 1998). If we look for parallels in the application of NPM reforms across the public services generally, we see many of the same approaches: tightening controls, cutting budgets, freezing new hirings, campaigning against waste, squeezing the system, and modernizing it through faster and more flexible approaches to budgeting, managing, accounting for a delivering services, and through marketization, that is, increasing user responsiveness and introducing competition, as we see in higher education (Pollitt and Boukaert, 2000).

The Changing Context of University Management

The context of university management has also changed in some particular ways. All major higher education systems have expanded enormously leading to rapid institutional growth. In 1960, the University of London was the

only university in the UK that had more than 30 000 students but it was a collegiate university and the students (and the staff) were managed in self-governing colleges. Almost 50 years later, at least 15 universities in the UK have over 30 000 students managed on a unitary institutional basis. The other UK institutions have grown proportionately: 15 universities (not necessarily the same ones) have turnovers of over £300 million, an unimaginable figure even 20 years ago. Universities have become big business and require business-like management. In a similar period, the financial contribution of the state has gone up many times prompting much more rigorous public accountability regimes. Public accountability has been extended beyond simply finance – into the quality of teaching monitored through quality-assessment regimes. In addition, the UK, Australia, and New Zealand have introduced formal research-assessment processes.

Competition was essentially reputational until the first published league tables began to appear. The later appearance of global league tables merely added a further dimension to the nature of the competition. Competition breeds stress, demands shorter decision-making timescales, and discounts equity in favor of more *dirigiste* approaches to resource allocation. At the same time, the recognition of the dependence of the knowledge economy on university outputs, both nationally and regionally, has led to creation of a third mission in most countries which requires universities to maximize their community and regional contributions. These contributions need clear management structures if they are to be effective and often entail the recruitment of *animateurs* from the private sector whose first responsibility is to their customers and not to the traditional mores of teaching and research (Goddard and Chatterton, 1999). Their instincts and role are different to those of the academic community.

Financial stringency, combined with marketization, has also been a forcing house for change. Rapid growth in student numbers, financed at marginal cost levels, and the impact of increasing marketization, together with a greater concentration of research monies into fewer universities have led to a steady worsening of staff–student ratios to levels which would have been considered unacceptable in university systems 20 years before, and to repeated rounds of academic restructuring where student demand has fallen. In the early 1980s in the UK, the period of the sharpest cuts imposed by the Thatcher government, questions were raised by, for example, the chairman of Unilever whether universities had “the organisational structures nor as yet the management skills” to cope with change of this nature (Durham, 1982): the Jarratt Report argued that vice-chancellors should be recognized as chief executives and that governing bodies should assert themselves over senates which were endemically liable to resist change and to act out of natural conservatism (CVCP, 1985), propositions that were given

legal validity in the constitutions of the new universities in 1992; the Lambert Report condemned management in some universities as “slow moving, bureaucratic and risk averse” and commended “dynamic management in an environment that cannot wait for the next committee meeting” (Lambert, 2003).

Managerialism and Collegiality in Practice

Thus, in most higher education systems in the UK, size, increasing competition, accountability, the demands of a broader mission, and financial stringency have in combination changed the management task in universities, not just at the institutional level but in the basic academic units of the faculties and academic departments. The solution for many university systems has been the adoption of a much more executive style of management, and a great deal less reliance on collegial decision making. Consensual appointment processes to fill senior management positions were changed on the argument put forward by one UK vice-chancellor that:

academics are not going to vote for a manager who advocates cutting their programmes. The result is that only those people with no plans or those who promise everyone whatever they wish to hear are elected. University managers, including deans and heads of departments should not be elected but should be selected for their management ability. This will give them dignity and authority. Also managers who are hired can be fired – a key element of accountability. (Schwarz, 2003)

In matters of governance too there was pressure, from the Jarratt Report onward to make universities more business like. In the UK, the Committee of University Chairmen, following a recommendation of the Lambert Report, adopted a code of governance for universities which was modeled on the Combined Code of Governance required of major companies by the Financial Services Authority. Many continental European university systems, which had previously operated without any lay (i.e., external members drawn largely from industry and the professions), established boards of governors broadly on the Anglo-Saxon model (Braun and Merrien, 1999; Kehm and Lanzendorf, 2006). Perhaps at the extreme end of this process, a survey of university governance in the UK described DeMontfort University, a post-1992 institution, as having:

a small Board of Governors working closely with a Chief Executive ... who really is the Chief Executive and has considerable delegated powers; the Chief Executive runs the institution with the Senior Executive including four Pro-Vice-Chancellors, two Associate Vice-Chancellors, the Director of Finance, the academic Registrar and the Director of Personnel”. (North Report, University of Oxford, Commission of Inquiry, 1997)

Both the Schwarz statement and the description of DeMontfort reflect managerialist approaches as to how universities should be run. To emphasize how far this represents a shift of opinion, it is worth comparing them with a quotation from a senior and successful vice-chancellor of a major UK civic university from the 1960s:

It is clear that the optimal distribution of responsibility for academic management is not the most economical of time and effort. A much smaller and more authoritarian oligarchy with a tight hierarchy of subordinates could reduce the size and complexity of the committee system. It would, however, be unacceptable for the valid reason that under it academic freedom would be restricted and academics would carry out research and teaching less well. The academic does not produce best performance to order. (Aitken, 1966)

It is worth asking whether the values to which Aitken subscribes still carry force. We can attempt to answer this in a number of ways. The first is to try to evaluate university performance. Here, the evidence looks pretty clear that whether we use the international (Shanghai Jiao Tong or the *Times Higher Education Supplement*), those universities which are toward the top end of the ranking lists place a high priority on participative management structures, while those at the bottom, such as DeMontfort, do not. It could be argued that in the specifically UK league tables the inherited wealth of Cambridge and Oxford overbalances the evidences were not York and Warwick, both 1960s universities, and both strongly collegial in management style not so high up (Shattock, 2003a). Similar evidence is provided by the USA with highly collegial universities at the top of the rankings and vest-pocket institutions at the bottom. Ehrenberg, writing about the top US universities says that: "It is hard to think of any decision made by the university in which faculty members do not feel they have a legitimate interest" (Ehrenberg, 2002). The decision by the president of Harvard to resign in the face of a critical vote by the College of Arts and Sciences, paralleled in the UK by the immediate resignation of the provost (vice-chancellor) of University College, London, on receipt of a critical round robin signed by 40 professors, provides illustration that in leading research-intensive universities the head of an institution feels himself/herself to be heavily dependent on the confidence of the academic community.

Universities and Business-Like Organizations

University management is often judged by external commentators through analogies with business. However, even by this yardstick the evidence we have is that collegiality

works well and particularly in crisis situations. In spite of the strictures of the chairman of Unilever (quoted above) no UK university went bankrupt, or even looked like going bankrupt in the period of severe cuts in 1981–1984. The university which faced the heaviest cuts (44%) dealt with them by asking every professor to tender his/her resignation to the vice-chancellor (not a single one demurred) and when the restructuring was agreed, by the senate as well as by the council, some letters were handed back to their authors and some were accepted. The university even bounced back, and created space to appoint some young new staff. Hardy, in case studies of how Canadian universities handled similar sharp budgetary reductions in the 1980s, identified different institutions' approaches as bureaucratic, technocratic, political, and collegial; she concluded that collegiality remained the most effective mechanism to manage competing pressures and was "more likely to encourage creativity and innovation" (Hardy, 1996).

Creativity and innovation are precisely the sought-after qualities by most successful companies, which is why leading business researchers argue that strategy is best formed by bottom-up rather than top-down methods (Ghoshal and Bartlett, 1993), that the role of senior management is more a retroactive legitimizer than in providing charismatic leadership (Quin, 1985) or that the task of top management "is less to spot and solve problems than to create an organisation that can spot and solve its own problems" (Hayes, 1985: 116). Professional and partnership organizations similarly work more on the basis of consensus than direction: Clifford Chance, the world's largest law firm, manages some of its corporate decision making on the basis of referenda among its 5000 partners worldwide; McKinsey's, the world's top management consultants, elect their top post by a ballot among the partners. The belief that business or accountancy or law firms operate best on a hierarchical managerialist basis is a notion that dates back to the age of manufacture rather than to the knowledge industries of the present. Kets de Vries notes that trust is an important element in leadership and "with trust comes candour, the willingness of people to speak their minds. When people are reluctant to discuss their ideas and thoughts openly realism disappears and the quality of decision-making deteriorates" (Ket de Vries, 2002).

Collegiality and Organizational Culture

Burgan, basing her argument on Drucker's concept of the place of 'knowledge workers' in the postindustrial society organization, suggests that:

Sophisticated, independent minded and highly trained workers require modes of participation within organisations if the benefits of their initiative and imagination are

to be realised. Further, the complexity of the organisations requires more rather than less discussion from within ... Thus decisions that seem right in the short run may never be assessed in the light of long range developments. (Burgan, 2006)

An organizational study of Bletchley Park, the wartime base for 'Enigma' which was crucial to winning World War II concludes, contradicting the argument that it was 'anarchic and amateurish,' that:

whilst the multiple lines of command and employing institutions and the highly compartmentalised organisation were in some sense problems, they gave rise to meritocratic, problem solving groups with a strong sense of group identification. Intriguingly, Bletchley Park seems to conform to many of the tenets of what are nowadays called 'knowledge intensive' or 'post-bureaucratic organisations'. (Grey and Sturdy, 2007)

This could just as easily be a description of a highly ranked twenty-first century university.

If managerialism is ineffective in managing institutions whose core business is teaching and research, where creativity and innovation are at a premium, does collegiality offer an alternative? The answer lies in the organizational culture of the particular university. In European countries where universities have operated as part of state bureaucracies, such as France and Spain, collegiality is often a force for conservatism and resistance to change. However, in universities which recognize the need to compete for talent, research rewards, and for the best students, management which combines the virtues of collegiality and the politics of consent with the disciplines of timeliness in decision making can create an organizational culture that is true to the institution's key functions. Clark, for example, sees no contradiction between collegiality and entrepreneurialism, and indeed would argue from his case studies that university transformation will occur only when "managerial and faculty values become intertwined and then expressed in daily operating procedures" (Clark, 1998). In modern conditions, however, senates/academic boards and governing bodies meet too infrequently and are usually too large and too inexperienced to manage institutions effectively. Many institutions have therefore created what Clark has called "a strengthened steering core"; this may either be a senior management team – that is, a group of full-time managers answerable to the chief executive (common in universities which have gone down the managerialist route) – or a body comprising both academics and administrators which is constitutionally answerable to senate and the governing body. A critical element in this latter model is whether the deans are members of the group; if they are, academic management becomes a central concern and the deans have the task of both reflecting faculty opinion to the centre and representing central

decisions to their faculties; if they are not, the group's decisions tend to become more centrist and managerial, and less academic, and the deans tend to become merely advocates for their faculties against central management, rather than key participants in institutional policymaking. The interrelationships between such a steering group and the senate and the governing body on the one hand, and the faculties and/or academic departments, on the other, will define the organizational culture of the institution.

Where does the vice-chancellor/chief executive's role sit in this new context of university management? Leadership can be expressed in various styles, but Collins, examining a group of companies which had radically improved their performance found that their chief executives were not charismatic leaders in the conventional sense and had no public profile at all (Collins, 2001). Goodall has found that: "The higher the global ranking of a university the more likely it is that the citations of its president will also be high ... better universities appoint better researchers to lead them" (Goodall, 2006). This ensures that such presidents possess what Ramsden sees as a key university leadership skill: "an understanding of how academics work and an ability to enter into their world" (Ramsden, 1998). Leadership in collegially managed universities will be distributed and not concentrated in a single person and the task of a vice-chancellor will be to build robust structures and strong teams not to lead the charge (Shattock, 2003b). "It's about listening, then deciding and then leading forward" and not about managerial direction and confrontation (Midgley and Macleod, 2003). Indeed, the ideal is perhaps summed up in the Chinese Taoist saying:

The wicked leader is he who the people despise.
The good leader is he who the people revere.
The great leader is he who the people say, 'We did it ourselves'. (Lao Zhi, quoted in Yihong, 2004)

Kogan and Hanney were equivocal about how far managerialism had become the dominant culture in UK universities but quoted one system leader as saying that "scholarly values are being to some extent suppressed in favour of business attitudes and criteria and ... if we're not careful, that will mean the downfall of something that is rather precious" (Kogan and Hanney, 2000). Marginson and Conside writing about the Australian scene were more critical:

In recent years there has been a concentration of decision-making at the point of institutional management and leadership. Certain decisions once made by national or state governments, about research deployment, for example, have been transferred to the universities themselves. Other decisions once made by academic units are now determined from above by professional managers and technicians. Many see this concentration of nodal powers as overdue, as essential to the effective running of universities in the manner of government departments or business

firms. Others see it as the primary cause of what they perceive as a crisis of university purposes and values. (Marginson and Considine, 2000c)

There can be little objection to the idea that, in the modern age, universities must be managed but by whom and in what manner are deeply contested questions. Managerialism, if it is defined as top-down nonconsensual management, is not an effective approach to running universities but collegiality without a corporate commitment to academic and other forms of success is not a reliable substitute.

Strategic Planning in Higher Education

L Zechlin, University of Duisburg-Essen, Duisburg, Germany

© 2010 Elsevier Ltd. All rights reserved.

For the last third of the twentieth century, higher education institutions around the world have been struggling under two different types of pressure: the first is financial, as the provision of public funds has been decreasing. The second refers to the political, economic, and social demands on higher education, which have been increasing. Meanwhile, state governments are withdrawing from the direct regulation of and responsibility for the higher education sector. Under the paradigms of new public management and public governance, higher education institutions have been endowed with greater autonomy for a new beginning. It is now up to the institutions to bridge the gap between increasing internal and external demands for societal services and the limited available resources by improving the efficiency and effectiveness of their work. The task requires professional management for all types of higher education institutions, from the Humboldtian universities, with their formerly state-controlled budgets, personnel, and organizations which are forced to create first their own management system, to the Anglo-Saxon and US-American universities that have to professionalize their management system. In terms of the triangle of coordination used by Clark (1983) to classify the national higher education systems according to the major influences of the state, market, or academic oligarchies, the global trend clearly indicates the increasing importance of the market and competition. Consequently, the model of the entrepreneurial university has emerged, which then necessitated the creation of methods and instruments appropriate for institutional leadership in the higher education sector. In this context, the issue of strategic planning takes on new importance for higher education institutions around the world.

The Basic Model for Strategic Planning

The basic model for strategic planning consists of several consecutive steps, beginning with a strategic analysis in which changes in an institution's environment and the resulting external demands are mapped out against the institution's internal potential. On the basis of the analysis, strategies with long-term goals are formulated and then the actions necessary for realizing the strategies are planned. These three steps, which are often accompanied by expertise from external advisors, fall within the narrow field of planning. The predetermined actions are then put into practice and lead to results on the basis of which the

actions, strategies, and analysis can be evaluated (**Figure 1**). Unexpected deviations come about either because of mistakes in the plans (inexact analysis, insufficient strategy derived from the analysis, or actions for change undertaken without sufficient reference to the strategy) or from mistakes in implementation. The main focus remains on the first three steps of the basic model: the rational, linear linkages between analysis, strategy for and planning of action for change. According to the original proponent of this approach, Ansoff (1965), planning should be based on expertise; mistakes in planning must therefore be rectified through more, or better, expertise.

Goals and Performance Areas

Most strategic plans in higher education are based on this primary model. They usually describe goals to be achieved across three distinct, hierarchical levels. The top level, for the normative management, contains statements referring to the long-term social gains to which higher education should contribute (vision and mission), and the associated underlying values by which to proceed. The middle level, the strategic-management area, includes mid- to long-term goals and objectives, as well as the strategies to be followed in order to reach them. Finally, the operative management area is found at the third level, where the actual actions for change (projects) are taken in order to accomplish the plans within the 5–10-year reference period.

A similar hierarchy, although with slightly different terminology, is characteristic of the planning logic behind the new public management approach (**Figure 2**). At the upper level is a strategic plan consisting of long-term goals for impact or outcomes. The higher education institution uses the plan to enumerate the kind of influence it aims to have on its social and economic environment; for example, contributing as a knowledge organization to the improvement of economic prosperity, political democracy, and social cohesion. Outreach to the community means that products resulting from teaching and research are conveyed beyond the institution to the surrounding environment. The strategic plan entails performance or output goals specifically for this purpose. In the area of teaching and learning, for example, the plan describes graduates in terms of quantity (e.g., the number in each study field) and quality (e.g., qualifications related to subject area, as well as methodological and social skills; international profile; and gender balance). For the areas of

research and knowledge transfer, the plan could refer to the number of patents, publications, citation frequency, etc. In end effect, the operative-management level steers the process intended to generate the preidentified desired outcomes or results.

In addition to the hierarchy of levels of objectives, there is also further differentiation between various performance areas. The purpose of higher education institutions as knowledge organizations is to make accessible to the public the knowledge existing within society and newly created through research. Higher education institutions accomplish this through teaching and learning as the means to preserve and convey existing knowledge, through research as the means to generate new knowledge and to prepare the next generation of scientists for further knowledge building. Most universities in UK, US, NZ, Australian, etc. would add to research and teaching/learning, service to or engagement with the community. Higher education institutions are not self-sufficient ivory towers; in fact, they exist precisely because of their impact on the external environment. These externally oriented performance areas are therefore essential to every higher education institution. In economic terms, they are the main business areas where higher education institutions define their policies in order to remain competitive within

the sector. It is important to distinguish between the externally oriented key processes and the internal services that the university provides in order to support these processes. In particular, such services include the make up of the internal financing system, as well as staff recruitment, information services, student services, technology transfer offices, and of course the strategic-planning system. The purpose of the internal services is to provide for internal clients/stakeholders; however, they remain closely related to the university's key processes and are certainly no less important than the externally oriented performance areas. In fact, the opposite can be argued: the performance capacity of an entrepreneurial university is more and more dependent on its internal management system, which is responsible – through appointment policies, for example – for the quality of the externally oriented key processes.

In order to reconcile all the various different demands placed on higher education today, strategic plans (see **Figure 3**) are often complicated undertakings. Normally, they consist of a general vision or mission statement followed by descriptions of the current situation in the respective area, strategic objectives, and the intended course of action for change. Many higher education institutions have published their strategic plans either in printed format or on the Internet, for example, all Australian universities, Radboud University Nijmegen (Netherlands), University of Graz (Austria), or University of Wisconsin-Madison (USA).

Figure 1 Planning cycle.

Changing the Basic Model

The basic model for rational planning has come under heavy criticism for years, primarily because it places so

8. Etc.

Figure 3 Outline of a strategic plan.

much emphasis on planning while neglecting issues of implementation – the very issues that usually come to the fore during the execution phase of the plans. An analysis steered by experts and implemented by management, the critics claim, assumes a division between thought and action that is not consonant with real life. Planning does not happen in isolation, but should be based on actions and deliberate reflection. In fact, empirical studies in management research have shown that the planning model did not determine the strategic performance of many successful enterprises. Instead, it was shown that the most successful enterprises remain extremely flexible and retain a high level of responsiveness with respect to the often-unpredictable external environment. What is more, they place great importance on experience and the implicit knowledge accumulated within the organization, and they rely on their ability to improvise.

There are numerous reasons for why more flexible organizations are the most successful: The outside world is so dynamic that only limited predictions can be made about what might happen – which renders long-term planning rather tenuous. The external environment is an elusive object for a strategic analysis because it is also determined by strategic players who analyze things from their own perspectives and change their behavior accordingly. Insights from systems theory and strategic theory indicate that the reciprocal observations from various analysts and their interaction make it necessary to adopt a high level of flexibility, and that alternating strategies need adjustments depending on the situation. It is also often the case that the actual members of an organization have quicker and more direct access to relevant information on changes in strategies by their competitors through their own external contacts than experts can provide for with their analyses. In order for this information source to be used to the best advantage, the available (but usually implicit) knowledge within the organization has to be mobilized to flow directly into the formation of strategically determined behavior – not only during the implementation phase of a predetermined plan. All of which leads to the point that the internal environment of an institution is equally as important as the external environment. It is also equally complex and can

Figure 4 Strategy deliberate and emergent (Mintzberg).

be characterized through various subsystems, perspectives, and usually its own brand of logic as well. Under such circumstances, patterns can emerge that would be recognized retroactively for their inherent logic and possibly serve as organizational plans for the future; however, they do not follow the rational-linear method of planning based on expert analysis followed by separate implementation (specifically Schreyögg, 1999, 2002).

This theory of the breakdown in planning is particularly well developed in Henry Mintzberg's work. Mintzberg defines intentions that become implemented as deliberate strategies. Meanwhile, plans that were identified during the initial phases but remained unrealized must be left aside because of the focus on the first three steps in planning (see Figure 1). He further distinguishes between deliberate strategies and emergent strategies that develop as a result of the system. Realized strategies are based on the combined sum of all of these approaches (Figure 4).

In his book *Strategy Safari* (1999), Mintzberg used Honda's conquest of the American motorcycle market as a good example of emergent strategies. The planned strategy called for the production of heavy machines, but successful penetration of the market only became possible when the players involved happened to notice that the greater demand was in fact for small machines. Mintzberg goes on to cite an impressive study covering 100 of the 500 fastest growing American businesses. According to the study's findings, 41% of the companies had absolutely no business plan at all, 26% worked from a sketch scribbled on a piece of paper, 5% just used a financing plan, while only 28% had a fully formulated business plan.

It is important to note that higher education institutions are special kinds of organizations that are fundamentally different from economic enterprises. Similar to accounting and consulting companies, hospitals, or schools, higher education institutions are knowledge organizations, otherwise known as expert organizations or professional organizations. Knowledge, their most important capital,

does not belong to the organization but remains in the hands of the experts. The experts are the actual owners of the strategically most crucial resource – the very resource on which the university's performance and reputation depend. Even the assessment of the quality of this knowledge can only be conducted by experts, most of who are affiliated with other universities, that is the scientific community. In organization theory, universities are among the loosely coupled systems (Weick, 1976), and their fundamental strengths come directly out of the unplanned, curiosity-driven development of their own systems. Hierarchical strategies for steering such organizations risk being less than effective or can even – in the worst-case scenario – destroy productive-development potential.

There are very few empirical studies on the forms and effects of strategic planning in higher education. However, it appears safe to assume that the universities that are successfully positioned with regard to the competitive market have made good use of the findings in management research on emergent strategies and of the available information on the particularities of professional organizations. These models indicate that leadership should place great value on observation, communication, flexibility, and reflection with regard to changes within and outside the university. Leadership has to be able to cope with ambivalence and contradiction without neglecting the necessity of a strategic orientation for the organization. Leadership duties do not entail prescribing or pre-setting a strategy as much as they refer to the steering of a process framing strategic change. This process is not necessarily a matter of imposing normative, strategic, and operative goals upon different levels of hierarchy and thereby executing and controlling a strategic program that was devised in this manner. It is actually more about developing a rough strategic framework that promotes a common orientation for the entire institution. The framework encourages mutually beneficial behavior, but also allows possibilities for self-determined actions by organizational subsystems (departments, institutes, etc.) and their individual members, who can use their respective specific expertise productively within the semi-autonomous units. In this context, the basic model that included situation analysis, targeting goals, actions for change, and evaluation should in fact be preserved. However, the reciprocity between thinking and action will be reinforced through frequent and repeated loops of reflection on the process. This kind of development is visible in the literature as a new-found emphasis on strategic management rather than strategic planning.

Different Perspectives on Strategy

Thus, there is an abundance of different approaches to strategic planning. In some cases, they intersect with each

other or complement each other, in other cases they cancel each other out. In *Strategy Safari* (1999), Mintzberg differentiates between prescriptive approaches (what he calls the design school, planning school, and positioning school), descriptive methods where certain aspects come to the fore (entrepreneurial school, cognitive school, learning school, cultural school, power school, and environmental school), and the configuration school, which combines these approaches. Taking the perspective of organizational development, Morgan (1986) identifies different organizational pictures depicted by strategy developers, leading to different methods of procedure. They portray organizations as a machine, as an organism, as a brain, as culture, as a political system, as a psychological prison, or as an instrument of power. It is impossible to develop an abstract, standard formula for determining the direction a higher education institution should follow in its strategic development. The answer depends on the institution's identity, on the current context and environment in which it operates, and of course on its various potentials. Deciding which methodological approach to take is already the first step in developing a strategy that must be carried forward by the institution and in which it is also subject to the interplay between intentionally planned and emergent elements.

Although there is no single, right approach to strategic planning, certain basic types can be identified that can function (more or less) singly or in combination with each other, depending on the context, timing, and current status of the organization. Whittington (2001) makes a simple but definite distinction that can easily be adapted to the higher education system by asking two questions: The first is regarding the objectives of the strategy (What is strategy for?) and addresses whether the targeted outcomes are aligned one-dimensionally toward maximizing profits or if multiple, diverse objectives can be targeted. The second refers to the processes of developing strategy (How is strategy done?), with which Whittington distinguishes between planned strategies and emergent developing strategies. Meanwhile, this taxonomy can be combined with the one adopted by Nagel and Wimmer (2002) in which the formulation of strategic objectives is identified according to whether they are developed by the leadership or external experts, or whether they emerge out of the system itself. This approach also distinguishes between processes developed implicitly or explicitly. The combined methodologies lead to a four-field matrix, which can be used as an analytical grid and applied to the higher education sector in order to produce the four distinct approaches to strategic development in higher education (Figure 5).

The upper left quadrant shows the classic approach to strategy formulation and implementation, in which the institutional leadership determines the objectives and designs the necessary implementation processes. Such an approach includes, for example, fundamental reorganizing

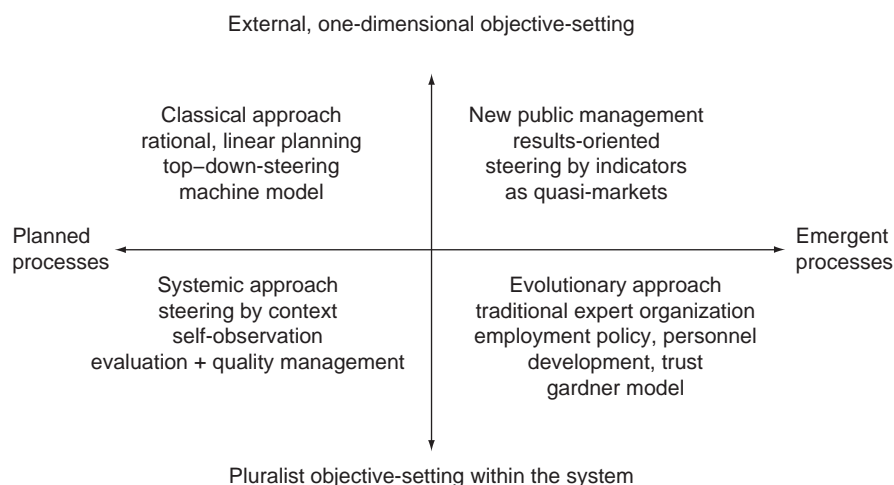

Figure 5 Strategic fields in higher education development.

processes, such as consolidating separate departments into larger faculties or implementing mergers that rely on the central authority to take responsibility for decision making within a given timeframe. The upper right quadrant also shows an approach that uses objectives set through external input, but here the conception and implementation of the requisite transfer measures are undertaken within the system itself. This is the main activity field for new public management, which as a consequence of its product logic is focused on steering by output. It thus requires results, such as increased fundraising, the production of more graduates, or a higher number of doctorates; however, the way in which these results are achieved is determined by the system itself. The lower right quadrant shows the evolutionary approach that aligns with the paradigm of the expert organization. This is the management model of the classic Humboldtian university; it focuses on attracting good scientists who cannot be steered but who are entrusted by the organization to do their work within the recognized limitations of the institution. The lower left quadrant shows the systemic approach of higher education development. This emphasizes processes organized through self-observation of the system, from which conclusions or consequences are then drawn. The main fields of activity here are evaluation and quality management.

It is important that the matrix not be mistaken as a grid for rating good or bad approaches to strategy. All approaches are legitimate and can work. The adoption of any approach can be justifiable according to the specific situation, time constraints for decision making, culture and life cycle of the higher education institution, and the purpose of the decision. There is no right approach to strategic planning; there are many approaches to be considered for each context. Strategic development occurs in each of these fields, accomplished through collective effort by the players in each field. What follows is then a model that aligns with Mintzberg's (1999) ideas on

configuration. This is where the issues of leadership and the competencies of the leadership team and their relationships to objective, rational planning come to the fore. People in leadership positions have to have access to an entire array of approaches and methodology for strategic planning and development, and they have to be able to apply them together appropriately. Then leadership has less to do with the conceptualization of the strategy, than with the conceptualization of processes through which strategy is developed as an achievement of the system. The entrepreneurial university also requires just this kind of entrepreneurial thinking and acting leadership team.

When the basic model for strategic planning (the sequence of analysis, setting objectives, actions for change, and evaluation) is decentralized through such flexibility in the objectives, methodology, and participants, it remains both meaningful and, for a well-ordered strategic process, even indispensable. It shifts from being a linear progression and becomes a reflective, learning cycle that feeds back into the organization (Argyris and Schön, 1996), where the decisions that are made remain alterable and new options are opened. In order to allow the cycle of reflection to work, however, the university's loosely linked experts and subunits all have to be involved with the development, implementation, and revision of the strategy.

Methods and Instruments

Certain methods and instruments have emerged in strategic management as particularly useful for those involved in the four steps of analysis, strategy formulation, actions for change, and evaluation. Of course, such instruments can generate certain routines that run the risk of taking on a life of their own; however, they also contribute to anchoring the change process to the very structure of the institution rather than allowing it to remain merely as an agenda of a

certain group of individuals. This is necessary in order to ensure stability within the process of reform. Three of the instruments that are relevant to the fields of analysis and objective setting are described briefly below.

Strengths, Weaknesses, Opportunities, and Threats Analysis

Strengths, weaknesses, opportunities, and threats (SWOT) analyses are instruments commonly used in higher education today. The intention behind the tool is to compare the institution's internal potential, or its current strengths and weaknesses, with the opportunities and threats that emerge from an analysis of the external environment. The comparison reveals what goals and actions for change can be developed. For example, in most continental European higher education systems, universities display a relatively strong homogeneity. In the coming years, the trends toward entrepreneurialism and competition could result in greater diversity of institutions within the higher education sector. They may profile themselves as research universities, access-providing institutions targeting broader population groups, or as higher education institutions that specialize in certain areas of research but otherwise hone their strengths in teaching and learning. SWOT analyses take the external context into consideration (What are the strengths and weaknesses of the most important competing universities and colleges? What are the foreseeable social needs?) in order to assess separate areas of the institution and determine if they are more appropriately positioned for a profile in research or teaching. The results of the analysis then serve as the foundation for creating a competitive profile and for the institution's strategic positioning in a more diverse higher education landscape.

Working on the assumption that the people who know most about an institution's development potential are the actual members of the respective institution, workshops, group presentations, and moderated podium discussions should be convened in order to make the implicit knowledge explicit (Nonaka and Takeuchi, 1995) and to effectively compile all the necessary information. In order to assemble information on developments in the university's external environment, it is best to draw on expert panels, surveys, and other sources. When the SWOT analysis is condensed into strategic objectives, they should be discussed in top-down/bottom-up planning sessions with the various subunits, departments, etc. before they are adopted at the central level as binding goals for strategic development. In this way, the entire exercise should become an institution-wide strategic process; it should be informed by expert knowledge and advice, but the outcomes should occur as a result of the collective work by all members of the university.

In order for the SWOT analysis to reach the desired depth, it should be oriented toward separate performance fields of an institution or faculty. These are the above-mentioned key processes of research, development of junior academics, and teaching and learning, as well as the central services (budget, staff development, information technology (IT) services, etc.). With these in mind, goals should then be formulated for the respective performance areas. Meanwhile, it is important that the objectives should not be worked out in too much detail. They should remain as a robust but nonprescriptive catalog of goals that can serve as an orienting framework for the university, not a constrictive directive.

Portfolio Analysis

Besides the more discursive, communicative approaches, a more quantitative, figure-oriented instrument can also be used to describe the actual status of an institution. One such instrument is the portfolio (**Figure 6**), which depicts separate features of the university as compared to the respective features of competing institutions. The analysis for this instrument should again be focused on the separate performance areas of research, development of junior academics, teaching and learning, etc., or the results will be too unspecific to be useful. However, unlike the SWOT-analysis, the portfolio technique is dependent on quantifiable measures, which means the various performance areas have to be converted into measurable dimensions. By using two parameters, the *x*- and *y*-axes of the portfolio for instance, it is possible to plot the relative competitive position in teaching (graduates and students per professor, graduates' success on the labor market), research (external funding, concluded promotions per professor), and preparation of junior academics (number of doctoral students and postgraduates who receive offers as professors or assistant professors at other institutions). Since this approach is mainly concerned with the positioning of the institution in a competitive market, comparative data from an institution with a similar profile are required. The data can be obtained either through benchmarking clubs founded for this purpose, or from available official statistics sources.

Internal Contract Management

When higher education institutions are above a certain size, it becomes problematic that strategy formulation is a process to be undertaken by the entire university, across various and sundry subunits. This can be a problem not only during implementation, but during the very process of creating strategy as well. Meanwhile, a purely top-down approach from the center to the various departments would be just as counterproductive as a purely

Figure 6 Portfolio to ascertain relative strengths in research. The reticle represents the average of the respective subjects measured across all universities.

Performance area: teaching and learning				
Institutional goal	Services by sub-unit/department	Success criteria	Service needs	Budgetary needs

Figure 7 Goal and performance card.

bottom-up approach in which the central powers waited for the subunits to come up with some strategies. This is where an approach taken from new public management can be useful, namely contract management. This instrument uses collective negotiations on goals and activities between the central-university level and the different departments to arrive at a mutual agreement or contract. Thus, the desired institutional profile can be established as the strategic framework while it can still be made more compatible with the profiles and strategies of the respective departments. In fact, contract management serves as an instrument for both implementation and strategy, all at the same time.

Nevertheless, without a clear system and structure, and lacking strict financial and operational controls, contract management can easily become a merely futile exercise. The goal and performance cards have often been found

useful in the past. The cards are similar to the well-known balanced scorecard in business planning (Kaplan and Norton, 1996), but are designed to reflect the key processes and service provision in higher education.

By matching them to a specific type of performance area, the university's goals can be correlated with the results of different actions for change (services) produced by a faculty or department, and determined via negotiations between the institutional central leadership and the heads of the respective subunit. In order to enter into the negotiations, faculties should prepare their own strategy papers prior to the negotiations round. The institutional goals and the goals set by the subunit are then compared, and after two or three rounds can be consolidated into concrete objectives to be realized by the subunit. In order to assess outcomes fairly, it is very important to establish the criteria by which performance and success are to be

measured upon conclusion of the contract (usually 2 years) at the very beginning in the initial agreement. Meanwhile, potential service needs or financial needs encountered by the subunits while undertaking the activities also have to be enumerated. For example, a department that has agreed to increase the number of foreign exchange students may depend on certain services provided by the student secretariat or the international office; in order to provide the services, the office may then need new software, which has to be made available by the IT department. Such examples reveal glimpses into the complex interdependence of performance objectives within a higher education institution. It quickly becomes clear that contract management helps lower the dividing line between big-picture strategy and a policy of continual change by keeping the service providers very closely involved in the process. The results of the negotiations are set down in the contract between the central level and the subunit; the important outputs that result from the agreements are essential parts of the future strategic plan.

Contract management requires a large amount of time investment. Each round of negotiations between the institutional management and the respective subunits usually requires 2–3 h. There are normally at least two, if not three, meetings of that kind per subunit. The first round is mainly used to assemble the different expectations and possibilities, and to prepare for further discussions. Some results may already be recognizable during the second round; however, a number of points will probably remain open and in need of revision, so the results can usually only be confirmed after the conclusion of the third round. In between the different discussion rounds, time is also needed for internal consensus building and bilateral clarifications. In the end, the entire process normally takes about 3 months. In the instances where the discussion rounds have been used as opportunities for mutual reflection and exchange, and when they have succeeded in making the lurking, implicit institutional knowledge manifest and useful, the productivity of the planning process has paid for itself as a major contribution toward making the university a truly integrated higher education organization.

The Changing Role of University Presidents, Vice-Chancellors and Rectors

M F Green and P D Eckel, American Council on Education, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

In this age of the growing knowledge economy, pressures on higher education around the world are mounting. Governments, industry, social agencies, and citizens at large are increasingly relying on colleges and universities to educate the young and old, prepare the workforce, and contribute to the nation's economic growth; make technological and scientific breakthroughs; and address society's social ills. These pressures, in turn, heighten the demands and challenges of leading and governing colleges and universities. This article focuses on the changing environment worldwide for higher education and its impact on the role and challenges of campus administrators, specifically the president, rector, and vice-chancellor, referred to collectively as institutional heads. The first section examines two major forces for change shaping institutional management, leadership, and governance: the changing relationships between institutions and their governments, and the intensified market environment. The second section discusses the effects of these forces on institutional management and governance, focusing on the move from collegial governance to managerialism and the resulting tensions. The final section explores the changing role of institutional heads, describing four key factors shaping that role and exploring the tensions arising from the role of institutional head as change agent.

The Context for Change

The role of institutional head is shaped strongly by two important and interrelated external institutional-change drivers – the policy environment and market forces. Certainly, these are not the only drivers of change – changing demographics, advances in technology, pressures for accountability, advances in knowledge, and increasing reliance on higher education to stimulate and support economic development are also factors. However, the policy environment and market forces represent two broad and powerful sets of conditions that play a major role in determining the current challenges and future directions of higher education.

The Policy Environment: The Changing Relationship with Government

Governments around the world are changing their relationships with their public universities, albeit along different

dimensions and to different degrees. In some instances, the key government agencies are at the national or federal level, such as South Africa, Japan, and England. In other instances, such as Switzerland, Canada, the US, and Germany, the state or provincial governments are the key players. Driving many of the changes is the growing philosophy of new public management (NPM), a trend in which the public agencies concerned with higher education adopt the economic market as the dominant model, which is noted by deregulation, the creation of (quasi-) markets for public services, performance-based contracting, policies that foster competition, the use of market incentives and levers, and the rise of performance indicators and auditing systems (Middlehurst, 2004; Mok and Lo, 2002; Sporn, 2006). Singh (2001: 10) summarizes the effects of these beliefs on higher education:

- the requirement of higher education to demonstrate efficiency, effectiveness, and value for money through business re-engineering drives, integration into public finance and accounting systems, external quality assurance, and other accountability frameworks;
- declining investments of public funds, costs passed to students, and the requirement to do more with less (e.g., massification of access at existing or reduced levels of funding); pressure to diversify funding, thus reducing the primary responsibility of the state for public higher education and allowing other funders to exert pressures;
- the dominance of managerial and entrepreneurial approaches resulting in running higher education institutions like income-generating business;
- the privatization of higher education encouraging competition;
- the increasing development curriculum reforms intended to appeal to employers and students as customers and clients; and
- shift of public and private funding from basic to applied research, increased emphasis on academic/industry links, greater concern with issues of intellectual property rights, and the prioritization of research for product development and commercialization.

The effects of this emergent philosophy are being experienced around the world. For example, in Finland, the 1999 development plan for education and research sought to improve quality through evaluation and enhanced competition and is characterized by a management-by-results

principle. The Danish 2003 University Act created greater institutional autonomy, including the ability of institutions to appoint external board members, and fostered increased managerialism as rectors, deans, and department heads now are appointed rather than elected (Schmidt, 2006). Swiss universities have been granted greater degrees of autonomy, provided with global budgets that have attached to them performance metrics (Schenker-Wicki and Hürlimann, 2005). Australian universities are also quickly adapting to market-driven policies (Margison and Considine, 2000) and US universities are increasingly becoming even more sophisticated market actors (Slaughter and Rhoades, 2004) in a system that has traditionally been market sensitive.

Changing Market Environment

Three major aspects of the changing market environment are prominent in shaping the course of higher education: the rising demands and opportunities of the knowledge economy, increased competition among universities, and the push and pull of globalization.

The knowledge economy

As the knowledge economy becomes more deeply established, universities find themselves, as the European Union explicitly states “at the crossroads of research, education and innovation” (Commission of the European Communities, 2003: 5). They are primary producers of advanced knowledge, which is an essential raw material of the new economy, and they play an essential role in creating both the highly educated workers and consumers on which the knowledge economy relies (Slaughter and Rhoades, 2004). The knowledge economy furthermore favors (and is willing to pay for) what universities have in abundance. Former Harvard President Derek Bok argues that regardless of other drivers that pushed US campuses to be more entrepreneurial (such as declining state support, changing public policies, or unclear academic values), “none of these stimuli would have borne such abundant fruit had it not been for the rapid growth of money-making opportunities provided by a more technologically sophisticated, knowledge-based economy” (Bok, 2003: 15).

Competition

Market activity further intensifies competition among higher education institutions within and across borders. This competition takes many forms. Institutions compete not only for public and private funding, but also for students, academic talent, prestige, and media attention. They must determine their market niche, and distinguish themselves from other institutions through branding. In addition, the competitive field has widened. For-profit universities, corporate providers, educational companies, and distance-learning institutions are now a significant part of the competitive landscape in some countries.

For example, nearly 90% of private higher education institutions in Malaysia are for profit, as are approximately two-thirds of Brazil's. In the Philippines, 47% of students attend for-profit institutions, as do 18% of Chilean students (Kinser and Levy, 2006). Furthermore, with the rise of information technology and online education, competitors are now no more than a click away, making geographic location less important. Governments in Singapore, Germany, and China, to name a few, are investing significantly to create world-class universities (Altbach, 2000; Labi, 2006a; Morhman, 2005). A major aim of the Bologna process is to create a European higher education space that will be more competitive in research as well as more attractive to foreign students.

Globalization

The influences of globalization and internationalization further shape the competitive market for higher education. Cross-border or transnational education, in which providers and programs move across national boundaries to offer their degrees (Knight, 2002), is one response to globalization whose long-term impact is as yet undetermined. To extend their reach to students in foreign countries, institutions are establishing degree programs either on their own or with partner universities, governments, foundations or private businesses. Some governments, often under the auspices of the World Trade Organization (WTO) are developing policies and initiatives that encourage (or do not prevent) foreign providers from offering degrees. Countries such as Congo, Jamaica, and Sierra Leone are actively encouraging the entry of foreign institutions (Knight, 2002). Other countries such as Singapore, Qatar, and the United Arab Emirates are going even further by providing foreign institutions with financial incentives, tax-free zones, and infrastructure (including rent-free or below-market leases) to encourage and support foreign providers (Green *et al.*, 2007). At the same time, the globalization of trade and business and rising predominance of English also help to make foreign degrees, particularly from universities in Anglophone countries, increasingly desirable.

Institutional Management and Governance: From Collegial to Managerial to Entrepreneurial Institutions

The effect of new relationships with governments, and greater market pressures have been accompanied by greater institutional autonomy and heightened need for institutions to be more managerial – that is, compete and be more businesslike, efficient, strategic, responsive to stakeholders, and entrepreneurial. Gumpert and Sporn (1999) attribute the rise of managerialism to three interdependent dynamics: resource dependency motivated by

organizational survival; institutional isomorphism motivated by legitimacy concerns; and professional authority motivated by a struggle for professional identity.

Although few scholars or practitioners dispute that managerialism is on the rise worldwide, it is important to note that there are significant differences not only among nations, but also within them, according to institutional mission and type. For-profit institutions are more corporate than nonprofits in terms of culture and management and governance practices. US community colleges and new universities in the UK (i.e., institutions that were polytechnics prior to 1992) have weaker traditions of faculty dominance in decision making than 4-year institutions in the US or old universities. In South Africa, historical institutional differences shaped the extent to which transformational initiatives engaged faculty and other stakeholders or were top-down efforts (Kulati and Moja, 2006). The significant differences among nations are widely recognized. For example, as a result of many European and Latin American countries' traditions of strong faculty bodies and elected rectors, managerialism developed later and is less pervasive than in the United States, Canada, the United Kingdom, or Australia.

Managerialism in the Collegium

Managerialism is often seen as conflicting with traditional notions of collegial governance. However, there is no single conception of managerialism; it can be more or less strident and doctrinaire, more or less adaptive and useful. Cloete and Kulati (2003) distinguish between strategic managerialism – a soft approach in which management techniques are applied to run institutions more efficiently and effectively, and unwavering entrepreneurs, who see higher education institutions as businesses, as distinct from being run like a business. The latter model is characterized by top-down decision making, disempowerment of the faculty – who are viewed as employees rather than partners – and a profound cultural shift toward corporate rather than academic values.

In contrast with managerialism, collegial governance emphasizes the traditional role that academic staff play in making key decisions about all aspects of institutional functioning and directions. It values scholarly engagement, expertise, negotiation and consensus, collaboration, shared governance and decision making, and rationality. (It is appropriate to note, however, that the rise of managerialism has caused some to romanticize the collegiate model of governance, conjuring an idealized academic world many agree never existed.)

Although some argue that traditional models of shared governance are too slow and cumbersome to enable institutions to respond to a rapidly changing environment, others maintain that the corporatization of university management is dangerous for the social purposes and

long-term well-being of higher education (Duderstadt, 2001; Burgan, 2006; Johnson and Cross, 2004; Currie and Vidovich, 1998; Kirp, 2003; Scott, 2001; Cloete and Kulati, 2003). The more abrupt the rise of market orientation in a particular country – and increase in the power vested in institutional administrators – the greater the potential for tension (Green, 1997; Edwards, 1997; Amaral *et al.*, 2003; Shattock, 2003, 2006). Thus, a key challenge of higher education leadership and governance today is to foster governance processes that are deliberative and inclusive, and at the same time responsive, agile, and opportunistic – two seemingly contradictory sets of demands. Effective governance incorporates tradition, academic values, and scholarly community as well as new ways of doing business, leveraging institutional resources, and quickly marshalling institutional strengths (Eckel, 2006).

Emerging Organizational Models

Clark (1998) proposes a model of the entrepreneurial university that enables institutions to combine elements of both managerialism and traditional academic culture (which, he asserts, cannot be ignored) so as to enable institutions to increase their capacity to respond to demands that are both increasing in number and intensifying and be more active in charting their courses. The entrepreneurial university is characterized by five elements: a strengthened steering core; an enhanced development periphery, a discretionary funding base; a stimulated heartland; and an entrepreneurial belief. The strengthened steering core consists of a strong administrative backbone throughout the entire institution at all levels. There are strong collegial connections between faculty and administrators and shared governance. The enhanced development periphery includes various outreach administrative units research centers that may be closely or loosely linked to the administrative core and the academic (heartland) departments. These units provide important links to external groups and enable the university to be more flexible and responsive. A diversified funding base enhances institutional discretion and allows the university greater independence from any single source. The traditional academic departments in the heartland of the institution must be brought into the change process. The interest in and ability of different fields and departments to embrace an entrepreneurial spirit will vary; for example, science and technology will likely move faster, it is important that habits of change be taken up across the institution. Finally, institutions will need to undergo a cultural shift to reconfigure themselves as entrepreneurial universities; this is a long-term undertaking that permits lasting change.

Australian researchers Margison and Considine (2000) are less sanguine than Clark about the ability of a fruitful blend of managerialism and academic traditions. They doubt the capacity of institutions to transform themselves

in ways that do not threaten collegial forms of decision making. Their model of the enterprise university – and all Australian universities, they assert, are to some degree enterprise universities – “joins a mixed public–private economy to a quasi-business culture and to academic traditions partly reconstituted, partly republican, and partly broken” (p. 236). There are many variations on the enterprise university, but they note that the common characteristic is a weakening of traditional academic processes.

Structural Changes and the Rise of Governing Boards

Changing demands and new ways of doing business are also driving institutional structural changes. Heightened demands for connections to external stakeholders and intensified pressures for accountability have led to the rise of governing boards around the world. A distinguishing feature of these boards is that they draw many, if not most, members from outside the institution. Their functions are generally to create ties to the local community, provide fiscal oversight, foster and support entrepreneurial activities, and ensure that institutions are accountable to the larger society. Governing boards strengthen the role of institutional leaders through their oversight of institutional strategy and management. Shattock (2003) outlines seven contributions of governing boards: technical and professional advice; taking the long view; acting as the referee for internal arguments; acting as critical friends; participating in technical aspects of governance, such as audit and remuneration committees; reading the environment; and appointing the vice-chancellor.

Governing boards in the United States, Canada, the United Kingdom, South Africa, and Australia have these general responsibilities. Other countries have moved to the adoption of different types of governing boards or placing external members on decision-making bodies that formerly had internal institutional membership. For example, reforms in Sweden led to the creation of university councils of directors, chaired by the rector and most of whose members are appointed by the government. Legislation enacted in the Netherlands in 1999 created a board for each university, whose five members are appointed by the minister of education in consultation with the university. Since 1983, Spanish universities have had social councils, a majority of whose members are from outside the university. Italy has created similar bodies (Amaral and Magalhães, 2002). Austrian legislation in 2002 created institutional governing boards of five to nine external members that select the rector from a proposal by the academic senate (Pechar, 2003). Australian councils have moved to greater reliance on representatives of business as members (Margison and Considine, 2000).

Lay governing boards – that is, boards whose members are external to the institution – can contribute positively

to the university. They bring expertise, connections to the community, an ability to see the long-term picture for the institution, and have a broad view of the environment in which the institution functions. However, they are not without their drawbacks and dangers. Governing board members may have little understanding of how institutions function, or may be unclear about the role of the board. Infrequent meetings make it difficult for board members to have an in-depth knowledge of the institution. Thus, they may defer uncritically to management or be tempted to dwell on the familiar aspects of operation, finance, and investment (Chait *et al.*, 1996).

As the voices of the lay members of governing boards become more numerous and prominent, and their call for institutions to be more market sensitive, fast acting, and generally businesslike, the potential for conflict with faculty values and academic traditions increase. Institutional effectiveness is strengthened when there is a healthy balance of a strong academic senate or academic board and a strong governing board characterized by true participation of the academic community and open communications between the bodies.

The Role of the Institutional Head

Just as institutional management and governance are being reshaped by the forces described in the first section above, so is the role of the institutional head. The role is highly varied and complex, and includes administrative, political, and entrepreneurial components (Birnbaum and Eckel, 2005). As a leader, the institutional head envisions the future, serves as an institutional symbol, facilitates the hard work of change, and sets the tone (Green, 1997). As administrator or manager, he or she develops and carries out policies, creates plans, determines budgets, supervises and evaluates subordinates, monitors systems, and designs and implements accountability schema. As a politician, that individual responds to multiple constituencies and interest groups, negotiates differing perspectives and priorities, and forms coalitions to get things accomplished. As entrepreneur, the institutional head develops and exploits markets, secures new resources, fosters innovation, and, in many countries, participates in fund raising.

The balance among these roles and the relative time the institutional head devotes to different aspects of the job varies considerably within and across nations. In the United States, presidents delegate most academic matters to the chief academic officer, who bears the title of provost, vice-president for academic affairs, or dean of instruction (in community colleges), or dean of the college or faculty (in liberal arts colleges). According to American Council on Education survey data, US presidents report that their primary use of time is, in descending order, fund raising, budget and financial management, community relations,

strategic planning and governing board relations, and a mix of fiscal and external issues (ACE, 2007). In the United Kingdom, vice-chancellors in old universities play an important role in leading the academic enterprise; at the same time, they focus on external relations (Smith *et al.*, 1999). In other countries with strong government steering and less market orientation, the institutional head generally focuses more on academic matters and less on external duties.

Forces Shaping the Role of the Institutional Head

The four main forces shaping the role of the institutional head are:

1. *Culture.* Institutional heads operate within their national cultures, as well as in the academic culture. Cultural values underlie a society's assumption about the role of higher education in that country – for example, whether higher education acts autonomously from government direction or is an extension of civil service. The norms regarding individual and collective behaviors in an academic community are cultural creations. In some societies, such as the United States, with its strong individualistic and market orientation, leadership is usually equated with assertive behaviors; leaders are exhorted to demonstrate their individual leadership. In others, such as Japan, it is unseemly for the rector to appear to lead too vigorously (Ishikawa, 1997). However, social norms can change, especially in response to important shifts in the external environment or strong pressures on higher education institution. The demise of communism and the end of apartheid in South Africa had profound consequences for the belief systems shaping higher education and its leaders in those respective countries.
Leaders are also shaped by academic cultures. In spite of notable difference of national cultural norms, traditional academic institutions seem to have more cultural similarities that derive from their academic mission than differences that can be attributed to the country in which they are located. The academic values of unfettered inquiry, the pursuit of knowledge for its own sake, the quest for freedom from external interference, and the dedication to preparing the next generation of leaders, professionals, and citizens transcend countries and cultures. In addition, the academy values shared decision making and has a tradition of selecting leaders from within the academic culture. Academic institutions are historically loosely coupled institutions composed of highly independent schools and faculty members who are more connected and loyal to their disciplines than their institutions. Several factors further shape the role of the institutional leader.
2. *Institutional mission.* The top job varies according to whether the college or university is in a system defined as elite – shaping the mind and character of a relatively small ruling class for elite roles, or mass – transmitting the skills and preparation for an involvement in technical and elite roles by a broad population (Trow, 2006). Trow notes that universities in elite systems tend to resemble each other, be more homogenous in their students and academic staffs, and narrower in scope and mission. They are run by small staffs and governed by powerful senior academics. Their administrations consist of academics who leave their scholarly posts for brief periods. For example, the institutional head is typically appointed or elected to a fixed term. In contrast, universities in mass systems are more differentiated from one another, having a wide range of programs and offerings and, in turn, having a broader set of interested stakeholders. Their administrations are large and differentiated with professionals fulfilling specialized roles, including a more professionalized and experienced institutional head. The drive to widen participation around the world makes the distinction of elite and mass institutions more applicable within nations than across them.
3. *The role of the state, the market, and the academic oligarchy.* A set of factors shaping the role of the institutional head and his or her level of authority is the relative weight of state authority, the market, and the academic oligarchy, three elements that Clark (1983) combines into a triangular model of interdependence and coordination. In the dirigiste or state-controlled model, countries have strong ministries, broad regulatory powers, high dependence on government funding, and low institutional autonomy. The combination of strong ministries and low institutional autonomy work to limit the role and influence of the institutional head. Examples include many African nations, Gulf-region states, China, Russia, and former Soviet republics, as well as some Western European nations. An extreme example can be found in some African nations that vest great authority in the university chancellor (usually the head of state) who appoints rectors and in some cases their deputies and other administrative officers, and approves the appointment of elected faculty and students to councils. In these countries, presidential authority to steer institutional direction is curtailed. Ironically, while the vice-chancellor or rector may have limited say in the larger strategic and policy issues, he or she may have significant involvement in and power over many minor matters (Mwiria, 2003).
Institutions that are highly market driven tend to see institutional heads as having a relatively high degree of authority as compared to campus leaders in other situations. They are selected by the governing board

or council, and generally move into the top positions through progressive moves up the administrative ranks, becoming professional administrators at some point in their career. Other countries that are transitioning toward more market-oriented systems are strengthening the role of the institutional head and their ascensions are following similar paths. However, this model is not a single one, varying much by institutional type and country. The term chief executive officer (CEO) is often used to describe this type of position and to suggest a growing similarity to corporate leadership. However, even when the CEO has relatively high formal power and authority – which may include control over resource allocation and appointments of the senior management team and other administrators – her or his influence is often limited by faculty-governance mechanisms and institutional culture. This is the case in the United States, where in spite of the perception that US presidents have a great deal of power, in reality, they must negotiate with the faculty, build consensus among various stakeholders about directions for change, and take care not to alienate internal or external constituencies with high-handed decision making.

Finally, in some countries the academic oligarchy, rather than administrative or government/ministerial authority, plays the dominant role in shaping institutional decision-making processes, thus limiting the rector's power. The push to democratize Eastern and Central European universities immediately after the fall of communism resulted in greater autonomy of the schools within a university and enhanced faculty participation, but left the rectors weak and unable to exercise their formal powers (Scott, 2006). In Western European countries such as France, Spain, and Greece, as well as some developing countries, the rector's authority is constrained compared to their counterparts in the United States or the United Kingdom, since the individual faculties hold a great deal of power and many other institutional bodies must approve new initiatives (Taylor *et al.*, 2007). When academics play a central role in the selection of their leader, they further hamper the institutional head's authority because of pressures on the institutional head to remain in their stakeholders' favor (Bloom and Rosovsky, 2006).

4. *Method of appointment and career patterns.* A fourth set of factors that affect how the institutional head functions is the selection process. Whether the institutional head is appointed or elected affects legitimacy, formal authority, and relationships with stakeholders. The appointed head (often the CEO model) tends to have more formal authority, and arguably less legitimacy, with the faculty than the elected rector. The US president is appointed by the governing board, with highly variable levels of input from faculty, staff, and students.

He or she serves at the pleasure of the board, and under formal agreements that are increasingly codified in a contract (renewable) of 3–5 years. Newly appointed US presidents most often come from senior administrative positions outside the institution (64%), and 21% have served previously as presidents. Furthermore, not all presidents are academics. Thirteen percent of the presidents held their most recent position outside of academe, and more than 60% had some experience outside higher education sometime during their careers (ACE, 2007). In contrast, a study of 16 UK vice-chancellors appointed between 2002 and 2004 indicated that 20% were internal promotions from the position of deputy or pro-vice-chancellor and another 14% internal promotions from a senior academic position; 29% were in those senior management positions in other institutions; and 11% were vice-chancellors in their immediate prior position (Breakwell, 2006). These data parallel those in a larger data set on 341 vice-chancellors appointed since 1960 (Smith *et al.*, 1999). That database indicated that more than 90% had careers in academia. Twelve percent made horizontal moves from other vice-chancellorships, and a third were internal promotions.

The Latin American and European rector, in comparison to the US president or British vice-chancellor, tends to be elected to specific terms, often renewable, directly by senior faculty or from a representative governance body and usually comes from the senior academic ranks of that institution. They expect to return to teaching after serving as rector. Unlike the US president, rectors often campaign for the post. As rectors may not move up the administrative ladder in a career progression from dean, to vice-president or deputy vice-chancellor, they are likely to be less experienced in leadership and management and less well prepared for the job (Taylor *et al.*, 2007). However, several European countries have moved from elections to appointments, including the Netherlands, Sweden, and Austria. Denmark and Norway are in the process of making such changes (Taylor *et al.*, 2007).

The third pathway to the presidency is via government appointment. This ministerial model may be prevalent in systems where universities are subject to administrative law and university administrators are civil servants or where ideology dictates national policy, particularly in nondemocratic countries (Green, 1997). It is most often associated with governments that exercise considerable control over higher education, often in an undemocratic context. Until approximately 10 years ago, the ministerial model was operating widely in Central Europe and many parts of Asia and Africa. However, the push for democracy in some nations and many of the changes discussed throughout this article are pushing some countries to rethink the ministerial appointment model.

The Institutional Head as Change Leader

In hiring institutional heads, the expectation of the governing body is generally that the president or vice-chancellor will move the institution forward, that is, lead positive change. Scholars disagree on the impact that leaders actually have on institutions. While some scholars assert that leaders have a minimal impact in the ambiguous and anarchic culture of higher education (Cohen and March, 1986; Bennis, 1976), most others believe that leadership matters. Even if leadership does matter, it is difficult to gauge how much it matters, making the job of the rector frustrating as well as difficult. Higher education institutions have inconsistent and ambiguous goals, making timely feedback difficult. Furthermore, most universities do not really know how students learn or understand the essential processes involved in creating civically minded students or globally competent citizens. Different stakeholders have different indicators of success. Thus, a successful institution/leader is a contested concept (Birnbaum, 1988).

Different approaches to leading change work under different circumstances. In the absence of crises or very strong external mandates for change, leaders generally need to work within the culture to change it (Kezar and Eckel, 2002). This is a slow and long-term approach. The costs are the slowness and the gradual nature of the change process, the benefits are establishing a culture of change, establishing ownership of the new directions, and working through the inevitable conflicts and suspicions (Eckel *et al.*, 1999). Leaders who are perceived as pushing too hard against established institutional norms or moving too quickly with a change agenda generally meet resistance from academics. In some instances, the resulting loss of mutual trust can cost the institutional head his or her job. The efforts of a new vice-chancellor at Oxford University to change the governance structure angered professors, who viewed the proposed new structure of an academic board as unnecessary and intrusive and reducing opportunities for faculty participation in collegial decision making (Labi, 2006b; North, 2006). The controversy is emblematic of a larger debate in the UK and in other countries with relatively strong institutional heads, about who initiates change, at what pace, and the balance of power between vice-chancellors or presidents and faculty. Tension with the faculty can be costly, as is illustrated by the high-profile case of the resignation of former Harvard University president Lawrence Summers. US presidents commenting on recent presidential oustings noted that what gets presidents into trouble are relationships and process issues, rather than the goals (Fain, 2006). Three recent departures of Canadian presidents suggest that the pressures on university presidents to perform are powerful around the world. The pressure to enhance institutional performance and meet many different stakeholders' needs without creating firestorms

of controversy are key challenges for institutional heads (Alphonso, 2007).

There is no single model of leading change. Effective change leadership will vary with the institutional climate and traditions, the level of turbulence in the external environment, and the intensity of external pressures for change, and the strengths and proclivities of the individual leader. The different approaches that were taken in the volatile and contested environment of South Africa provide a good case in point. Kulati and Moja (2006) describe different leadership responses to the challenges of transformation in the postapartheid era. One set of approaches, transformational leadership combines strong leadership from the top with consultation and respect for the institution's intellectual agenda and prevailing institutional culture. In one variation, called reformed collegialism, the emphasis is on understanding and supporting the academic heart of the institution as the driver for change. A second variation, called transformative managerialism emphasizes driving transformation from the center. In this case, power is centralized, decentralized, and recentralized. The top leadership group makes key decisions, which are implemented by the deans at the school level and then taken back to the center for approval. Other leaders took a more managerial approach, characterized by a strong center aiming to make the institution competitive and market oriented. There were also variations within the managerial approach, with some leaders applying managerial techniques to make the institution more efficient and effective while acknowledging the centrality of academics (strategic managerialism), and others seeking to reshape the institution in more profound ways so that it is competitive and market oriented (unwavering entrepreneurialism). Kulati and Moja also point to failures of leadership, caused largely by institutional conditions resulting from a historical legacy, inexperienced new leadership, and external policy pressures. Crisis leadership occurred mostly, but not entirely at the South African historically black universities, which experienced sudden declines in enrolment that threatened their existence. The crisis was characterized by a breakdown in governance, poor management, and conflict. Leadership at the top proceeded by crisis management, making strategic steering impossible. The South African case illustrates the difficulty of prescribing approaches to leading change. National context and institutional history and culture play have a significant impact on the leadership strategies that fit a particular place and time.

Conclusion

This article has demonstrated that the evolving relationship between government and higher education and

the growing pressures of the market have resulted in a growing managerialism in higher education institutions and strains between collegial governance and decision making and external demands placed on institutions. Regardless of the institutional starting point being highly market-driven (such as in the US or Australia) or being in a centralized system, such as France or Japan, growing managerialism is characterized by greater executive power, a professionalized administration, a diminished role for faculty in decision making, and a shift in values. Increased institutional autonomy and accountability and greater competitiveness are also putting greater pressures on institutional heads to provide strategic leadership for their institutions and to be externally focused. In some nations, institutional heads are clearly CEOs with those specific roles; in others, institutional heads are combining more traditional roles as academic leaders who are first among equals with features of the CEO position.

The Changing Roles of University Governing Boards and Councils

The Changing Context of University Governance

Factors that Drive Changes in Governance

With very few exceptions governments around the world are faced with a growing demand for higher education from an increasing proportion of their population. In countries where mass higher education is available to the traditional age group of 18–24, there is also a demand from the mature adult population wishing to catch up on what it had missed or to learn new skills. The implications of these trends for the way that the higher education sector is governed are that:

- The scale of the number of institutions makes central direction difficult; a central ministry might be able to have coherent managerial supervision of 50 institutions, but central control is difficult when there are 300.
- The growth in demand from different types of clientele inevitably leads to different types of institution emerging; the sector becomes more diverse and again harder to manage.
- The funding required for an expanded sector is too much for the state to fund; the options for overcoming this involve encouraging cost-sharing and income-generation or sharing the burden with the private sector. Both these raise administrative complications, often requiring new agencies of the state for functions such as regulating the private sector or managing loan schemes, etc.
- The increasing size and complexity of the higher education sector requires greater specialist knowledge than is usually found in civil service structures that are based on the rotation of generalists from one ministry post to another.

These factors have several structural and procedural consequences:

- Ministries of education hive off their higher education activities into separate ministries of higher education (sometimes linked with science, research, or the development of skills).
- New specialist agencies (which we shall call buffer bodies) are created to take on the complex role of funding or managing higher education institutions for the minister responsible.
- These buffer bodies have a scope that usually covers public and private provision – although some countries

prefer to regulate private providers through separate agencies.

- As higher education systems expand, the quality agenda assumes a growing importance and governments set up quality agencies to monitor and inspect the quality of provision. These are often focused on the private sector where the risks of poor quality are high.
- The role of the central state ministry is to focus on developing strategy and setting policy rather than managing institutions in detail.
- Where the state and its agencies withdraw from detailed supervision of institutional affairs, institutions are granted greater autonomy to manage their own affairs.
- The state in consequence develops different methods of monitoring and management. Institutions are held accountable not for the details of their expenditure but for their achievement of agreed strategic plans.

There are two consequences of these changes: a reconsideration of the balance between autonomy and accountability and an increase in the managerial pressures on university leaders.

The key question that governments face is how much control they should exercise over universities. In **Table 1** Fielden (2008) has described the various models of ownership which influence the degree of control.

In the universities that are seen as a core part of the public sector with financial and staffing regulations drawn directly from the civil service, as in some European countries, the scope for granting autonomy in financial and staffing matters will inevitably be limited. Thus, we find that in countries where academics are civil servants, they have to seek approval before they travel overseas and decisions on their appointment and promotion are taken at a national level. The statutory basis of universities can also limit freedoms; thus, in New Zealand universities are designated as crown corporations and do not own their assets.

It is a generally accepted principle that universities operate more effectively, if given autonomy in key decisions. The debate centers on what powers and controls should be retained by the ministry, statewide governing board, or buffer body that has supervision of institutions. The areas where there is the greatest difference in practice internationally are:

- *Setting a cap on overall student numbers.* Since most countries fund the largest part of public higher education

from taxation, they consider themselves justified in limiting the number of students. However, some countries have a more relaxed view when there is a mixed public/private funding.

- *Setting the level of tuition fees.* In view of the intense political interest in student fees, almost no country leaves the setting of undergraduate tuition fees in public universities to the decision of individual boards. However this rule does not apply to fees for postgraduates, external or open/distance learning students, and international students, where the institution can make the decision. For example, in Sri Lanka public universities can generate considerable income from charges to external degree students, who can gain

Table 1 Various models of ownership which influence the degree of control

<i>Institutional governance model</i>	<i>Status of public universities</i>	<i>Examples in</i>
A. State control	Can be agency of the MOE, or a state-owned corporation	Malaysia
B. Semi-autonomous	Can be agency of the MOE, a state-owned corporation or a statutory body	New Zealand, Italy, and France
C. Semi-independent	A statutory body, a charity or a nonprofit corporation subject to MOE control	Singapore
D. Independent	A statutory body, charity or nonprofit corporation with no government participation and control linked to national strategies and related only to public funding	Australia and United Kingdom

From Fielden, J. (2008). Global trends in university governance. *Education Working Paper Series No 9*. Washington, DC: World Bank.

university awards, but with limited tutorial input from university staff. This income is outside government control.

- *Choosing what programs or courses to offer.* Developed countries set limits on the numbers in high-cost strategic disciplines such as medicine and dentistry and consequently control the opening of medical schools or new medical programs. In some other countries the state seeks to approve the creation of all new programs or, at a higher level, of new faculties and broad program areas.
- *Appointing and then promoting new academic staff.* Even where institutions are largely autonomous, the State may want some say in the numbers of academic staff. For many years the United Kingdom had a ruling that the number of professors could not exceed a certain percentage of the total staff numbers; this control has been abandoned.
- *Selling or acquiring assets.* States are usually very nervous at giving publicly funded institutions the power to dispose of assets. As a result they seek to be involved in the decision in some way.
- *Borrowing money.* There is a similar reluctance to allow institutions the freedom to borrow money from the commercial sector as this usually requires the creation of mortgage charges over publicly funded assets.

As a general rule we find that control is the tightest in developing countries, which is often due to the inheritance of colonial systems and control cultures. An illustration of how extreme this can be is in the area of financial control (Table 2).

Once the state has decided on the extent of freedom, it must devise appropriate procedures for ensuring accountability. The motives for this are obvious: to ensure as far as is possible that higher education achieves the strategic goals set for it by the state; to maintain the quality of the provision offered to students; and to ensure that public money is spent wisely with no fraud, corruption, or

Table 2 Different approaches to financial control

<i>Topic</i>	<i>Centralized control</i>	<i>Full autonomy</i>
Annual budgets	Agreed in detail by MOE or the funding body	Agreed by the Board (but possibly reported to MOE or the buffer body)
Expenditure	Line item control so that institutions cannot switch expenditure between the agreed budget headings	Total freedom to allocate and spend as required within the overall total grant or budget awarded by the MOE
Underspending at the end of an accounting period	Surrender of all underspent sums to MOE/Ministry of Finance	Freedom to carry forward underspending (and to absorb any overspendings from future funds within limits)
External earnings from nongovernment sources	Surrender to the Ministry of Finance or MOE of all external earnings	Freedom to retain and spend freely all sums earned from nongovernment sources
Tuition fees for domestic and international students	Fees cannot be charged or, if they are, have to be set at a fixed rate and then surrendered to the Ministry of Finance	Fee levels can be set freely and the money retained without affecting the budget allocation from the government

From Fielden, J. (2008). Global trends in university governance. *Education Working Paper Series No 9*. Washington, DC: World Bank.

unethical practices. (Salmi, 2008) describes the type of corruption or fraudulent practice that is becoming increasingly common.

In the same paper Salmi (2008) describes the many forms that accountability can take

legal requirements such as licensing, financial audits and reports, quality assurance procedures such as program or institutional accreditation, benchmarking exercises to compare programs across institutions, professional qualification examinations, budget allocation mechanisms that reward performance, and oversight structures such as governing boards with representation from external stakeholders.

The most significant control mechanism is a review of an institution's strategic plan and the extent to which it is achieving any national policy goals or targets set by the ministry. In recent years governments have been adopting the approach of consulting the sector over the development of a national strategy for higher education and, once this has been agreed, requiring institutions to prepare their own strategic investment plans for meeting the national goals. New Zealand adopts this model as the tertiary Education Commission expects institutions to submit investment plans and Australia has followed a similar path.

Accountability is achieved not only through establishing regulatory control mechanisms and monitoring procedures, but also through information requests. While most governments aim to ensure as light a touch as possible, there are pressures from politicians and the public for more and more information on how higher education operates and reviews its effectiveness. In addition, there is a tendency for ministers of education to achieve office on the basis of election promises which usually involve the development of policies that require new forms of regulation and monitoring. The risk therefore is that, as formal control systems are removed, they are replaced by rigorous reporting requirements. In England, for example, the scale of monitoring and reporting has become so heavy that the buffer body itself has established a target for lightening the accountability burden and created a formal entity called the Higher Education Regulation Review Group for reviewing any new accountability and reporting burdens that are planned. **Table 3** illustrates the scale of regulation and reporting in 2008. Some would consider this excessive in a country that has an image of giving autonomy to universities.

From this analysis, we can draw some conclusions that are relevant to institutional governance and the role of university councils or boards:

- The state is increasingly reliant on institutions governing themselves effectively, once it decides to abandon detailed control of university operations.

Table 3 Reporting and regulation in England

-
- Detailed targets set for domestic student numbers, the social class of students and their home location with rewards for achievement and penalties for failure.
 - Semimandatory requirements on management good practice in risk management, procurement, human resource management, etc.
 - Audits by the funding body of governance and management processes.
 - Production of strategies for property, human resources, teaching, and learning.
 - An expectation that the institutions will also have strategies for widening participation (greater access), research, finance, ICT, e-learning, and development of links with industry.
 - Extensive external audits of finance, teaching quality, and achievement of all the national strategies.
 - Special funding pockets for *ad hoc* policy priorities which have conditions attached.
 - National laws on health and safety, racial, sexual, or age discrimination that require formal annual reports.
-

- This places a big accountability burden on university councils and the institutional leadership and leads inevitably to greater use of managerial mechanisms and techniques by the academic leadership.
- Once the state frees institutions from detailed monitoring, they are able to develop unique strategies that are often related to their region or community and this brings with it the need for local and regional representation in decision-making.

University Councils or Boards

The Changing Role of Councils

Traditional collegial models of university government are under attack. A controversial example of this was the attempt in 2006–2007 by a new vice-chancellor at Oxford to limit the powers of the 3500-strong Congregation of the University and its 39 autonomous colleges by strengthening the central authority of a new university council. He was only partially successful, since both Oxford and Cambridge have a deeply engrained and democratic approach to governance and are wholly atypical of the British system as a whole. However, in other countries, legislation has been introduced with the same aim, for example:

- In Austria, legislation introduced a university council with the power to appoint the rector and prepare institutional plans.
- As part of reforms creating national university corporations, in 2004 Japan established a three-tier system with an administrative council, an academic council and an executive board.
- When the United Kingdom gave its polytechnics university status in 1989, the legislation stated that overall

authority should rest with a board of governors which would have authority over an academic board.

- In the Netherlands and Sweden, legislation has established governing or supervisory boards chaired by external members.

Thus, the dominant pattern that is emerging is of a governance structure in which there are three main players: the board or council, an academic board or senate, and the executive. Where there is a Higher Education Act, it is common for the roles of the council and the senate to be defined broadly in the legislation and this also usually defines the relationship between the council and the vice-chancellor/rector. In the latter case it is usual for the legislation to state the accountability of the rector to the board as head of the executive.

The relationship between the council and the academic board is not always easy. In the United Kingdom, for example, it is now accepted that the council “has legally unambiguous authority for the governance of the university,” meaning that the academic board is legally subservient to it (Committee of University Chairs, 2006). But this legal position can be ignored when financial and academic values conflict. In a recent UK example, the senate at the University of Warwick rejected a proposal approved by the university council to establish a campus in Singapore on the grounds that it feared that its academic freedom in Singapore would be constrained. Such a relationship is sometimes referred to as one of creative tension.

Academic boards are usually large bodies and thus not ideally suited to detailed decision-making. Many of them began with the collegial principle that every professor was entitled to be a member and this still holds in some jurisdictions. Their size and the infrequency of their meetings (usually three times a year) has restricted their ability to participate in the immediate and responsive decisions that are now required. As a result an increasing number of academic decisions are made by senior academic members of the executive rather than by academic board. The general trend is therefore towards academic boards losing some of their powers to councils and the executive, but this depends to a great extent on the way decision-making structures operate within the institution. If the rector is the chair of the academic board, there is a greater chance of the decisions of both bodies being coordinated rather than duplicated or contradictory.

The executive, headed by the rector or vice-chancellor, is acquiring a greater say over key decisions largely due to the growing intensity and complexity of managing an institution. No council can master all the technical intricacies of university management and must focus on the key strategies and performance indicators. As all councils devolve full responsibility for management to their executive, they must develop performance indicators that can

assess whether the university is meeting the strategic goals they have set and whether the board itself is being effective. The chief executive is the key player in making this happen and the job specifications for the post are becoming increasingly demanding. Breakwell and Tytherleigh (2008) found that very few vice-chancellors in the United Kingdom had professional management qualifications and there was little evidence of nonacademic experience and yet they concluded that “VC’s are expected to combine academic credibility with all the other competences expected of the leaders of any large commercial businesses that have political significance.”

The Composition of Councils

There is a consistent trend toward a reduction in the size of university councils. In the United States, the board of trustees usually has no more than 12–15 members, although in the model followed in the United Kingdom and the British Commonwealth, it was a larger body numbering between 30 and 50. Australia recommends a number in the range from 15 to 22, while Denmark and New Zealand have recently set a maximum number of less than 15, whereas the post-1992 universities in the United Kingdom can appoint up to 24 members. A recent survey of governance in 20 African countries (Lao and Saint, 2008) has shown that in 70% of the countries, councils had less than 30 members. The managerial demands on councils have tended to increase the number of their meetings as well as reduce their size.

The composition of councils is also changing with a general trend toward the appointment of more members from outside the university system. Sweden, the post-1992 sector in the United Kingdom, Australia, Denmark, Norway, and Tanzania all require a majority of council members to be appointed from external constituencies. In Africa also, this was true for over 50% of the 20 African countries surveyed by Lao and Saint. However, there is a wide variation in practice in designating the origin of external members and who can appoint them. There are various models:

- election of some or all members by various internal constituencies inside the university;
- appointment by the national or state government;
- appointment by the Minister of the recommended people nominated by the board;
- appointment by the board without any outside involvement; and
- nomination by the government or external representative bodies of persons to fill an allotted place.

Many universities have one or more representatives of their central or local government on their council and some institutions in small countries specify that a certain number of members shall be from another country in order to ward against academic isolation. In the United

States, the practice in the composition of boards of state universities varies greatly but a database of the composition, term of service, modes of appointment, and degree of State control over nominations has been compiled by the Association of Governing Bodies (AGBs).

Membership of a university council has long been considered a prestige appointment, which the AGB has designated “the Crown Jewel of public service,” as it is usually unpaid. However, it is becoming increasingly onerous as the weight of accountability shifts on to the council. This is beginning to spawn the provision of training programs for members of council as well as formal requirements for appraisal and performance review. The leading proponents in this are the AGB and the Committee of University Chairs (CUC) in the United Kingdom. In Australia a requirement to offer management development programs to board members is under legislation. The UK’s Leadership Foundation and the CUC have developed a formidable array of training and briefing materials as well as role descriptions, and templates and guidelines for performance review. The message that emerges is that membership of university boards now demands a professional approach and is not to be undertaken lightly.

The frequency of board meetings varies greatly between countries. In the United Kingdom, only three meetings a year were considered necessary but this number is gradually increasing. The AGB provides advice to new trustees in the United States and suggests that in public universities there be ten meetings a year of about 4 h each, while in private institutions there could be only four meetings but lasting an average of 7 h each.

A consequence of this professionalization is that in some countries, vacancies on university boards are carefully planned and skills audits of the existing membership are undertaken to decide what particular competencies are needed in any new appointments. Boards increasingly feel the need to be able to draw on legal, financial, marketing, human resource, and property expertise in their decision-making. This has inevitably led to the use of advertising or external search agencies to find board members, rather than traditional methods of word-of-mouth or personal contact. One other factor in appointments is the need to have a board that represents the society or region in which the university is located with appropriate ethnic and gender balance. These points make the management of the board’s recruitment and membership an increasingly complex matter.

The Chair of the Board or Council

The relationship between the chair and the vice-chancellor/rector is also a key element in an institution’s success. If that relationship does not work, there will be problems, since the chair of the council has to have full confidence in his chief executive and is in any event responsible for appraising his/

her performance in many countries. In legal terms, the chair is responsible to the government for the performance of the university and has to have an appropriate executive to ensure that the strategies and plans are put into effect. A direct consequence of making the university board responsible for the university’s performance is that the government will hold the chair accountable and not the vice-chancellor.

A key issue is how the chair of a board is selected, since so much responsibility now rests on the board. There is a wide variation in the method of selecting and appointing chairs of a council which are broadly similar to the ways of selecting board members. In Sweden and the Netherlands the government appoints the chair for a 3-year term, whereas in Ireland and the United Kingdom it is usual for the members of the board to agree on the appointment of one of them. Again, the role is unpaid and part-time, but since the time required can be significantly more than that of a normal member (up to 1 day a week in some circumstances), this represents a considerable commitment on the part of the chair.

The Search for Good Governance

A key issue for governments is whether they intervene at all to promote good governance by the university council and its executive. As the members of boards increasingly come to be drawn from all walks of society and the complexity of university operations grows, there is every reason for the state (or some buffer agency) to set up support systems for board members. There is consequently a general trend to the development of guidance and codes of practice for boards; recent examples of this have been produced in the United States, Denmark, Australia, Ireland, and the United Kingdom.

- In Ireland the Irish Universities Association and the buffer body, the Higher Education Authority, published a *Governance Code of Legislation, Principles, Best Practice and Guidelines* which was developed jointly by both parties and goes well beyond the realm of monitoring financial accountability.
- Another example is the set of National Governance Protocols for Higher Education Institutions developed by the Australian government in 2003.
- A code of voluntary good practice guidelines for boards and board members was developed by the Committee of University Chairs in the United Kingdom. This also sets out what it calls a *Statement of Primary Responsibilities* that describes the role of the board.
- In Denmark a committee on university boards produced *Recommendations for Good University Governance in Denmark* in 2003, which defined what the role of boards was, since they were a new feature of the system under the University Act 2003.

- The AGB in the United States offers a consultancy service for university boards and over 800 have turned to it for help; it also publishes a regular flow of advisory booklets aimed at trustees.

The state is becoming increasingly interested in how boards and universities exercise their autonomy and it seems very likely that their regulatory instincts will begin to make guidelines and codes of practice mandatory rather than optional.

Conclusions

The increasing complexity and scale of higher education provision is making it much harder for governments to exercise direct control over institutions and there is a global trend towards granting them greater autonomy in return for holding them accountable for the achievement of strategic goals.

This places responsibility for achieving the national goals for higher education squarely on the universities' boards and councils. In parallel, structural and process changes are occurring within these boards: they are becoming smaller; their membership is changing to contain much greater representation from external stakeholders; they are comprised of people with specialist skills rather than philanthropic amateurs; and together with their executive they are expected to master the setting of performance targets backed by strategic and operational plans. Being a member of a board is becoming a demanding and professional role, requiring specialist staff development and support. Governments are increasingly seeing it as their role to set guidelines for the performance of boards.

Glossary

Basic research – Research that is largely theoretical in emphasis and not focussed on particular industrial or social problems. Basic research is carried on mainly in major research intensive universities.

Block grant funding – Government funding to universities which comes in large allocations where universities have considerable say on its use. Increasingly block research funds are allocated based on assessment of institutional research quality and impact.

Innovation systems – Clusters of institutions involved in research and in R&D that together generate wealth based on the commercialization of intellectual property.

Intellectual property – Research outputs of commercial value that are protected by patents or copyright.

Patents – Legal instrument dealing with the ownership of intellectual property. Patents may be sold or owners may charge a licensing fee.

Priority setting – A process of establishing priorities with high ranked priorities attracting much large financial support.

Public research institutions – Government operated research bodies which are largely funded by Government. They carry out both basic and applied research.

Research commercialization – Process of transforming university discoveries and inventions in processes and products of commercial value.

Research quality frameworks – New approaches to the assessment of national research quality and impact.

Research universities – Universities that are strongly committed to research activities. Typically research universities have developed expensive facilities and employ large numbers of research only staff.

University rankings – Systems such as the Times Higher Education QS and Shanghai Jiang Tong that rank universities international primarily on the basis of the quality of their research.

Introduction

Universities are key elements in national innovation systems, carrying out extensive scientific and academic research, training future researchers and other skilled personnel, and generating and communicating new knowledge to students and the wider community. University research covers a wide range of academic fields and topic areas, adding to the stock of knowledge that guides new research agendas and feeds into PhD training. In addition, today substantial applied research is frequently undertaken by universities to serve the direct needs of industry by developing new products and industrial processes, and contributing solutions to social and economic issues (Harman, 2006).

A large proportion of university research activity is highly expensive, involving considerable staff time and high-level expertise, and often requiring the use of highly

expensive equipment and materials. For this reason, the level of internal and external research funding that universities can attract is of utmost importance in the production of high-quality research outputs, including scientific papers and discoveries and inventions that can be patented or otherwise protected under intellectual property legislation.

Research and the Research Functions of Universities

Scientific and academic research carried out in universities can be defined as critical and creative investigation undertaken on a systematic and rigorous basis, with the aim of extending knowledge or solving particular practical or theoretical problems. Extension of knowledge can be aimed at the discovery of previously unknown phenomena, development of explanatory theory and its application to new situations, and academic work that provides significant contributions to particular disciplines, tackles problems of social and economic significance, or produces original works of intellectual merit.

Since research activity varies considerably in terms of its disciplinary orientations, objectives, methodologies employed, and end products and their use, policymakers and academics find it convenient to make various distinctions, such as between basic and applied research, and between curiosity-driven and problem-driven research. Many countries now use Organization for Economic Development and Cooperation (OECD) categorization of research into pure basic research, strategic basic research, applied research, and experimental development (OECD, 2002), especially for data collection and reporting. While such categorization has utility in monitoring research performance and in discussions of research policy issues, it has been subject to criticism, especially as traditional boundaries are becoming increasingly blurred in many new multipartner and trans-disciplinary university research centers (Gibbons *et al.*, 1994).

Universities undertake research activities for a variety of reasons, but particularly important are strong academic commitments to the value of research and scholarship that are highlighted commonly in university charters and mission statements, and are integral elements of academic and disciplinary cultures. In addition, universities engage in research because of the recognition it attracts, its value in supporting teaching particularly at advanced levels, and as a means for providing service to the wider society.

Over the past half-century, most industrialized countries have defined the functions of universities in terms of threefold responsibilities to teaching, to research and scholarship, and to service (Clark, 1983). But over time, this definition of responsibilities has been somewhat redefined and elaborated. Particularly important has been a growing acceptance that in large, comprehensive, and

diversified higher education systems not all teachers should be required to conduct research as part of their employment conditions and not all higher education institutions should have an equal commitment to research. This has helped push increasing concentration of expensive and large-scale research in relatively small numbers of major research-intensive universities.

Apart from universities, other important research producers are public-sector research institutions (PRIs) and research laboratories operated by business firms. The balance of activity between these three different types of research performing bodies varies considerably between different countries and over time, depending particularly on private-sector industrial strength and research and development (R&D) capacity, and the extent of government support for public research. Funding for university research comes largely from governments, industrial partners, and various donors including alumni and philanthropic foundations.

Nations today generally face major challenges in a global environment where the role of knowledge is becoming increasingly important. Knowledge accumulation and application have become major factors in economic development and are increasingly being recognized as being central to the competitive advantage of nations. The ability of countries to select, adapt, and use knowledge is critical for sustained economic growth and improved living standards (World Bank, 2002). However, this capacity is not equally shared between nations, while scientific and technological knowledge yields its greatest benefits when there are strong linkages between leading universities and innovative companies.

The research functions of universities have changed to a major extent over the past two centuries. The classical European university concept of research-based teaching developed following the establishment by Wilhelm von Humboldt of the University of Berlin in 1810 and continues to be influential today, while the idea of the modern research university developed in the United States in the second-half of the nineteenth century. In the early part of the twentieth century, the research-university idea spread widely to many other industrial countries, with a strong emphasis being placed on the role of the university focusing primarily on basic research and research training, with some commitment to applied research but little to developmental research. The mission and fundamental values of the university at this stage were only moderately tied to the economy and employment of graduates. However, from World War II onward, demands made on scientific research for reasons of national defense and economic and social development brought universities more directly into contact with research users, leading to ongoing efforts to reform and redirect university research. While the classical-university idea retains considerable appeal within academia, increasingly modern universities are being forced to accept a wider research role and to become more directly involved with business, industry, and government (Geiger, 1993; OECD, 1998).

Research and the Role of Governments

Governments today play increasingly important roles in funding, stimulating, and directing research activity in universities. In doing so, they use a variety of policy instruments to achieve particular objectives, including allocation of block grants and specific purpose funds to institutions; funding research centers and individual researchers/research groups; establishment of major research centers of excellence; investment in large-scale research equipment and infrastructure; provision of economic incentives and disincentives (including subsidies, pricing structures, taxation concessions, and charges); regulation (such as legislation relating to intellectual property); the provision of information; and persuasion and advocacy.

Governments face new pressures and challenges related to their role in research funding. They need to respond to demands from a more diverse set of stakeholders, including not only the research community but also research users and interest groups representing particular types of consumers of research knowledge. Governments also need to take account of important changes that are taking place in research enterprises with new efforts to capture research benefits to meet social and economic needs while research costs are rapidly increasing with increased use of highly sophisticated and expensive equipment and other infrastructure support. A further challenge is a general shift away from an almost exclusive emphasis on disciplinary research toward more multidisciplinary research, directly responsive to societal needs and carried out with more interaction between different research performers. This trend has been described by Gibbons *et al.* (1994) as the shift from mode 1 to mode 2 research. Mode 1 research takes place within traditional disciplinary settings whereas mode 2 research emphasizes the importance of knowledge application and usually takes place in multidisciplinary settings. Other challenges include new accountability demands, the struggle to ensure long-term sustainability of research enterprises, and the need to maintain supply of highly trained PhD graduates. Supply of trained personnel depends on capacity in PhD training, the ability of individuals to secure PhD training abroad or attract foreign-trained scientists, and success in addressing problems of brain drain to other countries.

Governments have responded to these new challenges in different ways. According to a major report entitled, *Governance of Public Research* (2003), OECD member countries are responding to new challenges by enhanced stakeholder involvement in priority setting; restructuring research-funding arrangements by redefining responsibilities; combining agencies or developing new mechanisms of coordination; reviewing and renewing R&D funding mechanisms with a strong emphasis on use of competitive arrangements based on performance and merit;

undertaking major funding initiatives to strengthen infrastructure support; encouraging enhanced partnerships between universities, public research institutes (PRIs) and private firms; and reforming and restructuring PRIs.

Public Funding of R&D

Public funding of university research and R&D is a major instrument used by governments to steer science systems and to capture economic and social benefits more effectively. Many countries have embarked on reforms in funding in response to new demands and opportunities, enhancing their strategic-planning capacity and paying more attention to the social and economic environment and to the evolving patterns of relationships between stakeholders. Overall, the volume of R&D funding has increased, although public funding is generally increasing at a lesser rate than private funding (OECD, 2003).

Traditionally, governments financed a high proportion of university research in industrialized countries as a public good, but in the 1990s such funding declined with the result that universities were increasingly forced to seek new sources of financial support. Meanwhile, government funding increased for mission-oriented and contract-based research that are more dependent on output and performance criteria. This forced universities to perform more short-term and market-oriented research.

Almost all OECD countries in recent years have increased their public funding of R&D, although generally such increases have achieved little more than keeping pace with the expansion of national economies (OECD, 2003). As a share of gross domestic product (GDP), funding for R&D in universities and other PRIs remained flat at about 0.61% between 1981 and 2000 for OECD countries generally, although there were some major variations between countries (OECD, 2003). Nearly all countries reported their intention to increase funding for the future, but generally increases are expected to be mainly in priority areas and in new programs where funding is on a highly competitive basis.

Different types of government funding mechanisms are widely used, particularly institutional or block grants, project funding, and special programs funding, but in each case, there is increased use of competitive mechanisms and funding allocations based on performance. Each of these is discussed in some detail below:

- *Institutional or block grant funding.* This takes different forms, although in most countries traditionally it was based on student enrolments or the number of research units (or chairs such as in Japan). Generally, such funding came without conditions, although more recently a clear trend has been to separate institutional funding for research from institutional funding for teaching, and

for allocations for mission-oriented research funding on a competitive basis to increase while long-term general institutional research funding further declines.

Many OECD countries including the UK, Australia, and New Zealand use separate streams of institutional funding for research, with allocations being based on quality and/or performance. The provision of government funding for both institutions as well as individual researchers/research groups is often referred to as a dual system of research funding. While Australia has used simple performance indicators (external research grants, higher degree completions, and publication outputs) to allocate institutional research funding to universities, the UK higher education funding authorities have used data generated by the research assessment exercises (RAEs) run at intervals of 4–5 years. More recently, New Zealand has opted for a modified version of the UK RAE based on assessments of research quality conducted every 4 years by some 70 different panels of experts. While throughout the 1990s, the Australian research quantum scheme allocated about 5% of total operating grant funding to institutions for research support on the basis of performance indicators, the Higher Education Funding Council of England allocated some 20% of total government funding on the basis of RAE assessments, resulting in leading research universities (e.g., Oxford, Cambridge, and Imperial College) gaining much larger amounts from their research allocations than their teaching allocations (Harman, 2000). Currently, both the UK and Australian systems are under review. While the UK intends to abandon the RAE after the 2008 assessment, Australia plans to move to a research-quality framework, which will involve separate assessments of the quality and impact of research in each university in 12 different major disciplinary areas.

- *Project funding.* This involves competitive allocations on the basis of applications submitted in response to notifications or calls for tenders, with evaluation using some kind of peer-review process. In some senses, project funding is similar to business funding of R&D in that it tends to be contract based, with specific objectives and milestones. In a number of countries, project funding has been expanded to include projects with joint government and industry support.
- *Special programs.* These are becoming increasingly common. In general, they are linked to priority areas with funding being allocated on a competitive basis, often for centers of excellence, or special research centers involving universities and other partners. Centers of excellence have been established in many Asian Pacific countries including Japan, Australia, and New Zealand. Japan launched a new university resource-allocation-prioritization program in 2002 called the twenty-first-century COE (center of excellence)

program with the aim of promoting research units of world-class excellence in selected fields. The fields supported in 2002 were life science, chemistry and materials science, information, electrical and electronics, humanities, and interdisciplinary subjects. Each research unit selected was allocated resources around JPY 100–500 million for 5 years. In November 2002, some 113 research units at 50 institutions were selected out of 464 applications from 163 institutions. Australia has programs supporting special research centers, key centers of teaching and research, cooperative research centers (multisite centers jointly funded by government and industry) and a small group of mega-centers in strategic areas such as biotechnology and information and communications technology. In 2001, New Zealand established a center of research excellence fund to support world-class centers expected to be involved in both research and knowledge-transfer activities (Ministry of Education, 2001).

In a number of advanced countries, an important trend is for increased proportion of R&D to be financed and performed by business. However, in Japan, business support for higher education and public research institutions has increased only slightly but is still relatively small, while in Korea business funding for higher education research has decreased. However, this reduction has been compensated by increased funding from the government, with an increase over last two decades of about 100%. Other funding for research comes from universities' own resources, endowments, and patent licensing fees. In Japan and Korea, 5% or more of research funding comes from other sources.

Across advanced regional economies governments are increasingly linking funding allocations to evaluation and assessment. Detailed assessments sometimes are made prior to new initiatives while ongoing assessments of performance are increasingly common. Traditionally, evaluation procedures were mainly based on the use of peer review of project applications but governments now are using in-depth reviews and various performance indicators, such as total external funding attracted, and numbers of publications, patents, start-ups, awards, and prizes.

Concentration, Selectivity, and Priority Setting

Developed nations generally are putting increased emphasis on concentration of research funding among a limited number of institutions, departments, and researchers in order to develop larger groups of highly qualified and productive researchers who have access to superior equipment, facilities, and technical and financial support. This process is often referred to as achieving a critical mass of

researchers. Even wealthy countries recognize that research resources are limited, and therefore pursue such policies of selectivity and concentration.

Priority setting refers to processes of strategic choice with the aim of increasing returns on investment in research (Harman, 2000). Some fields of research or particular research centers or research projects are selected over others to receive preferential funding. Many governments are moving increasingly to setting national research priorities. In some cases, priority setting is driven by reductions in government budgets but more commonly priority setting is favored to make decisions when governments face strong pressures to provide larger allocations to particular areas, such as biotechnology, nanotechnology, or information and communications technology.

Governments use a variety of priority-setting mechanisms, including national science and technology plans, advisory bodies, and foresight processes and public consultation, while universities tend to depend on strategic plans, research management plans, and particular competitive-funding mechanisms. Some countries (such as Japan, Norway, and Hungary) use a top-down approach where central governments adopt explicit strategies, policies, or plans that specify priority areas for research. In these countries, plus others such as Korea, Germany, Netherlands, and Denmark, central advisory bodies make recommendations about priorities. At the other end of the spectrum, is the bottom-up decentralized approach such as in United States, Canada, and Sweden where a number of advisory bodies provide recommendations to different government agencies.

Quality Research and Research-Quality Frameworks

Governments are becoming increasingly concerned not only to build up their R&D capacity but also to ensure that university research outputs are at the highest possible international standards, and are also highly relevant to local industry and business. Assessments of quality are based mainly on peer review or the use of quantitative data or performance indicators. Peer review is a generic term that includes the notions of merit review, refereeing by anonymous referees, expert judgment, peer advice, and peer evaluation. However, in making judgments about research, it is often desirable to take into account the judgments of a range of different research users who should be able to verify claims by researchers about quality and impact. Quantitative data on research output and quality can simply rely on lists of publications, conference papers and presentations, and patents. However, for comparative analysis, the measures used most commonly are bibliometrics comprising publication numbers and associated citations. Citations are a measure of the

impact of particular research papers on the disciplines involved by assessing the number of times a particular article is cited (or referred to) by other authors.

A number of governments in developed countries have established research-quality frameworks that serve a number of purposes, but most important they provide consistent and comprehensive approaches to assessing the quality and impact of research activities in universities, particularly publicly funded research. Such assessments can: inform governments and the wider public about the quality and impact of research and its standing internationally; guide resource allocation, especially the allocation of major block research grants; and provide inputs into policy development, especially with regard to research priorities. While many countries use data from quality assessments to determine funding allocations, some countries do not. Examples of the latter are the Netherlands national evaluations system for publicly funded research, and the German research foundation rankings.

Apart from the quality frameworks developed by governments, both research groups and major newspapers have developed methodologies to rank universities internationally. Rankings developed by the Institute of Higher Education of Shanghai Jiao Tong University rely largely on quantitative research indicators, whereas others such as those of the UK *Times Higher Education Supplement* and the Melbourne Institute of Applied Economic and Social Research use wider definitions of quality and include other performance measures related to teaching and student characteristics.

University Research Links with Industry

Universities in many countries are establishing closer and more effective links with other research providers and stakeholders, particularly PRIs, industry laboratories, business firms, and government laboratories. These links take a variety of different forms, including joint research centers and research appointments, shared use of facilities, industry funding of university research, and consultancy arrangements between universities and research users.

In the United Kingdom, for example, a rapid increase in university-industry collaboration since the 1980s has led to a variety of different partnership arrangements with many positive outcomes including an impressive increase in the number of joint scientific publications. By the late 1990s, joint university-industry scientific papers accounted for about half of all industrial scientific output (Calvert and Patel, 2002). These new arrangements have increasingly broken down traditional arrangements in modern economies where universities and PRIs were viewed as being responsible for basic scientific and precommercial research, while industrial firms performed the bulk of applied research and product development.

On the whole, the new university–industry research links in many leading industrialized countries are working well to the mutual benefit of various partners. University links with industry provide universities with substantial research support, consulting opportunities, financial and project support for postgraduate students, opportunities for graduate employment, and opportunities for academics to gain insights into new technical developments within industry. On the other hand, industry benefits substantially from partnerships through access to university expertise and facilities, access to university intellectual property, and the supply of well-trained graduates.

Particularly important partnerships in a number of countries are based on new research centers with multiuniversity partners as well as partners from PRIs, government departments, and business firms. An example in the Asia Pacific region is the Australian Cooperative Research Centre (CRC) program that has resulted in establishment of some 70 multisite centers. Funding is provided by the Australian Government as well as by partners including universities, government research organizations, government ministries, and industry and business.

While governments, universities, and the researchers involved in partnerships are generally supportive of university–industry partnerships, critics allege that such partnerships threaten traditional academic values, distort the balance between basic and applied research, and corrupt academics with commercial values to the extent that in some cases there is serious neglect of teaching and research responsibilities. It is also alleged that industry contracts lead researchers to withhold scientific information from colleagues and delay publication, thus adversely affecting the free flow of scientific information. While some academic studies have highlighted what they see as dangers in close relationships between universities and industry, particularly the impact on academic work and values, forcing scientists to abandon the traditional cooperative mode of research (Dickson, 1984; Kenney, 1986), other studies have provided strong evidence that many academic researchers increasingly accept the concept that profit generated from research need not corrupt academic work, and conclude that, to date, any adverse affects on academic behavior have been limited. Particularly important in addressing criticisms of the new commercialism have been the American studies by Blumenthal and colleagues. One study (Blumenthal *et al.*, 1986) reporting on a survey of 1200 biotechnology researchers in 40 major American universities found that researchers with industrial support publish at higher rates, patent more frequently, and participate more substantially in administrative and professional activities. At the same time, researchers with industry funds are much more likely than other biotechnology researchers to report that their research has resulted in trade secrets and that commercial considerations have influenced their choice of research projects. Similar findings were found in

an Australian study (Harman, 1999) which reported that compared to other colleagues, industry-funded science and technology academics in leading Australian universities had better publication records, spent longer hours at work each week, and allocated more time on postgraduate teaching, administration, committee work, and interaction with colleagues.

Research Commercialization

Since the early 1980s, first in America, and more recently in many other developed countries, governments and research-intensive universities have put considerable effort into the protection and commercialization of intellectual property of commercial value arising from university-generated inventions and discoveries. The process of commercialization is usually referred to as research commercialization or technology transfer. Intellectual property is a broad term used to refer to the various rights that the law gives for the protection of creative effort, especially the protection of economic investment in creative effort through experimentation, discoveries, or activities of the mind.

Rapid growth in research commercialization efforts has been driven by recognition of the value of intellectual property and by the desire of universities to generate additional income. In addition, governments and universities have become increasingly concerned with national competitive advantage in the age of globalization while universities seek to demonstrate their commitment to the public interest and through enhanced relationships with business firms generate increased political support for public investment in research. Governments, on the other hand, seek to capture the benefits of university research to facilitate economic and social development, and to generate national wealth.

Laws and policies governing the ownership of intellectual property vary considerably between countries. In summary, a number of countries follow United States practice where generally intellectual property arising from federally funded projects is held by universities, but accompanied by arrangements for academics and their departments to share in the financial returns from commercialization after all costs incurred have been met. The other model is that found in Sweden and a number of continental European countries, where individual academic creators own the intellectual property resulting from their university research except for work covered by contractual agreements with firms.

A small number of the leading universities in industrialized countries generate considerable revenue each year through research-commercialization efforts, particularly licensing of patents and creation of university start-up companies based on university discoveries or

inventions. For example, in the US, the University of California system generates about US\$180m per annum and Stanford University about US\$50m per annum in research-commercialization revenue. However, for many universities, licensing of patents and income from spin-off companies is likely to constitute no more than relatively small proportions of total university research financial support.

Mobility of PhD Students and Scientists

S Avveduto, National Research Council, Institute for Research on Population and Social Policies, Rome, Italy

© 2010 Elsevier Ltd. All rights reserved.

Mobility of the highly skilled can be approached from different points of view: as a human resource policy question, as an equity problem between world regions at different levels of development, or as a migration-policy topic, just to mention the most relevant ones. Human resources are the crucial element for development, and all investments in their education and positive utilization are considered essential for the general well-being of society and the economy. In this framework, the internationalization of education and research-career patterns are a basic component in order to enhance the development of a better workforce – a workforce particularly devoted to research, science, and technology, and specifically made up of PhD graduates and scientists. Mobility is unanimously considered an efficient means of knowledge diffusion and technology transfer. The border between mobility and migration for the highly skilled often becomes less evident.

According to most scholars, comparing the mobility of brains to an escape from one's country of origin, is no longer considered in our globalized society. Rather, we refer to it as the free circulation of people and ideas and not as a drain of intelligence.

Mobility of skilled people and specifically of scientists, researchers, and PhD students and graduates is a complex phenomenon and can be considered from different perspectives. It is a typical two-sided question. Positive and negative aspects can be found in an event that could apparently be considered neutral. An excess of mobility is likely to cause as many problems as its absence.

The need to confront, cooperate, and work with other scientists is somehow innate in the research activity itself. The question is to determine the optimal share of mobility in a career, in an institution, or in a country. If this share is either exceeded or not reached, problems may arise. Of course, there is no standard tool that can help in quantifying the optimum level. However, the analysis of positive and negative effects of mobility can help in choosing its right balance.

At an individual, institutional, or country level, the advantages of having a mobile highly skilled workforce and of cooperating, studying, and working in a different environment with foreign partners, are rather obvious and the positive potentialities of this experience are self-explanatory. The risks lie essentially in missing the opportunity to fully develop the positive spillover of this experience or in the changing nature of mobility – from a temporary experience to a permanent escape.

When considering scientists' and PhD students' mobility, we refer to an occurrence which has its roots well into the Middle Ages. The very first mobility in this sector may be found in university students who were in reality, the intellectual elite of that period. They were known as *clerici vagantes* and they used to move within and across nations in order to attend the best *universitates*. Such universities, each had their own area of specialty where the elite students could find the best knowledge available. Much, if not all, has changed since then, but the essence of moving around to find the best options, to work and learn, to come across new ways of thinking, to confront other cultures and ideas, and to understand what is happening outside the borders of our own intellectual village, is the essence of modern science and higher education. This desire for good research and knowledge diffusion has remained virtually unchanged throughout the centuries. The mobility of highly skilled personnel has taken place with relative continuity, in different forms and with different consistencies, since the mid-nineteenth century into the early twentieth century, when a proper science and research career could be acquired. A number of elite migrants, including professionals and scholars, left their home countries for foreign destinations in order to start new businesses or enter cultural and scientific activities. We can recognize the importance of skilled immigrants in several countries and fields of activities – in firms, research laboratories, and universities. The flow of people has been influenced by many factors that, before and during World War II, also included political or racial persecutions. Such conditions, for instance, forced many scientists to migrate to the United States from Europe. In this case, the term brain drain rather than mobility was used. This expression first appeared in the late 1950s and was used for the first time in an official document by the Royal Society in the 1960s in order to explain the movement of British scientists from the country (Royal Society, 1963). Brain drain refers to an excess of flow of talented people who are induced to leave their home country to find better scientific working conditions.

Nowadays, the percentage of mobility is considered one of the indicators of a healthy and innovative system of higher education and science. Many international agencies and supranational bodies (UNESCO, 1998; OECD, 2001; European Commission, 2007) state that both government and institutions should promote national and international mobility of PhD students and scientists as an essential element in enhancing the quality and relevance

of those systems. However, the problems associated with brain drain are still not over. This is especially the case if applied to the drain of talent from less-developed countries, whose return to home countries after a mobility experience is very problematical (Thorn and Holm-Nielsen, 2006). From 1990 to 2000, 5 million tertiary-educated adults moved from a less-developed nation to a more developed one, while 2 million moved between more developed nations (OECD, 2007a). The International Organization for Migration (IOM) estimates that over 300 000 professionals from African countries live and work in Europe and North America, and a large number of professionals, especially health workers, intend to migrate from their home countries (WHO, 2004).

In absolute terms, the largest stock of educated emigrants are from Europe, Southern and Eastern Asia, and, to a lesser extent, Central America. Nevertheless, as a proportion of the local educated labor force, the highest rates are found in Central America and Africa. Between 1990 and 2000, these regions also experienced the strongest increase in brain drain (Docquier and Marfouk, 2004).

The magnetism of some countries for researchers and PhD students and graduates over others is indisputable. The United States has always been and still is an important pole of attraction for skilled people. In fact 40% of its foreign-born, adult population have a tertiary-level education. Since the early 1990s, over 1 million highly skilled professionals, from India, China, Russia, and a few Organization for Economic Cooperation and Development (OECD) countries such as Canada, the United Kingdom, and Germany, migrated to the United States under the H-1B temporary-visa program.

The direction of flows of highly skilled people benefits most of the OECD countries, and recent figures (Figure 1) show that only a few countries: Mexico, Korea, Ireland, Poland, Finland, and some Central and Eastern European countries, experienced a net loss of people. The rest of OECD countries experienced a net inflow (Dumont and Lemaitre, 2005).

As for mobility of PhD students, the figures on foreign participation in science and engineering (S&E) doctoral education in the United States are often used to obtain indicators of global flows, the United States having the strongest attraction for PhD students wishing to complete their education abroad.

The National Science Foundation (Oliver, 2007) states that after 2 years of decline, US enrolment of foreign graduate students in S&E fields increased in 2006. The increase was largely due to first-time, full-time enrolment of foreign students, which grew 16% over the 2005 level.

From 1989 to 2003, foreign students earned nearly 40% of US S&E doctorates, with Asian students representing about 55% of this group. Students from European Union (EU) countries have totaled about 10% of all foreign doctorate recipients in the United States.

The largest Asian sources were China with about 34 000 S&E doctorates from 1989 to 2003, Taiwan with 14 800, and South Korea and India with about 14 500 each. These four sources accounted for nearly 90% of all Asian recipients of US S&E doctorates. Asian recipients of US S&E doctorates are far more likely than EU students to earn an engineering doctorate: 35–38% compared with 17–21% of EU students, while the US average is 13–15% (NSF, 2007).

Figure 1 Immigrant and emigrant population 15+ with tertiary education in OECD countries – thousands. From Dumont J. C. and Lemaitre, G. (2005). Counting immigrants and expatriates in OECD countries: A new perspective. *OECD Social Employment and Migration Working Papers*, N. 25. Paris: OECD.

PhD Students' and Scientists' Mobility: Main Questions

Mobility occurs essentially as an individual choice but can be encouraged and favored by institutional or national programs and regulations that are aimed at promoting the circulation of researchers and scholars.

All OECD countries have a variety of policies to encourage PhD students and researchers to be mobile either at a national or institutional level. Such policies include monetary incentives and are targeted toward specific groups and at different scales.

Mobility of PhD Students

The mobility of PhD students faces questions of opportunity and feasibility of international research training, within a research-education process. Objectives and benefits of international mobility are to be set and barriers to internationalization considered.

The opportunity of having an experience abroad is often considered, both by students and professors, as highly desirable, and perceived as a value per se. The research program they carry out may require a visit to a foreign university to collect data or perform experimenting in structures not available at home. But to these formal attainments, some informal, and not easily quantifiable, ones should also be added.

The main achievements are linked to personal, cultural, and scientific growth that PhD students can acquire when exposed to a different scientific and training milieu. Objectives and benefits of international mobility therefore expose PhD students to new scientific and cultural contexts, allowing broader professional and human experience and consequently improved competences and capacity to integrate in new job situations.

Converging research results point out that both concrete results, such as help with dissertation work, and intangible ones, such as personal development, are regarded as valuable outcomes for PhD students studying abroad (Kyvik *et al.*, 1999; OECD, 2001).

The Organization and Structure of Exchange: Motivations and Procedures

A wide variety of different procedures affects the PhD students' choice to go abroad and organize a study period in a foreign university. It is not a single decision-making process which leads the student to a chosen destination. A well-organized process can make doctoral students well aware, from the very beginning of their PhD course, of the opportunity to carry out part of their research abroad. However, it may also happen that only personal initiatives of professors, in advising and guiding students, or of

students themselves, in making applications and independent arrangements, prevail.

Although organizational models differ greatly, the motivations and procedures for choosing the country to study in, and the best period to go there, tend to converge. An international experience is perceived to be most fruitful if it takes place not at the very beginning of the doctoral education but after at least the first year. It may be advisable to spend the first year at home to develop acquired knowledge, to prepare the research proposal properly, and start working under the supervision of a supervisor.

At the final stage of preparation of the dissertation, it is as well perceived that staying in the home country university may be preferable. During the intermediate year(s) of a doctoral course after having consolidated the initial stage, students can benefit from coming to terms with an international context.

As for the country of destination, in many cases, the choice points toward a university which has a tradition of joint research with the *alma mater*, which may also simplify arrangements and eliminate some difficulties.

Regarding the optimal duration of the study period abroad, a variety of different opinions may be considered. Respondents to direct surveys agreed that a period of 6 months is the best one, since it allows for an initial period of acclimatization, while leaving a reasonable amount of time to draw academic benefit from the experience.

The average period of the stay abroad varies from 3 to 6 months for scientific and art subjects. Medicine presents a longer rate of staying (around a year), while engineers tend stay abroad shorter periods (around 3 months).

The various choices are consistent from different perspectives if the study period abroad is either considered useful to strengthen research work already advanced, or part of a less-developed study and research activity maybe more learning oriented, which would thus in many cases include things such as coursework thought in sessions with a supervisor, private tutorials, if appropriate, and lectures.

Problems and Obstacles May Hamper a Proper Mobility Experience

The problems to face may be objective – that is, mainly of an economic, bureaucratic, and logistic nature – or subjective – that is, knowledge of languages, adapting to the new environment, interaction with different subjects and styles of study. Difficulties also arise in delays in work on the thesis, in relationships with professors of the hosting university, or at home with a lack of motivation and support in a too nationally oriented environment.

The role of the university can be very important in fostering international mobility; helping students to cover the expenses and disseminating information widely, are the first relevant objectives to be met. The value of an international experience is to be considered highly relevant in a

proper research training, and so universities and research institutions are increasingly committed in ensuring that the students have this opportunity.

Mobility of Scientists

Programs for researchers and scientists are typically directed at young researchers with the aim of providing them with a specific mobility program that covers part of their relevant expenses. During the middle of an expatriate's research career, such policies are used to attract them back to their home countries. Many policy tools are set up to provide direct incentives to foreign researchers to encourage them to choose a specific country or institution as the preferred place for their mobility experience. Countries such as Korea, for instance, have provided their scientists and researchers living abroad with attractive conditions for returning home, creating positions for them, and offering adequate structures and salaries. The know-how acquired abroad can be beneficially used to serve the home country, and a positive circle of knowledge transfer can be set up. The main flows consist of information and communication technology (ICT) specialists, engineers, and researchers.

At a supranational level, we can point out, for instance, the Marie Curie Actions of the EU in providing European Reintegration Grants (ERG) and International Reintegration Grants (IRG) to researchers. Within the EU, special norms have been developed in order to ease the entry of foreign researchers who wish to carry out scientific research within the EU. The European Commission (EC), for instance, introduced a directive (Directive 2005/71/EC) to regulate the procedures of special scientific visas.

The researchers' visa package contains admission procedures of and visa facilitation for third-country researchers entering the EC to obtain a special permission to enter, stay, and work in the EU in order to carry out scientific research. This allows researchers to exceed the foreigners' quotas in a single state and to pass quickly through the immigration authorities' procedures.

In the United States, a series of special visas (the H-1B visa) allow the entrance of temporary specialty workers, among which scientists or immigrants with extraordinary ability in sciences, arts, education (and also business or athletics, the O-1 visa), are included. The figures on immigration through these visas are currently used to check the flow of highly skilled workers among countries and particularly toward the United States (Regets, 2007).

Universities have played a main role in promoting mobility and fostering what has been called academic migration (Altbach, 2004). Each single university may have its own policies and programs addressed to different kinds of graduate and postgraduate or professors and scholars and offer many types of mobility opportunities.

These may vary from the short-term leave to a year-round commitment.

Mobility schemes per se do not necessarily encompass a high level of mobility to be obtained by a country. However, it is clear that without these schemes, entering into a mobility experience proves to be quite difficult. Studies have proved that the absence of a mobility scheme is an obstacle to mobility. As an EC Green Paper stated: "It should be stressed that the obstacles to mobility are necessarily more difficult to overcome for those who 'spontaneously' seek to undertake training in another Member Country" (European Commission, 1996).

Mobility Indicators and Measurements

Indicators of stock and flow of mobility include the following: (1) occupation mobility, such as a demand for specific skills or flexibility of skills; (2) sector mobility, that is, changes from one sector of activity to another such as from a university to the private sector; and (3) international mobility, from one country to another. The last one can encompass the two previous types of mobility because changing country can also mean changing occupation or one's sector of employment. It is likely, for instance, that a researcher working in a university in his own country moves to the private sector in another.

The measurement of mobility of scientists is not an easy task. This is particularly the case for international mobility, as the indicators to track the outgoing personnel are far weaker than those to track ingoing ones. We should rely mostly on the latter as, when leaving an institution or a country, it is not at all a common practice to inform the former employer or a central agency of the directions of the next move either in terms of employment destination or the foreign country which the employee is planning to travel to. Barring a few countries (e.g., the European Nordic ones that can rely on a very detailed and updated register of all employment changes for each citizen), most countries do not have a central register that can be used to track scientists and PhD graduates' movements across professions, institutions, sectors, and countries. The relevant information is kept by each source separately and a cross-comparison is always very difficult to make.

As for international mobility, it is more likely that one will find information and figures on scientists in the incoming country rather than the country of origin. The country of destination, due to immigration regulations, might have a more detailed record of all skilled immigrants where relevant data on scientists can be found.

Tracking mobility of PhD students is, in principle, an easier task especially if they move within a specific structured program. Each university and research institution they are studying in, keep track of PhD students' movement, and the trajectories under their choices can

be visible at this level. A thorough picture of the phenomenon is, also in this case, more difficult to draw.

Reasons to Move

International mobility is marked by different reasons that encourage movement, push-and-pull factors inducing people to leave their institution, sector, or country and driving them toward different places that are thought to be more attractive.

Pull factors may be identified in the offer, available in the countries, of grants and scholarships that multiply the number of positions. Push factors include direct government or institutional policies created by the sending countries that stimulate the demand as well as programs specifically directed to provide funding and facilities.

To measure mobility reliability and validity and to fully develop the right indicators to do this, it is necessary to analyze the various dimensions relevant to individuals, institutions, and nations. These include: the number of people involved; level of qualification; gender; age profile; length of time, duration, and time interval between the different experiences; type of motivations; push-and-pull factors; barriers and incentives; economic and scientific impact; benefits and losses in personal and institutional terms; and policies to allow individuals, institutions, and countries to benefit most from the mobility experience.

A number of different factors either pertaining to the public or the private sphere influence international mobility. Why people decide to move and why they choose one destination over another remains largely part of individual choice but some motivations are common and some incentives can be determined.

The general framework is influenced by legislative regulations concerning immigration in the host country and general migration policy of the country of origin that can facilitate or hinder the mobility choice.

Working conditions in the country of destination have an important influence on the decision to move. Countries with poor working and/or studying conditions are, of course, less attractive. However, countries with good working/studying conditions may also become unattractive due to factors such as high cost of living, difficulties in settling (finding adequate housing, etc.). The entire set of factors to be considered should certainly take into account personal reasons, such as family ties, a milieu of reasons, such as cultural circumstances, or standards to be met, such as language requirements and qualifications needed. But wider facets such as policies and accessibility to mobility schemes; supply and demand of scientists and researchers in the country of destination; salary and pay-scale levels; qualifications required; and career prospects are also highly relevant.

To acquire a more precise picture of a PhD graduate's profile across countries, and to track their moves, either

as employees or geographically, OECD, in collaboration with United Nations Educational, Scientific and Cultural Organization (UNESCO) and European Statistics (EUROSTAT), launched an international review. This review desires to contribute to the understanding of the scale, directions, and drives of international mobility of PhD graduates and scientists. The international project on Careers of Doctorate Holders (CDH) has thus been set up and should provide comparable data on these groups and their international mobility. The project is at present gathering figures and data on researchers in all stages of their career (OECD, 2007a). The OECD–Group on Steering and Funding of Research Institutions (SFRI) have collected data and policy information at the institutional level, including institutional practices, and on foreign (temporary and permanent) researchers working in the public research sector to complement the picture in member countries (OECD, 2007b).

Many attempts have been made to come up with a reasonable picture of mobility by using direct survey tools that can give a more accurate picture of trends. Such direct surveys allow for an in-depth investigation of the reasons and outcomes of mobility.

As a study carried out for the EC on mobility of scientists points out (Hansen, 2003), the professional factors that drew migrants to foreign countries (i.e., pull factors) have been defined as follows: a large proportion of interviewees stated the possibility of finding better opportunities to work at the forefront of scientific research in their field or to acquire new scientific training and to specialize in a field that was insufficiently developed in their home country. But other factors may be considered pertaining to the personal sphere. Many researchers mentioned the desire to have more freedom in their work and personal life as an important factor in the decision to move (Figure 2).

<i>Reasons</i>	<i>Country EU 25</i>	<i>Country USA</i>
Career advancement	87.9	51.9
Employer reputation	74.0	61.1
Access to leading edge technologies	73.3	29.6
R&D funding	69.8	24.1
Professional networking	67.7	46.3
Employment/business opportunities	56.1	25.9
Salary	54.0	18.5
Adventure	48.8	53.7
Education	45.6	20.4

Figure 2 European and US Scientists' main reasons to move abroad from their home country (percentage of positive answers to the survey questions). From Hansen, W. (2003). Merit survey on flows of qualified scientists. *Final Report Project: Brain Drain Migration Flows of Qualified Scientists*. Brussels: European Commission.

The scientists share both positive and negative evaluations of their mobility experience. The positive ones prevail because mobile scholars feel they are in high-level working environments that produce good-quality results and offer resources and access to scientific equipment. The negative evaluation is commonly due to obstacles linked to bureaucratic red tape and difficulties in obtaining work permits and residence visas.

Postdoctorals and young researchers also complain of the fear of losing opportunities at home and of leaving them to people who preferred staying in the home institution even if at a lower level.

The Timing and Effects of International Mobility: Positive and Negative Outcomes

International mobility includes both short- and long-term experiences and its timing and duration are relevant to a scientist's career.

In the initial stage, mobility commonly takes place just after the completed PhD and may be the first step in a research career.

Immediately after graduation, the possibilities of considering moving out of the home country for a longer period, are higher than for graduates leaving the home country at a later stage. These graduates already present in the host country may be interested in pursuing or accepting a job offer and thus starting a career in the host country. As stated in the NSF studies, the propensity to stay in the host country (the United States in this case) and accept a solid job offer is relevant (NSF, 2006). The mobility experience may, however, take place at a later stage and its meaning and influence on the career choices may be far different.

One obvious benefit of receiving one's PhD abroad is also the much higher probability of getting employment in the country where the PhD has been awarded. In the

United States, one of the most attractive countries to complete a PhD, EU citizens account for 25% of doctorates awarded. This trend has continued since 1991 to the early years of 2000 and places them between 3% and 4% of all those awarded in the United States. The share of employment offers that European PhD graduates obtained is very relevant. In the mentioned period, 45% of graduates planned to stay on in the United States as they received a firm employment offer in the country (Figure 3).

Direct and indirect effects of international mobility can be registered on science, technology, and higher education systems, on human capital, and labor markets of the sending and receiving countries, and at an individual level.

The main positive and negative effects have been studied and cataloged (Regets, 2001). As for the possible positive effects on science, technology, and higher education systems of sending countries, it should be mentioned that this has led to an opening of knowledge flows and collaboration between countries and an increase in ties and networking between foreign research institutions. Specifically for the science system, the return of natives with a foreign education and, in general, highly skilled human capital may prove, directly or indirectly, to be of benefit. The return of mobile researchers means that the country of origin will acquire this new knowledge and experience gained, due to it being brought back upon the citizen's return.

The returnees may in fact bring back valuable entrepreneurship or management skills and give the home country a better insight into export opportunities for technology or into access to global networks.

A recent study of 127 developing countries conducted in 1990 and 2000, respectively, suggested that doubling the emigration rate of the highly skilled led to a 5% increase in gross human capital formation among the native population (Beine *et al.*, 2006). This may mean that scientists' migration may turn out to be a positive

Figure 3 European Union with PhD obtained in the United States with firm employment offer planning to locate in the United States (from 1991 to 2000). Firm offer total: 45.1; in higher education: 59.4; in business sector: 22.6; and in government/pnp: 18.0. From SRS, NSF.

Table 1 Foreign students enrolled in doctoral programs, 2002

<i>Country</i>	<i>Number of foreign doctoral students</i>
Switzerland	5359
Belgium	1990
United Kingdom	22 824
United States (2001)	78 884
Australia	8033
Denmark	872
Austria	2705
Canada	4655
Norway	727
Sweden	3147
Spain	8677
Czech Republic	1367
Hungary	496
Finland	1350
New Zealand	341
Portugal	718
Iceland	2
Korea	649
Turkey (1999)	378
Slovak Republic	110
Mexico	99
Italy	218

From OECD, Education Database, 2006, 2008.

asset for the less-developed countries as well. Researchers produce public goods that can also be shared across borders. They are particularly important as innovation and development agents for the economy, and beneficial effects of their work outcome may spread over different sectors of the economy.

Beneficial effects may also arise when using foreign facilities not available in the country of origin to further that country's research and development (R&D) agenda (i.e., big science facilities).

The receiving countries may benefit from hosting researchers and scientists. This may also turn into an increased R&D and economic activity, due to the availability of additional highly skilled workers, which favors entrepreneurship, especially in high-growth areas. Receiving countries also benefit from stronger knowledge flows and collaboration with sending countries. Diversity and creativity are certainly further promoted by the melting pot of the intellectual mix brought about by the inflow of people with different backgrounds.

A number of negative effects on science, technology, and higher education systems can also be envisaged. For the sending countries, the most-studied effect of highly skilled labor leaving its country of origin is the well-known and mentioned brain drain. This departure may mean losing part of the national ability to generate high-level activities that thus may lead to a weaker intellectual and productive capacity. Similarly, the country of origin will miss out if the outcome of the research, not the

process, is of value, as, for example, in a postdoctoral's research. Patents, for example, may provide instant benefit to the host country with little or no likely benefits for the country of origin.

A direct loss can be envisaged also in purely economic terms. The investment made in tertiary education becomes a benefit for another nation and may be perceived waste of national resources that gives poor returns from public investment.

Summary

The simple and traditional model brain drain/brain gain is no longer adequate to explain the complex movements of the highly skilled population, to describe and explain international mobility patterns and, even more, the consequences that these movements generate on the creation of knowledge and knowledge investments. The attention given by policy analysts and international organizations to these issues has been rapidly growing in recent years in order to develop a common framework for analysis (OECD, 2001, 2002).

Potential effects of mobility have been recognized to be positive or negative, both for the sending and receiving countries. Science and education policies must carefully take these potential effects into consideration to prevent possible drawbacks or, at the other end, to favor the positive spillover.

The envisioned global effect of increased mobility in higher education, science, and technology may be found in the best use of highly qualified people. But the analysis of the effects of highly qualified international migrations on investments in human capital is still to be fully developed. There are not yet consolidated indicators that can ease the measurement of the various effects of international mobility of highly skilled human resources.

Many questions are raised about the meaning and reasons for mobility. What helps and hinders international mobility? What are the driving and resisting forces? What barriers are still to be removed and what actions can ease the mobility process? A wise mix of incentives and schemes seems to be the best way of promoting mobility. The value of an international mobility experience is generally highly considered both by PhD students and scientists. It is part of the personal scientific and cultural growth and may result in being the first step in a research career for PhD graduates. The difficulties in organizing a stay abroad may result in personal and objective problems needing to be overcome, concerning the financing, location, etc. A supranational intervention is a suitable means to simplify international relations and overcome differences in local legislation, through a lightweight normative role, acting as a catalyst and leaving institutions and individuals free to organize mobility.

National Science Policy and Universities

Glossary

Research quantum – In the early stages of the development of Australian competitive funding policies, a small component of institutional grants was based on their “research quantum,” assessed by a set of quantitative performance indicators.

Triple helix – The metaphor adopted by Etzkowitz and Leydesdorff to characterise the increasingly complex relationships between universities, industries, and governments, in which they may take on each other's roles.

Science policy has tended, in practice, to denote policy for research and development in the natural sciences, even in national contexts where science is a more comprehensive concept. In recent years, this tendency has been reinforced as the aims of national science policies center increasingly on innovation.

From Benign Neglect to Managed Instrumentalism

At one time, there was no equivocation about national science policies as far as they affected universities. The Humboldtian creed may not have been adopted in its full extravagance everywhere but its key assumptions held good in most Western European and Anglophone countries. As Neave observed, it established the research university legend, with its protective barrier ensuring separation of the world of interests from the world of knowledge. Universities would not be involved in the consequences of the knowledge that they created. Research would be driven by internal dialog between individuals in disciplinary communities.

In the science-push model, too, as enunciated by Vannevar Bush in 1945, science was assumed to be a largely unquestioned public good which would serendipitously yield new discoveries and technologies that would, in turn, enhance defense capabilities, economic development, and social well-being. In many countries, therefore, science policy in general and its application to university finance, governance, and evaluation enjoyed a form of benign neglect. Universities received funding for research accommodation, equipment, and materials from national

authorities mainly on the proposals made by the academics who would use them, without much, if any, reference to national priorities or objectives. These proposals would be driven by academic curiosity. Such criteria that applied were those of the perceived research excellence of the applicants, perhaps interrogated by systems of peer review. Academic research staffing was usually funded by what was required for their other key function – the education of students.

The fact that there were no declared policies did not mean that academic work made no contribution to economic and social development, and two world wars helped to accelerate the demands for relevance. In the UK, for example, a national physics laboratory was founded in order to bring scientific knowledge to bear upon industrial and commercial practice, and, in 1918, the Haldane report asserted the need for research which could support the activities of government. However, the idea of a deliberate science policy was explicitly and repeatedly rejected.

The 1970s brought a turning point. Governments became more directive on science policy. Science became an increasingly important but less distinctive component of public policies, in consequence of which scientists lost some of their authority and autonomy and universities some of their exceptionalism.

The drivers of these developments were multiple and interconnected. Conceptions of the nature of science, its modes of production, and its functions in societies shifted with the emergence of knowledge societies and knowledge economies. A new generation of industries appeared, characterized by synergy between research universities and rapid technological advance. A wider set of changes generated new conceptions of the state and its administration. The 1970s saw radical reappraisals of Keynesian economics and the growing influence of neoliberalism. Arguments for limiting public expenditure and increasing the role of the private sector became powerful forces. They are evident in new forms of public management, involving a blurring of the boundaries between the state and the market. All these developments had implications for relationships between universities and both the state and other sectors of society, notably industry and commerce.

In the last two decades, the internationalization of higher education and research, in the form of cross-border collaborations between academics and their institutions, has accelerated. The influence upon national policies of economic globalization has grown, challenging the power of the nation-state and, ultimately, national policies, too.

[†] Deceased

Changing Assumptions About Science and Science Policies

There were intimations of change in the 1960s. De Solla Price's pioneering work in scientometrics, demonstrating the exponential growth of science, laid the ground for governments to introduce more rational methods of resource allocation in this field. In 1971, the Organization for Economic Cooperation and Development (OECD)'s landmark Brooks report, asserted the need for governments to set the direction of science and its funding within a framework of economic and social goals.

With the emergence of knowledge societies, science has come to be seen as a prime strategic resource in the race for economic competitiveness but it has also been exposed to wider social criticism. Scientists, indeed the academic profession as a whole, began to be regarded as an interest group whose demands might be measured against other contending interests.

Distinctions between basic or curiosity-driven research and applied research were blurred in the introduction and growing importance in public funding of strategic or potentially exploitable research.

Foresight policies were adopted in a number of countries in the 1980s. They entailed bringing together scientists, industrialists, government officials, and others to identify strategic research areas and emerging technologies with most potential for commercial exploitation or social benefit (Martin, 1996).

Clearly, long-established boundaries and distributions of power in the governance of science were being broken down. Boundary blurring was evident in new conceptions of knowledge production. Technological innovation was perceived as more directly dependent on and often intertwined with scientific practice. The science-technology relationship began to be characterized as a dynamic system involving connections and feedback loops between multiple parties, academic and industrial, users as well as producers of innovation. Gibbons and his colleagues discerned a radical shift between two modes of knowledge production, from mode 1 (knowledge generated within disciplines) to mode 2, transdisciplinary knowledge, created within a context of application. This formulation has been criticized on the grounds that such a polarized framework is oversimplifying and fails to recognize scientific diversity and the past importance of contexts in many fields. However, it has been an influential reference point both in the academic literature and among policymakers.

National Science Policies

First, a theme now common to developed and developing countries across the world is the belief on the part of

governments that research and development (R&D) are essential to national economies.

The new surge of economic instrumentalism on the part of governments has several concomitants. While the USA has in the past been distinctive in its unequivocal commitment to competitive allocation systems for research monies, such systems have now been widely embraced, including by some mainland European countries, traditionally committed to equality of status for universities. The purpose is, in part, efficiency but, even more, the support, through concentration and selectivity, of research excellence, is seen now as the key to technological innovation.

The movement toward competitive allocation emerged earliest and most evidently in the UK's research assessment exercise (RAE) but was followed by Australia's competitive assessment of the research quantum. Research councils were historically the providers of resources for researcher-inspired work. Now in both of these countries, they specify priority areas which accord with those determined by central government. Australian Research Council funding is directed largely toward four areas. Hard science priorities predominate and social sciences and humanities are incorporated in them (Meek *et al.*, 2010). A recurrent theme is that funding of applied and strategic R&D has increased, at the expense of pure or basic research.

An almost universally evident policy has been to encourage close working relationships between universities and businesses. Major objectives here have increasingly crystallized round the advancement of innovation. Policies emphasize the role of universities in the development of small- and medium-sized enterprises (SMEs), widely seen as sources of technological innovation, and encourage university-industry partnerships in educational as well as research activities. Governments seek to endorse substantial changes of beliefs in universities and business about the purposes and production of research in societies and the need to enhance research capacity in industries: the functions of doctoral education are now generally seen as extending well beyond the reproduction of the academic profession. Governments want more rapid technology transfer, other forms of knowledge transfer, more exchange relationships, and more collaborative production of knowledge between businesses and academic institutions.

A second major set of objectives in policies designed to bring universities and business closer together has been to encourage industries to take a greater share of the financing of research and universities to engage actively in markets and reduce their dependence on public funds.

The context of all these policies has been an overall decline in the public funding of universities, simultaneous with the increase in the demands upon them. Financial incentives and sanctions have been probably the most potent of the instruments adopted by governments in the science policy arena. Output-based performance measurement, national systems of evaluation, and quality

assurance have also been increasingly important tools for change in universities, even if the direct linkage between evaluation and funding established in the UK RAE has not been widely followed, at least until recently.

The growing use of such policy instruments is one dimension of new models of public sector management. Governments have established clearer direction for higher education and science policies: many, for example, require universities to submit research plans. However, they have sought, too, not only to reduce universities' financial dependence on the state but also, at least in policy rhetoric, to eschew mechanisms of detailed state control. Universities have been encouraged to enhance their capacities for strategic decision making, albeit within strong national priorities, and to replace collegial with managerial modes of governance, although this trend has been taken further in Anglophone countries than in mainland Europe.

The developments outlined represent the loosening of boundaries between the functions of universities and industry, and the blurring of distinctions between public and private funding and the roles of the state and the market in science policy. However, governments have also encouraged academics and universities to move further into academic capitalism. Slaughter and Leslie adopted this term in the mid-1990s not only to denote academic movement into markets to seek external funds but also to signal the encroachment of the profit motive into the academy and the potential it created for contradictions between public and private sector cultures in the research environment.

This is most clearly demonstrated in the widespread changes in the laws governing Intellectual Property Rights (IPR), led by the USA (Bayh Dole Act 1980) but followed by the UK, Australia, and some mainland European countries. As a result, universities were freed to claim IPR over new knowledge developed in state-funded research projects and significantly enhance their patenting and licensing activities. Individuals and institutions have also been encouraged by governments to form their own spin-out companies to capitalize on their discoveries, although, again, this trend was established earlier in Anglophone countries.

Science policies based on the idea of the knowledge economy are increasingly widely diffused across the world, including in the rising economies of Latin America, India, China, and others in the Asia-Pacific region. China, for example, has seen an exponential growth in the funding of research and development by government and, even more, by industry. It is now ranked fifth in the world on the measure of its share of scientific publications and is moving rapidly toward its goal of a successful knowledge-based economy.

In the space available, it is not possible to examine movements in higher education research in the developing world. Certain features are, however, common to such

systems. None can draw on resources comparable to those available to the countries of the north and west and they devote significantly smaller proportions of their gross national product on R&D. India, for example, allocates .69%, Brazil, .82%, and China 1.4%. As Zakri indicates, capacity development is a prime task for such countries. The overriding objective is to produce R&D that is relevant to economic and social needs. This may leave little or no research and scholarship in the humanities or social sciences.

It is increasingly difficult to discuss national science policies without reference to transnational organizations and policymaking. The European Union (EU) is a prime example. It is now a growing influence upon the national science policies of all European countries, including non-members of the EU, as it seeks to align EU and national science policies and create a Europe of knowledge through an integrated innovation agenda, incorporating higher education and research (van Vught, 2010).

State–University Relations

Science policies have been major triggers of change in the functions of universities in nation states. Key issues are their meaning for academic autonomy and for authority and dependency relationships between states and universities, which are complex and sometimes paradoxical.

Theorists of the postindustrial society predicted that universities would become axial structures of the emerging knowledge societies. National policies have reflected this view in the roles allocated to universities and in the more explicit requirements that they help bring about economic transformation.

In some countries where higher education and research activities are subject to both a federal and a state or provincial authority, shifts in the balance of that authority reflect their growing national strategic importance. In Australia and Canada, the federal authorities have increasingly occupied a more dominant role in the financing of and policies for research, and some have given tax concessions to industry engaged in research. Soft federalism has given way to direct funding and a panoply of guidance and instruction. In the USA, while the system remains loosely tied together, both federal and state funding has increased; an important feature is the extent to which some states seek economic advantage by financing research, most often in the burgeoning biomedical fields. Germany has both enhanced the federal financing role and yielded detailed powers to the *Länder*.

An increasingly influential conceptualization of changed relationships among universities, government, and industry, particularly in regional policies, is Etzkowitz and Leydesdorff's (1997) triple helix. The development of regions of knowledge is seen by national governments, as

well as by the EU, as critical to the growth of national economies in a global context. It constitutes a strong example of universities, governments, and businesses combining to construct a common goal, which they could not achieve by operating separately. Universities are often the initiators of such region-oriented ambitions and invest substantially in their realization.

Prima facie, universities' decreased financial dependence on state funding gives them more autonomy through greater diversity of funding and the freedom to compete in a range of markets, according to their chosen missions and specific strengths.

However, most remain substantially dependent on public funding. As such, their choices are structured by national priorities that privilege particular types of research, notably strategic research, in particular fields, such as life sciences, nanotechnology, and information and communication technologies.

Universities are more publicly accountable and while evaluations of their work are still carried out largely by peers, their achievements are measured against criteria reflecting the needs of the state as well as academic judgment. In some countries, notably the UK and Australia, they are subject to performance indicators and given guidance backed in differing degrees by persuasion and incentives.

Several components of public policies combine to support inequalities in the power and dependency relationships between the state and universities. In some instances (e.g., mainland Europe), they create and in others (e.g., the UK and the USA), they reinforce the stratification of universities in terms of reputation and command of resources. Larger and older institutions are more heavily represented among the beneficiaries of national and EU selective and competitive funding. High performers in national evaluations not only enhance their reputations but also are more successful in securing funding and partnerships in the private and nonprofit sectors.

Policies promoting university–industry links may have the opposite types of effect for financially weaker and less-established universities. They may have to accept funds for developing routine contract research that do not cover their full costs and then to recoup these from their public funding. This is likely to weaken them further: partly because research strength needs money and partly because it shifts the balance of their research effort away from more prestigious forms of research.

Meanwhile, as national and transnational policies contribute to the growing power of the strongest universities, they also loosen the relationships between these institutions and their nation-states. Most European states encourage their universities to take advantage of the EU framework funding programs, which reward generation of international networks and other forms of international collaboration between universities and also between universities and innovative industries. These funds, undoubtedly have a

powerful leverage effect on universities' research planning, despite being relatively small as a proportion of total funding. (The sixth framework program, for example, represented only 5% of the total expenditure on research by EU member states.) Advantageous in themselves, they may open up further international funding possibilities and orient institutions toward global markets. Similarly, national policies fueling some of their institutions' ambitions to join the ranks of newly defined world-class universities may encourage them to become more distanced from their national identity.

The University: Institutional and Epistemic Issues

Changes in national policies since the late 1970s have implications for university functions, structures, values, and modes of knowledge production.

There has been a quantum leap in the number and types of links between universities and industry, beginning in the USA, although both there and in the UK, big increases in research collaborations anticipated the major national policy measures (Dill, 2010; Calvert and Patel, 2002). The concept of a third task, additional to research and teaching and broadly defined in terms of knowledge transfer beyond their own boundaries, is increasingly prominent in university missions. Policy changes stimulated a large, if differential, rise in licensing and patenting activities and substantial growth in the formation by individuals and institutions of spin-out companies.

These have been powerful influences in the adoption by universities of more corporate and managerial regimes. There is a general trend toward a concentration of authority at the center, but universities with strong research reputations sustain more collegial or interactive styles of management than others.

However, academics no longer have a monopoly of influence on university culture and organization. All universities have incorporated a more diverse workforce, including an enlarged group of (in Rhoades' terms) managerial professionals, staff with advanced degrees and qualifications who are neither faculty nor senior administrators. Faculty were no more than 30% of all personnel on US campuses and 55% of all professionals in 2006, down from 65% just two decades earlier.

Related phenomena are the growth and diversification of interstitial structures in universities to cope with new functions connected with income generation, knowledge transfer, academic capitalism, and mediation between public, private, and nonprofit bodies at local, regional, national, and international levels.

Academic work, too, has been subject to substantial structural change. National policies for research selectivity and concentration have been replicated by universities,

resulting in the abolition of some departments, the reconfiguration of others and, most notably, the proliferation of different types of basic units superimposed on departmental structures. Indeed, increasingly, universities regard these interdisciplinary and transdisciplinary research institutes and centers, with their associated graduate schools, as their flagships.

These developments are regarded by some as fragmenting discipline-based structures and relationships within universities, undermining the knowledge base and exacerbating already strong pressures for separating research from teaching, particularly at first-degree level, responsibility for which may remain with departments. Research suggests that academic values and identities remain strongly rooted in disciplines, which are still widely seen as providing the foundations of innovative research. However, against this, it is argued, first, that many successful researchers see no contradiction between strong disciplinary identities and agendas and interdisciplinary collaborations; second, that the latter generate new forms of integration and new epistemic communities, reflecting both changing internalist constructions of knowledge and externally defined problems or needs.

There is no doubt that universities have embraced activities and working relationships which challenge long-held assumptions that academic and industry-based scientists belong to two knowledge-production systems with, according to Dasgupta and David (1994), distinct, if not contradictory sets of goals, norms, rules, and rewards, those of academic or open science and those of for-profit or proprietary science. Academic science operates a reputation-based reward system, geared to the production of public knowledge. Academic scientists compete for authority in their fields, through primacy in defining and solving scientific problems. They have seen the university as according them the freedom to choose their own agendas and the prestige associated with curiosity-driven research. These views remain strongly represented among university researchers, even where their leaders are promoting commercialization and social engagement. However, in industry-based science, the rewards are financial, firms set the agendas, and the goal is private knowledge. Hence the norm of secrecy is paramount.

Dasgupta and David argue that a shift toward such norms in universities might undermine the existing (not perfect but functional) complementarity between academic and proprietary science. A reduction in academic freedom and opportunities for curiosity-driven research, combined with greater emphasis on financial rewards, might seriously erode the attractions of academic careers and so threaten not only new research directions but also the flow to industry of well-trained scientists perceived as essential for industry's capacity to exploit new knowledge.

Others take a different view about the collapse of well-established boundaries, between academe and industry and public and private knowledge regimes. They argue that revolutionary changes are occurring in

the production of knowledge but that it is possible for universities to manage the resulting contradictions. Research on the implications for academic research standards of university entry into the commercial arena shows that academic and commercial success can be mutually reinforcing: the most active collaborators with industry are also, largely, the highest ranking research universities, although lower ranked universities may work with industry in limited specialist areas. However, according to Owen-Smith (2005), universities have to learn how to make commercialization work so as to sustain academic freedom and creativity and make money. Over time, the number of academic publications declines with continued pursuit of high-volume patenting. A minority of universities have realized they need more sophisticated strategies, focused on high-impact patents, which are positively associated with high-impact academic publications.

This study reinforces but sharpens the research indicating that national policies may have exaggerated the financial rewards to universities from academic capitalism. In most universities in the US and the UK, the costs of administering technology transfer offices (TTOs) outweigh the income generated, although in the US this is less true of well-resourced and private universities. High returns depend heavily on a few highly marketable discoveries.

These findings seem to support an argument put forward by Geuna in 1998 that has profound implications: that the challenges of a new era are opening up an unbridgeable gap between universities; only a few elite research universities will fully adapt to the new demands and also manage to retain some of the assumed defining features of universities; and many will be marginalized and little influenced by international changes in the production of knowledge.

As yet, nevertheless, significant uncertainties remain about what such changes may mean for the future of universities. More systematic analysis of emerging categories of university is now beginning to take us beyond rather crude observations of enhanced stratification. But most research on the consequences of new modes of working still concentrates on highly ranked institutions and basic units. Not enough is known about the others, although, according to Mansfield and Lee, significant contributions to innovation in major US firms came from them in the mid-1990s.

Given that the major advances into commercialization are confined to a handful of scientific fields, that national and university commitment to curiosity-driven science, the humanities, and the social sciences has declined and that the status of mode 1 knowledge production is uncertain, there is important research to be done on the consequences for what might be called the epistemic ecologies, as well as the institutional identities, of all but possibly the most well-endowed and academically prestigious institutions. There is now a growing sense of the need for more collaboration between higher education studies and the social studies of science, if significant progress is to be made on such research questions.

A final research issue arises from the fact that the balance of academic literature on science policy remains heavily weighted toward the OECD countries, although science is now a key component of most national policies.

Conclusion

The story related here is of great change. Professional autonomies have been confronted by determined policies of what has been conceived as the public utility. Much academic freedom may remain but unequally distributed and conditioned by priorities, mediated largely through funding and established in the polity rather than academe.

Policy is substantially based on neoliberal concepts of economic progress. The age of Keynesian deficiency funding has given way to the imperative to act as if in a market place. Yet, there is a paradox here. Along with liberal declarations about institutional freedom and the need for diversity have come increasingly tight policy frameworks, making for greater uniformity and imitation.

Intensified attempts to engage universities with the private sector, together with reduced support for basic science, the humanities, and the social sciences, have raised large questions about the university as an institution and the nature of its contributions to societies.

Research Commercialization

S Slaughter, University of Georgia, Athens, GA, USA

© 2010 Elsevier Ltd. All rights reserved.

As more and more students attend post-secondary education and state support per student declines, faculty, administrators, trustees, regents and state officials are searching for ways to expand university revenues. One strategy is commercialization of research. To maintain or expand resources, faculty are increasingly encouraged to compete for external dollars tied to market-related research. Market-related research is referred to variously as applied, commercial, strategic, and targeted research. The external monies at which commercial research is aimed come in the form of partnerships with industry and government, technology transfer, royalties and licenses, equity holdings in faculty start-up companies, and income related to incubators and research parks. Another strategy for securing external dollars is through the marketing and sales of educational products and services, ranging from learning enhancement tools to digital education. Generally, institutional and professorial market or market-like efforts to secure external monies can be conceptualized as academic capitalism.

This article focuses on a single aspect of academic capitalism: commercialization of research. The following topics are covered: broad policy changes that made research commercialization possible; patents; start-up or spin-off companies; research parks and incubators; copyright; and the infrastructure required by universities to manage research commercialization. Although the article is comparative, the focus is on the United States because it has led research commercialization.

Policy Changes

Academic capitalism depends on the rise of the neoliberal state, which now characterizes English-speaking industrialized countries such as Australia, Canada, the United States, and the United Kingdom. The European Union (EU) does not embrace neoliberalism as closely as the English-speaking countries, but is in the process of adopting many of its practices with regard to higher education generally and research commercialization, specifically. In the United States, research universities came to maturity after World War II, during the great expansion of post-secondary education in the 1950s and 1960s, in the era of embedded liberalism. Embedded liberalism was a reaction to classic liberalism and sought to constrain capitalism to avoid depression, poverty, and social unrest. To achieve these ends, social and political oversight, regulatory and

planning functions were embedded in the state. The common goals of embedded liberal states were full employment, economic growth, and the welfare of the citizenry. If necessary, the state intervened in market processes to reach these goals. Keynesian monetary policies were characteristic of the embedded liberal state.

In contrast, neoliberalism is:

...a theory of political economic practices that proposes that human well-being can best be advanced by liberating individual entrepreneurial freedoms and skills within an institutional framework characterized by strong private property rights, free markets and free trade. The role of the state is to create and preserve an institutional framework appropriate to such practices (Harvey, 2005).

Although neoliberal theory minimizes the role of the state, in practice state subsidies and oversight are not minimized; rather they shift to new areas. In particular, and important with regard to higher education, subsidies shift from broad general appropriations for the public good – for example, low tuition – to user taxes and fees – for example, high tuition – which emphasize individual rather than social gains accrued as a result of higher education. In general, higher education shifts from a public good knowledge/learning regime to an academic capitalist knowledge/learning regime. The academic capitalist knowledge/learning regime would not be possible without the neoliberal state. However, the relationship is bidirectional and higher education is in many respects the exemplar neoliberal state agency in that it is flexible, entrepreneurial, and essential to the maintenance and expansion of a knowledge economy.

The history of public policy in the United States illustrates the rise of the neoliberal state in research commercialization. Prior to the Bayh-Dole Act (1980), federal policy in the United States placed discoveries made with federal grant funds in the public domain. Although universities were permitted to secure patents from the federal agency that funded their research, a relatively small number of universities patented by engaging in this process. The 1980 Bayh-Dole Act signaled a more general encouragement of university research commercialization. It gave universities title to inventions discovered with federal research and development funds. Bayh-Dole made university technology transfer to the private sector an important outcome of federally financed research, and allowed exclusive licensing of publicly funded research to achieve that policy goal.

The Bayh-Dole Act gave new and concrete meaning to the phrase “commodification of knowledge.” As potential patent holders, university trustees and administrators require faculty to disclose all research that can be protected intellectual property. Faculty begin to conceptualize their discoveries as products or processes, private, valuable, and licensable, not necessarily as knowledge to share publicly with a community of scholars.

The Bayh-Dole Act, for which representatives of research universities and business lobbied intensively, was only one piece of a broader bi-partisan competitiveness strategy developed by the US Congress. Beginning in the 1980s, an array of legislation – ranging from research tax credits to technology transfer – was passed that laid the ground work for the competitiveness coalition. For example, the Federal Courts Improvements Act (1982) created a new Court of Appeals for the Federal Circuit (CAFC) which handled patent appeals from district courts, thereby ending forum shopping in intellectual property cases, creating a more uniform approach to patents. The new court led the way for a greatly strengthened approach to intellectual property, which eventually allowed patents on genetically engineered bacteria, genetically altered mice, particular gene sequences, surgical methods, computer software, financial products, and methods for conducting auctions on the World Wide Web.

Similar changes occurred in the United Kingdom, beginning under Margaret Thatcher’s government, and in Australia, under the Hawke government. Canada lagged behind, but in the 1990s neoliberal policy at both the provincial- and federal-level policy heavily promoted research commercialization. In the 2000s, the EU began a research commercialization program, drawing heavily on the models provided by the English-speaking countries.

Patents

Prior to 1981, fewer than 250 patents were issued to US universities per year. The number of new patent applications more than quintupled between Fiscal Year 1991 and Fiscal Year 2003, indicating the growing effort and increasing success of universities in obtaining patent protection for their technology. The number of institutions awarded patents increased by more than 60% (to 198) between the late 1980s and 2003. Both public and private institutions participated in this rise. Success in obtaining patents seems to depend more on other resources, which are discussed below under infrastructure.

Despite the increase in institutions receiving patents, the distribution of patenting activity has remained highly concentrated among a few major research universities. Among the top 100 research and development (R&D) institutions, the top 25 recipients between 1994 and

2003 accounted for 55% of all academic patents in 2003, a share that has remained constant for two decades. Including the next 75 largest recipients increases the share to more than 80% of patents granted to all institutions since 1987. The growth in academic patents occurred primarily in the life sciences and biotechnology. Of the top 100 US research universities, ten institutions generated 66% of profits received from technology licensing. Less research-intensive institutions with small technology licensing programs or institutions that are new to technology licensing generally experience annual losses.

The EU demonstrates a similar pattern. Although the growth of university owned and invented patents has increased, university licensing is not profitable for most universities. The success of a small number of institutions may have exacerbated the differences among universities within the EU with regard to resources for research and development.

US universities responded to the changing policy opportunities by developing intellectual property policies that simultaneously offered powerful incentives for faculty to patent and expanded institutional control over intellectual property.

Royalties

The various US university patent and/or intellectual property policies offer a wide range of royalty splits among faculty, department and/or college, and university. The most generous policies split royalties with faculty 50–50. At the bottom of range of royalty splits, faculty receive one-third of the royalty income. Private universities tend to be less generous than public ones, with many offering faculty one-third of the income from their licenses. When policies change over time, they usually give faculty a lower percentage of royalties. Whether it is one-third or one-half, the incentives for faculty are powerful.

Personnel Coverage

In 1970s and 1980s, a number of patent policies covered only inventors. By the mid-1990s, they included faculty, staff, graduate students, post-doctoral fellows, non-employees who participate in university research projects, visiting faculty and, occasionally, undergraduates. If these personnel engage in research that might lead to an invention with market potential, they are required to disclose it, so an institutional decision about ownership and patenting can be made.

Exceptions

US universities had long claimed ownership of discoveries made by faculty; the decisive court cases were heard in

the 1950s. However, initially, there were exceptions to universities' ownership claims to intellectual property patented by faculty. If faculty made the discoveries on their own time, using their own resources, and not availing themselves of university facilities, they could claim a patent for themselves – for example, if they invented something in the summer, in their garage work room. As the academic capitalist knowledge/learning regime developed, definitions of time, resources, and facilities use were specified to the point where it became very difficult for faculty to assert any claims to ownership of invention. For example, policies frequently have guidelines that indicate that if researchers or other personnel use anything but routinely available office equipment and commercially available software or library materials generally available in nonuniversity locations, they are making substantial use of university resources and therefore the university owns the intellectual property.

Initially, state system and institutional policies addressed only patents. Over the years, the forms of intellectual property covered multiplied. Among those included were: licensing income, milestone payments, equity interest, mask work, which charts the topography of a semiconductor chip product, material transfer agreements, tangible property (cell lines, software, and composite matter), trade secrets, and copyright.

The multiple forms of market activity pursued by universities together with faculty's close involvement in them created many opportunities for conflict of interest. Factors that increase the possibilities of conflict of interest for faculty are: increased magnitude of personal compensation; growing numbers of financial relationships between a creator and a company; greater commitment of a faculty's time to a company; faculty or administrators holding equity in a company; involvement of trainees or students in a company; and involvement of patients or human subjects in company research trials. In other words, the risk of conflict of interest increases the more closely faculty members or creators of intellectual property are involved with market activity. Conflict-of-interest policies have proliferated and become more detailed. However, few call for close monitoring of faculty or institutional administrators, suggesting the primary purpose of such policies is to protect institutions from liability in legal cases.

Start-Up Companies, Research Parks, and Incubators

As universities became involved in research commercialization, they began to be regarded by state and federal policymakers and institutional leaders as engines of economic development. Universities became the center of a cluster of economic activities directed toward economic

growth in the state or region in which they were located. Licensing of inventions to local and regional companies was at the core of economic development activities, but start-up companies, research parks, and incubators also grew rapidly. These latter activities were seen as a way to spur regional economic development, particularly growth of high-paying jobs.

Start-Up Companies

Start-up companies began to increase rapidly among research universities in the 1980s. Start-ups are new companies dependent on licensing institutions' technology for their formation. Sometimes universities take an equity position in these companies. The investment can be limited to free use of the license, or can involve cash, or arrangement of venture capital partners to fund the company.

The number of equity deals spread rapidly among research universities. In 1994, the first year the Association for University Technology Managers reported such data, there were 175 start-up companies in US universities; in 2001, 402 new start-ups were reported. Equity provides several advantages over licensing: it gives universities options or financial claims on companies' future income; equity deals align interests of university and firm with regard to rapid commercialization of technology; and it signals to interested investors the universities' certainty about the worth of the technology. If the start-up company is successful, it moves from being privately held to being opened to public investment through an initial public offering (IPO), which greatly increases the worth of the stock of the company, and the monetary returns to the university. On the downside, taking equity involves risk of failure and loss of funds, while start-ups also often take up large amounts of faculty time.

Research Parks

University research parks generally house technology-based organizations or companies that seek to benefit from the host university's knowledge base and researchers. By housing the research park, the university encourages technology transfer. In addition to financial gain from technology transfer in which they are participants – for example, the research park may house university start-up companies – research parks often provide opportunities for students and faculty to participate in entrepreneurial science. The community and region gain if technology transfer results in economic development.

Research parks grew rapidly in the mid-1980s and a large number are currently in the planning states. Currently, there are 81 research parks associated with universities, and an additional 27 are being planned.

Information technology and biosciences are often the focus of research parks.

The contribution of research parks to economic development is unclear. The only studies of research parks to date account only for growth of employment within the park itself – about 8.4% over the life of a park. Approximately 50% of the parks were initially funded with public moneys, of which the public sector supported about 70% of initial park cost. Many research parks house activities unrelated to university research and development, in effect serving as a real estate operation on the part of the university, receiving income from rents.

Incubators

About 50% of research parks include incubators. In general, incubators foster start-up companies. As in the case of research parks, there are not a large number of studies of incubators. One study indicated that approximately half of start-up companies failed unequivocally in 3 years, while approximately 30% left the incubator and went out of their own. Start-ups with technology licenses from the sponsoring university and linkages to university faculty were less likely to fail, but less likely to leave the incubator at the end of 3 years.

Other Forms of Commercialization

Technology is arguably more reliably transferred to the market by means other than patents and other forms of university-owned intellectual property. Managers of industrial R&D repeatedly stress that the most important contribution of universities to innovation is training of scientists and engineers. They stress the importance of public research, highlighting transfer channels such as public papers and reports, conferences, informal exchange, consulting, and other forms of university–industry partnerships that do not depend on intellectual property. Patents are most important for the biological sciences, which account for the largest amount. They are less important in fields such as engineering, materials sciences, and computer science.

Copyright

The Telecommunications Act of 1996 dramatically altered the industry regulatory framework. Prior to 1996, the 1934 Communications Act, as implemented through the Federal Communications Commission, authorized separate monopolies: broadcast, cable, wire, wireless, and satellite. The 1996 Telecommunications Act deregulated these various industries, creating a competitive climate that favored

growth of the Internet, World Wide Web, and electronic (e)-business, all of which utilized previously separated communications media in new patterns. Deregulation of telecommunications created numerous possibilities for an academic capitalism knowledge/learning regime, ranging from software to distance education.

The Digital Millennium Copyright Act (DMCA) of 1998 protects digital property by prohibiting unauthorized access to a copyrighted work as well as unauthorized copying of a copyrighted work. The DMCA is far-reaching and covers an array of technologies, from web casting to hyperlinks, online directories, search engines, and the content of the materials made available by these technologies. Not only are citizens (and students) penalized for unauthorized access, but devices and services that circumvent copyright are also prohibited. The law very deliberately seeks to develop electronic commerce and associated technologies by strengthening protections of all forms of digital property. There are some exceptions, the broadest being for law enforcement and intelligence. The other exceptions are quite narrow.

US universities and colleges copyright some forms of software as well as educational products, tests and measurements, and other marketable products able to generate external revenues for colleges and universities. Examples are the Minnesota Multiphasic Personality Inventory, developed by the University of Minnesota and a video demonstrating minimal incision aortic surgery, developed at the University of Wisconsin. Most US universities now have copyright policies that claim institutional ownership of products created with university resources, all products developed by administrative personnel, and products stemming from work-for-hire contracts. Over time, university protection of intellectual products by copyright has become more inclusive.

Infrastructure

Commercialization of research entails considerable infrastructure development on the part of universities. Most universities now fund technology transfer offices, many also fund research parks and incubators and economic development offices. The managerial capacity in US colleges and universities has greatly expanded. The new functions are many: surveilling institutional employees' intellectual property activity to ensure capture by the system or institution through faculty disclosures; reviewing and evaluating faculty disclosures; technology licensing; supervision of royalty flows, including distribution of funds within institutions; reinvestment of funds in new market activities; litigation to defend intellectual property; evaluation of intellectual property for institutional equity investments; monitoring and occasionally administering corporations in which the institution holds equity;

overseeing IPOs; developing and monitoring market activity for conflict-of-interest issues. As colleges and universities become more involved in academic capitalism, they hire more managerial professional staff. Expanded managerial capacity institutionalizes business activity in colleges and universities by allowing segments to directly engage the market.

Studies of university income from intellectual property suggests that the following contributes to success: past interactions with industry; hiring and retaining star faculty; greater numbers of experienced technology licensing officers; close ties to venture capital prior to initiation of a start-up company; and a culture supportive of entrepreneurial endeavor.

Some related costs which are rarely included in cost-benefit analyses of commercialization of research are: establishment or expansion of arms-length organizations, usually foundations, that distance market ventures from public institutions, institutional research boards (IRBs), which approve research with human subjects, essential to clinical trials of pharmaceutical and medical devices products; administrative policy development, ranging from conflict-of-interest policies to ownership policies; and faculty time. Faculty time is consumed in several ways. For example, faculty participate on committees such as IRB advisory committees, intellectual property committees, and conflict-of-interest committees. When faculty are involved in start-up companies, or in incubator activities, they very often work closely with the new firm, taking time away from other forms of research, including grants writing, as well as teaching and committee work.

As the infrastructure for commercialization at universities develops in the United States, it articulates with dense networks in the broader society that support research. These networks range from the National Institutes of Health, and the other federal mission agencies that provide research funding, to hospitals, venture capitalists, state economic development agencies, and to small firms. Over time, these networks become more closely interwoven, promoting rapid commercialization through regional and national links. The union of graduate education and research in US research universities promotes interdisciplinarity that fosters innovation. In general, the US system is more heterogeneous than others. Europe, for example, has a less diverse group of public research institutions that works in narrower scientific areas, and lacks upstream public funding agencies such as the National Institutes of Health.

Conclusion

In general, academic capitalism promotes research commercialization that shifts the emphasis of universities toward graduate-level science and technology. This

occurs because of the infrastructure costs discussed above. Rather than becoming a source of funding for undergraduate liberal arts and professional programs, in which the large majority of students are enrolled, research commercialization usually calls for greater expenditure on infrastructure and perceived high-opportunity product investments. Although funds from research commercialization are returned to universities to support education and research, many universities have moved away from defraying general support programs and instead invest these funds in further commercialization efforts.

Through shifts in incentive systems, emphasis is placed on entrepreneurial research. One indicator is the dramatic rise in patenting by universities. Another is the flattening of scientific journal publishing rates. The number of science and engineering (S&E) articles by authors based in the United States has remained flat since 1992, even though real R&D expenditures and the number of researchers continued to rise. A similar shift was also seen in Canada, the United Kingdom, and the Netherlands. At the same time, a rapid growth of article citations in patents occurred. The growth of citations of scientific research in patents points to the close ties between research and products that are research driven, primarily in the life sciences. Taken together, the rise in patenting, the flattening of article production, and the growth of citations of science in patents suggest a realignment of the research system to promote commercialization.

Most of the literature on research commercialization appears in economics journals or in specialty journals, such as *Research Policy* and *Management Science*. This literature is focused primarily on S&E fields, especially activity in the life sciences, and on increasing innovation and economic development, and on expanding the revenue from university intellectual property. Generally, it takes the position that for economic development to continue, innovation to occur, and revenue to increase more institutional funds should be invested into the infrastructure described above. This literature does not address the university as an organization engaged in undergraduate education across an array of fields other than science and technology, nor does it directly address the critique of research commercialization, which has appeared in a variety of disciplines and also reaches across disciplines.

The critique of research commercialization points out that most research universities do not make money on technology transfer even though they expend substantial sums. Even among the top-rated US universities, only a small number generate a substantial revenue stream, and many of the infrastructure costs discussed above are not figured in the net costs. Even when research universities do generate substantial revenues, these are only a fraction of the grant and contract support from public and industrial sources. Patent and licensing income was \$850 million for

academic institutions in 2004, as compared to \$42 billion in support for grant and contract support for academic research and development.

Another strand of critique points to the erosion of the scientific commons through the expansion of private rights in intellectual property. This critique notes that rapidly published open science contributes to scientific advance. As the number of patents and copyrights increases, access to the scientific commons decreases, and at some point in the not-too-distant future, scientific advances may be slowed and innovation stifled. A related critique notes that as greater numbers of university scientists become involved in commercial research, the university loses its claim to represent disinterested knowledge. If the majority of molecular biologists serves on the boards of biotechnology corporations, how can these scientists and the universities that have invested in their intellectual property impartially judge the merit of the science? This critique makes the case that commercialization undercuts a central public function of universities: disinterested assessment of knowledge.

The broadest level of critique suggests that commercialization of research contributes to undermining public trust in universities. This critique suggests that commercialization of research may be funded by undergraduate tuition rises. As tuition has dramatically increased, so has the amount of funds research universities spend on research: institutional expenditures for research rose from 11% in 1972 to approximately 20% in 2004. High tuition for undergraduates without concomitant attention to them may cause the public to lose trust in higher education, which undercuts support.

Patents dramatically illustrate the growth of the academic capitalist knowledge/learning regime. Patents, licensing and running royalties, start-up companies, and universities' equity positions in corporations built on faculty patents are market behaviors that involve nonprofit institutions in profit taking. Yet, colleges and universities are not market entities because they do not disburse profits to shareholders. Instead, funds from external market revenues are plowed back into the institutions. In some ways, colleges and universities that patent are able to cross the traditional borders between public and private, engaging in practices that best meet their needs for generating external revenues. If patenting, which is expensive, fails to lead to licenses and royalties, the state bears the cost in the case of public institutions. Similarly, the start-up corporations initiated by universities are in many ways a form of state-subsidized capitalism. Start-ups are risky undertaking: only one in ten is likely to succeed. However, faculty and universities are spared the discipline of the market in that there are relatively few direct penalties for failure. Income from royalties and licenses are tax free, so long as the profits are returned to the university. Although patenting and technology transfer are generally portrayed

as a win-win endeavor, a relatively small number of large research universities are the only ones to generate substantial external revenues. For many smaller colleges and universities, the cost of maintaining a technology transfer office exceeds any revenues.

Research Quality Assessment

I McNay, University of Greenwich, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Quality of research is assessed at various stages: in reviewing proposals for project funding; within a team as work progresses; at output stage when reports are presented, or articles submitted for publication, or new drugs or inventions seek development funding; when outcomes are clear after research-based changes are made in policy or practice. Major programs by research councils, foundations, or governments can be reviewed.

Over the past 20 years, national processes for research-quality assessment have been introduced across the world, led by the United Kingdom and other countries with an Anglo-Saxon influence. The drivers for this development included massification, marketization, new public management, and the development of the evaluative (Neave, 1998) or regulatory (King, 2007) state. Growth in student numbers caused a shift in the concept of university academic staff from combining roles in both teaching and research, specifically where, as in the United Kingdom and Australia, binary systems were merged into unitary ones, or where professional-education institutions were funded by the same body as more purely academic ones, as in New Zealand. There was a perceived need to identify research active (= productive) staff so that funding followed function and performance. This was seen as part of a competitive strategy in a globalized knowledge economy where research becomes a commodity and outputs become assets (Broadhead and Howard, 1998). The results of the assessment then informed funding strategies or, indeed, broader strategic steering. Publication of results provided comparative quality data to inform customer choice and created competitive imperatives to improve performance. Such competition, either in bids or in the research-assessment game (Lucas, 2006), was followed by concentration of funds and a belief in a minimum critical mass of research groupings to attain world-class status. Research, therefore, became better managed and administered (McNay, 1997, 2007), though there has been continuous debate about the evaluative and regulatory frameworks for the assessment exercises, and even about definitions of research and therefore what should be included in any assessments.

This article covers only work done within academic contexts; work in the commercial world has a different set of conditioning factors and criteria. Different national approaches to recognition of research excellence in higher education (HE) are identified. It then considers more fully those HE systems with extensive evaluation

exercises – the processes used and the criteria applied. It records recent moves to international comparative exercises. Finally, it summarizes some of the critical issues arising from research on assessing the assessment and the responses by academic staff subjected to evaluation.

National Models

In the United States, public universities are not funded at federal level for research infrastructure. Branch *et al.* (2001) offer a primer on 11 different evaluation methodologies in use by different agencies and states (Michelson, 2006: 555). The only nation-wide evaluation is by proxy, through reputational rankings of research doctoral programs. Michelson identifies trends in research evaluation across major federal agencies, such as the National Science Foundation (NSF) and National Institutes for Health (NIH), that fund research and development (R&D), linked to a further purpose of such evaluations – justification of further, increased government funding to those agencies and their programs. That is a driving force for similar programs such as the European Union (EU) Framework or the agendas of the UK research councils as part of the government's comprehensive spending review. At the European level, Luukkonen (2003) identifies some difficulties in evaluating the EU Framework program, applicable also at lower levels: there are changing political agendas and the objectives are fuzzy. They embrace promoting competitiveness, and advancing cohesion, quality of life, job creation, and sustainable development in the member states. For particular programs, evaluation may even start by negotiating objectives and desirable outcomes, which suggests poor criteria setting at an earlier stage. The impact studies cited by Luukkonen suggest that many outcomes are intangible, and related to learning and networking, not to commercial or economic effects.

In the United States, the political agenda is also an influence, but, within a constantly evolving and shifting context for the evaluation task, set by the Government Performance and Results Act, Michelson detects moves to standardization and harmonization of methodologies across agencies with increasing use of quantitative data, particularly bibliometric analysis, but paired with a “renewed focus on utilizing qualitative indicators . . . to create more appropriate hybrid methodologies that can capture a wider range of variables related to a programme's performance” (p. 558). The European approach is more qualitative, using surveys

and interviews with participants on their perceptions of impact. Hybrid approaches will help avoid the trap of false precision (Lawrence, 2003: 261) and allow the most appropriate and relevant measures to be used. So, fitness for purpose becomes the quality criterion for *post hoc* evaluation methods; that should also, surely, be a major criterion for assessing projects at the proposal stage.

Key terms in these last two paragraphs – programs, projects, proposals, purposes, perceptions of impact – indicate an emerging framework for the focus of research-quality assessment. There are two other elements that come through in country studies: people and products, with the latter concerned mainly with output – publications, patents, licences, and other such artifacts – rather than outcomes – the impacts on the real world – which are harder to assess in terms of isolating cause/effect relationships and which may only be visible beyond the timeframe within which evaluation reports have to be prepared. The other key variable in many countries is the organization level on which the assessment focuses, when this relates to overall performance, rather than being program or project specific. Different approaches use a combination of product–each piece of output–people, using a portfolio approach, group–team, academic unit–field of enquiry/discipline, or institution.

The people-based processes range from Mexico and Spain to New Zealand. In the first two, individual academics put forward their portfolio for evaluation and accreditation after judgment by peers. This is organized through a national body. In Spain, this is the *Agencia Nacional de Evaluación y Prospectiva*. Submissions, which are voluntary, are made every 6 years and success means a small salary increment: 100 euros a month for all successful *sexenios*. Although the results are formally confidential, professors become labeled as *tres sexenios*, or however many they have completed – the process began in 1986.

In New Zealand, performance-based research funding was introduced in 2003, to replace funding related to student numbers, though student numbers still condition the total quantum of research funds available for distribution to institutions. It is compulsory for all academic staff to submit a portfolio, which is assessed within the institution with judgments submitted to a set of external peer-review panels for validation, resulting in a personal grade – A, B, C, R – where the last implies reject as not research active, or not at a recognized level. These personal-quality grades, again supposedly confidential, are aggregated at subject and institutional level and weighted in a funding formula that also takes into account quantitative data on research-degree completions and external research income in a ratio of 60:25:15. There has been an open debate on the first round of the exercise (Bakker *et al.*, 2006) but the second round of judgments proceeded before a formal review was completed.

In the smaller European countries, systematic research-quality assessment is usually done, if at all, at

institutional level. Sorensen (2003) notes the gentler touch in Scandinavia compared to the United Kingdom, as well as the greater emphasis in Denmark on innovation and interaction with the user community. For Norway, Larsen (2000) records the continuing tradition of institutional autonomy and academic freedom such that evaluation is at institutional level. The major concern among his respondents was about the use of research programs as a policy instrument, following the establishment of a single research council and encouragement from the ministry for research results to be documented and evaluated, as the governance of research responds to pressure for a more coherent policy frame.

Presentations to the United Nations Educational, Scientific and Cultural Organization (UNESCO) Forum on Research Management showed that across major world regions – Latin America and the Caribbean, Africa, Arab countries in the Middle East, and much of Central and Eastern Europe – research-quality assessment is done at input/bid stage or is conducted at institutional level related to staff promotions and internal strategic development and resource allocation. Little systematic assessment is conducted at the national level (Braddock and Neave, 2002; UNESCO, 2006).

In emergent economies in Southeast Asia, there is concentrated funding to achieve world-class competitive levels. In South Korea, this is the Brain Korea 21 project (BK21). This focused funding on selected departments with a resultant increase in publication productivity. In the People's Republic of China, two projects – Project 211 and Project 985 – had a similar aim, and process but with selected institutions, not departments. Full-impact studies are not yet available for either country, and both have had a surge in student numbers putting extra pressure on the system. There are concerns about the criteria for selecting the favored institutions, with Kim (2007) recording the Matthew effect in Korea – to those who have will be given, from those who have not will be taken away the little they have. For China, Lai and Lo (2007) have concerns about the impact on decisions of *guanxi* – social and professional network connections and contacts, so that who you know is more important than how good you are. That, of course, is true in many other countries where an established cadre of researchers controls who can join the club.

Institutional audit locates research evaluation in a whole institution context, and so can link it to teaching, enterprise, knowledge transfer, and the environment in terms of facilities. Often, such linkages are not made (McNay, 2009: 38), and research is evaluated in isolation from its contribution to teaching, to the student experience, and to economic, technological, or social improvements, or even to research-related activities such as collaborative links, capacity development beyond the university, or developmental engagement with practice. There is a growing body of work giving evidence of

the essential relationship between research and teaching (Southampton Solent University, 2007).

Campbell (2003) examined four countries and classified them as types A and B. The type A two – United Kingdom and Netherlands – have comprehensive ex-post research evaluations, covering and addressing all disciplines at national level (p. 98). In Germany and Austria – the type-B pairing – he found a contrasting approach: pluralized and situational with a variety of individual and *ad hoc* evaluations (p. 113). He put Finland and Switzerland close to the type-B cluster. There was no correlation between approaches and the percentage of research funded from general university funds, which in Austria and the Netherlands was over 70% and in the United Kingdom was below 40%. In Germany and Switzerland, as in the United States and Canada, infrastructure funding comes from the canton, province, or state, not the federal governments, which fund major projects. Von Tunzelmann and Mbula (2003) detected an emergent interest in federal-level assessment in Canada. The situation in Germany is also changing. The German Research Foundation (DFG) has published periodically a ranking of research institutions based on funding approvals. There is now to be a rating exercise, every 5 or 6 years using a seven-point scale decided by expert panels, and influencing future funding. This comes close to the UK model. In Pakistan, there is a ranking exercise, with research output as one criterion. Results are not made public, but individual heads of institutions are given their position against each criterion, in an attempt to promote development through competition based on benchmarking.

Campbell noted a trend toward increasing funding through programs and projects, allowing research to be tied more closely to strategic national priorities. That is true across most countries and is manifest in the development of institutional contracts – Finland, Denmark, and Germany – or in designation of centers/networks of excellence – Switzerland, Norway, Japan, Australia – where continued funding is dependent on satisfactory evaluation. In South Africa, most research funding is from national-level state agencies, linked to nation building and renewal. Sweden is one country still resisting this close alignment, and does not tie funding to output-based evaluation. Ireland, despite a tenfold increase in R&D spending over the past decade, is another country not yet embedded in performance-based funding. Student numbers are still a dominant conditioner of funding in countries such as Italy and Hungary, and it is worth noting that a major element in the Finnish contract is the number of completed research degrees.

Trends noted by von Tunzelmann and Mbula (2003) include:

- A shift to formative evaluation linked to prospective funding.
- The increased use of international comparators – benchmarking or bibliometrics, though both have underdeveloped theoretical and processual bases, with only the Flanders region of Belgium having developed any level of sophisticated use of bibliometrics, and then only for a limited range of science-based subjects. Norway is moving to make increased use of them for research funding decisions.
- Greater emphasis on institutional self-evaluation. This often has a three-stage process of internal evaluation, external peer assessment based on that self-evaluation, and a final public report agreed between the institution and the external government agency. That is the model in the Netherlands, France, Switzerland, and Norway.

Those trends may be a balance to shifts to performance-based funding (PBF). The Netherlands and New Zealand are moving to join countries in which PBF is well established, such as the United Kingdom, Poland, Slovakia, Hong Kong, and Australia. The difficulty, then, is to separate the impact of esteem based on the quality rating from the impact of the economics of selective funding. A study of South Africa by Auf der Hyde and Mouton (2007) shows a decline in output per person and a withdrawal of some staff from assessment after the link of funding to performance was discontinued. Himanen *et al.* (2009) used longitudinal Organization for Economic Cooperation and Development (OECD) data on five countries – Netherlands, United Kingdom, Norway, Finland, and Australia – to conclude that:

There is no straightforward relation between the competitive funding environment and research performance . . . The impact of incentives on research performance appears to be quite short-term and sometimes even negative. However, the model of state steering does have an effect. The institutional steering model, which emphasises university independence from the state, seems to be the most beneficial to research performance. (p. 429)

The next sections provide greater detail on four countries with long-established systems and processes.

The Netherlands

In the Netherlands the national evaluation system for publicly funded research aims to improve research quality, to improve research leadership and management, and to provide accountability. Institutions – universities and other research organizations – conduct a self-evaluation every 3 years with external evaluation every 6 years. The self-evaluation documents look back 5 years and also forward 5 years, giving data on funding, staffing, research context and culture, researcher training (capacity building), esteem factors, collaborations, and external validations. The criteria used by the external assessment are

quality – indicators of recognition and identification of future potential for innovative work; productivity (output); relevance – impact on the scientific community and broader society; and vitality – quality of leadership and management. The resultant profiles are reputational and do not (yet) have any formal, direct impact on funding – the emphasis is on formative assessment. The process is now conducted by an independent foundation – Quality Assurance Netherlands Universities (QANU) – set up by the Association of Dutch Universities (VSNU). There are still five grades of quality, but with a shift to have four positives and only one negative, from a previous balance of 2 + 1 + 2.

Hong Kong

In Hong Kong, there has been a research-assessment exercise (RAE) since 1993 (Hong Kong University Grants Committee, 2006). It is conducted through panels of expert reviewers, based on cost centers and aims to inform decisions on funding. It applies a single threshold of quality – a level of excellence appropriate to the discipline in Hong Kong and showing evidence of international excellence. That threshold has been raised over the four exercises, the latest in 2006. The evidence presented includes an institutional self-assessment including a statement of research strategy including research philosophy, vision, and priorities in relation to the role and stage of development of the institution (the Hong Kong University Grants Committee (UGC) wants to promote institutional role diversity). Academic staff submit up to six outputs, identifying the best four, and one can be enough to satisfy the threshold requirements. They are assessed against all four of the Carnegie scholarships – discovery, integration, transmission/teaching, and application (Boyer, 1990). The quality criteria demand an element of innovation; a contribution to scholarship; public accessibility; generalizability; and an interest to peers. Research should support and illuminate teaching and learning, and outputs with social relevance are encouraged. Institutions should demonstrate sustainability of research work and evidence of deep collaboration. Results are confidential and no individuals are rated.

United Kingdom

In the United Kingdom, the sixth RAE took place in 2007/8, with changes from previous exercises and further changes to come after proposals presented as part of the 2007 budget speech by the Chancellor of the Exchequer (Minister of Finance), which points to the driving force behind the exercise. Previously, expert panels – over 60 – had rated four outputs per staff member submitted as being of international, national, or subnational quality, and arrived at an average grade for a unit of assessment,

usually an academic department. There was a seven-point scale depending on the balance of quality of output across those three categories. Funding was gradually withdrawn from all but the top two grades in successive exercises. Each unit also submitted a statement of research strategy and environment, and data on research degree students and research income, but the major element in judgment was the output. So, judgment was on individual output, grading was at unit level, and funding was to the institution with no requirement to allocate it to units or to staff who had generated it. The amount allocated was on a formula of V (number of staff, i.e., volume) \times SQ (the price per subject adjusted on a scale reflecting quality rating). Those last two elements were not revealed until after submission of bids, and the criteria for quality judgment were fuzzy; so much of the exercise was seen as a game (Lucas, 2006; McNay, 2003). If fewer staff were submitted, the balance of output could be shifted – the quality rating might be higher, but the volume multiplier was lower. Different panels operated different standards, and so choice of which panel to use was also part of the game. To add to complexity, funding decisions vary across the four constituent countries of the United Kingdom (McNay, 2007).

For the 2007/8 exercise, there were still panels, but output was given a grade profile, not a single average, and the overall unit profile was conditioned by separate ratings of environment and esteem indicators. Work was judged against three main criteria – originality, significance, and rigor. There were four grades (and an unclassified rating), ranging from world leading, through internationally excellent, but . . . , recognized internationally to recognized nationally. Every panel gave its own interpretation of those terms and also decided on the balance between output, environment, and esteem factors, with the first counting for between 50% and 90% of the final profile, and the other two between 5% and 40% each. Much time was invested in divining meanings of the policy texts. The assumption that funding would be restricted to the top two grades and further concentrated in a very small number of universities proved to be unfounded, with a commitment to fund excellence wherever it was found. The shift to profiling output, and away from a single grade for an academic unit showed that 17% of outputs were deemed world leading (4*) and 37% were internationally excellent. That total of 54% can be compared to the 2001 result, when 55% of individual academics were in units rated at 5 or 5*. The change was that, for 2008, 150 out of 159 institutions had work in the top category (Corbyn, 2008). There was a consequent shift in funding away from concentration on a few elite institutions, where four institutions received 30% of the resources allocated to a flatter, more widespread distribution.

A review of the 2001 exercise had found only four respondents from over 400 in favor of a move to using

an exclusively metrics-based funding system, mainly matching research income from external sources. A Treasury-led initiative subsequently proposed moving to such a metrics-based system for the future. Much agitated discussion has moderated that somewhat to a hybrid model, but there are hints of more emphasis on impact beyond academic circles (Corbyn, 2009b) – the political pressure, based on respect for the market is very evident. It is worth noting that, in the United Kingdom, the research councils were based previously within the government's department of trade and industry; the whole of HE is now within a super-ministry of business, innovation, and skills, with obvious implications for the priority functions of the sector.

Australia

Australia was moving in the opposite direction, after an expert group, chaired by the person who had reviewed the UK 2001 exercise, recommended adoption of something close to the UK model. The previous approach had resulted from a rejection of that approach in the light of evidence from McNay's work (Bourke, 1997; McNay, 1997). It had used three metrics as proxy for quality – number of publications, external research income, and research student numbers and completions. The new system (DAG, 2006) was to use panels to assess quality and impact. The quality descriptors echo those of the United Kingdom, with four acceptable grades ranging from world leading through meeting world standards of excellence, recognized internationally as excellent to methodologically sound . . . and of high originality, significance and rigor. Those three terms apply within all grades, and the top two also add reference to work of particular significance to Australia. Impact would be assessed separately and at longer intervals, also using a five-point scale. The top grade – A – was where “adoption of the research has produced an outstanding social, economic, environmental and/or cultural benefit for the wider community, regionally within Australia, nationally or internationally.” Next down, adoption has produced significant benefit. Level C has produced “new policies, products, attitudes, behaviours, and/or outlooks in the end-user community,” and the lowest recognized grade has “engaged with the end-user community to address . . . an issue.” However, after the politicians changed the policy, the people changed the politicians in 2008 and a further review is underway as this is being written.

International Initiatives

Since many universities now aim to be world class (Lang, 2005), a number of international comparative exercises have developed in recent years. Internal institutional evaluations may be informed by voluntary audits of

whole institutional performance through the European Association of Universities, or participation in benchmarking exercises through the European Centre for Strategic Management of Universities (ESMU). The Association of Commonwealth Universities also conducts benchmarking (Kirkland *et al.*, 2006). The OECD has a program on research management (Connell, 2004), as does UNESCO.

Shanghai Jiao Tong University produces an academic ranking of world universities (Ranking Group, 2004; Liu and Cheng, 2005), based on research indicators, such as prize winners among academic staff and alumni (including dead ones), articles in (only) *Science* and *Nature*, citations, using Science Citation Index (SCI) and the Social Science Citation Index (SSCI). Arts and humanities are excluded from the exercise. So, there are several criticisms of methodology (O'Leary, 2004; Harfi and Mathieu, 2007). UNESCO has set up an international rankings expert group to promote dialog on this topic among stakeholders (Merisotis and Sadlak, 2005; Merisotis and Leegwater, 2007) but there are many problems of comparability as well as methodology to overcome.

Key Issues

Those extended descriptions of diverse approaches serve to show the complexity of the task and the degree of prescription that can be imported into guidelines for making a complex judgment. In many cases there are concerns about criteria, processes, and evidence. The final section turns to some issues to consider for any extended process of research-quality assessment.

The first issue is the framework for judgment. What are the boundaries to research? How far should it be judged in relation to other functions that might be seen as discrete? Approaches based on whole institutional audit as in Ireland, Finland, or the Netherlands can make the linkages clearer in the self-assessment and allow fuller integration into corporate strategies. In the Netherlands, the process covers research units outside the universities. In Hong Kong, research evaluation links all four of Boyer's scholarships – of discovery, integration, transmission, and application. In the United Kingdom, the emphasis is on the first. There is specific separation of quality assessment of teaching from assessment of research. They are done by separate processes and neither informs the other. By contrast, in the United States, the NSF has a specific criterion in merit review of projects requiring integration of research and education; in New Zealand, the PBRF aims to enhance the quality of research-based teaching. In the United Kingdom, there have also been criticisms by the Education Ministry, Parliamentary Committees, and some research councils that the RAE approach gives too little weight to interdisciplinary work, applied work, and

to research derived from professional and practice contexts, despite the presence on panels of user representatives (McNay, 2007). In Scandinavia, more importance is given to innovation and links with practice related to application and knowledge transfer. The Australian approach, hitherto, has given greater emphasis to income from the market as a proxy measure for quality, linked to relevance and applicability, but this risks transferring control of the research agenda to one of short-term pressures demanding immediate results, and undermining basic, blue skies work. Harman (2005) suggests that academics do accommodate to such an environment and negotiate degrees of autonomy within it. The proposals for assessing impact, now overtaken by political change, had been considered an improvement in recognizing research users as legitimate stakeholders in assessing quality.

Autonomy is a second issue, especially when linked to funding. Research locates within an institutional framework and can be judged against its contribution to institutional strategic objectives. Projects funded within national or international programs will have fitness for purpose as a dominant criterion with the purpose defined within strategic priorities set within a wide socioeconomic policy framework. The twin issues, then, are how far such a criterion should also apply to other research, and to what degree the research agenda should be set by researchers themselves. There is, now, considerable evidence (MacGregor *et al.*, 2006; Morris and Rip, 2006; McNay, 2007) that assessment exercises affect the behavior both of researchers in their choice of projects and of research leaders/managers who set priorities within institutions and select staff for sponsorship and submission to the processes of assessment. Any link of assessment outcomes to PBF increases the impact on behavior (Liefner, 2003). Geuna and Martin (2003), having reviewed approaches in 12 countries, warn that PBRF may have initial benefits outweighing costs, but over time produces diminishing returns. They tabulate 15 factors under both advantages and drawbacks.

Among the claimed advantages are:

1. *Efficiency.* It is low cost; cuts out poor research; encourages discipline in completion and publication; and resource concentration through competition gives an incentive for improvement, with a meritocratic reward system for individuals that encourages inclusive engagement.
2. *Policy fit.* The accountability framework encourages a more explicit and coherent institutional strategy which can be linked to changing priorities, while allowing autonomy to researchers, diversity of practice, room for longer-term work, and support to links with teaching.

Their list of drawbacks challenges some of those items:

1. Resources may not flow to the best, with allocative power held by a small number of officials, which reduces incentives and motivation.

2. Rewarding past performance discourages innovation and can promote homogeneity, not diversity.
3. Links with teaching or policy priorities may be notional at best, and so may provoke further, excessive government interference to achieve objectives.
4. The process can be staff intensive and expensive.

A third set of issues revolves around the balance between formative and summative assessment, particularly if the latter has punitive financial consequences. There is some evidence from the United Kingdom, Australia, and New Zealand that lower-rated and lesser-funded units give better value for money (Grichting, 1996; Hazledine and Kurniawan, 2006), that their gearing between state funding and entrepreneurial income is better than for the elite few (Adams, 2005a, b), and that investment in improvement, with incentives for achievement, would yield greater leverage for quality enhancement across national systems.

The fourth issue is the level at which assessment is targeted, and results published. Most data collection starts with single items of output, but, increasingly, weight is now put on organization-context factors and a robust research culture. Paradoxically, outside project/program evaluations, the research team is rarely a focus. A review by Avital and Collopy (2001) found that evaluative studies were conducted at unit level, possibly because those levels were where the controllable enablers of productivity operate. Panels in the United Kingdom, Australia, and New Zealand relate to disciplines, but most research is interdisciplinary. The structural units awarded a grade are often built around the discipline in the context of teaching, but synergy with teaching may not be a quality criterion. In the United Kingdom, at least, members of interdisciplinary research teams, working across departmental boundaries, are separated from their research environment in the RAE submissions. Published results will always be used by the media to create league tables, to identify winners/losers, or the best/the rest binaries (Valadkhani and Worthington, 2006). More nuanced, formative feedback, with its narrative of strengths and weaknesses and potential, escapes the mass media, which may be why institutional audits have had less publicity than exercises where a score is awarded.

Those conditioning factors affect the evidence submitted for assessment. If methodological rigor is dominant, then the primary evidence is in project descriptions and published output. If relevance to policy and practice is a key concern, then input from users and evidence of outcomes assumes greater importance. Some outcomes may not be in published form and may take a considerable time to be evident, with causality between intervention and outcome difficult to audit. If international standing and competitiveness are strategic aims, esteem factors from the international community need to be collated. If institutional or departmental potential for improvement are key to

investment decisions, internal infrastructure, staff qualifications and continuing development, capacity building, and nurturing of new talent need to be demonstrated.

All of those then feed in to the most disputatious issue – what process to use. The Australian Expert Advisory Group (2005) dismissed the known benchmarking exercises, leading to league tables, because they are based on a narrow range of performance measures and have no input from end users. The Group's main debate, as with others in countries covered in this review, was between a peer-review process and a model based on performance indicators (PIs), labeled metrics in some contexts. They noted the debate in New Zealand recorded by the OECD (2004). The listings that follow draw on the Group's work and also on Scott (2006), Sastry and Bekhradnia (2006a, 2006b), and McNay (2003, 2007).

Advantages Claimed for Metrics/PIs

Some of the advantages of the PIs are:

- PIs can provide incentives for productivity, for recruitment, and retention of high-performing staff, for quality supervision to enhance student completions, and for generation of external funds;
- they can provide clear criteria for reward systems;
- data exist or are easy to collect;
- there are low transaction costs; and
- measures are transparent, formulaic, and so easily communicated and understood.

Possible Disadvantages in the Use of PIs/Metrics

Some of the disadvantages of the use of PIs are:

- the choice of metrics is not value free, so some work may gain and other work lose, depending on choice and weighting;
- if income is used as a metric, the control passes to those commissioning work, who may not support open publication of critical or unwelcome findings, or commission work with that risk;
- many more unsuccessful bids will be made, leading to inefficient use of time, and to reduced cooperation in a competitive context;
- some areas are more suited to commercial funding than others;
- quantity is not quality, nor is income necessarily an indicator of quality output;
- citations are not yet a reliable indicator, and are susceptible to manipulation;
- staff recruitment and selection for submission would favor established researchers, not newer ones without a record against the indicators, nor women taking career breaks;

- efforts to meet PI targets may displace commitment to teaching, student support, or community service; and
- if optimizing income is a main aim, there is potential for corruption of values and mission drift.

Advantages Claimed for Expert/Peer Review

Some of the advantages claimed for expert/peer review are:

- there is direct engagement with research output;
- a wide range of factors and criteria can be considered;
- the dynamic of development can be assessed to indicate potential;
- formative feedback can be provided;
- international expertise can be drawn upon through panel membership;
- centers of excellence can be identified;
- quantitative and benchmarking data are not excluded;
- bids can locate performance within interpretation of research and strategic priorities, allowing some element of made to measure in relation to fitness for purpose;
- trust of fellow professionals makes acceptance of judgments easier;
- a fuller, more rounded judgment will emerge; and
- the process can be located within differing disciplinary frameworks and fields of practice to recognize different research traditions and approaches.

Possible Disadvantages of Peer-Review Approaches

Some of the disadvantages of the peer-review approaches are:

- it is staff intensive and has high costs;
- it institutionalizes and legitimizes collective prejudice, thereby underrating new and nonmainstream approaches favoring, say, econometrics over feminist economics, and promoting convergence on a conservative agenda, entrenching academic traditionalism;
- little weight is given to the end users, so there is dominance of a perspective from the closed academic community, using academic journals, downplaying interaction with the wider community of practice, and communication/dissemination through professional or popular journals;
- panels are inconsistent across disciplines and over time;
- criteria may be obscure and the process opaque rather than transparent;
- there are concerns about equity of treatment on gender grounds, and of newer institutions, given the base of most panel members; and
- it has led to recruitment practices favoring high-performing stars who may not be those best suited to nourishing and mentoring others.

Conclusion

Finally, given the complexity of the process, the contentiousness of some approaches, as listed above, constant changes for political reasons (which means a short shelf life for some of the descriptions above), and the ingenuity of academics within an organic, fluid and flexible system, there will always be unexpected, unintended, and, perhaps, undesirable consequences, to balance the positive responses that arise from acceptance of the legitimacy of accountability and the striving for excellence, efficiency, and effectiveness that it may promote. In the United Kingdom, for instance, teaching programs have been closed down following less-than-excellent grades for research. Use of a hybrid process, clarity of objectives and criteria, transparency of approaches, robust data, linking of research strategy to that for other areas – teaching, enterprise, and community development – and, above all, sensitivity to consequences, will optimize the acceptance and validity of research-quality assessment.

The Management of University Research

J Kirkland, The Association of Commonwealth Universities, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Background

The definition and scope of university research management is changing rapidly. While research has always required some degree of management in order to achieve its objectives, historically this was the province of the research team itself, together with such administrative assistance as may be available within the academic department. In many countries, such decentralized mechanisms were tied to the perceived right of tenured academic staff to set their own research agendas, utilizing time and often other resources provided by their employing institutions.

Most of this process took place with little or no regulation by the central university, or in some cases even the academic department concerned. In an age where the majority of research needs could be met from within the university system, external funding was seen an 'optional extra,' to be sourced and negotiated by the individual research team. In this classical model, the role of the university was one of very minimal regulation – for example, the provision of a basic accounting mechanism to satisfy the demands of audit. There was little expectation that additional resources would make a significant difference to the overall finances of the institution.

The Changing Environment

In essence, the main change in recent years has been the development of a much sharper distinction between research methodology and research management. The former relates to the means of conducting the research itself, ensuring that the results are of an appropriate standard. The expertise required for this is clearly academic, in most cases discipline based, and responsibility remains within the academic staff structure. Research management concerns broader issues, such as ensuring that staff are able and motivated to conduct such work, that it meets the needs of stakeholders (including the host university) and that the results are effectively utilized. The academic research team remains critical to this process, but it is increasingly supported (and monitored) by others. Research management has increasingly been seen as an issue to be conducted at the level of the institution.

Although the pace of change has varied, abandonment of this laissez-faire policy has been a common feature to most regions over the past 25 years. The pace of this change has not been even. The longest established

tradition of research administration can be found in the United States, whilst a survey by Stackhouse and Day (2005) amongst Commonwealth countries confirmed that developed countries generally were much further advanced. The same work also demonstrated, however, that the trend was becoming increasingly evident in developing countries also. Hazelkorn (2005) also demonstrated differences between types of institution. Her study of 25 new universities, many without strong research traditions, in 16 countries showed a capacity to align institutional competences to the external environment. In each of these cases, a primary motivation for change came from outside the academic institution, and to some extent outside the higher education system as a whole. Whilst the precise nature of change varies, it has been possible to advance a model of how research management systems develop in three (possibly overlapping) stages – awareness raising, the development of structures at institutional level, and the development of external support mechanisms which help ensure the sustainability of such structures (Kirkland, 2008).

Several interrelated themes can be identified. The first of these is the desire of governments for more accountability from universities. This has been pursued through a combination of incentives and threats and, although universities retain formal autonomy over the allocation of their own resources, has required the central university at least to collect a great deal more information about its own activities. The South African system tied university research funding directly to the publications by its researchers and the citations of their work published in designated peer review journals. Research Assessment Exercises in the United Kingdom have sought to allocate core research funding according to performance on a range of criteria, including publications, research income, research students, and 'environment and esteem.' In each case, although performance is broken down by unit of assessment, reporting is coordinated by the institution. Thus, the university has a need to know what research is being conducted, and develop its own evaluation mechanisms.

Linked to accountability has been a move toward more competition and selectivity. Research evaluation exercises, in the United Kingdom and elsewhere, have sought to ensure that core research funds are increasingly allocated according to criteria of quality and performance. The proportion of research funding allocated from 'core' sources has declined, with that from sources such as government departments, charitable bodies, business and industry, and

international bodies that allocate their funds on a competitive, project-by-project basis showing strong growth in the first half of this decade. In Australia, external research income almost trebled in the decade to 2003, allowing the Australian Vice-Chancellors Committee to point out that for every dollar provided by Commonwealth grants in 2001, universities earned just under AUD 1.40 from other sources. By 2003, this figure had risen to almost AUD 1.60. In Canada, the sponsored research income of the leading 50 research universities rose by between 12% and 24% in each of the five years to 2004. The New Zealand Department of Education reported that over two-thirds of university research income is now competitively won, and that the income from such contracts more than doubled in the six years to 2003. In the United Kingdom, income from competitively won grants and contracts increased by almost 90% in the 8 years to 2004. There is no certainty that this growth will remain, in Canada the *Research Infosource* report for 2008 showed only 'pedestrian' growth, concluding that "the heady days of 10–20% growth have clearly ended, and at the time of writing it remains uncertain how vulnerable university research income will be to recession." However, the increasingly competitive nature of research is likely to remain a permanent feature, requiring the development of new skills for academic teams and those who support them.

Increased accountability and competition have also led to a growth in the transparency of institutional finances. More than ever before, it is possible for institutions to identify which staff are responsible for earning the bulk of their research income. More importantly, this information is available to staff themselves. This has led to a shift in the balance of power between institutions and staff, with increased pressure on institutions to allocate earnings back to those responsible for creating them. Moves toward more decentralized financing systems, in which areas of universities receive a higher proportion of their indirect earnings from research, but are required to be responsible for costs such as space, heating, and lighting, which would previously have been seen as a central charge, have furthered this process.

Three external factors have also encouraged the more active institutional management of research. The first is the increased recognition by governments that universities have a key role to play as a catalyst for wider social and economic development, and that the dissemination of research activity, particularly through knowledge transfer to users in the private sector, has an important role to play in this.

To policy makers, the argument that better utilization of research which has already been financed – much of it through the public funding – could be facilitated at relatively little expense has proved attractive. Universities have embraced these arguments, while stressing that such expenditure should supplement, rather than replace,

existing income sources. A 2006 report from the Australian Vice-Chancellor's Committee argued that expenditure on knowledge transfer should be 2% of total university expenditure. Although such income has expanded significantly, progress has been slower than many anticipated. Annual surveys of North American institutions by the Association of University Technology Managers since 1996 confirm that the majority recover less than 2% of their research expenditure through such income. In an African context Heher (2005) argues that an understanding of the likely returns is critical to policy making, with unrealistic expectations being likely to lead to dysfunctional policy decisions. One implication of this may be that less-formal mechanisms of knowledge transfer, such as consultancy, continuing education, and outreach activity may have more impact than formal licensing and transfer arrangements, although they are less visible and capable of being quantified. Another is that spin-off companies, which may return less directly to the system but have wider benefits in terms of job creation and economic development, might have more long-term impact than licensing arrangements that derive direct revenue to the university.

The second external factor has been the strong growth in collaborative and interdisciplinary research. Collaboration has increased both between and within sectors, and internationally, partly as a result of better communications and the increased need to be competitive, but partly, too, as a result of developments in funding. Examples of nationally based programs include the linkage schemes of the Australian Research Councils, LINK, and Knowledge Transfer Partnerships in the United Kingdom and the opportunities for large-scale consortia under the European Union Framework program, where almost two-thirds of the EUR 50.5 billion budget agreed for Framework Program 7 in December 2006 is listed under the heading of collaborative research. Many national governments have also devised schemes with the specific intention of bringing university and private-sector research teams together. The growing complexity of these relationships has led to the development of a significant body of academic work analyzing the relationships between universities, industry, and government using a 'triple-helix' model (e.g., Etzkowitz, 2002).

All of the above factors have contributed to a significant increase in the complexity of the environment surrounding university research, which can be described as a third external factor. External research contracts are now not only critical to the research base of universities, but to the core business of those funding them. As a result, the relatively friendly and informal relationships that once governed projects have been replaced by a more formal, legal one, in which universities have onerous obligations to deliver. These obligations are supplemented by wider expectations of society – for example, the requirement to observe increasingly complex expectations in the field of research ethics, the need to ensure that laboratories are

kept secure and confidential, and that valuable intellectual property is not compromised by premature disclosure. Each of these areas has required universities – who typically sign research contracts as corporate bodies and have the obligation to deliver on such obligations – to more closely regulate the activities of individual staff and research teams who deliver the research.

An Emerging Profession

Against this background, contemporary research management can be defined as including activities through which an institution seeks to add value to its research activity, but which do not form part of the research process itself. This does not imply that all such activity take place at the center. Despite their rapid growth in recent years, central research management or support units represent only a small fraction of research-related personnel within the typical university. Given the remoteness of central administrators from the research process, there has been renewed emphasis on the training of researchers themselves in basic management issues, such as project management, reporting and the identification of intellectual property. As central research support units get bigger, progressive universities are seeking to decentralize them. In a recent international benchmarking study commissioned by the Higher Education Funding Council for England, Canadian institutions in particular reported a trend to physically locate research administration staff within faculties, both as a way of increasing credibility and of getting closer to the research process, and any emerging problems. Personal skills – such as the ability to forge good relationships – also featured highly among the attributes identified as being important by research managers themselves in an international survey by Stackhouse (2008).

The biggest growth of activity has, however, been at the level of the central institution, where it is no exaggeration to describe the rapid growth of personnel as leading to the establishment of an entirely new research management profession. The extent of this development can be seen in the survey by Stackhouse, in which 82% found that ‘research manager’ was a suitable title for their work, and 71% were full time on research management activities, the largest minority being in Africa, where the majority still combined research management with other, typically academic roles. The new profession combines elements of traditional administrative responsibilities – such as finance, human resources, and registry – with relatively new ones, such as targeted marketing, customer relations, intellectual property management, and licensing. Key elements of the profession are gradually being put in place, covering professional standards, training and organizations. In most developed countries, a clear network of university research managers exists, and in some cases

more than one. Developing countries are beginning to catch up on this process, as evidenced by the formation of such networks in Southern and Western Africa in recent years. While no internationally recognized qualification exists in the area, the Society of Research Administrators International has operated an accreditation scheme for its members for the past 15 years, and the Higher Education Funding Council for England established a project in 2008 to investigate the establishment of a professional institute for research managers (Green and Langley, 2009).

The Functions of Research Management

The precise boundaries of the new profession are still emerging – as can be seen by areas of overlap between this article and others in this encyclopedia. Most commonly, it is regarded as a continuum which follows the research process itself – from identifying a project and source of funding, through presenting proposals to sponsors, recruiting appropriate staff, negotiating contractual terms and budgets with external sponsors to project management and reporting, financial controls, identification and protection of intellectual property, its commercial exploitation, and dissemination to wider society. There remains unevenness in the extent to which these are addressed comprehensively. Stackhouse and Day (2005) found four models of research management provision – ranging from the one-stop-shop – now increasingly prevalent in developed country universities, through multiple, partial, and even no specific provision, the latter being more likely in developing countries.

Where comprehensive provision is available, functions are commonly divided into ‘pre’ and ‘post award’ activities, a distinction that probably originated in the United States and is increasingly reflected in the organization of professional activity at university and national level. It is noticeable that, as the size and complexity of research support offices increases, distinctions of this nature are becoming increasingly prevalent. Technology transfer and licensing offices, for example, are increasingly separated from those that administer research projects, while separate professional organizations tend to exist for different stages of the process. In the United States, this can be seen through the distinction between the Society of Research Administrators (SRA) and Association of University Technology Managers (AUTM), and in the United Kingdom between the Association of Research Managers and Administrators (ARMA) and Association for University Research and Industry Links (AURIL). The distinction is increasingly justified in terms of the different skill sets required, although this argument requires some caution. Communication between ‘pre’ and ‘post’ award functions continues to be important since, for

example, if contracts are not negotiated thoroughly from the outset, the capacity of a university to own and exploit its intellectual property subsequently may be limited.

There is no universally accepted definition of what constitutes pre and post award activity. However, an international benchmarking exercise commissioned by the Higher Education Funding Council for England (HEFCE) in 2004–05 divided pre-award activity into four areas – the development of internal research strategy, retention and support for academic staff, promotion of university research capacity and the submission and authorization of externally funded work. Post award topics were identified as project management and control, the commercial exploitation of research and dissemination of research to wider society. The intensive benchmarking process which resulted involved fifteen institutions from nine countries – Australia, Canada, China, India, Japan, New Zealand, South Africa, United Kingdom, and United States. The participants went on to identify a list of 87 institutional good practice statements (Bjarnason *et al.*, 2006).

On the evidence from these institutions, it seems clear that the relationship between research management offices and the development of internal research strategy is still emerging. In many universities, the research management function is regarded as being exclusively concerned with externally funded research projects, and is located within the administrative structure (although sometimes formally supervised by a ‘Deputy Vice-Chancellor – Research’ of other senior academic). Distribution and management of internal research funds, by contrast, is often seen as a function of the academic committee system. Although there were examples of overlap – such as cases where the Head of the Research Management office was invited to serve on the university research committee, the common separation of the two strands of activity raised questions about how far both strands of funding were being effectively integrated into a common research strategy for the whole institution.

The retention and support of research staff represents a further area where the boundaries of research management are unclear. In many universities, this is regarded as the province of human resources, staff development, or academic departments. Research managers, however, are becoming involved in several ways. An understanding of current staff expertise and aspirations is vital to their role of promoting the university, discussed below. Training is being provided in areas such as research ethics, publication, and intellectual property, where the distinction between research methodology and research management is a fine one. Some research managers are working with their institutions to devise and implement incentives packages to motivate staff to seek external funds, and ensure loyalty from those who are successful. Value judgments are also required from research managers about where to devote their time and resources. One participant in the HEFCE program reported that

his office had made an (unpublicized) decision to focus on no more than 60% of academic staff. The remainder were either unlikely to develop an externally funded research profile, however, much support was offered, or so successful already that the central office was unlikely to add value.

External promotion of university research capacity involves the identification of funding opportunities, matching these to available expertise and supporting staff in their applications. In addition, there is a wider promotional role (sometimes shared with a public relations, communications, or marketing office) which ensures that the university research is generally well known and respected among target groups, and maintains contact with key funding agencies to identify potential trends in policy before these emerge publicly.

The role of most research management offices in this area is one of adding value to the activities of academic staff. It remains the case that the main source of information, development of consortia, and proposal writing is through academic networks. Thus, effective mentoring and support within the home department is likely to be as important a factor in the development of staff as any central mechanisms.

The increased complexity of the research environment, however, has strengthened the need for professional research support. The increasing number of funding bodies allocating research grants on a competitive basis, often combined with a desire to see collaboration across disciplinary boundaries and increasing pressure on teaching and administrative functions, makes the funding environment difficult to track within traditional academic departments. The same also applies to professional support at institutional level. Increasingly, the tracking of funding opportunities is undertaken through ‘buying in’ to commercially operated subscription services, such as the ‘Research-Research,’ and the ‘Community of Science,’ which offer increasingly sophisticated facilities to filter opportunities and target these to the needs of specific academics.

Two other significant trends have been the increased specialization of staff time within the research support office, and an increase in internal peer review mechanisms. Initially, research staff time was more likely to concentrate on specific sources of funding, such as government departments, charitable bodies and the business and industry – itself increasingly segmented into sectors. As research functions have grown further, it has increasingly been possible for individuals to concentrate on specific departments or groups of individuals within the institution. The increased tendency for universities to formally review applications before submission reflects not only the increased complexity of funder needs, but a concern for reputation and quality control. Although such review is still largely academic based, its emergence could mark the start of a further phase in the development of

institutional research management – from a model predominantly of supporting the research activity of individual academics, to one of regulating it.

The need for regulation is clearer in the area of contractual terms and conditions. Given the increasingly commercial nature of contracts, and the obligations and potential liabilities that universities assume in them, it is surprising that relatively few research offices contain qualified lawyers, instead calling on specialist external companies of the wider legal expertise of their universities as required, and also that the amount of litigation to result from university research contracts remains relatively modest. An explanation sometimes advanced for this is that, although complex, the key legal issues in such agreements are repeated from contract to contract. Nonetheless, universities assuming obligations such as the need to observe strict confidentiality need both to pass these on to individual staff at laboratory level, and ensure that appropriate procedures are in place. Those who do not do so remain vulnerable.

The issue of contractual obligations is related to that of costing and pricing research projects. Where universities were willing to undertake research at less than the full economic cost it may have been reasonable to require that sponsors accept less than commercial standards of delivery, intellectual property, or confidentiality. Increasingly, however, universities have sought to recover such costs, for example, through the Transparent Approach to Costing (TRAC) developed by the higher education funding bodies in the United Kingdom since 2001.

As more attention has been focused on post award management, universities have been forced to take a realistic view on the balance between the roles of center, department and individual investigator. As one Asian participant in the HEFCE benchmarking exercise stated:

We have about 3,600 full and associate professors, but only about fifty staff working for research management at college and university level ... about 10,000 research projects are going on every year. It is impossible for administrators to manage the projects directly.

In these circumstances, strategy has concentrated on finding a balance between central monitoring and the training of those responsible for compliance on a day to day level. Ensuring that obligations are brought to the attention of departmental heads and principal investigators is a prerequisite, but unlikely to be sufficient. Other approaches have included more systematic training programs for academics on research management issues, and systems of incentives and penalties that shift the responsibility for noncompliance or ever spending downwards. The area is, however, still evolving and one in which many universities remain vulnerable.

Finally, post-award management requires procedure for the closure of projects and dissemination of results. Emphasis in this area has too often been placed on

commercial exploitation, through the sale or licensing of intellectual property or establishment of spin-out companies. This can be explained by pressure from universities and governments to see tangible returns that can be quantified. As noted above, however, activity of this type is likely to result from a small minority of projects only. In recent years, there has been increased recognition that innovation is a more incremental process than previously imagined, rather than being driven by sudden leaps forward, and that what is transferred between universities and society (in a two-way process) is better classified in terms of broad knowledge than more specific technology.

University research management will increasingly need to reflect this reality. As the profession expands, one might expect to see rigorous procedures for the identification and protection of intellectual property, with others for systematic analysis of research results, customer satisfaction, and wider dissemination and strategies. These in turn will require consideration of the boundaries between research management offices and those for external relations, media, and continuing education, which tend to have some responsibility for such areas at present. The issue of incentives may also need to be addressed; at present academics and their departments are more likely to respond to those measures which are more quantifiable. Often this involves seeking their next research project rather than disseminating the results of the last one.

Conclusion

The exceptional rate of change in research management in recent years has largely been a reaction to the external environment in which university research take place, rather than the result of decisions taken within the sector. Since this environment is still not a stable one, it is reasonable to assume that further change and development will take place over the next decade. The establishment of a discrete research management profession, with its own norms, values, and communication channels, provides a useful extra dimension to the debate over the future of academic research, which universities and policy makers should increasingly value.

Glossary

Discipline – A defined body of knowledge for learning, research and instruction.

Interdisciplinary – Two or more disciplinary bodies of knowledge interacting in research, learning or instruction.

PhD – Doctor of Philosophy (or DPhil), formal, advanced degree study at university which applies to a wide array of disciplines in the humanities and sciences.

Postdoctoral fellow – Research appointment for someone who has completed a doctoral degree.

S&E – Science and engineering.

S&T – Science and technology (incorporates computer and information science).

STEM – Science, technology, engineering and mathematics.

Transdisciplinary – Transcending disciplinary boundaries in research, learning or instruction.

Introduction: The Role of Science in a Modern Society

Science is fundamental to the fabric of modern societies and their economic prosperity. Scientific knowledge and advancement are acknowledged as crucial to industrial modernity and technological advancement, forming the powerhouse of a modern world.

A nation's ability to generate fundamental knowledge which can enable innovation and transformation into technological applications stems directly from its scientific capacity. This capacity rests in two areas. The first is the level of national scientific literacy. A high level of science literacy within a country's population provides the skills and insights needed to inform discussion, policy, and decisions about the interpretation of scientific discoveries and their appropriate use to advance social and material progress (see e.g., FASTS, 2006). The second area is a nation's scientists. Their research and its outcomes are central to economic competitiveness, underpinning a nation's social well-being and material progress.

The exponential growth of knowledge and consequently, scientific disciplines, together with advanced research techniques and often expensive equipment for experimentation

make science a major national investment. However, science is not confined to national boundaries. It is international in character and language and there is a global market for scientists.

In particular from the mid-twentieth century, the USA has been recognized internationally as dominating scientific research and the science labor market. Its research universities are major attractors of international students to undertake PhDs and postdoctoral training. The European Research Area was created in 2000 by the European Union as a means of harnessing and extending the European research and science capacity to attract scientists and industry investment in European scientific research and hence make Europe more competitive with the USA (EU, 2007). In 2005, European universities awarded 43% of all Organization for Economic Cooperation and Development (OECD) university degrees in science and engineering, compared to 22% for the USA, and 57% of all doctorates (OECD, 2007a). This increasing international competitiveness from Europe challenges the US preeminence in science research and development. Other challenges from science and education investment and development are seen to come from Japan and the Republic of Korea and strongly developing countries such as China and India. Overall, in the decade 1996–2005 most countries have significantly increased their research investment (UNESCO, 2007).

A competitive global market for science raises important questions for individual countries about the recruitment, retention, and career structures of the scientists it trains, as well as forcing it to consider fundamental aspects of the education and training of its scientists.

The Nature of Science and a Scientist's Role

Science is the systematic study of natural phenomena of the living and nonliving world. It is defined as “a branch of study that deals either with a connected body of demonstrated truths or with observed facts systematically classified and more or less comprehended by general laws and which includes reliable methods for the discovery of new truth in its own domain” (Shorter Oxford English Dictionary, 2002).

Within the taxonomies of knowledge fields, science is categorized as a hard knowledge area, reflecting the cumulative, atomistic structure of knowledge. Scientific

knowledge develops in a linear progression and current discoveries can trace their lineage in a hierarchical fashion, not unlike a family tree. Within this process of steady accretion, there is a clarity of the criteria for establishing or refuting claims of new knowledge and boundaries are clearly defined and circumscribed.

The scientific disciplines are numerous and varied, ranging from theoretical, experimental, observational, and technological subject areas. This spectrum covers what have been termed pure and applied fields where the former investigate fundamental phenomena and the latter focus more on the practical application of scientific research to specific human needs, such as the various forms of engineering. Central to science, in particular in the experimental and observational disciplines, is the scientific method. This is a process of investigation through experimentation, observation, and modeling of natural phenomena in a reproducible way which can lead to predictions, theories, and laws.

Thus, scientists are professionals engaged in the conception and creation of new knowledge, products, processes, methods, and systems and are directly involved in the management of research projects (OECD, 2007a).

Originally one of the seven liberal arts (natural philosophy) studied in the medieval university, science in the twenty-first century spans a wide array of ever-increasing disciplines, subdisciplines, and interdisciplinary fields. Scientists are the creators of increasingly specialized scientific knowledge and the complexity of scientific knowledge is reflected in increased diversity of the roles scientists play. They work in a number of different public- and private-sector contexts and organizations, spanning universities, research and scientific institutes, industry, and government. There is a steady trend in most developed Western countries for science graduates to be employed by government and industry with less than half of all science PhDs moving into academic positions (Enders and de Weert, 2004a).

The work of a scientist includes the generation and discovery of new knowledge, the application of new discoveries, and the communication of scientific advancements to a wide variety of audiences. Scientists span a huge array of disciplines across the physical and life sciences, encompassing many subdisciplines and an increasing array of interdisciplinary fields. The discussion here is not on an examination of the range of scientific specialties, rather it is an acknowledgment of the breadth and diversity of scientific fields and an examination of the key issues shared across these disciplines in training new scientists. Thus, the discussion below is inclusive of these vast disciplinary fields. Studies of various aspects of science and national policies also use a number of different categorizations. These can be quite simply science or they may be science and technology (S&T) to specifically indicate the inclusion of computer and information science, science and engineering (S&E), and science, technology, engineering, and mathematics

(STEM). The discussion here is inclusive of all these categorizations.

The Training of New Scientists

To become a scientist is to embark on an increasingly specialized course of study through school and university, culminating in the most advanced form of scientific research training and apprenticeship, a PhD. Following this the scientists' career generally embarks on a period as a journeyman through postdoctoral experience, through independent researcher and leader.

Early Science Education and Training

Given the sequential, cumulative nature of scientific knowledge the training of a scientist arguably commences during the school years, continuing into initial degree study before a person is sufficiently grounded to embark on specialized advanced study and research. Consequently, the most important themes in the literature are the attraction of sufficient and the best students into science at all education stages, the quality and relevance of science curricula, and, the supply of well-trained science teachers.

An emerging benchmark is the outcomes of education systems through student achievement in various academic literacies undertaken by the OECD through its Programme for International Student Assessment (PISA) studies. The 2006 PISA study examined scientific literacy by assessing student knowledge, skills, and attitudes at the end of their compulsory schooling years in OECD member and nonmember countries. It also examined system characteristics as well as school and human resources impacting on science education. This represented 400 000 students in 57 countries representing 90% of the world economy (OECD, 2007b).

National performance in scientific literacy varies greatly across the countries surveyed. Particularly important for national capacity in science, only 37% of students stated that they would like a career involving science with only 21% interested in doing advanced science. Reinforcing the findings of research studies in many countries about the lack of sufficient qualified science teachers, 62% of schools had vacant science teaching positions. In these schools with science teaching vacancies, 65% of principals reported that instruction was hampered by a lack of qualified science teachers.

The literature on the postsecondary study of science continues the themes of student numbers, student quality, and the quality of the science experience and curriculum. Having sufficient numbers of good quality undergraduate science students is crucial to the pipeline effect of feeding advanced research-degree science training. Various studies of student subject selection indicate that students find

science difficult and believe that they will be more academically successful in nonscience disciplines (Convert and Gugenheim, 2005). Consequently, there are national concerns about the numbers of students entering and graduating with science degrees. In 2005, the OECD averaged 7.4% of graduates in science, 5.4% in mathematics and computer science, and 12.2% in engineering (OECD, 2007c).

There are discussions about the structure and relevance of university science curricula for the early twenty-first century given the growth and complexity of scientific knowledge and the increasing need to have science graduates work in transdisciplinary and interdisciplinary contexts (Bill *et al.*, 2001). Science faculties at undergraduate level are developing education and research opportunities for science students to gain experience in research projects, interdisciplinary research, and also industry-supported research. It has been found that undergraduate student participation in research results in greater likelihood of pursuit of PhD study and a career in science (Hancock *et al.*, 2007; Hunter *et al.*, 2007). Overall, the aims of undergraduate science curricula are to provide a rich science experience which includes real research involvement and enables interaction with researchers in a variety of science disciplines as well as with postdoctoral fellows and graduate students.

The Role and Nature of the PhD

The PhD is the essential training ground for future scientists, followed by a period as a postdoctoral fellow. It represents the highest level of formal education and is a degree involving independent and original research.

In most countries, initial training is essentially within universities or similar higher education institutions commencing from bachelor degree to PhD levels of training. Depending on the national system, the bachelor's degree may include an additional honors year in which research training commences, followed by a PhD, or it may progress through bachelor to master's degree and then PhD. However, irrespective of national education system, for many decades, the PhD has been the accepted and expected route of training for a scientist in all developed countries. Attainment of a PhD is then often followed by postdoctoral employment prior to entry into an academic or scientific career in the public or private sectors.

The PhD has developed from its origins in the Humboldtian university of nineteenth-century Germany as an apprenticeship model of gaining research independence and certification as a master researcher or master scientist. Within this framework the trainee researcher, or emerging scientist, learns under guidance the tools of the trade, establishing credibility among peers as being able to identify significant questions arising from the discipline based on the cumulative advancement of the specialization.

It is considered the essential training in the culture, language, values, and methods of the discipline in particular and of science in general. By the end of the PhD, the apprentice or trainee has become an independent researcher and scientist who is a specialist in a particular field of knowledge. The research is predominantly discipline-focused, and pure research, aimed at advancement of the discipline, although increasingly applied, interdisciplinary and transdisciplinary research projects are also undertaken.

While the specific requirements for a PhD reflect national variations, common to all is the requirement of original academic research submitted as a thesis or dissertation which is examined by a group of experts. The examination process, again reflecting national variations, may be either as written expert assessment of the dissertation or it may involve an oral defense of the research by the candidate before a panel of expert examiners.

Spanning international interests the current literature on the PhD and training of new scientists can be summarized into five main themes: (1) the appropriate duration of the PhD; (2) achieving a balance between the in-depth specialization required by the research and social and business demands for breadth; (3) tensions between the traditional pure research approach to the PhD and the development of new, diversified modes of knowledge production; (4) the development of varied organizational structures and arrangements for PhD research compared with the disciplinary or department-based programs; and, (5) reinvigorating the notion of a steward of science.

Duration of the PhD

There is much national variation in the duration of PhD programs. However, on average a PhD requires 3–5 years of full-time research, but durations of 4–8 years may be more typical in some countries, such as in the USA, where the US Department of Education records 7 years as the median time to obtain the degree (USNEI, 2007). In recent years, governments in most English-speaking nations and member countries of the European Union have been examining their PhD structures with a view to realizing comparability of quality and standards cross nationally as well as promoting mobility for newly trained science PhDs. Underlying these reviews are also state concerns with efficiency, relevance, and the strengthening of national economic and scientific competitiveness. A key consideration in PhD duration is, however, the degree of research preparation that science PhDs have prior to entry. In systems where there is practice of a research honors year following undergraduate study or a research masters, then PhD completion within a 3–4 year time span may be more achievable than where such prior preparation is not customary. However, where such prior research preparation does not exist, then science PhD programs need to incorporate research method and

skill-development courses, hence extending the duration of the doctorate and the nature of the science training.

Balancing specialization and breadth

The second issue is the balancing of advanced specialization with breadth of knowledge and skills required of scientists by industry and society. The literature reflects the views of scientists, policymakers, and researchers that a broader, generic skill set to accompany research specialization is required (Balatti *et al.*, 2004; DEST, 2005; Enders and de Weert, 2004; Getzoff *et al.*, 2003; Teitelbaum, 2006). This has seen the development of taught courses within the PhD, which many attribute to the American model of the PhD. The purposes of such courses is to provide the broadening experience through learning about new knowledge developed, as well as in some countries, to provide additional training in scientific-research methods. The requirement of original scientific research and the development of an independent research scientist remain the central purposes of the PhD. However, such courses are seen to complement and enhance the PhD training through fostering breadth of knowledge and developing general skills and flexibility alongside the specialization necessitated by the conduct of original research. External pressures to reconceptualize PhD training from the traditional preparation for an academic career reflect that in many countries, significant numbers of science PhDs in the past two decades do not embark on academic careers, instead gaining employment in government and private organizations. Given this trend, additional courses need to cover interpersonal and professional skills training as well as career-development courses. Thus PhD programs in general, as well as in science more specifically, include the three key components of mastery of a specialization within the discipline or subdiscipline, broad knowledge of associated fields, and the development of professional skills.

Diversified modes of knowledge production

The third theme is the impact of new, diversified modes of knowledge production on doctoral training. The traditional view has been that a science PhD addresses problems arising from the discipline of a pure research nature. However, the distinctions between pure and applied research have been steadily blurring and the increased interest and involvement of industry in scientific research heighten the focus on problem solving arising in the context of application. Further, alongside the disciplinary imperative, and in part resulting from it, there is the emergence of interdisciplinary and transdisciplinary research problems. Such problems draw on knowledge and skills across a range of disciplines, subdisciplines, and specializations. This development can be seen as a fundamental shift within science and research more generally in the mode of knowledge production from what have been described as inward looking, disciplinary paradigms to more outward-looking

approaches, in which education and research are shaped in a continuous interaction with professions and business outside the university environment. The most influential model to capture this change is that of mode 1 and mode 2 forms of knowledge production (Gibbons *et al.*, 1994, 2001). The terms highlight the shift in emphasis between pure and applied research and research questions generated from within the discipline to ones shaped by social and economic influences and activity. Alongside pure research problems generated from the discipline are added interdisciplinary and transdisciplinary research oriented toward social and economic imperatives rather than disciplinary ones. The temptation is to see mode 1 and mode 2 as a dichotomy; more realistic, however, is to acknowledge that there is a spectrum of modes of knowledge production. There are implications for both the nature and type of research questions undertaken for the PhD as well as the range of inquiry methods and the location or site of production of the PhD (see theme 4 below).

Varied organizational structures and arrangements for PhD research

Connected with the third theme of the diversification of the mode of knowledge production are the more varied organizational structures and arrangements for PhD research (Enders and de Weert, 2004). There are two key developments in this regard. The first is the growth of flatter university structures to accommodate interdisciplinary research problems. Such structures may reside within existing faculties or departments in the form of centers or institutes and are normally of fixed duration to enable adaptation to the constantly changing disciplinary and interdisciplinary knowledge. The second development is that such structures and arrangements involve the inclusion of research partners external to the university or research institute through the establishment of science research programs in centers and consortia combining university and industry resources (see e.g., Harman, 2004). This may involve joint funding of scientific research often including PhD scholarships. The involvement of external partners enables an experience with real-world problems experienced in industry with access to testing and application in real contexts. Potentially, the innovation and development of new products in competitive international science markets are strengthened. Hence, increasingly there may be joint arrangements between universities and the private sector in the training of science PhDs, leading to an increased blurring of the boundaries between public and private sector. Such arrangements are often encouraged by national science and research policies where governments in many countries over the past two decades have promoted closer involvement and interaction between universities and the private sector. Japan, however, may represent a counterexample where its tradition of industrially trained PhDs have been found to be poor at contributing to research

in new and emerging fields. Here, the effort is to encourage future innovation through the promotion of university science PhD training with a focus on basic research (NSF, 2000).

Stewardship: The responsibilities of a scientist

A consistent theme in the writings of scientific professional associations is professional ethics or professional code of conduct. While the issues of professionalism, ethics, and codes of conduct are perpetual, the more recent discussions are framed in terms of social and disciplinary expectations of a scientist. Most recently, this notion of professional responsibility and ethics has been termed stewardship in the Carnegie studies of the doctorate (Golde *et al.*, 2006). Their investigations re-affirm the important role of PhD graduates in relation to the ethical and moral aspects of their work as leaders in their discipline. The discussions emphasize the role of the PhD in identity building and transformation from student to professional. This transformation involves an appreciation of a larger sense of purpose than just the discipline and individual careers to encompass a set of roles and skills, as well as a set of principles. Thus, to graduate from a PhD as a new scientist, there is not just an obligation to discover and generate new knowledge but also to transmit, critique, and use knowledge in moral, ethical, and responsible ways. Hence, fundamental in the training of new scientists is the development of a set of qualities and values that ensure “the continuing health of the discipline and how to preserve the best of the past for those who will follow. Stewards are concerned with how to foster renewal and creativity. Perhaps most important, a steward considers how to prepare and initiate the next generation of stewards” (Golde *et al.*, 2006: 13).

Following the PhD there are prospects for employment as a scientist within government agencies, industry, or as independent researchers in a university or research institute. For employment in the latter, further training at postdoctoral level is considered a prerequisite as an independent scientist.

Gaining Employment as a Scientist: Postdoctoral Training and Career Paths

The postdoctoral stage forms the critical final step in the training of new scientists prior to appointment as a scientist in a university or research institute. It represents a period of independent but loosely supervised research training, post the PhD. There is no formal qualification since during postdoctoral training these new scientists are no longer students but employees. The postdoctoral position is dedicated to research rather than teaching and may be funded by the university or research institute in which it is offered, or, funded independently through external

research-granting agencies. The position has multiple aims: to diversify technical skills; to obtain a deeper understanding of the cutting edge of the discipline; and to enable continued development of research networks.

The laboratory where the postdoctoral fellow resides provides mentorship to assist in the move to a long-term position as an independent scientist, since to progress from a PhD directly to a tenured academic position would be the exception rather than the norm. Over recent decades, a period as a postdoctoral fellow has become the accepted route to an independent scientific career and the appointee is expected to publish the results of his/her own research during the appointment period. Postdoctoral appointments for periods of 3–5 years are common before appointment as an independent scientist. Mobility is an important factor in the postdoctoral stage, since a postdoctoral position is likely to be in a different institution from the PhD stage and even in a different country.

Since the 1990s, there have been numerous surveys of holders of postdoctoral positions with recurring findings of dissatisfaction. A major issue has been that new scientists have held numerous sequential postdoctoral positions without gaining employment as an independent scientist in a permanent position. Postdoctoral appointments have become holding bays rather than stepping stones to continuing appointments. Consequently, the literature documents increasing dissatisfaction with the lack of career paths, employment conditions, and salaries attached to postdoctoral positions together with the need for ongoing career and professional development (Singer, 2004; Association of American Universities Committee on Postdoctoral Education, 1998).

Within the scientific community and for national governments, the underlying concern rests with the long-term attractiveness and capacity of the scientific labor market. The evidence from many countries is that there is an unacceptably high rate of attrition in early scientific careers (Preston, 2004). Of particular concern is the emerging evidence of the aging scientific workforce and the increasing age at which new scientists obtain their first independent research grant (Bravo, 2006).

The situation is further complicated by differing reports on supply and demand in the science labor market. There are contradictory reports of either a surplus or a shortage of scientists with discussions often reflecting snapshots of a particular period of time, selected science fields, and specific countries. Recurring themes, however, are the unattractiveness of scientific careers in terms of remuneration and advancement, insufficient academic positions within universities, and the personal costs associated with the continued need for mobility in establishing a scientific career. Of particular national concern should be that the continued growth in science PhD graduates and postdoctoral fellows since the late 1990s in Western, developed countries such as the USA, the UK,

Canada, and Australia, has resulted from an expansion of international doctoral growth rather than domestic growth (Moguerou, 2005). Science doctorate holders from Europe and South East Asia are most likely to move to, or remain in, the USA (Auriol, 2007; Cerny and Nerad, 2002). The long-term concern is that once these international graduates and postdoctoral students return to their countries, the host nation will be left with a shortage of qualified scientists within a competitive international market. As more nations establish themselves as education hubs and with the continued scientific development in countries such as India and China, global competition for new scientists will become much fiercer.

Introduction

Academic freedom is a freedom distinctive to academic institutions and those who work in them: it safeguards their freedom to undertake academic activities and fulfill the academic mission. This freedom derives from the academic commitment to the pursuit of knowledge by means of open inquiry. It is not an absolute freedom, nor is there unanimity on its interpretation and application, which is subject to the changing circumstances of academic life. Proponents also appeal to broader human rights such as freedom of thought, conscience, religion, expression, assembly and association; however, academic freedom has a more restricted meaning – it enshrines such rights only as they apply to the performance of academic duties.

A statement from the first Global Colloquium of University Presidents in 2005 sets out the core principle: “At its simplest, academic freedom may be defined as the freedom to conduct research, teach, speak and publish, subject to the norms and standards of scholarly inquiry, without interference or penalty, wherever the search for truth and understanding may lead.” Such declarations typically rely on two complementary premises. First, that the pursuit of knowledge is dependent on freedom of inquiry and the university accordingly needs to be protected from political, religious, or other forms of interference. Second, that the university is a core institution of

civil society and best performs that role if it is able to conduct its own affairs.

Academic freedom is codified and promulgated in various statements by universities, academic associations, governments, and international organizations. The Lima Declaration of the World University Service in 1988 defined it as the “freedom of members of the academic community, individually or collectively, in the pursuit, development and transmission of knowledge, through research, study, discussion, documentation, production, creation, teaching, lecturing and writing.” In 1997, the *United Nations Educational, Scientific, and Cultural Organization* (UNESCO) adopted a recommendation concerning the status of higher education personnel, and Article 27 defines academic freedom as “the right, without constriction by prescribed doctrine, to freedom of teaching and discussion, freedom in carrying out research and disseminating and publishing the results thereof, freedom to express freely their opinion about the institution or system in which they work, freedom from institutional censorship and freedom to participate in professional or representative bodies.”

The conventional understanding of academic freedom is one of freedom from coercion, principally outside coercion from the state or other agencies, though extending to improper interference by university authorities in the performance of academic duties. There is also an element of positive freedom, especially in aspects of activity such as research that depend upon institutional support.

History

Academic freedom had its historical origins in the universities of medieval Europe. The freedom of the academic institution was established first. It arose as these early universities sought greater autonomy from church and state, and advanced as conformity gave way to religious difference. From the status of the university as a self-governing corporation came the principle of institutional autonomy, which carried over to the national systems of higher education that were established in the nineteenth and twentieth centuries; from toleration and religious liberty came the idea of an independent intellectual community; from doctrines of political and economic liberalism came the principle of freedom of thought and the metaphor of free competition among ideas; and from a new emphasis on education as a process of discovery, articulated most influentially by Wilhelm von Humboldt in early nineteenth-century Germany, came the idea that teaching and research were interdependent activities joined in an untrammelled pursuit of truth.

The modern understanding of academic freedom was shaped decisively by the rise of science. The branches of scientific research that were established in universities in the nineteenth century were based on the understanding that knowledge was produced by a continuous process of inquiry, that hypotheses had to be verified, and that verification must follow certain rules in a procedure that required a trained expertise. From these principles came the custom of peer judgment guided by scientific criteria of honesty (a commitment to truth), neutrality (the subordination of beliefs in the search for truth), and testifiability (the publication of findings so that their truth could be tested).

Here already, the meaning of academic freedom was extending beyond the institutional freedom of the university to the intellectual freedom of those who worked within it. It was the application of the methods of natural science to social inquiry that led to a further extension: the formation of the academic disciplines of economics, politics, sociology, and history, and the conviction of practitioners that their investigations could and should improve institutions and social practices, created a new dimension of academic freedom – freedom of commentary.

This idea of professional privilege was associated with the special status of the university as a self-regulating intellectual community. It found expression in the German concepts of *Lehrfreiheit*, denoting the distinctive prerogatives of the academic profession, and *Lernfreiheit*, the freedom of students to determine their studies, attendance at classes, and living arrangements. This latter aspect of academic freedom, the entitlements of students, has since been extended significantly to encompass principles of equal opportunity and affirmative action. Thus,

the International Covenant of the United Nations on Economic, Social and Cultural Rights commits signatory nations both to the provision of higher education (“in particular by the progressive introduction of free education”) and to the elimination of “discrimination of any kind as to race, color, sex, language, religion, political or other opinion, nation or social origin, property birth or other status.”

Institutional Autonomy

Arrangements for safeguarding university autonomy vary widely. In continental Europe, where the modern university developed as a state institution, it has been codified in legislation. In Latin America, many universities include the word *autonoma* in their titles. In the United States, Britain, and its dominions, where civic universities supplemented the original religious foundations, autonomy was inherent in the independent status and self-governing character of the institution. None of these arrangements were secure. State systems of higher education were vulnerable to government interference (and even the legislative safeguards were omitted from many of the university systems created in the new nation-states of Africa and Asia after World War II), while civic universities were subject to intervention from lay members of their governing bodies.

As the result of changes in higher education over the past three decades, such formal differences have narrowed and institutional arrangements have tended to converge. The rapid expansion of higher education and increased public investment in teaching and research brought corresponding expectations of accountability. More than this, universities became a key determinant of competitive advantage in the globalized information economy. They were subjected to institutional devolution as systems of market competition were introduced to maximize their efficiency and effectiveness, and far more intrusive interference as governments redirected their procedures and priorities. These developments led one commentator to question the received wisdom of institutional autonomy: “far from being naturally ‘outside’ government,” Simon Marginson wrote, “the modern university is a product of government.”

Nevertheless, it remains a distinctive institution with a large measure of formal independence and practical control over its activities. The institutional autonomy of the university typically includes determination of the appointment of staff and selection of students; the establishment of courses and award of degrees; and the initiation of research and dissemination of knowledge. However many universities lack at least some of these powers: some governments determine policies for selecting students, some continue to control the appointment of

staff, and some intervene directly in the choice of the senior executive officer. Other restrictions on institutional autonomy are discussed below.

Freedom of Academics

The freedom of academics is distinct from institutional autonomy, for it is possible for a university to have a large measure of autonomy but restrict the freedom of its members. This freedom also found formal expression in many European countries, while it remained implicit in the Anglophone universities until associations of academics attempted to secure recognition of their entitlements.

The impetus in the United States was the dismissal of some prominent social scientists for public statements critical of big business. The formation of the American Association of University Professors (AAUP) in 1915 allowed the publication of a Declaration of Principles by its Committee on Academic Freedom and Tenure, asserting freedom of research, teaching, and extramural utterance and action. It argued that academic freedom was an indispensable attribute of a university if it was to advance knowledge, succeed in its educational mission, and contribute to social progress. More than this, the authors asserted that while a university teacher accepted a responsibility to the university authority, “in the essentials of his professional activity his duty is to the wider public to which the institution itself is morally amenable.”

Although the college presidents who formed the Association of American Colleges in the same year rejected this Declaration of Principles, their own Academic Freedom Commission produced its own report in 1922. After a series of joint conferences, the two parties finally agreed in 1940 upon the Statement of Principles on Academic Freedom and Tenure. The statement accepted that “institutions of higher education are conducted for the common good” and “the common good depends upon the free search for truth and its free exposition.” Each of the three freedoms advanced by the AAUP was affirmed, and each with its corresponding responsibilities. Teachers were entitled to full freedom in research, subject to adequate performance in other duties and a suitable arrangement concerning financial benefits. They were entitled to freedom in the classroom, but should be careful not to introduce into their teaching controversial matter which has no relation to their subject. They were also entitled to speak or write as citizens free of institutional censorship or discipline, so long as they recognized that their special position in the community imposed special obligations of accuracy, restraint, and respect for the opinions of others.

The Statement, which has since been amended and reaffirmed, is endorsed by more than 140 learned bodies, and frequently cited by courts, distinguishes the approach to academic freedom followed in the United States from other countries. In Britain, Australia, Canada, New Zealand, and

South Africa academic staff associations concerned themselves with academic freedom, and in some cases secured agreements with university authorities, but nowhere with the same level of detail or measure of acceptance. Where the American approach used voluntary associations to specify the entitlements of academics, these other countries relied far more on customary practice – though they also have resorted to the courts and in some cases moved toward the legislative approach of other countries.

Historically, the freedom of academics was circumscribed by the religious nature of the university. David Hume’s atheism precluded him from appointment to Edinburgh University in the eighteenth century, and well into the nineteenth century; only men in holy orders of the Church of England were eligible for fellowships of Oxford and Cambridge. Heresy and immorality continued to be grounds for dismissal in Britain and elsewhere into the twentieth century, but by then the most common reasons for refusing or terminating an academic appointment were secular. The cases in the United States that stimulated the formation of the AAUP in 1915 arose from the expression of unpopular views on controversial issues, and similar cases of victimization occurred in many other countries.

Beyond these restrictions on freedom of public commentary, academic freedom was curtailed by increased demands of loyalty to the state. Aliens were removed from many universities in World War I; the Soviet Union purged its universities in the 1920s, and in 1933, German universities were required to dismiss all persons of Jewish ancestry or socialist belief. During the Cold War, a number of American universities imposed loyalty tests, and many dismissals followed. Other Western countries followed similar practices, and the German *Berufsverbot* (a policy of banning individuals whose loyalty to the constitution of the German Federal Republic was in question) remained in the 1970s, while communist regimes in Eastern Europe, China, and elsewhere applied the Soviet insistence on political conformity to their universities. Surveys of academic freedom in many countries reveal the persistence of such expectations and practices.

The protection of academic freedom in teaching, research, and public commentary is based on appropriate procedures for appointment, tenure, promotion, and reward. It is expected that appointments will be made on merit by due process that allows all qualified applicants to be considered; similarly, confirmation of tenure, promotion, and other decisions affecting academics are expected to involve peer assessment and be based on performance of duties. The AAUP’s 1940 Statement of Principles places particular emphasis on tenure as a protection against victimization.

Such academic freedom is not absolute. As Edward Shils observed, it does not extend to charlatans, plagiarists, or cranks, but is reserved for academics to enable

them to discharge their academic duties. Hence, the introduction of political or other convictions inside the classroom should be consistent with the nature of the class (it would be appropriate to express a judgment on global warming in a geography lecture but not one on literature) and should allow for alternative judgments. It allows academics to determine their research projects and decide how they are to be conducted, provided they are consistent with the disciplinary expertise of the researcher and conducted honestly. It accepts the legitimacy of public commentary as part of the free exchange that is integral to the university's civic role, with the expectation that they will uphold the standards of their profession and the reputation of their institution. Recent controversies over this aspect of academic freedom are considered below.

Freedom of Students

The freedom of students embodied in the nineteenth-century German understanding of *Lernfreiheit* was a freedom to learn. It marked out the privileged status of the student in a hierarchical society, denoting an independence from parental supervision and an absence of administrative coercion in the pursuit of learning. Once qualified to undertake university studies, the student was entitled to move from one university to another, choosing which classes to attend and when to sit examinations.

Both then and later, this understanding of student freedom did not have the same force in other countries. The undergraduate enjoyed a privileged status in older universities but it derived from the exclusiveness of the institution rather than a prerogative to pursue learning as he chose. If their supervision of studies was light, the collegiate foundations imposed residential requirements and exercised a pastoral responsibility for their charges. The growth of civic universities in the twentieth century brought increasingly detailed programs of study, tuition, and assessment, and continuing restrictions on the extracurricular activities of students: representative student associations were allowed a limited autonomy but controls were imposed on their publications and political activities.

These constraints were challenged in the 1960s as part of the upsurge in student radicalism that wracked campuses in Europe, America, and beyond. The principal concern of student radicals was to contest government policies, especially the Vietnam War, and drew on the idea of the university as a distinctive institution of civil society with a particular capacity and entitlement to challenge orthodoxies. This claim extended to the expanded role of the university and its complicity in military and industrial activity, and soon involved demands for greater student control of the university – although these demands called into question the university's autonomy as an independent and politically neutral institution.

From the turmoil on the campuses of the United States came a joint statement on rights and freedoms of students in 1967, which spelt out the freedom of association, expression, publication, and participation in institutional government. The joint statement also laid down procedural standards for disciplinary proceedings against students. It also recognized that students "should be free to take reasoned objection to the data or view offered in any course of study," an aspect of student freedom that has since become a particular source of contention.

Student protests in the late 1960s and early 1970s played a major role in Europe, Latin America, and several Asian countries. Especially where civil rights were weak and freedom of speech curtailed, the university provided opportunities for discussion, criticism, and political opposition. Some of the restrictions on students' freedom of association derive from this fact. The destruction of the World Trade Center on 11 September 2001 was followed by new restrictions on student activities regarded as linked to terrorism in the United States, the United Kingdom, and other countries.

Restrictions on Academic Freedom

Academic freedom was never absolute and remains contested. The freedom it demarcates is restricted to particular pursuits, and the meanings attached to it have emerged through a constant process of contestation. As with other freedoms, it establishes protection from interference but in doing so imposes restrictions. Moreover, since academic freedom applies to different aspects of academic activity, the protections and restrictions operate within the university: rights claimed by academics have implications both for institutional autonomy and student freedom. The present arguments over restrictions on academic freedom arise partly from these differences and partly from disagreements over the purpose of the university as it has expanded in size, function, and importance.

Institutional Autonomy

The older university was a training institution for a small number of learned professions and a custodian of higher learning. The university sector now undertakes the education and vocational preparation of the majority of the population of industrialized countries, and is itself a major industry, while the expansion of higher education in developing countries has been even more rapid. The university is the principal site of knowledge production in the information economy, and the source of expertise that enters into every corner of social life. The growth of universities, and the increased competition among them as well as with alternative providers, exceeds the capacity

or willingness of governments to fund them, so that they are increasingly dependent on alternative sources of income.

One consequence of a mass system of higher education is a much greater variety of participants. The inclusion of women, ethnic and religious minorities, and other groups brought new procedures for equal and affirmative action, new curricular demands, and new norms of behavior. Speech codes, in particular, brought allegations that universities were imposing political correctness at the expense of freedom of expression. These arguments are particularly marked in the United States but have arisen in other countries where multiculturalism and identity politics operate.

A less discussed but more significant effect of the present circumstances of the university has been on its management and procedures. As the higher education sector has become more dependent on nonpublic sources of income, it has commercialized much of its teaching and research, and adopted new methods of management. University administration has expanded in size and complexity, employing business models to plan, finance, manage, and measure academic activity. Business partnerships and contracts often impose restrictions on intellectual property that inhibit the free exchange of information. The enterprise university pays particular attention to its corporate image, and seeks to restrict adverse publicity. Universities have never been immune from laws of supply and demand, and one justification for academic freedom was to insulate intellectual judgments from market forces; this separation has become less clear.

These restrictions of academic freedom are mostly self-imposed, but can be traced to a diminution of institutional autonomy. While governments have reduced their contribution to operating budgets, they have intervened to make universities serve national objectives. The governing bodies of formally self-governing universities have been required to conform to the model of the company board; changes in management and staff policies have in some cases been required as a condition of government funding; specific-purpose funding is used in place of general grants, and competitive performance is used to determine allocations; and public research agencies commonly identify areas of commercial opportunity or national interest.

Finally, universities are now expected to meet much greater expectations of public accountability. If they were once neglected, they are now of direct interest to a mass clientele and a constant source of news and media commentary. As they became central to the operations of government, economy, and society, many of their older immunities have been withdrawn. The university is a public institution that depends upon public support and is expected to serve its public; but in order to do so it requires respect for its distinctive nature. The shifting

boundaries of institutional autonomy are formed by this interrelationship of dependence and independence.

Academic Freedom

Many of the recent developments summarized above have implications for the freedom of academics. The establishment of academic freedom was linked to the growing self-confidence and self-esteem of the academic profession, and to the collegial forms of academic life as a vocation. The growth of the higher education industry, the emergence of alternative providers, closer links with industry, and new forms of management have weakened that special status. Academics are now far more closely regulated in the performance of their duties. Tenure is no longer the norm; the connection between teaching and research is weaker; research is more likely to be dependent upon obtaining external funding, and also to be subject to restrictive codes of ethics; especially in the humanities and social sciences, public commentary has become more hazardous.

In 1975, the United States Senator William Proxmire invented the Golden Fleece Award for wasteful public expenditure and conferred the first award on the country's principal research agency, the National Science Foundation, because it had provided a grant of US\$84 000 for a study of why people fall in love. In the following decade, the Thatcher government waged a similar campaign against the British agency, the Social Sciences Research Council, for funding left-wing researchers and supporting arcane projects – the example singled out for ridicule was a study of village life in Poland.

Similar invigilation of research and publications spread to other countries, and foreshadowed the culture wars waged by neo-conservatives. Commonly associated with allegations of political correctness, betrayal of the Western canon and abandonment of truth for postmodernist nihilism, these media campaigns have done considerable damage to individual reputations and academic disciplines. They clearly impinge on the principle that academics should be free to conduct teaching and research without vilification or intimidation.

Student Freedom

A similar development arose in 2001 with the formation of Students for Academic Freedom in the United States, with the purpose of protecting students from an alleged liberal bias in the classroom. The organization drafted an academic bill of rights, defining academic freedom as the freedom to teach and learn in an atmosphere of intellectual diversity, and claiming that liberal arts faculties

at most universities are politically and philosophically one-sided. It claims to have over 150 chapters and its website coordinates publicity for members' reports of partisan indoctrination, anti-Americanism, refusal to allow conservative perspectives and profanity. Two states have passed legislation based on its bill of rights.

Access and Equity in Higher Education

G Baldwin and R James, The University of Melbourne, Melbourne, VIC, Australia

© 2010 Elsevier Ltd. All rights reserved.

The rates and patterns of access to and participation in higher education are significant policy issues in most countries. Social equity in the patterns of access to higher education is often depicted to be one of three criteria for the quality of a national higher education system, alongside effectiveness and efficiency. The literature on access and equity in higher education is thus vast, including national analyses and related policy documents, research reports, and comparative international reports by bodies such as the Organization for Economic Co-Operation and Development (OECD), United Nations Educational, Scientific, and Cultural Organization (UNESCO), and the World Bank. Contemporary research into access and equity is tightly interwoven with wider policy issues and research questions, including the purposes of higher education, the funding of higher education, the assessment of academic achievement, and the changing character of higher education delivery and patterns of teaching and learning.

An analysis of the patterns of access and equity in higher education systems across the world produces a paradoxical picture of great diversity on the one hand and remarkable uniformity on the other. The rates of participation vary enormously, yet significant expansion has been virtually global over the last 50 years, driven by public demand, labor-market demand for higher skill levels, and government policies designed to improve national economic competitiveness. Despite massive growth, inequities persist in all societies, if the measure of equity is the extent to which the demographic profile of students in higher education matches the profile of the community as a whole. However, the bases of disadvantage vary according to social, economic, and political contexts. The widespread and seemingly intractable source of disadvantage is low socioeconomic status (SES), but that disadvantage takes various forms in different countries. In developing countries, poorer students have little chance of gaining entry into higher education, while in many of the developed countries they will tend to find places in the less-prestigious institutions and fields of study. The extent to which expansion has ameliorated disadvantage is a subject of intense debate, with some commentators arguing that it has actually widened the gap between rich and poor, and others taking a more positive view of recent progress. Regardless, policies and programs designed to create more equitable access appear to have had mixed success.

The Availability of Data on Higher Education Participation

Much of the research into access and equity has focused on solving the daunting problems of data gathering, so that countries have accurate information on the progress they are making toward the extension of higher education to all capable of benefiting from it. The work done in recent years by international bodies to develop reliable data systems for monitoring higher education is discussed in detail later. It is evident that many problems remain and there will continue to be much debate about the validity of data.

Many individual countries have developed extensive databases for monitoring access and equity in their higher education systems. Australia, for example, collects and analyzes detailed information on access, participation, and completion rates, considering a wide range of factors including age, gender, SES, locality, ethnicity, and disability. This data collection has become increasingly detailed and sophisticated over the last 30 years and time-series analyses are published every year, allowing for detailed investigation of trends (e.g., Coates and Krause, 2005). Australia has the advantage of dealing with a centralized, almost entirely public system. In contrast, while there is extensive data collection in the United States, the national picture is not as easy to analyze because of the highly decentralized nature of the higher education system.

The extent and quality of data vary considerably among different countries, again in largely predictable ways: poorer countries generally do not have the resources to devote to extensive data collection and analysis. A further problem is that, as different systems have developed, there has been little agreement on methodologies and definitions. Perhaps, the most basic disagreement has been over the meaning of the term higher education and particularly the place of technical education, which takes a variety of forms in different countries.

Much complex, useful, work has been done by the OECD, UNESCO, and the World Bank, to establish common definitions and procedures. Thus, for example, the categorization of tertiary education into type A (theoretically based programs which are designed to provide qualifications for entry into advanced research programs and professions with high-skill requirements and which lead to the equivalent of bachelor, master, or diploma

degrees) and type B (more occupationally oriented programs which prepare for direct entry into the labor market and are typically of shorter duration) has been widely accepted as a meaningful distinction, although there are still uncertainties about where particular systems should be placed. Further, the data relating to type B systems tend to be much patchier and less reliable than those for type A. In general, higher education is taken to coincide with tertiary type A programs. It has been argued by Clancy and Goastellac (2007) that entry rates should not be used at all, since, as the OECD points out that there is overlap between types A and B, the two rates cannot be added to give an overall rate. This is true if one is considering tertiary as opposed to higher education, but this distinction is not universally agreed upon.

The Global Expansion of Higher Education Participation

Despite the problems associated with the lack of comparable international data, some overall participation trends are evident. Martin Trow's seminal paper, *Problems in the Transition from Elite to Mass Higher Education*, written in 1973, has provided a valuable theoretical framework for understanding the rapid changes in higher education systems since the middle of the twentieth century. The framework defines three ideal types of elite, mass, and universal systems of higher education, defined as those in which 0–15%, 16–50%, and over 50% of the relevant age groups,

respectively, participate in higher education. In an updated version of this paper (Trow, 2006), Trow argues that the United States, as the country which has led the way toward universal access, offers the best model for others to follow. Other developed, industrialized countries are at the mass stage, moving toward the universal. Although he does not deal specifically with developing countries, most of these, according to his schema, are still attempting to move from the elite to the mass stage. However, there are some notable exceptions – Russia, Chile, and Argentina – which are discussed further below.

Despite this variation, the overall picture is clear. In the high-income countries (those in the OECD), expansion of higher education started after World War II, gathered pace in the 1960s and 1970s, slowed a little through the 1980s, and took off again in the 1990s. At the other end of the income scale, in poorer countries, such as those in sub-Saharan Africa and parts of Asia, the expansion started later and still lags well behind the growth in the wealthiest countries. In relative terms, this expansion appears quite dramatic but it started from a very low base, so the gap between rich and poor countries would seem to be widening. It may well be that, in attempting to increase the opportunities for their own citizens, developed countries are increasing the relative disadvantage of their less-developed neighbors. **Figure 1** presents World Bank gross tertiary enrolment (GER) data which highlight the regional discrepancies in growth rates, expressed as the number of students participating in tertiary education as a percentage of the number of people in the age cohort.

Figure 1 Tertiary gross enrolment ratio (GER) by region (%). The data are for 2000 or most recent year. The regional classification does not include any high-income countries. From World Bank – *International Handbook of Higher Education*, p. 448.

However, for those committed to reducing the global participation imbalances in higher education, there are grounds for optimism in the figures produced by UNESCO and the OECD, which suggest that, between 1995 and 2003, the group of middle-income nations analyzed as the world education indicator (WEI) countries saw greater expansion in their higher education systems than the high-income OECD countries – 77% as opposed to 43%. These countries are: India, China, Peru, Zimbabwe, Egypt, Indonesia, Chile, Russia, Jordan, Thailand, Paraguay, Jamaica, Argentina, Tunisia, Malaysia, the Philippines, and Brazil. Further, the UNESCO report points out that, in terms of entry rates, a number of these countries had better results than OECD countries, with Argentina, Chile, and Russia above the OECD average. These impressive rates suggest that Trow's analysis may be too narrowly focused on Western Europe and North America. One of the problems in interpreting these data, however, is that some systems (e.g., such as Argentina) have high noncompletion rates, which raises the question of whether entry into higher education is a useful measure or whether completion rates are more revealing. This is but one of the complex methodological problems which hinders research and analysis in this area.

Higher Education Access and the Underrepresentation of Population Subgroups

Despite the extraordinary expansion of access to higher education, social inequities in participation exist in all nations regardless of the stage of development of their systems. In a number of nations, the expansion of higher education systems from elite to mass access has placed renewed attention on the demographic composition of the student population. To some extent, the level of overall participation defines the characteristics of the equity considerations.

The concern for equitable participation in higher education is underpinned by the goal of achieving individual social justice and the belief that increased participation in higher education of people from educationally disadvantaged groups is important for the long-term social and economic integration of these groups. The concept of equity is open to a number of interpretations. Equality of opportunity is often referred to as fair access without discrimination on gender, class, ethnicity, or other personal characteristics and without explicit or implicit barriers to participation, such as the cost of tuition fees and living expenses while studying. Increasingly, in the diverse systems in the mass stage, equality of outcomes has become a more salient objective, in recognition that greater equity in access to higher education may not lead to greater equality in outcomes should the personal and career

outcomes differ markedly across universities or fields of study. A comprehensive consideration of equity might therefore look not only at broad access but also the type of higher education in which people participate – the nature of institution, the field of study, and the level of study – as well as retention rates, completion rates, and graduate outcomes.

Though equity is often depicted in terms of individual social justice, one of the most common measures of educational advantage and disadvantage has been the patterns of representation of subgroups in national populations. The social and demographic factors associated with subgroup underrepresentation vary across nations and cultures. The community groups underrepresented include indigenous people, ethnic minorities, women, people from lower socioeconomic backgrounds, people from rural or remote areas, and people with disabilities. The position of ethnic minorities ranges from gross underrepresentation to significant overrepresentation, depending on the historical, social, and demographic circumstances. The extent of disadvantage associated with rural locations depends to some extent on the size of the country (James *et al.*, 1999). Access for students with a disability has advanced much more in some nations than others (Ebersold and Evans, 2003).

Women's participation in higher education remains an issue. In some countries, women are still underrepresented but in others they are clearly in the majority, although not necessarily in all fields of study or at all levels of awards. **Table 1** shows the sizable variation in the UNESCO gender parity index (GPI), which is the ratio of males to females (a GPI of 1.00 indicates parity, and greater than 1.00 indicates more females than males). All of these GPIs rose between 1999 and 2004 with the exception of sub-Saharan Africa.

In most nations, social class or SES is the most reliable predictor of the likelihood that an individual will participate in higher education. One German study in the 1990s (Schnitzer *et al.*, 1999) reported that, of 100 lower social background children only 33 reached upper secondary school and only eight entered higher education. In contrast, of 100 upper social background children, 84 reached upper secondary and 72 entered higher education.

Table 1 UNESCO gender parity index for all tertiary enrolments, 2004 (ratio of males to females, including type A and type B)

Arab states	0.95
Central and Eastern Europe	1.25
Central Asia	1.05
East Asia and the Pacific	0.89
Latin America and the Caribbean	1.17
North America and Western Europe	1.32
South and West Asia	0.70
Sub-Saharan Africa	0.61

The Higher Education Funding Council for England has reported that young people from the most prosperous areas are 5–6 times more likely to go to university than young working-class people in particular areas of disadvantage (HEFCE, 2007). Finland is an important example because despite a highly egalitarian public school system, higher education participation is skewed according to parental educational backgrounds. The OECD thematic review of tertiary education (Davis *et al.*, 2006) reported that:

...large inequalities in access to tertiary education by social origin still persist in Finland. Participation rates in university education among young students (aged 20–24) differ considerably according to the educational background of their parents. The relative chance of entering university education has remained at least ten times higher during the last decades for those coming from academic home background compared to students from less educated families. The expansion of the tertiary system appears to have narrowed the relative advantage of an academic home background to seven-fold.

In many nations, the expansion of participation has done little to influence the participation share for low socioeconomic students. In Australia, for example, the proportion of low socioeconomic background students in higher education remained virtually static at close to 14.5% (against a community reference point of 25%) in the period 1996–2005, during which time the overall growth in enrolment of domestic students was 17% (DEST – Department of Education, Science and Training, 2006). In the USA, some commentators have argued that continued growth has created greater social inequality in the nature of higher education participation (Astin and Oseguera, 2004), resulting from standardized entry testing used for selection purposes and rising tuition costs.

Despite the significance of SES in determining the likelihood of higher education participation, by its nature it is a difficult concept to define and measure. This has a range of implications, including for efforts to broaden access and for the collection of data policy for comparison and monitoring purposes. Various approaches have been used, all with limitations, including parental occupations and educational levels, family income levels, and geographical indicators such as the zipcode or postal code of home address.

Numerous factors underlie the underrepresentation of certain groups. The interrelationships between these factors are not well understood. Nonetheless, the underrepresentation of certain subgroups in higher education is a result of the combined effects of lower school-completion rates, lower levels of educational attainment in schools – thus limiting opportunities in the circumstances of competitive entry based on academic achievement – lower levels of educational aspiration, and lower perceptions

of the personal and career relevance of higher education, alienation from the culture of universities, and a range of interrelated financial factors: the expense of university fees, the lack of availability of income support while studying, and the loss of potential income while studying. Some of these factors are explicit barriers to participation; others are not literally barriers but reflect that absence of family, school, or community environments that lead to the development of higher education aspiration. The imbalances in higher education participation often reflect endemic educational disadvantage that begins in the earliest years of schooling.

The underrepresentation of certain groups of people has led to policy responses in many developed nations. Policies and programs designed to achieve more equitable access to higher education have been implemented at both national and institutional levels. Equity initiatives have taken a number of forms, including the removal or reduction of perceived barriers, such as scholarships to fully or partially meet the cost of fees, compensatory admission for students with lower levels of school achievement as a result of family or personal hardship of educational disadvantage, and programs described as affirmative action that focus on subgroup membership as the basis for admission. Policies for affirmative action or positive discrimination have been contentious for they conflict with conceptions that entry to higher education should be based on merit. The admission of people with lower levels of educational attainment has been seen by some to lower academic standards and to take places away from those who deserve them. Specific affirmative action programs in the United States have been successfully challenged in legal cases that have significant ramifications for public and institutional policy (Allen, 2005).

The effects of equity policies are not clear. Almost paradoxically, expansion has made it difficult to assess whether gains have been made with equity. Certainly, at the aggregate level, policies appear not to have significantly reduced the persistent, proportional underrepresentation of certain subgroups of people. However, it is the case that higher numbers of people from previously underrepresented groups are participating in higher education in the nations with expanded systems. Whether this is an effect simply of expansion or a result of equity initiatives, or both, is difficult to discern.

It is increasingly evident that there are significant limits to the capacity of policies centered in higher education to address the problems of group underrepresentation for the higher socioeconomic groups are more successful in gaining access to higher education, and to the most prestigious universities and fields, partly because of higher school-completion rates and higher levels of school achievement. Investment in schooling, including in the earlier years, is an essential element of a coordinated policy approach to widening higher education access.

The Issues and Areas for Research in the Context of Increased Demand for Higher Education

The Limits to Expansion

Against the background of great complexity and difficulty in monitoring the rapid expansion of higher education around the globe, the reasons for it are starkly clear and simple. It is a general perception that postindustrial societies require higher levels of education, and the heightened aspirations of individuals and their families in a globalized world are seen as depending on education. One of the most interesting aspects of this field is the extent to which the goal of universal higher education seems to have been accepted by most governments around the world. The rhetoric associated with the knowledge economy seems to be virtually unchallenged. Any doubts that what we may be witnessing is largely creeping (or perhaps galloping) credentialism are silenced by research which demonstrates that more education is strongly associated with increased productivity. Whether there is any limit to this acceleration remains unclear.

Collecting Data to Track Access and Equity

A range of indicators has been developed to address the issue of what is the most meaningful way of gauging higher education participation in societies. As Trow points out, the use of a young-adult age group as a reference point for participation rates is becoming increasingly problematic, as more mature students enter higher education and the ideal model moves toward the concept of lifelong learning. Therefore, in addition to entry and graduation data, the OECD and UNESCO calculate the average number of years of higher education completed by citizens and projected future levels based on growth at lower educational levels. Clancy and Goastellac (2007) propose that a composite measure is needed, one which incorporates three participation and two outcome indicators.

Another area in which new measures and collection systems are urgently required is transnational enrolments. As more students enter higher education programs in other countries, they can slip through the data-gathering net. In Australia, for instance, although information about international students is collected, it is not analyzed with the data relating to domestic students and is seen, probably appropriately, as not relevant to the monitoring of equity in participation within the host country. There is as yet no comprehensive system for monitoring these patterns internationally. The need is clear: a large proportion of citizens of low-income countries who gain entry into higher education do so in countries other than their own. Issues of access and equity in higher education need to be addressed

globally as well as nationally and for this more comprehensive and refined databases are essential. Further, present conceptions of SES are firmly grounded in national economic, social, and cultural frameworks and a new understanding is needed of how participation rates vary by social class in a global higher education environment.

The Concept of Meritocratic Entry

Merit and equity continue to be in tension. The concept of equity in elite systems of higher education has been partly based on the meritocratic principle that certain people are deserving of higher education on the basis of untapped intellectual potential. Yet, Trow (1973) speculated that as systems moved from mass to universal participation, access would move from being a right to an obligation, and that meritocratic admissions and compensatory programs for equity would be replaced by open access and equality of group achievement, on the basis of either class or ethnicity. There is little evidence of this occurring on a wide scale, even in the most expanded systems. Instead, there is the coexistence of meritocratic and open-access admissions, with institutions adopting differing stances toward student recruitment and selection in relation to their hierarchical position within highly diversified systems – emphasis in admissions policy for some institutions shifts from the challenge of fair, meritocratic selection toward the active recruitment of students, including people with lower levels of academic achievement.

Within the most expanded higher education systems, institutional diversity heightens competition for the places in the most prestigious universities: students compete for entry to what are perceived to be the best universities, while in turn the more prestigious universities compete for students with the highest level of school achievement. The importance of higher education as a positional good to some extent prevails.

Open Access

A relatively new layer of the higher education hierarchy has been added in recent decades, with the development of open institutions. The concept of openness applies primarily to admissions policies. To varying extents in different countries, entry is open to any student with minimal educational qualifications or, in some cases, to any individual who wishes to attempt a course, without any prerequisites. Increasingly, this concept has become associated with distance-learning procedures which, again to varying degrees, are used to minimize costs. Although supporters of distance education in its more traditional forms argue that it should be no cheaper to fund than face-to-face teaching, there is no doubt that the forms it is now taking (including increasing use of online learning) are intended to be significantly less expensive. In some

developing countries, these institutions have developed into mega-universities with the largest in China (the China Central Radio and Television University) enrolling approximately 2 million students. While such programs offer valuable opportunities to many people who would not be able to engage in higher education in any other form, the status of these qualifications is generally lower than those from traditional universities and the outcomes for students patchy. High proportions of students fail to complete their courses in open institutions. Again, although the data are quite inadequate in this area, it is clear that students in these programs are more likely to be from disadvantaged groups.

Funding Expansion

If there is general agreement about the desirability of universal higher education, no country seems to have found a very satisfactory answer to the obvious question of how this is to be funded. The United States, the richest nation in the world, has probably come closest, although numerous commentators, politicians, and university leaders have drawn attention to the signs of strain even in that system. There have been four main responses, which again have been strikingly consistent across the range of national systems, and which have important implications for access and equity. These are: ongoing reductions in funding per unit of student load (i.e., average expenditure per student), increasing stratification of institutional types, the development of open university programs, and privatization. All of these powerful trends are analyzed elsewhere in this encyclopedia. They will be considered here only in relation to equity issues. For it is a striking irony that, in order to increase access to higher education, governments have had to adopt policies which have the potential to exacerbate existing inequities. Decreased average funding rates would not in themselves have this effect, if applied equally. However, in many countries distribution is unequal, with some sectors of higher education being much less expensive to fund than others. This inevitably coincides with a hierarchy of prestige and, in turn, with different outcomes for students in terms of employment and earnings. Evidence from a number of countries indicates that members of disadvantaged groups are much more likely to attend less-prestigious institutions.

The Impact of Privatization

A further effect of the inability of governments to fund higher education adequately is a very rapid process of privatization, which takes a variety of forms. Privatization involves students paying increasing proportions of the costs of their education, either directly to private

institutions or back to governments in the form of upfront or delayed payments. The term can also be applied to the process of raising substantial funds from private enterprise or individuals. Ability to pay will obviously disadvantage individuals from lower socioeconomic groups, although the Higher Education Contribution Scheme (HECS) devised in Australia and adapted by some other countries does offer the option of delayed payment which is only required when a certain income threshold has been reached – that is, in theory, when the individual has acquired the ability to pay. Another form of privatization is subsidization of a set number of higher education places, while allowing individuals who do not win one of these places, to pay the full costs of their education. Unfortunately, another universal pattern seems to be that academic results tend to reflect socioeconomic differences, so that the low SES students who are more likely to miss out on the subsidized places are those least likely to be able to afford full fees. In a familiar vicious cycle, the most prestigious institutions are those most likely to benefit from privatization, in terms of attracting full fee-paying students, business support, and private donations, so the gap in quality and outcomes is likely to widen further.

Conclusion

The expansion of higher education systems from elite to mass to universal systems has not resolved inequities in access. Of course, in this context, equity is a relative concept. Just as with poverty, the definition cannot be absolute, but is determined by comparisons between groups. It is undeniably true that, in every country in the world, more citizens are receiving the benefits of higher education than ever before. The fact that comparative inequities persist should not cloud recognition of the achievement involved in the massive expansion of the last half-century.

Access and equity in higher education remain important issues for public policy in most countries. In the more expanded systems, institutional stratification has invited growing consideration of whether equity should be considered at the level of system, institution, or field of study. A major issue for research and policy during the next decade is the development of a new conceptualization of equity that takes into account the globalization of higher education and international student flows.

Boundaries of Institutional Autonomy and their Impact on Higher Education

V L Meek, University of Melbourne, Parkville, Victoria, Australia

Introduction

Institutional autonomy and the related concepts of academic or scientific freedom are defining characteristics of academe. "The university is the corporate realization of man's basic determination to know" (Jaspers, 1960: 20), and it is this classic notion of knowledge as sacrosanct upon which arguments for the autonomy of the university are ultimately grounded. Traditionally, it was assumed that the purpose or idea of the university was best served by its separation from government, on the one hand, and society, on the other. The state served as the guardian rather than the determiner of academic principles, with the issue being "how far higher education institutions are licensed to be free to set their own norms, or even to be in conflict or tension with the society that sponsors them to be its antibodies" (Kogan, 1984: 67). For most contemporary higher education institutions, however, the boundaries of institutional autonomy have become exceedingly porous.

Institutional autonomy is a relative concept, conditional on a variety of historical, cultural, political, and economic factors. Institutional autonomy is not in itself a guarantee of academic freedom, and the degree of genuine institutional autonomy has waxed and waned over the years in accordance with large-scale political changes in national systems of higher education. For example, within the context of the so-called European continental model of higher education governance, considerable enhancement of university autonomy may be observed over recent decades, while it is arguable that higher education institutions operating under the Anglo-Saxon tradition have moved in the opposite direction (Trow, 2005). It appears that the autonomy of Japan's national universities is being considerably strengthened with their transformation into "national university corporations" (Arimoto, 2006). In every political jurisdiction, the degree of autonomy enjoyed by higher education institutions varies according to type and function of the institution, with universities at the top of most autonomy hierarchies. Looked at historically and cross-culturally, the autonomy of higher education institutions and the principles underpinning it are in a state of constant flux.

One approach to better understanding how the boundaries of institutional autonomy shift over time and space is to view the phenomenon from both external and internal perspectives. The external environment in which

universities operate and various powerful stakeholders in that environment – politicians, employers, parents, etc. – place limits on what higher education institutions can and cannot do. However, autonomy is also bound by the university's own internal dynamics – by the ways in which it is managed and governed and the mechanisms it uses to distribute power and decision making. Moreover, autonomy itself can be defined from a number of perspectives.

Definitions

Much of the recent changes in higher education in many jurisdictions involve questions of institutional autonomy and academic freedom. However, the autonomy debate is not new nor is it restricted to any one country, except in its details (see Ashby, 1966; Berdahl, 1988). Moreover, debates about autonomy are often more emotive than analytically rigorous, and, from an analytical perspective, a distinction needs to be made between academic (maybe better phrased as scientific or academic freedom) and institutional autonomies. Drawing on Ashby (1966), Berdahl (1988: 7) defines academic freedom as the "freedom of the individual scholar in his/her teaching and research to pursue truth wherever it seems to lead without fear of punishment or termination of employment for having offended some political, religious, or social orthodoxy." On the other hand, "institutional autonomy... is typically viewed as the right to self-determination in the appointment of academic staff, student admission, teaching content and methods, standards control, priority setting and future development" (Kayrooz, 2006: 4).

In its literal sense, no higher education institution has complete autonomy; autonomy is not an all-or-nothing issue. There is an important distinction between the autonomous university as a self-governing scientific and educational community in a dynamic relationship with society, and the university as autarchy – totally self-sufficient and having absolute sovereignty (Zgaga, 1997). Higher education institutions will always be subject to some demand to be publicly accountable, whether the institutions themselves are public or private. Society has too much of an interest in higher education to allow autarchy or pure autonomy to prevail. According to Ashby (1966: 296), what is important is to examine the "essential ingredients" of institutional autonomy:

1. Freedom to select staff and students and to determine the conditions under which they remain in the university.
2. Freedom to determine curriculum content and degree standards.
3. Freedom to allocate funds (within the amounts available) across different categories of expenditures.

Drawing again upon Ashby, Berdahl (1988:7) further subdivides autonomy into substantive and procedural issues: “*substantive autonomy* is the power of the university or college in its corporate form to determine its own goals and programs . . . ; *procedural autonomy* is the power of the university or college in its corporate form to determine the means by which its goals and programs will be pursued” Interferences in procedural autonomy – for example, control over purchasing – “can be an enormous bother to Academe, and often even counter-productive to efficiency, but still usually do not prevent universities or colleges from ultimately achieving their goals. In contrast, governmental actions that affect substantive goals affect the heart of Academe” (Berdahl, 1988: 8–9).

Generally, in many countries, substantive autonomy has either been maintained, as in Australia and Britain, or is being substantially increased, as in many continental European nations. However, simultaneously, institutions are being held more accountable to governments and a variety of other external stakeholders for achievement of their goals and missions. The nature and detail of procedural autonomy wax and wane in all countries, to the great annoyance of institutional administrators.

Rather than viewing autonomy as an absolute, it should be viewed as a relational issue involving the balance of power between institutions and government, on the one hand, and between management and the academic profession within institutions, on the other. Direct threats to academic freedom are more closely associated with the internal balance of power between executive and collegial governance than with external intervention, although the executive arm of the institution may act as a proxy for government bureaucrats.

External Boundaries of Institutional Autonomy

What is important to understand is not the strengthening or weakening of the boundaries of institutional autonomy *per se*, but the demands of changing social and political contexts that set the limits on the degree to which higher education institutions can behave as independent actors. Historically, the most important external political factor determining the autonomy of the university was the church – now almost everywhere replaced by the state.

Although, nearly everywhere, legislative frameworks set the broad boundaries within which autonomy is exercised, the autonomy of the university as a legal

entity varies in its detail from country to country and over different historical periods. In Australia, for example, what constitutes a university is defined by legislation, as are a set of protocols that specify its functions. In the USA, the term university is used much more freely, while in the former eastern European block of now newly emerging states – such as the Czech Republic and Slovenia – the legal autonomy of the university as a corporate body is being created from a collection of disparate state-controlled faculties and research institutes.

However, more important than the legislative framework, in which higher education institutions operate, is the impact on institutional autonomy of the demands of government, consumers, and other stakeholders for the enhanced accountability, relevance, and contribution to the knowledge economy of higher education institutions. Neoliberal reforms of higher education systems, the imperatives of New Public Management, and international trade agreements all have an impact on institutional autonomy. Supranational agreements, such as the Bologna process in Europe, and global initiatives, such as the WTA General Agreement on Trade in Services (GATS) and International Monetary Fund (IMF) funding stipulations in developing countries, all have the potential to curtail institutional autonomy. “Institutional Autonomy becomes a contingent item in a broader political and economic agenda” (IAU, 2006: 2). Moreover, as Zgaga (1997: 124) notes, “the discussion of the external dimension of university autonomy includes not only the relationship to the state – that is, the regulation of the legal system and funding – but also to civil society, its heterogeneous needs, value orientations, individual and group aspirations, etc. And this relationship is not necessarily always harmonious.”

In relation to the external environment, two powerful and interrelated concepts presently reshaping university autonomy are that of the Service University – the shift of higher education from a public to a consumer good – and market steering of higher education systems. The Service University is responsive and relevant to the needs of clients and stakeholders, and with it “comes the notion of ‘conditional autonomy’, this is institutional autonomy subject to rendering accounts to public and to financial providers” (IAU, 2006: 2). Supposedly, the ideals of the Service University are best achieved under market-like conditions that demand competitive and responsive behavior from institutions.

The notion of the Service University is tightly bound to those of government deregulation, accountability, and market competition – a belief in the hidden hand of the marketplace as a powerful mechanism for bending the goals of higher education institutions to the needs of society. “In the new market context of higher education, policy makers are seeking to redesign systems of higher education to address the newly conflicting demands of institutional autonomy and public accountability” (Dill, 2001: 23).

It is argued, in several jurisdictions, that market competition – as opposed to centralized state control – is better able to produce innovative, adaptive, and responsive higher education institutions. Underpinning this shift in government steering of higher education from what Van Vught (1989) termed the state-control model to the state-supervising model is the ideology of economic rationalism. Apparently, universities and colleges must become more economically efficient through such means as greater competition in a more open academic market, through the strengthening of institutional management along the lines employed by major corporations, and through improved public accountability. The shift from state to consumer control reflects a belief that market forces, rather than state intervention, will make institutions more cost effective and better managed, as well as making higher education systems more fluid and responsive to client needs and demands. Somewhat paradoxically, as discussed in more detail below, while in many nations the direct legislative control of higher education institutions has been relaxed, academic leaders and rank-and-file staff feel that the autonomy of their institutions has diminished significantly.

Universities have always competed with one another for students, resources, and prestige. However, it has only been since the late 1990s that the concept of the market has helped regulate the relationship between institutions and government, on the one hand, and between institutions and the broader community, on the other. Government is not totally disinterested in the regulation of higher education as is evidenced by increasing emphasis on quality control and other system-wide accountability measures. However, in order to ensure that higher education will cost less while better serving national economic priorities, the concept or metaphor of the market has become “central to a number of discourses which constitute the current policy agendas of governments . . . and educational institutions. Education is currently being thought of in market terms and markets of various sorts are guiding priorities and funding” (Kenway *et al.*, 1993: 2).

There may be a relationship between institutional autonomy and the multiplicity of funding sources upon which the institution is dependent – the less dependent on any single source of funding, the greater the degree of autonomy. However, what is at issue here is not the multiplicity of funding sources *per se*, but rather the structures of control embedded in particular types of funding mechanisms. In this sense, market forces may be more of a threat to institutional autonomy than government policy and centralized control ever was. There is a potential rigidity to the market, for “market forces create more, not less bureaucracy which by its very nature needs to see, taste and manipulate *objective* performance indicators so that the operators of bureaucracy . . . can evaluate what constitutes value for money” (McElwee, 1992: 191).

Universities compete with one another in attempting to interpret how best to take advantage of external and other financial incentives, and, in so doing, have been caught in a continuous process of trying to second guess both the market and government policy. While the relationship between universities and government may nominally be centered on autonomy, it is actually based on funding rewards to institutions that support governmental objectives which result in university competition for funding and enforced conformity to governmental goals. Somewhat paradoxically, universities are given the freedom to conform. Neave (1996) encapsulates this seeming paradox in what he terms as the “law of anticipated results.” The law of anticipated results operates at the institutional level – giving the impression of autonomous institutional action to what is, in fact, an institutional reaction to actual or anticipated external forces, directives, or events. Institutions interpret what is or will be required by governmental policy and act accordingly, making it considerably difficult to determine whether change is institutionally driven or externally imposed. Thus, “the rhetoric of public policy is often at odds with the institutional behaviour it elicits” (Neave, 1996: 30). Many institutional leaders report that their autonomy has been restricted. Possibly, it may be the general competitive environment that governmental policies help create, rather than the policies *per se*, that institutional leaders perceive as unduly constraining their activities and freedom.

The market – as a form of social coordination – has in many jurisdictions replaced state bureaucracy as the primary regulator of higher education. In a totally free market, no one is in control. However, governments everywhere regulate markets and “a mix of factors, including values and legal systems, determines at any moment the balance between market coordination and other forms of social coordination” (Geiger, 2004: 233). In many countries, the higher education market is balanced by a number of accountability measures, for example, external quality assurance frameworks for both teaching and research. While accountability may be seen as a threat to the self-referential autonomy of the university, it is only one aspect of the institution’s relationship with society and “other relationships, if cultivated alongside accountability, can work to strengthen university autonomy rather than weaken it” (Gibbons, 1998: 58). Several students of higher education have argued that in the last few decades what has been lost in the relationship between higher education institutions and society is not so much autonomy as trust (Trow, 2005).

Internal Boundaries of Institutional Autonomy

The higher education institution itself, incorporating its governance and management control structures, is an

important determinant of institutional autonomy. The university as an organization or institution in itself provides boundaries to its autonomy. In addition, internal organizational design is often directly related to external political, social, and economic pressures.

Philosophers of higher education have long recognized the tension between the idea of the university and the institutional form within which that idea is realized: “The institution is simultaneously indispensable and a standing threat to the idea of the university”, as Jaspers (1960: 51) pointed out shortly after World War II. Half a century later, Marginson and Considine (2000: 8) make a similar observation: “It has become all too easy to imagine the university without one or another of the academic disciplines; it is impossible to imagine the academic disciplines without their institutional setting, and its governance.” Alternatively, as Jaspers (1960: 83) puts it: “The university exists only to the extent that it is institutionalized. The idea becomes concrete in the institution . . . Yet ‘institution’ necessarily implies compromises. The idea is never perfectly realized. Because of this a permanent state of tension exists at the university between the idea and the shortcomings of the institutional and corporate reality.”

The realities of the external environment in which the modern university operates have changed, some would say transformed utterly, its present internal organizational form. In many countries, market-steering at the sector level has, in turn, changed the way in which universities are managed, decisions made, and power distributed within the organization.

There is one school of thought that considers management principles as universal: good management practice can be transferred from organization to organization despite the line of business of a particular organization. Coupled with this is the belief that the university – like any large organization – requires corporate style management, strong leadership, and clear lines of authority. Others, however, argue the unique features and professional character of higher education institutions – higher education institutions are professional organizations, and in all professional organizations there is an inherent tension between professional autonomy and management prerogative, but with the balance of power leaning toward the professional community.

According to Clark (1983), academic groups and disciplines in competition with one another create boundaries between themselves in order to avoid direct conflict. However, the current emphasis on market competition and corporate management coupled with increasing demands for accountability and economic relevance are making professional group insulation increasingly difficult, with some claiming that we are now experiencing a basic re-norming of the academic profession (Slaughter and Leslie, 1997). The movement from a collegial to a managerial approach in higher education is challenging

traditional academic professional loyalties. Trow (1983: 122) wrote, in the early 1980s, that “the chief protection of the autonomy of the universities lies in the expertise of their staff . . . [A]cademics’ monopoly on expertise and their need for freedom to direct their own advanced instruction and research, place limits respectively on governmental control . . . and the bureaucratisation of the organization of university work.” A quarter-century later, academe’s monopoly of knowledge and complete control over setting the research and teaching agenda are severely contested (Gibbons, 1998). In the neoliberal corporate university, strong management – rather than academic excellence – is the “lynchpin of university ‘performance’ and competitive position” (Mollis and Marginson, 2002: 321).

Despite policy statements at various political levels to the contrary, there have been a number of reports indicating that many in the academic community believe that higher education institutions have lost autonomy and the freedom to determine their own directions (Meek, 2003). In several jurisdictions, this has created a strong them/us attitude between universities and government and severely eroded academic morale; in addition, within institutions, there are serious tensions among management levels as to how higher education institutions should be run. “Presidents and rectors in many countries . . . now find themselves engaged in extensive negotiations with ministries and governments over issues of internal governance, managerial flexibility, and authority for program approval” (Dill, 2001: 22).

The political context in which universities operate has always moderated the degree of institutional autonomy. Furthermore, the way in which the political context prescribes boundaries to institutional autonomy, in turn, determines the way in which the institution determines the autonomy of its members. The market steering of higher education and the competitive environment in which institutions must operate have strengthened the role of the executive and central management to the detriment, some would argue, of academic freedom. Tapper and Salter (1995: 59), for example, state that “the link between institutional and individual autonomy within the British university systems has been broken. A decline in the autonomy of the dons has been matched by an actual enhancement of the autonomy of the universities as institutions.”

The movement of the university away from strict state bureaucratic control toward enhanced institutional autonomy is a characteristic of many national higher education systems. Even in countries with an historical predilection toward strong university autonomy, there is a concerted effort on the part of the state to strengthen governance and management at the institutional level, possibly with an implied assumption that it is the job of management to bring recalcitrant academics into line.

Several higher education institutions themselves have called for greater autonomy from state control in order to more effectively compete, be more entrepreneurial, and develop a competitive culture.

Several factors have led to greater market-like competition among universities, for example, the presumption of the global ascendancy of capitalism following the end of the Cold War; the movement from the welfare state to the competitive state with an emphasis on maximizing returns on investment more so than general welfare; government as service purchaser rather than service provider; movement of the state from manager of public values to manager of scarce resources; and the ascent of neoliberal ideology and its emphasis on lower taxes, smaller government, and the presumption that higher education is more of a private, than a public, good.

The shift of higher education from a public to a consumer good has several consequences for institutional autonomy. A shift toward consumerism and the student as client, for example, has not only enhanced the notion of user-pays, but has given the client in a consumer's market a good deal of control over what they pay for. The greater orientation to student as consumer and education as product has changed the balance of power within many universities. Theoretically, consumers purchase what they want and are always right. It has been argued that, in the USA (Geiger, 2004), through student consumerism, power has shifted from universities to students, and the university has largely lost control over the design of the undergraduate curriculum. In a market driven by student demand, student choice coordinates the curriculum. This relationship significantly detracts from student learning and limits the autonomy of the university to provide what is, in the opinion of its professional staff, the most appropriate educational product: "The market power of students has consistently shifted the balance in the direction of 'customers'" (Geiger, 2004: 246).

There appears to be a paradox embedded in the relationship between market coordination and institutional autonomy: while universities with sufficient autonomy from the state are best able to adapt to national markets through enhancing quality and competitiveness, responding to these incentives may detract from providing direct service to state citizens (Newman *et al.*, 2004). "The marketplace has . . . brought universities greater resources, better students, a far larger capacity for advancing knowledge, and a more productive role in the . . . economy. At the same time, it has diminished the sovereignty of universities over their own activities, weakened their mission of serving the public, and created through growing commercial entanglements at least the potential for undermining their privileged role as disinterested arbiters of knowledge" (Geiger, 2004: 265).

Another paradox in the autonomy debate is that, with the enhancement of institutional autonomy and the

corresponding loosening of strict state control, the rights of individual scholars to set their own individual research and teaching agendas free from outside direction appear to have diminished. "In a remarkable accomplishment of living with contradiction, the university . . . has for an extended part of its history been able to reconcile [a] firm insistence on autonomy with the persistence of an institutional relationship between the university and the state that was both utterly non-autonomous and characterized by more or less total dependence on both the regulatory and providential tutelage of the state over the university – with the one notable exception, of course, of not directly interfering with the individual professor's 'autonomy'" (Weiler, 2003: 7). A more autonomous relationship between the state and the university has strengthened institutional autonomy, self-governance, and self-determination in the belief that this will make the institution more effective in setting goals and strategic directions and in mobilizing resources. The right to decide basic institutional objectives, and how their achievement will be resourced, has seemingly shifted from academic professionals to institutional management: "Institutional autonomy competes with individual autonomy" (Weiler, 2003: 8).

It seems that the twenty-first century Service University has shifted its orientation from social knowledge to market knowledge and that the "development of a market oriented university supersedes academic decision making" (Buchbinder, 1993: 335). According to Newson (1993: 298): "These new forms of decision making fundamentally undermine a conception of the university as an autonomous, self-directing, peer-review and professional-authority based institution, and thus changes the politics of how academic work is accomplished."

Conclusion

Clearly, the boundaries of institutional autonomy in higher education have become more porous. However, academics and the institutions they inhabit are far from being totally directed by the forces of managerialism or the market. Maton (2005: 699), drawing on Bourdieu's field theory, makes a distinction between positional autonomy – power distribution between positions within the field of higher education and those external to it – and relational autonomy: relative control over work practices, aims, measures of achievement, etc., *vis-a-vis* external influences. Relational autonomy has been the most weakened of the two. "The notion that social and economic goals are served by enabling universities to create and transmit knowledge as ends in themselves has been replaced within policy discourse by an utilitarian view of higher education as an instrument for achieving politically desirable outcomes" (Maton, 2005: 699). However, with respect to positional autonomy, "the agents responsible

for enacting these principles remain overwhelmingly located within higher education.” In addition, there is evidence to suggest (Meek, 2003) that academe is more adroit, than often assumed, in turning policy discourses concerning external accountabilities and social and economic relevance to its own ends. The autonomy of the university was never absolute, and its boundaries will remain contested.

Diversity of Higher Education

U Teichler, University of Kassel, Kassel, Germany

© 2010 Elsevier Ltd. All rights reserved.

Major Distinctions

The key activities of higher education – teaching and learning, research, and, possibly, service – are undertaken in diverse institutional settings. The settings vary according to the tasks and functions; the composition as well as the level and substance of activities; the stages of study programs, etc.

In referring to the macro-level of society, the term higher education system is employed as a rule for all higher education institutions within a country. This is because higher education, in spite of the universalistic nature of some disciplines, international cooperation and exchange, and cosmopolitan attitudes of many scholars, is strongly shaped by modes of supervision and funding, organizational rules, curricular practices, etc. usually determined within individual countries.

The most obvious single element of diversity is that of disciplines. Theories, methods, and areas of knowledge develop their specific territories of discourse, and institutions of higher education, as a rule, are subdivided into disciplinary units.

The major debate on diversity, however, addresses variations between institutional segments in which teaching, learning, and research are undertaken – it might be called the shape, pattern, or structure of the higher education system, whereby attention is paid notably to institutional and program types, levels of study programs, or levels and profiles of the individual institutions of higher education or the individual departments. Some studies, though, include other dimensions as well, such as organizational differences (e.g., Birnbaum, 1983; Huisman, 1995), the financial regime of the institutions (notably public vs. private higher education), and the modes of educational delivery (such as distance education).

The debate on diversity is popular and controversial, because policies in this domain are widely viewed as being very powerful: the shape and size of the system, though continuously changing incrementally, are often regulated by external actors, for example, governments and parliaments, and these externally driven regulations might have a strong influence on the internal activities and thus on the services higher education actually provides to society.

Classifications

Descriptions of higher education systems employ a bewildering diversity of concepts, terms, and dimensions. This

even holds true for the term higher education. Until about 1950, the term university was mostly employed. The term higher education became popular notably, when politicians began to point out that other institutions, characterized by a predominant teaching function, have much in common with universities. Since about the 1980s, the term tertiary education gained popularity by underscoring that all education for students beyond the typical age of secondary education can be viewed as sharing somewhat of a common function, though the level of intellectual ambition and the link to scientific knowledge might vary.

Higher education systems are described concretely (see Teichler, 2007a) in most cases according to:

- types of higher education institutions or types of programs,
- levels of programs, and
- variations in reputation and prestige, and, possibly, according to the substantive profiles of institutions and study programs.

In characterizing the differences named, most actors and observers:

- sort differences between institutional settings to a varying extent as vertical (in terms of levels of quality, reputation, selectivity, etc.) and horizontal (in terms of substantive profiles, conceptual schools, etc.);
- refer to a varying extent about formal elements employed in laws, other regulations, and any official descriptions (e.g., institutional types, levels of programs, official functions of study programs) and informal elements (e.g., profiles and reputation);
- make a distinction between diversity within higher education institutions (internal, intra-institutional, or program diversity) or between higher education institutions (external, inter-institutional, or intra-institutional diversity).

Often, these terms aimed to describe the overall character of the higher education system according to the kinds and degrees of variety of the institutional setting. A higher education system might be characterized as:

- unitary, if one institutional type clearly dominates: in the past, Italy was often taken as an example of a system where more or less all institutions were universities and most study programs were long;
- binary, if two major types of higher education are seen as characteristic, for example, polytechnics, colleges of advanced education, *Fachhochschulen*, etc.;

- multilevel, if the type of system can be sorted better according to the levels of the study programs than according to the types of institutions of higher education and according to institutional types. For example, the French system was often classified according to programs of the first 2 years of study (baccalaureate +2; e.g., vocational programs at *écoles*, the first half of university programs, and preparatory classes for *grandes écoles*), programs leading eventually to the university degrees and degrees of the *grandes écoles*, and finally advanced programs (baccalaureate + 6 and more); and
- comprehensive systems, if diversity is predominantly taken care of intra-institutional differences rather than through differences between institutions: This was envisaged in the 1970s but eventually never fully realized through the establishment of a few *Gesamthochschulen* in Germany and through the incorporation of some higher education institutions with short study programs into universities in Sweden.

In some countries, specific classifications are undertaken to characterize their higher education system. For example, the Carnegie classification in the US groups institutions of higher education notably according to their involvement in research and doctoral training: research universities, comprehensive universities (with selective areas of high-quality research and doctoral programs), 4-year colleges, etc.

Finally, some classifications characterize the functions of institutional diversification. The US higher education researcher Martin Trow (1974) coined the words elite higher education, mass higher education, and universal higher education. His widely known concept often is misunderstood as directly depicting historical stages of the overall higher education system (mass higher education substituting elite higher education). According to Trow, however, elite higher education is supplemented by mass higher education when about 15% of the corresponding age group enrol, and eventually by universal higher education, when about 50% enrol. Mass higher education serves best those students additionally enrolling in higher education institutions and is at the most, moderately involved in research, thereby protecting elite higher education which serves a select student population and is strongly involved in research. This functional diversification, according to Trow, does not necessarily correspond to an institutional diversification.

Types of Higher Education Institutions and Study Programs

In the early 1950s, about 10% of the corresponding age group were enrolled at institutions of higher education

in the US, while the enrolment rate was about 3–5% in most other economically advanced countries. Thereafter, the view spread soon that a growing proportion of highly educated persons in the labor force contributes substantially to economic growth. In the 1960s, educational expansion was increasingly interpreted as serving both economic growth and the reduction of unequal opportunity in access to advanced levels of education. Moreover, educational systems had become more open in general, and a rising percentage of the population wanted to enrol.

In the wake of increasing enrolment rates, the view spread in Europe that a substantial expansion was not feasible in the relatively costly setting of universities characterized by a close link between teaching and research and by relatively long study programs. Furthermore, the notion dominating in the US that the growing number of students was bound to be more diverse in terms of motivations, academic talents, and future job prospects, and would be served best by a diversification of higher education was accepted in Europe as well. However, in contrast to the US, clear distinctions between types of higher education institutions and possibly between the overall duration of study programs became the most popular approach in Europe from the 1960s onward for a considerable period (see Teichler, 1988). Three early national reforms are named most frequently in this context:

- Polytechnics were established in the United Kingdom in the early 1960s. They required in principle the same entry qualifications as universities and had the same types of degree programs, but their level of academic ambition was more moderate and many of the programs had a stronger vocational emphasis. Polytechnics have striven more strongly to become similar to universities than to strengthen their specific profile, and they eventually were named universities in 1992.
- During the 1960s as well, *Instituts Universitaire de Technologie* (IUTs) were established in France as specific units within universities offering 2-year programs which turned out to be more select and demanding than the existing programs in post-secondary *écoles*, but clearly were more applied than university programs. Various IUT programs were extended to 3 years when a convergent system of study programs and degrees was advocated in Europe in the late 1990s.
- Since 1970, *Fachhochschulen* were established in the Federal Republic of Germany as a second institutional type. One year less prior schooling than at universities was the required entry quality qualification, possibly including vocational training. The study programs were slightly shorter and more applied than at universities. Since about 2000, these institutions (recently called in English universities of applied sciences) began to introduce a bachelor and master structure, whereby

majority of master programs have an applied emphasis, while some aim to be similarly theoretical as those at universities.

Efforts, for example by the Organization for Economic Co-Operation and Development (OECD), to formulate generally acceptable terms for these new institutions and programs were not successful. Nonuniversity higher education was viewed as too prerogative to that sector. Short-cycle higher education was not applicable in all cases, and alternatives to universities (OECD, 1991) were viewed as too general. Eventually, the international organizations used abstract terms such as tertiary type A and tertiary type B. The three most often named characteristics of the second type of higher education institutions (see Teichler, 1988) do not apply in all cases:

- The second type was expected to concentrate on teaching and learning. The teaching load of academics was substantially higher than that of those at universities. However, applied research was seen as an important function in some countries.
- The study programs were in most cases shorter, but not consistently across all countries.
- The study programs had an applied curricular emphasis, but again, this distinction was more strongly accentuated in some countries than in others.

Views differed in Europe whether the sectors should be primarily differentiated according to types of higher education institutions or according to types of study programs. In some instances, varied types of programs under a single institutional roof were advocated as superior because they could offer students a more open choice during the course of study and because one could expect a cross-fertilization of the various approaches.

Actually, the second type of higher education institutions constantly tried to redefine its role through partially underscoring its specifics and concurrently by trying to move closer to the universities in various respects (teaching load, teachers' salaries, research function, etc.).

Almost silently, as far as the overtones of higher education policy debates are concerned, a third type of institutions and study programs emerged. According to OECD statistics, the entry rates to tertiary education increased in economically advanced countries from less than 40% on average in the 1990s to more than 60% in the middle of the first decade of the twenty-first century. This includes in some countries up to about one-third of persons enrolled in tertiary programs not being considered higher education. These programs require in some countries the same number of years of prior schooling as university programs, in some countries somewhat less of prior schooling, and in some others, these are advanced vocational training programs, often following a first

vocational training program, for example, technician training programs subsequent to, for example, car mechanic training programs.

Levels of Study Programs

Intra-institutional diversity according to teaching and learning, though, had a long tradition in a substantial number of countries as regards levels of study programs. In contrast to countries such as Germany, the Netherlands, or Italy, where long university programs existed, Anglo-Saxon countries had a second level of study programs, that is, master programs subsequent to bachelor programs. Northern European countries had upper *kandidat* programs subsequent to lower *kandidat* programs, and France had the *maîtrise* subsequent to the licence in some fields of study. These stage systems of study programs and degrees had different functions in the various countries: In France and Northern European countries, one could leave the system earlier if one wanted to become a teacher outside the sector of the academic secondary schools. In the United Kingdom and Japan, the first degree was generally viewed until recently as the normal entry qualification to all high-level occupations. In the US, the masters or professional degrees gradually became the entry qualification for high-level careers while the bachelor opened up only the second-ranking career avenues.

In the late 1990s, ministers in charge of higher education – initially from four countries in the Sorbonne Declaration in 1998 and thereafter from 29 countries in the Bologna Declaration of 1999 – called for the establishment of a convergent stage system of study programs and degrees in Europe within about a decade. In fact, many institutions of higher education established bachelor programs – often for a period of 3 years, but some up to 4 years – and subsequent master programs – most often for a period of 2 years, but some for 1 or 1.5 years. Universities were called to arrange the bachelor programs in a way that they turn out to be a meaningful entry qualification for employment rather than a *de facto* interim qualification for studying up to a masters program.

As a consequence, stages of study programs and degrees certainly became the single most important formal dimension of diversification more or less all over the world. It remained an open question, though, whether diversification by types of higher education institutions would persist thus, underscoring horizontal differences by the substance of the study programs and the competences striven for, or even be strengthened, or whether diversity by institutional type of higher education would gradually erode as a consequence of the increased emphasis on levels.

The various official policy documents published in the so-called Bologna Process do not address explicitly the

issue whether efforts to establish a convergent system of stages of study programs and degrees were expected to have any implication for horizontal diversity according to profiles of study programs. These documents only point out that the policy in favor of structural convergence should not exert pressure for curricular convergence among national higher education systems.

Reputational Diversification and Rankings

Higher education systems traditionally differed substantially according to the extent of informal vertical diversity. In the US and Japan, the range of quality and reputation between the universities at the top and at the bottom was always extreme as compared to European countries. Thereby, research, graduate education, and to some extent the quality of entering undergraduate students were seen as the most salient dimensions of vertical distinction in the US. In Japan, in contrast, most emphasis was placed on the entry level of students and the careers of the graduates. In the UK, a few universities were viewed as clearly excelling both in research and in the quality of study programs. In France, the top *grandes écoles* were viewed as far superior to the other institutions as far as graduate careers were concerned, while hardly any research was undertaken traditionally at these institutions.

Other higher education systems were characterized by some degree of hierarchy according to institutional reputation, though clearly flatter than the above-named countries, for example, Australia, Canada, or Sweden. Finally, Germany is generally viewed by experts as a large economically advanced country with the flattest reputational hierarchy among universities.

Since about the late 1970s, we note in Europe a gradually rising popularity of a steeper stratification of the higher education system. The belief began to spread among experts that top quality in research was achieved more easily through a higher degree of concentration of resources and top scholars in a small number of institutions. Since the 1990s, the *Zeitgeist* clearly moved toward a stronger popularity of steep differences between higher education institutions as far as academic reputation is concerned. In various countries, the funding system and other steering mechanisms were rearranged in order to facilitate a steeper vertical diversification among the universities. Moreover, international ranking lists of world-class universities gained popularity.

The advocates of a fierce race for ranks usually claim that economic success of a country increasingly becomes dependent on cutting-edge breakthroughs in knowledge, which can be fostered by financial investments into the apex of the higher education system. Moreover, ranking lists are viewed as both contributing to competition

beneficial for quality enhancements and to transparency essential for rational and quality-reinforcing choices (see various arguments in Sadlak and Liu, 2007).

The critics, first, question the validity of indicators employed. Second, they question the rationales of the stratification policies, for example, that success in learning depends on homogenous environments and that the quality of work of individual scholars and research institutions largely depends on the university as a whole. Third, they point out negative side effects, for example, increasing advertising activities of higher education institutions, data faking, and efforts to improve in terms of indicators instead of quality as such; reinforcement of past prestige hierarchies thus support labelism and credentialism rather than meritocratic reward, discourage those who are not the most successful ones in the race, and undermine horizontal diversity according to profiles of research approaches and study programs (see the arguments collected in Teichler, 2007a).

Major Explanatory Concepts

The public discourse as well as the literature in this domain do not merely address the configuration of the system, but also try to explain its causes. Three documents show the variety of explanations.

The organizers of an expert conference on diversity and convergence in higher education held in the early 1990s identified three major theoretical perspectives on diversity (Meek *et al.* 1996):

- *The internal perspective.* According to Burton Clark, “it is the academic discipline engine that invariably drives higher education institutions and systems to differentiation.” The “uncontrolled drive towards ever-increasing disciplinary specialisation is not always obvious; it often results in incremental or ... ‘unannounced cumulative change.’ But it is these changes ... that ultimately shapes higher education institutions and systems, making them evermore complex in an environment where operational diversification is far more important than nominal integration” (Meek *et al.*, 1996: 207). The authors argue that, according to Clark, “subject partitioning, program affiliation, subject dignification and subject dispersion” contribute to increasing diversity (Meek *et al.*, 1996: 213).
- *The systemic perspective.* According to Guy Neave, patterns of the higher education system are strongly affected by actors, notably those at national and supra-national levels. Neave names various “forces that work for and against homogenization or integrity”, and “no higher education institution or system moves inevitably towards either homogenization or diversification” (Meek *et al.*, 1996: 207). Neave does not only name

contradicting forces, but also names ambivalent realities rather than a clear trend toward a single direction: “whether a particular system is ‘diverging or converging is largely a function of where we focus our attention’” (Meek *et al.*, 1996: 208).

- *The environment perspective.* According to Frans van Vught, higher education institutions are “located within a supra-system consisting of the social, political and economic environment” (Meek *et al.*, 1996: 209, 210). Institutions of higher education “constantly survey the environment to identify opportunities and risks with respects to obtaining the resources . . . Those institutions that ‘read’ the environment correctly survive, those who do not perish” (Meek *et al.*, 1996: 210). In principle, a varied environment, thus, leads to increased diversity, while an isomorphic and uniform environment encourages a decrease of diversity. Van Vught views national governments as strong actors mostly opting for homogenous systems or types of higher education and thus contributing to a low degree of diversity.

According to the authors of the above study, the various countries analyzed “are themselves substantially divergent in terms of national approaches to diversity” (Meek *et al.*, 1996: 234). The various theoretical efforts help to “provide a better understanding of the complexity surrounding questions of diversity and convergence in higher education” (Meek *et al.*, 1996), but there might be more questions raised than answered.

In a synthesis of debates and analyses from the 1970s to the early 1990s, Ulrich Teichler (2007b: 124–125) points out that various scholars have opted for various developmental theories in their efforts to explain the dynamics of structural change in higher education.

- “The ‘*expansion and diversification*’ theory . . . had the strongest impact on the public debate. Accordingly, expansion of higher education creates pressures for diversification because the needs of the learners and other potential users become more varied and because, as many actors believe, these varied needs might be more readily met through a certain ‘division of labour’ among institutions.
- A second type of theory, ‘*drift*’ theories, also became very popular. Types of higher education institutions are not necessarily very faithful in pursuing the goals they were expected to pursue when they were initially established. According to these theories, different types of higher education institutions are eager to pursue their initial mission at most for a short period after they had been newly founded or upgraded. After some period, they begin to consider themselves as competitors to other types of higher education institutions. . . . the almost universal ‘academic drift’ . . . Similar reasoning, although with different expectations, was frequently employed in the 1980s. Many experts suggest that the tight labour market for graduates

from purely academic fields had triggered a trend of ‘vocational drift,’ ‘vocationalism’ or ‘professionalism.’

- A third type of approach might be called ‘flexibilization’ theories. . . . In contrast to the first theory, they point at weaknesses in segmented institutional types serving clearly distinct needs. Over time, soft models and broad ranges might be superior . . . Accordingly, late selection in pre-career education, permeability of educational careers, compensatory measures for the disadvantaged, soft diversified structures of higher education, and the establishment of a life-long education system contribute to a soft system in three respects: no decision in the educational career would be considered as definite, the model could satisfy both the advocates and critics of educational expansion, and it would finally facilitate rapid adaptations, if major problems occurred.
- Finally, we note ‘*cyclical*’ theories of the structural development of higher education. According to these theories, certain structural patterns and policies come and go in cycles. For example, opening up of educational avenues and a reduction of the differences between varied types of institutions and programs might be on the agenda at times when a shortage of graduates is felt, whereas segmentation and hierarchization of higher education is favored or just taking place, when fears of over-supply or ‘over-education’ dominate the scene”

In a recent analysis, Frans van Vught (2008: 153–154) argues that organizational theories are the most crucial ones in explaining policies and trends regarding diversity in higher education. He points out three theoretical perspectives:

- “The population ecology approach is based on the Darwinian evolutionary point of view. . . . (it) concentrates on the sources of variability and homogeneity of organizational forms. . . . In doing so, it pays considerable attention to population dynamics, especially the processes of competition among diverse organizations for limited resources such as membership, capital and legitimacy.”
- “The resource dependency perspective stresses the mutual processes of interaction between organizations and their environments. According to this approach, organizations on the one hand are dependent on their environments (which primarily consists of other organizations) but on the other hand these organizations are also able to influence their environments”
- “The institutional isomorphism approach stresses that in order to survive, organizations have to adapt to the existence of and pressures by other organizations in their environment. These adaptation processes tend to lead to homogenization, as organizations react more or less similarly to uniform environmental conditions. Isomorphism is a constraining process that forces organizations to resemble other organizations that face the same set of environmental conditions.”

Drawing from these concepts, van Vught (2008: 20) formulates two propositions which he considers relevant for the current developments of higher education systems: (1) the larger the uniformity of the environmental conditions of higher education organizations, the lower the level of diversity of higher education systems and (2) the larger the influence of academic norms and values in a higher education organization, the lower the level of diversity of the higher education system.

Obviously, all the conceptual frameworks named are fruitful in pointing out elements possibly contributing to the changing extent of vertical and horizontal diversity in higher education. Not a single one, however, can claim to come close to a theory of diversity in higher education.

Concluding Observations

National higher education systems cannot be completely uniform. They have to serve different motives, talents, and job perspectives of their students. Not all institutions of higher education or their subunits can serve teaching and research equally. There are quality differences, and there has to be room for a diversity of aims and paradigms in teaching and research.

The increase of student enrolment and the growth of research activities seem to reinforce the view that diversification is the best response, that is, a constant growth of variety both according to the level of quality and reputation and to substantive profiles of research and study programs. Already in the 1960s and 1970s, many experts and actors considered a highly diverse higher education system such as in the US as the modern response. However, deficits of such a model were pointed out as well; various options of diversification were chosen, for example, varied types of higher education institutions in some European countries, and incremental trends did not necessarily move toward increased diversification.

National systems of higher education seem to keep certain characteristics for a long period, but are characterized as well by a constant unrest of those sectors or institutions not at the apex of the reputational hierarchy. In highly regulated systems, we noted collective efforts of upward mobility, while in less-regulated systems individual institutions try to upgrade their status.

Obviously, the growth of student numbers and research activities seems to call for increased vertical and horizontal diversity. In contrast, competition within higher education tends to undermine horizontal diversity and reinforce vertical diversity only as a consequence of imitation behavior according to the success dimensions of the most highly reputed individual institutions or institutional types. In contrast to Martin Trow's initial expectation that elite higher education needs protection in the

process of higher education expansion, horizontal diversity and programmatic profiles other than those popular at top institutions need protection in order to secure diverse services of higher education to society.

Obviously, a certain degree of segmentation within higher education is viewed as necessary to ensure pride in and care of distinct profiles of study programs. However, segmentation is viewed as creating barriers for permeability if students want to correct their educational choices and if academics want to embark on new activities. Therefore, the political debate on the strengths and weaknesses of different models of diversity is driven by a permanent search for a soft system, that is, a creative mix of stability and flexibility.

The views about the strengths and weaknesses of certain patterns of the higher education systems depend strongly on the emphasis placed either on the research or on the teaching and learning function. By and large, steep vertical stratification of higher education is more often claimed to be beneficial for research than for teaching and learning.

In recent years, the variety of different national options as regards the pattern of their higher education systems seems to diminish. On the one hand, we note that most European countries move toward the establishment of a convergent system of study programs and degrees, thereby aiming to make the levels of study programs and degrees the single most important dimension of institutional diversity. On the other hand, institutions of higher education increasingly view themselves as competitors in the race for high quality and reputation amid trends and policies to create more steeply stratified national higher education systems or even move toward an even more steeply stratified world higher education system.

During any period of major changes and reforms of the institutional patterns of the higher education system, sweeping statements are made about the miraculous strength of certain models. In contrast, Neave (2006: 246) pointed out that in various European countries, the policies of advocating diversity primarily through varied institutional types were woefully unsubstantiated. Similarly, current efforts to reinforce competition for world-class universities and to create more steep vertical diversity are based on empirical badly founded claims and even of disinterest in asking key questions about the strengths and weaknesses of this model as compared to alternative models, that is, a lower extent of vertical diversity and a stronger element of horizontal diversity.

Employability of University Graduates and Graduate Outcomes

J Brennan, The Open University, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Graduate employment is a subject of frequent political and research attention these days. This is because presumed high levels of employability of graduates provides a large part of the justification for the massive expansion of higher education which has occurred in most developed and many developing countries over the last 20 years or so. This justification is twofold. First, the promise of well-paid employment fuels the social demand for higher education. Young people and their parents see higher education as the essential route toward the achievement or the maintenance of a good social position and lifestyle. Second, governments see the expansion of higher education and the consequent increase in the numbers of graduates in the labor market as essential prerequisites for a successful economy. Hence, state investment in higher education becomes a public good with high rates of social return. Claims in recent years about the arrival of the knowledge economy with its high-level skills requirements have further accentuated the attention given to the second of these justifications and government targets for numbers of graduates in the labor force have been on the rise again.

The two justifications rest on somewhat different assumptions about the importance of higher education qualifications in the labor market. The social demand justification requires only that there is a positional advantage gained from possession of a degree. All that is required is evidence that employers prefer – for whatever reasons – to recruit and reward graduates more generously than people with lesser or no qualifications. However, the justification for greater state investment requires the additional assumption that graduates are recruited by employers because they will bring greater productivity to the enterprise and therefore to the economy and hence greater wealth to the nation. The greater productivity may be the result of the knowledge and skills acquired within higher education – the human capital argument; or it may be the result of the selectiveness of higher education institutions in identifying able young people – the screening argument. Or there may be no productivity at all with selection criteria for higher education entrance reflecting personal, social, and educational characteristics of little relevance to the workplace. The latter would still provide positional advantage to the graduates in terms of getting a job, but it would not bring the economic growth associated with greater productivity in doing the job.

In expanded systems of higher education, with in many cases well over 30% of the age group entering higher education, the selection or screening hypothesis becomes less plausible. Graduates can no longer be considered to constitute an elite. Thus, their greater employability must be seen to rest in the knowledge, skills, and competences they have acquired through higher education rather than through some set of innate qualities.

Yet, the elite conceptions of graduates die hard. Much research has been commissioned to determine whether graduates are getting jobs at all and, if so, whether these jobs are of a suitable graduate level. Since expansion of higher education implies that graduates will be entering new areas of the labor market, it becomes difficult to define graduate level and several typologies have been produced to represent different levels of employment, with some clearly regarded as being superior to others.

The next section of this article summarizes what we know about the kind of employment obtained by graduates. The following section considers the effects of increasingly differentiated higher education systems and new kinds of relationship between them and the labor market. The subsequent section considers the division of labor between higher education and employers in the development of employment-related knowledge and skills. The final section considers the effects of globalization, features of the knowledge society, and the need for education and training throughout the life course.

Graduates in Employment

Notwithstanding the concerns and scares about graduate unemployment that periodically surface in most countries from time to time, the evidence is pretty clear and consistent that graduates are more likely to be in work than nongraduates and are likely to earn more. Recent data published by the Organization for Economic Co-Operation and Development (OECD) show, for example, that 89% of male graduates and 79% of female graduates aged between 25 and 64 years participate in the labor force compared with the total participation rates of 82% men and 63% women. Unemployment rates among men are 3.5% for graduates compared with 5.7% overall, and for women 4.3% compared with 6.8%. Graduate earnings compared with people with upper secondary qualifications are typically 50% greater, the highest benefits apparently

going to British women (a 98% advantage compared with upper secondary education) and American men (an 88% advantage) (OECD, 2004).

A few years ago, the author summarized some of the main features of graduate employment as follows: graduates

- were unlikely to experience long-term unemployment;
- were likely to earn substantially more than people with an upper secondary education;
- were likely to experience high levels of job satisfaction and responsibility in the long term;
- were increasingly likely to experience a transitional period of several years between leaving higher education and entering “long-term” employment;
- have different experiences in the labour market according to what and where they studied, as well as according to a wide range of other educational and sociobiographical characteristics. (Brennan, 2001)

Further expansion of higher education does not appear to have changed this picture. A recent comparative study of graduates from 13 countries (Schomburg and Teichler, 2006) reported an average unemployment rate among graduates of only 4%, 4 years after graduation. Only Spain (with 13%) and France (with 10%) were significantly higher, although these latter cases do underline the point that graduate employment is not immune to the effects of general economic problems in particular countries and to changes over time. In most countries, graduate unemployment rates – though consistently low – do tend to rise and fall in line with the general economic state of the country.

Data on job quality are notoriously difficult to interpret but from the above study, we can note that 78% of employed graduates had permanent contracts of employment (again Spain was the exception with 50% of graduates on temporary contracts), that 6% were self-employed and the average annual gross income was 28.2 thousand euros. Seventy percent were in professional, managerial, and other high-level positions and a further 18% were employed as technicians and associate professional positions. Only 12% considered that they were in jobs which did not require advanced levels of educational attainment (Schomburg and Teichler, 2006: 136). Job satisfaction seemed quite reasonable with 64% of the sample indicating they were either satisfied or very satisfied with their current jobs.

Of course, aggregate figures can hide some important differences between groups of graduates. The subject of study is important in many countries, although sharp differences at the time of graduation tend to lessen with time. In the study mentioned above, the highest level of unemployment by subject was found among natural scientists (at 7%) and humanities graduates (at 6%) (Schomburg and Teichler, 2006: 82), illustrating the point

that it tends to be the graduates from nonvocational courses, irrespective of field, who are more likely to encounter difficulties in finding suitable employment. Other factors that can influence the employment prospects of particular groups of graduates include the status of the higher education institution attended, the social background, age, ethnicity and gender of the graduate, and experiences such as work placements and other employment-enhancing activities within higher education, although the effects of the latter tend not to be very great over the long term (Mason *et al.*, 2003).

All of this is indication that graduates are successful in getting jobs but not how well they are doing them. This second question – and a crucial one to the human capital argument – is less easy to answer. Some studies have seen graduate employment as largely reflecting processes of elite reproduction (e.g., Brown and Hesketh, 2004) following Bourdieu (1996). Others have indicated considerable skepticism about the claimed relationships between higher education and economic growth (e.g., Dore, 1976; Wolf, 2002).

Hard evidence of the ways in which higher education improves worker productivity is hard to come by. For example, we do not really know whether graduates are more productive than other workers, what makes some graduates more productive than other graduates, whether graduates make use of what they have learned in higher education when they enter the workplace, why employers prefer to recruit graduates – or certain types of graduates, and what is it – for example, ability, expertise, and ambition – that appears to give graduates the edge in the labor market. Answers to such questions are, at best, incomplete. They tend to be based on the perceptions of key actors – employers and graduates themselves. One can certainly point to voices of employers (though how representative one can never be sure) pointing to the deficiencies and limitations of the graduates they recruit; and surveys of graduates report a mixed picture:

Most graduates appreciated their studies and believed that learning in higher education was useful for coping with their job tasks. Yet, there was widespread critique of many aspects of higher education – certainly to a varying degree across countries and fields of study In sum, many graduates who were surveyed did not see close links between study and employment. Only 38% considered their field of study as the only one possible or the best for their area of work, and only half noted a frequent use of their specific area of knowledge. Rather, they perceived a broad range of job requirements which were to a certain extent served by the study programme and by a broad range of experiences prior to and alongside their studies. (Schomburg and Teichler, 2006: 139)

In short, most graduates get good jobs but we cannot be sure why.

Differentiation

One of the limitations of much of the research on graduate employment has been that it has dealt with aggregations, that is, it has told us about a mythical average graduate without distinguishing the effects of factors such as field of study, type of institution, age at time of study, gender, social and ethnic background, and, indeed, of many more factors. As higher education expands, it becomes increasingly differentiated, both in terms of its institutional forms and in the kinds of students it recruits. The social and educational factors interact to help determine the employment outcomes for the individual. As far as the graduate labor market itself is concerned, it is possible to distinguish between public and private enterprises, between small, medium and large employers, between different employment sectors and types of work, and to identify regional differences, all of which produce demand-side variations that we need to understand.

There have also been attempts to differentiate graduate jobs themselves. Kate Purcell and Peter Elias have elaborated a fivefold categorization of graduate jobs as follows (Purcell and Elias, 2004):

- “Traditional” graduate occupations
- “Modern” graduate occupations
- “New” graduate occupations
- “Niche” graduate occupations
- “Non”-graduate occupations

Distinctions of this sort are entirely valid but extremely time and context bound. After all, there was a time when graduate jobs were largely restricted to the clergy and running empires. They also tend to reflect different national traditions and labor-market characteristics. Such distinctions also reflect getting-a-job factors rather than doing-a-job factors. Clearly, as graduates have become more plentiful in the labor market, they have come to take a wider range of jobs. The question of the usefulness of their education to the job in question applies to all the categories. Is it helpful? Is it necessary? Is it sufficient? Even in something as self-evidently a graduate job as medicine, there is research to suggest that the most useful knowledge is gained on the job rather than at university (see Becker *et al.*, 1961).

So far, we have been skirting around one of the most fundamental why questions of all, that is, why is it that employers prefer to recruit graduates and, on the whole, elect to pay them more? Besides the screening and productivity answers, there is also the answer that employers want to get the best people, if only for reputational reasons, and are prepared to accept higher education's definition of who are the best. An expanded higher education system of course eventually fails to deliver this – it produces too many people who cannot

all be best – and so it becomes necessary to differentiate the system in status terms, to ensure the identification of an elite within a mass system.

It is in connection with the increasing differentiation of higher education, its student population, and the labor market itself that issues of employability begin to confront issues of social equity. This is another major variant of the why question. Is higher education principally about matching skills and talent to economic and employment need in order to generate economic growth (the human capital approach) or is it principally about ensuring that social classes and groups maintain their social positions and status (social reproduction approaches) or have greater and more equitable opportunities to improve their positions and status (social transformation approaches)? It may well of course do all of these things.

There are also important international differences to be borne in mind. National higher education systems differ in the extent of their vertical and horizontal differentiation, the former characterized by reputational range and the latter by functional or mission-related differences. There are also international differences in the role played by educational credentials in determining movement through the labor market. The two sorts of differences seem to be linked. Where possession of a specialist credential is a normal pre-entry requirement to a particular job, the educational system is likely to be structured to take account of functionally relevant labor-market differences. Where there is greater formal openness in the labor market – concerning who is theoretically eligible for appointment to a particular job – differentiation is likely to be more reputational and hierarchical. Broadly speaking, Anglo-Saxon-influenced systems tend to accord to the latter characteristics, while continental European-influenced systems tend toward the former. However, some convergence around the greater flexibilities and skills requirements of modern knowledge economies may also be identified.

Enhancing Employability

Higher education institutions in many countries have in recent years been making more explicit the ways in which their academic programs enhance the employability of their students. In many respects, this is in response to pressures from governments and to public expectations that investment in higher education should have real economic pay-off, for both the nation and the individual. Besides making existing activities more explicit, employability has also been the frequent object of new initiatives at both national, institutional, and program levels.

The focus on employability tends to shift attention from academic content and skills toward the more generic

and transferable things such as teamwork, communication skills, leadership, time management, initiative taking, and setting priorities. However, it can also include enhanced curriculum offerings in subjects such as languages and information technology.

Employability-enhancing initiatives vary according to whether they are optional or compulsory, institution-wide or program specific, and whether they are geared to getting a job or to doing one. Where they are optional, questions of take-up become important and the support or otherwise of academic staff can play a decisive role. Where they are compulsory, generally at the program level, whole programs may become vocationalized – geography becomes tourism, sociology becomes criminology, and English becomes creative writing. Particularly in Anglo-Saxon countries, provision of career-preparation modules within the curriculum may be designed to equip students for the job search, providing them with presentational skills with which to impress prospective employers. Such assistance is less likely to be provided in countries which have a much closer link between the subjects studied in higher education and future employment. In the latter, it is still subject knowledge and skills which are decisive for employment rather than the more generic skills.

These developments have not been without controversy, with some academics seeing them as threatening academic freedom and student choice. Acquiring the skills and dispositions necessary for working life should, from this perspective, be left until after graduation. However, the requirements of modern labor markets may call for a different approach. One American commentator notes that whereas new graduates used to have

extended time in their first position to develop interpersonal, applied reasoning, and self-management skills. . . . (but) the complex demands and pace of the new economy require college students to attain a better balance between their academic skills and people-related applied competencies before graduation. (Gardner, 1998: 60)

What may be at issue here is change in the balance of responsibilities between higher education and employers in the preparation of young people for working life.

Division of Labor between Higher Education and Employers

All jobs require some knowledge and skills but jobs differ in terms of where these knowledge and skills are acquired. Where graduates lack necessary knowledge and skills on entry to employment, it becomes the employer's responsibility to equip them. There are considerable differences in national traditions in how this division of

labor is worked out. For example, the French emphasis on professional education gives its higher education institutions – especially the *Grandes Ecoles* – a key role in professional formation, whereas this role has tended to be assumed by employers in the UK. In general, the longer first-degree courses in continental European higher education systems allow the inclusion of a greater volume of occupationally relevant preparation. The greater specificity of employment outcomes means that both students and their teachers have a much clearer picture of the kinds of employments they are destined for. Hence, greater preparation for them can be attempted. The Anglo-Saxon tradition has been more about providing an educational base of some breadth as a foundation for subsequent professional education and training often provided by employers. One hears the phrase “oven-ready” graduates used as a term of criticism for attempts to load too much of the responsibility for employment preparation onto higher education.

Transition between Higher Education and Employment

One of the reasons why there is periodic concern in many countries about graduate employment is that data are often available for only the first few months after graduation. This for many graduates is a period of transition, especially for graduates from the more nonvocational academic disciplines. Decisions about the future have to be made, job applications drafted, and, in many cases, additional qualifications secured. Initial temporary employment might be obtained as a short-term expedient, while longer-term decisions are thought through. Many graduates appear to start the job-search process rather late, perhaps putting off the evil day of commencing working life or concentrating on the successful completion of their higher education studies.

The study by Schomburg and Teichler referred to above notes that on average, graduates spend 6 months on their search for their first job after graduation. Around half had started their job search prior to graduation and, on average, about 25 contacts with employers had to be made before a final choice of job (Schomburg and Teichler, 2006: 135).

The study notes that the timing of initial regular employment after graduation varies significantly among graduates.

This reflects different traditions of transition to employment in the countries included, differences in the employability of graduates, different labour traditions according to country, economic sector and field of study and occupational area, as well as different options and strategies of graduates in the transition period. (Schomburg and Teichler, 2006: 135)

In this study, 40% were regularly employed in potentially long-term jobs immediately after graduating and a further 25% 6 months after, and a further 10% after 12 months. This left 25% of the graduates still looking for suitable work at the end of the first year after graduation. However, 4 years on, 84% were employed and a further 7% were in full-time graduate education and professional training (Schomburg and Teichler, 2006: 136). However, the first few years after graduating are a period of transition in another sense. Besides seeking a first suitable job, job changes during the first few years are common as is time spent in further study. A short period of unemployment is not all that uncommon, although this might be largely voluntary, for example, allowing time for the graduate to travel.

All of this indicates that it is unwise to view information on the early employment experiences of graduates as an indicator of graduate employment overall. However, various studies have suggested that a late transition into regular employment can be associated with relatively poor career prospects in the long term for particular graduates.

Globalization and the Knowledge Society

Much has been written about the new knowledge economies and their needs for greater supplies of well-qualified knowledge-workers. As has already been noted, it is this belief that has justified the rapid expansion of higher education internationally, despite the occasional voices of skeptics (e.g., Wolf, 2002; Brown and Hesketh, 2004). An ongoing international research project (the flexible professional in the knowledge society, a European Union (EU)-funded framework VI project) is addressing questions concerning the requirements made of graduates within knowledge societies and the following paragraphs draw on its conceptualization.

The term knowledge society or knowledge economy suggests not only the expansion of higher education and knowledge-intensive or high-technology sectors of the economy but also that the characteristics of the vast majority of work organizations are changing under the influence of the increasing importance of knowledge. This is important to acknowledge as it alters materially our notions of graduate jobs. Moreover, it has implications for the kinds of demands made of higher education graduates. The project distinguishes four such demands: expertise, functional flexibility, knowledge management, and mobilization of human resources.

Expertise refers to the possession of specialist knowledge, related to workplace productivity.

Functional flexibility is required because of rapid developments in technology, markets, organizations, and relevant knowledge. These make work dynamic and require graduates to be able to respond to diverse challenges and be

willing to rapidly acquire new knowledge. Knowledge management refers to the whole process of developing ideas and implementing them. Mobilization of human resources refers to the capacity to take responsibility for change, of oneself and of others. It is not only partly about leadership but also partly about self-steering and having the flexibility and skills to change the working environment.

Of course, not all graduates face all four demands and the reality of employment is of considerable diversity. The project has conceptualized this diversity in the following way, distinguishing between elite and mass and between specialist and generalist positions to give a four-fold classification as follows:

1. Elite specialists – the lawyers, doctors, accountants – need high status based on specialist expertise with recruitment highly regulated and based on possession of educational credentials, generally enjoying a protected position in the labor market.
2. Elite generalists – high-level managers, civil servants, top politicians, and advisors – need some expertise but functional flexibility and knowledge management are more important; recruitment sometimes is based on institutional prestige (Oxbridge, *Grandes Ecole*, Ivy League) more than credentials.
3. Mass specialists – engineers, nurses, and teachers – need specialist knowledge but do not need to be experts; strict entry requirements are based on credentials but supply much less rationed than elite specialists; therefore, these are more subject to labor-market fluctuations – possibility of status congestion (see Brown and Hesketh, 2004).
4. Mass generalists – marketing, sales, support staff, and administrators – for whom expertise/knowledge is much less important than an optimal mix of knowledge management, ability to mobilize available human resources, and functional flexibility. Recruitment is much less regulated than for the other categories.

These are positions in the knowledge society rather than subjects of study, types of higher education, or even types of graduates. Clearly, the expansion of higher education has given rise to a huge growth in the mass categories and most graduates in future are likely to find themselves in these sorts of positions.

Another current project suggests that the demand for certain elite specialists will increasingly be met within the global labor market with jobs transferring to low-wage economies possessing high-skills labor – China and India most commonly mentioned (Brown, 2004). However, this seems likely to affect only a limited number of occupations and employment fields.

A linked issue concerns the mobility of students and graduates as they use their higher education and its resultant qualifications in order to be geographically mobile. However, while 17.6% of the graduates surveyed in the

Schomburg and Teichler study had some international work or study experiences abroad during their higher education, only 2.7% were currently working abroad at the time of the survey (4 years after graduation). A further 5.2% had previously been employed abroad and 10.7% had occasional need to work abroad for short periods (Schomburg and Teichler, 2006: 127).

A further caveat must be made about the nature of the globalized knowledge society by pointing to the considerable national differences that exist in the nature of the relationships between higher education and employment. The Schomburg and Teichler study concludes that:

By and large, the . . . survey demonstrates so striking disparities of graduate employment and work in the 11 European countries and Japan that common elements seem to be at most secondary. (Schomburg and Teichler, 2006: 139)

Beyond the incontrovertible fact that graduates are more likely to be employed than nongraduates and will probably have better jobs, much else is going to depend on local labor-market conditions and on traditions of higher education's relationship with it. While there may be some signs of convergence between different national traditions – for example, in the Bologna process in Europe – it seems that multinational employers are also adapting themselves to different local circumstances in different parts of the world. While notions of knowledge economy and society provide useful conceptual tools with which to view graduate employment in different national and local contexts, it also seems likely that it will continue to be unwise to generalize empirically much beyond national (and in some places regional) settings.

Conclusion

In a paper based on work done for the United Nations Educational, Scientific, and Cultural Organization (UNESCO) a few years ago, Ulrich Teichler listed what he saw were some important biases in available information on graduate employment. These were:

- quantitative information is more extensive in the traditional graduate employment sectors (that are shrinking) and relatively weak in the newly emerging, atypical (and expanding) sectors;
- an imbalance between quantitative-structural and qualitative data (i.e. plenty of information on the whereabouts of graduates and their income, but much less on types of work tasks, extent to which knowledge acquired in HE is actually utilised);

- employers' statements are often taken as objective and factual;
- researchers assume that practitioners surveyed (employers, graduates) are 'experts' on links between skills and work tasks;
- research findings in individual countries are often over-interpreted as universal truth (Teichler, 2000).

A further bias in the research literature to the ones listed above is the focus on the early years of employment. Even if we are beginning to move beyond the fixation with first destinations, we still rely too heavily on information gained only during the first few years of employment. Evidence on transition is too often interpreted as evidence on employability.

Another source of bias is that most research – and contributions to debate – is undertaken by interested parties. There is sometimes a spin put on research findings to draw attention to the positives and the successes. Research that is focused on informing policy or enhancing practice may fail to challenge existing assumptions or raise questions that might produce uncomfortable answers.

Knowledge Society as a Discourse and as a Social Phenomenon

As a concept, knowledge society is very popular in modern societies, used by popular media, politicians, and academic researchers. Internet search through Yahoo! (in February 2007) gave about 59 800 000 entries for the concept knowledge society. Therefore, a useful starting point for understanding the many dimensions of knowledge society is to define it as a discourse which is based on certain intellectual starting points in the analyses of social realities of modern societies, while as a concept it tends to create its own images, expectations, and narratives. In this sense, knowledge society discourse describes the current situation in which knowledge society is both the objective of policies and debates and an agent promoting policies and debates concerning its potentials. This may be one of the reasons why knowledge society is and has constituted a set of lucrative ideas in modern societies, used by popular media, politicians, and academic researchers. The knowledge society discourse takes place in the context of globalization where higher education institutions are more important than ever as mediums in global knowledge economies. In a globalized world, higher education institutions are integral to the continuous flows of people, knowledge, information, technologies, products, and financial capital (Marginson, 2006).

Knowledge itself and the uses of knowledge are nothing new for mankind which understands itself through languages which are by themselves symbolic systems for cultivating and transferring knowledge. What makes the present situation of knowledge society exceptional is the quantity of knowledge (and information) produced daily and the use of information technologies in data-intensive processes. According to Bell (1973), the postindustrial society is a knowledge society for two reasons: "first, the sources of innovation are increasingly derivative from research and development (and more directly, there is a new relation between science and technology because of the centrality of theoretical knowledge); second, the weight of the society – measured by a larger proportion of Gross National Product and a larger share of employment – is increasingly in the knowledge field." The same notion has been repeated by Castells (1996) when analyzing the difference between previous modes of development with the mode of development of the digital world.

Knowledge Society as an Intellectual Device

As a concept, knowledge society, however, has its own history. The term knowledge society was first used by Lane (1966) whose concept of knowledgeable society describes the great optimism of the early 1960s, suggesting that science would allow for the possibility of a society in which common sense would be replaced by scientific reasoning. Drucker (1969) saw, in turn, that knowledge was central to society as the foundation of economy and social action. The use of the term knowledge society began to expand, in turn, with the studies of researchers such as Mansell and When (1998) and Stehr (1994) in the 1990s.

There can be found two main traditions in understanding and defining knowledge societies. The first emphasizes the importance of information technologies as the driving force of knowledge society or the information society, whereas the other focuses on knowledge and its importance in changing societies. The tradition of information societies continues the intellectual tradition begun by Machlup (1962) who analyzed the production and distribution of knowledge in the US. In this tradition, people have discussed the major transformations that are possible through harnessing electronic information processing technologies to the social and economic priorities of industrial societies. In this intellectual context, knowledge society is often understood as emerging from the simultaneous growth of the Internet, mobile telephony, and digital technologies with the third industrial revolution, which has seen much of the working population migrate to the service sector and has revolutionized the role of knowledge in societies (see UNESCO, 2005: 18).

However, according to a number of writers (Stehr, 1994; UNESCO, 2005), information society as a concept or notion tends to give a more limited and technically oriented description of the challenges in a modern society, even though intellectually it belongs to the same trend aiming to analyze social changes in postindustrial societies. The main critique against this perspective to changes in societies acknowledges the fact that knowledge always has a social function which is rooted in its production, distribution, and reproduction. The nature of these issues is not technical; rather it is political, because these qualities of information and knowledge are related to social structures and the uses of power in a society.

The distinction between information society and knowledge society is also rooted in the difference between knowledge and information. According to Bell (1973: 175), knowledge is “a set of organized statements of facts or ideas, presenting a reasoned judgment or an experimental result, which is transmitted to others through some communication medium in some systematic form.” Following the argument presented by Castells (1996), information is data that have been organized and communicated. Therefore, information remains a fixed stabilized form of knowledge, tied to time and users. For this reason, information may be used as a commodity and, therefore, bought or sold.

The second tradition of knowledge society aims to analyze the societal importance of knowledge responding to the sociological need for a theory of society that resonates with the new social realities. According to Stehr, conceptualizations of society based on the relationships between labor and property (capital) no longer provided the intellectual insight necessary to describe, understand, and explain modern societies. Stehr does not argue that labor and capital dynamics have disappeared; however, he argues that societal relationships cannot be explained without integrating the primacy of dynamics related to knowledge. In creating his own theory of modernization, knowledge society, Stehr (1994) suggests that modernization essentially involves multiple and necessarily unilinear processes of extension and enlargement. The question is: Does the nature of knowledge production change societies, cultures, and economics? The popularity of the term knowledge society is evidence in and by itself that understanding modern society as knowledge based indicates that the more conventional traditional understandings within societies are changing.

The idea of social change based on extension and enlargement is also familiar to higher education researchers. Martin Trow's assumption that the social role of higher education changes with the expansion of the student body has been accepted as an insightful conceptualization of mass higher education (Trow, 1974). Following this reasoning, it can be said that mass higher education is the dominant social form of higher education in the knowledge society. A similar trend has been noted by Clark (1983) who maintains that the main source of social dynamics in higher education is the expansion of knowledge, which leads to new research fields creating a demand for new chairs and professorships to be established for emerging disciplines. It also creates the need to establish new training programs and new higher education institutions, thus supporting the development of mass higher education systems. The emergence of knowledge societies and the expansion of higher education are historically simultaneous and may also have a causal relationship because knowledge production in itself supports growth in industrial production and creates new business activities.

Associated Concept of Learning Society

The discussion on learning societies coincided with the emerging knowledge society discourse aiming to describe potential relationships between knowledge and change in society from the perspective of teaching and learning. Originally, the concept of learning society referred to a new kind of society in which the old distinctions between formal and nonformal education were no longer valid (Hutchins, 1968). In this new context, lifelong learning becomes indispensable because there is a need to change workplaces and often professions and update knowledge during one's career. Crucial new skill in a learning society is also the ability to learn how to learn. Furthermore, learning is no longer the privilege of an elite or a same-age cohort, but it tends to cover the whole community and the whole lifetime of an individual (UNESCO, 2005). The notion of learning society supports many discourses of knowledge society. Both emphasize the centrality of knowledge production and lifelong learning of the labor force. These perspectives on the social role of education have also supported the expansion of higher education into mass higher education systems.

Higher Education and Knowledge Production

The importance of higher education in the knowledge society discourse emerges from the notion that changes in science, research, and technology have changed the social role of universities. There are two main perspectives concerning the recent transformation. The first asserts that a radical metamorphosis is taking place in the relationship between knowledge production and university institutions. Authors such as Gibbons *et al.* (1994), Nowotny *et al.* (2001), and Etzkowitz *et al.* (2000) propose that governments are promoting national prosperity by supporting new lucrative technologies together with universities which become engines of their regions. Gibbons *et al.* (1994) argue that a new form of knowledge production (mode 2) is replacing the traditional one (mode 1). Mode 1 knowledge had been produced within autonomous disciplinary contexts governed mainly by academic interests of a specific community, whereas mode 2 is produced in the context of application. Mode 2 is transdisciplinary research, characterized by heterogeneity and is more socially accountable and reflexive than mode 1 knowledge. In addition, they argue that universities are losing the monopoly of knowledge production, because knowledge may be produced in a variety of organizations and institutions.

The other variant of the metamorphosis thesis is the triple helix thesis which states that the university can play an enhanced role in innovation in increasingly knowledge-based societies. Etzkowitz and Leydesdorff

(2000) assert that the previously isolated institutional social spheres of university, government, and industry have become increasingly intertwined. This has brought academic, economic, and wider networks of social actors together in new constellations in the triple helix knowledge dynamics. Taking support from system theory thinking, Etzkowitz *et al.* (2000: 4) assert that four processes describe the major changes in the production, exchange, and use of knowledge in the triple helix model. These are internal transformations in each of the helices (academia, state, and industry), followed by the influence of one institutional sphere on another. The third process is the creation of a new combination of trilateral linkages, networks, and organizations among the three helices, while the fourth describes the effect of these interinstitutional networks both on their originating spheres and the larger society.

The characterization of knowledge production dynamics between mode 1 and 2 have been, however, criticized as being one-eyed and reductionistic, focusing on a relatively small domain of the vast diverse landscape of science in society. It has also been argued that the dichotomy of mode 1 and 2 presents two discrete ideal types that probably never existed in the real world. The ideological connection between this discourse and political neoliberalism has also been pointed out. The triple helix thesis is, in turn, problematic in its the assumption that all twenty-first-century universities will follow the developmental path of entrepreneurial universities (Tuunainen, 2005: 278–279).

A second, more moderate view of the transformation of knowledge production and universities holds that academic capitalism is challenging the traditional values found in higher education institutions, where an attempt is made to strengthen neoliberal values and management practices. Academic capitalism is a process which promotes competition and market-like behavior both inside higher education institutions and with their relations with business and society. Universities become fertile ground for entrepreneurial universities and academics. However, there are significant differences between disciplines in the academic world as regards their relationship with society (Slaughter and Leslie 1997; Slaughter and Rhoades, 2004).

All these different theoretical assumptions assert that the nature of universities as an organization is changing. It has been asserted that universities are becoming hybrid organizations (Slaughter and Leslie, 1997), or mode-2 institutions (Nowotny *et al.*, 2001) or entrepreneurial universities (Etzkowitz, 2003). According to Clark (1998), entrepreneurial universities should be able to capitalize on genuine connections to the academic heartland or central missions of the university, that is, teaching, research and service.

According to an empirical study by Marginson and Considine (2000), it is indeed evident that there is a general

pattern of modeling universities along the lines of enterprises. This new form of enterprise university has a strategically centralized leadership which is highly responsive to the external setting, it makes wide use of corporate and business forms, empties out academic governance, and weakens disciplinary identity. However, it does not appear as if mode 2 or the triple helix models constitute global trends, because knowledge production plays out differently in distinct types of universities. Old, established universities with strong academic and disciplinary cultures possess more power to resist and generate change, while other types of higher education institutions are more vulnerable to the new management ideas (Marginson and Considine, 2000). Furthermore, empirical research findings suggest that commercialization of academic research turns out to be in conflict with other university activities, most apparently, with publicly funded research and university teaching (Tuunainen, 2004). Empirical academic research has revealed that generalizing abstractions like mode 2 or triple helix model do not necessarily take into account the fact that academic work and universities are complex and often contradictory entities whose development is shaped by a combination of historical, political, and cultural characteristics.

Intellectual Property Rights and Public Good

Questions about the ownership of knowledge are typical examples of the emerging problems of higher education in the era of the knowledge society. There are two interrelated issues here. The first issue is related to the ownership of innovations. A number of countries have tried to solve this problem through legislation which regulates intellectual property rights of academics and universities. The first such act to be passed was the 1980 Bayh-Dole Act in the United States which gave ownership of intellectual property, arising from federally funded research, to universities (Etzkowitz *et al.*, 2000). However, the idea of intellectual property rights is challenged by the ethical basis of the open source development process, which is based on a vision of information and communication technologies as a public good, in which anyone is welcome to participate and all are invited to benefit. The second issue is related to student tuition fees. The question of who benefits from higher education is often translated into the question of who should pay for education. These fundamental topics are related to debates on private and public goods in higher education, because when these questions are combined with budget reductions in higher education, they easily produce debates on the problems of public higher education institutions.

Knowledge Society as a Political Goal

Governments virtually in all parts of world see the potential of the university as a resource to enhance innovation

environments and create a regime of science-based economic development. However, it is quite difficult to show empirically what this means in practice even though it is clear that governments all over the globe are willing to promote this third mission of universities in order to encourage universities to be active producers of innovations. In addition to nation-states, regional (such as European Union (EU)) and global dimensions of knowledge society discourse need to be addressed in order to have an overall picture of different political uses of knowledge society as concept.

Nation-States

At the level of nation states, knowledge society can be seen to have taken on distinct forms. Castells and Himanen (2002) forecast three alternative routes to knowledge society: (1) Silicon Valley – a market-driven, open society (USA), (2) Singapore – an authoritarian model of the knowledge society, and (3) the Finnish model – which describes an open, welfare-state-based knowledge society. This typology highlights the variety of possibilities to organize a knowledge society and that the notion can be defined and approached in different ways. The examples of Finland and the UK reveal the different approaches taken by national governments.

A Nordic example is provided by the Finnish experience of creating a national innovation strategy to promote cooperation between private companies and public authorities. The nation-state plays a significant role through various social actors which bring researchers and business companies together in order to focus resources on problems deemed to be of economically strategic importance. These are either development agencies which support cooperation between businessmen and researchers or public organizations which promote cooperation between the world of business and academic worlds. It is in this context that the role of higher education policy becomes important. In Finland, universities are seen and defined as part of the national innovation system aiming to increase the capacities of Finnish enterprises and the nation-state in general with regard to the international market place. The Finnish example also suggests that knowledge society is organized in and through networks. A network-based social system is a highly dynamic, open system, susceptible to innovating without threatening its balance.

In the UK, the purposes of universities in the learning society have been defined in the Dearing Report (1997) as inspiring and enabling individuals to develop their capabilities to the highest levels; increasing knowledge and understanding; serving the needs of the economy; and shaping a democratic and civilized society. These aims describe the importance of higher education to the personal development of the individual in contrast to short-term employment and education provided by corporate

training programs. It also emphasizes the functions of teaching and research in the development and dissemination of knowledge and, furthermore, expresses the economic value of both of these activities. Finally, this political report aimed at setting goals for the development of British higher education, also pays specific attention to the cultural and political value of higher education in maintaining and developing civil society (Laurillard, 2002).

Regional Level

In Europe, it is easy to find support for the idea that higher education should support national economic competitiveness in the global market place. In addition to European nation-states, knowledge society discourse has created its own imaginary social space in the EU itself. This argument is underlined on reading the European Commission's knowledge society homepage, which begins with the central objective of the Lisbon strategy: "to become the most competitive and dynamic knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion." This citation, in and by itself, indicates the importance of the topic for the EU. In order to reach this objective, Europe's education and training systems need to adapt both to the demands of the knowledge society and to the need for an improved level and quality of employment.

Developing Global Information Society with the Help of Higher Education

In a global perspective, the knowledge society may be characterized as a global information society (UNESCO, 2005). In the global context, the use of information technologies, the access to knowledge resources, and the political aspects of knowledge society are raised. In this perspective, a global information society emerges as one of the main challenges for development, because it is evident that the global information society is a political goal which is far from being reached. Specifically, in the beginning of the twenty-first century, only 11% of the world's population had access to the Internet and 90% of these connections were in leading industrialized economies in North America (30%), Europe (30%), and in the Asia-Pacific region (30%). In addition, 82% of the world's population accounted for only 10% of the Internet connections in the world (UNESCO, 2005). This disparity has been called the digital divide, which cuts across the globe, following the contours of social and economic capital distribution. The problem was not only due to lack of proximity to electricity grids but also due to the fact that interactive computers and Internet connections were expensive for the majority of mankind. This form of exclusion unites urban slum dwellers and the homeless as

well as remote villagers in developing countries. Digital divide is also related to contents, as sources of knowledge in several languages are not a characteristic of information and communication technologies. One should not forget, therefore, that knowledge society discourse is dominated by and focused on the Western cultural hemisphere and even there it is focused on the conditions of the relatively young, well-educated working-age citizens geographically located in the urban areas of a few rich countries.

The role of higher education is, however, seen crucial in the development of global information societies. The UNESCO (United Nations Educational, Scientific, and Cultural Organization) World Conference on Higher Education emphasized that the relevance of higher education means: (1) being politically responsive, (2) being responsive to the world of work, (3) being responsive to other levels of the education system, (4) being responsive to culture and cultures, (5) being responsive to all, (6) being responsive everywhere and all the time, and (7) being responsive to students and teachers. (UNESCO, 2005: 97).

Summary

This impressive list of social responsibilities expected from higher education clearly indicates that world communities have high hopes regarding higher education. It also indicates that the social role of higher education in the global information society is seen as crucial for the development of societies. Furthermore, the list of expectations highlights the central roles universities as producers of knowledge and educators of experts are assumed to play in knowledge societies. It also reveals the fact that knowledge society is a discourse which contains multiple and often conflicting expectations concerning the roles expected to be played by higher education institutions.

Higher Education and the Labor Market

J Enders, University of Twente, Enschede, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

The relationship between higher education and the labor market is among the key issues of scholarly debates whenever the qualification, certification, and status-distributive functions of higher education are at stake. While higher education was traditionally thought of as a means for the self-reproduction of the elite in society, massive educational expansion has stimulated growing interest in the study of change and stability in higher education institutions, curricula, and students; in the labor market and the employment system; and in the relationship between changes in higher education and changes in the labor market. As with many other concerns about (higher) education, the sources of growing theoretical and empirical insights in this area mainly lie in the social sciences. Most studies find their roots in business studies, economics, educational science, policy studies, public administration, and sociology. Quite a few studies have also been undertaken in interdisciplinary teams of scholars that tend to undermine strong assumptions in disciplinary perspectives on the principal nature of the relationship between higher education and the labor market.

This article offers an overview on the development of theoretical work and empirical insight on the relationship between higher education and the labor market in times of educational expansion. Structural–quantitative aspects in the development of the match and mismatch between higher education and the world of work as well as qualitative aspects of the demand and supply of competencies and skills are addressed. Further attention is given to growing insights into the institutional embeddedness of higher education and the labor market in cross-national comparative perspectives and their change and stability over time. Comparison is made between the utility and limitations of different models explaining the ongoing adaptation between higher education and the labor market by providing international examples of empirical research.

Quantitative Aspects

In the course of massification of higher education, a lot of concern was and still is about the quantitative match or mismatch between higher education and the labor market. Public debates and scholarly reflections in this area started in the 1960s with high hopes for more equal opportunities and economic prosperity through

investment in education and training. The expansion of higher education occurred as part of a larger societal development that was accompanied by a flourishing public sector. Its expansionist logic proceeded on a dual track, offering new educational opportunities as well as new employment opportunities in education, health, and welfare in a kind of self-vindicating system (Nowotny, 1995). The 1970s faced the end of the dream of everlasting economic prosperity. The pessimistic view spread that expansion of higher education had gone too far and that graduates' skills no longer matched the needs of the employment system. The debate was marked by sharp disagreements over a presumed overeducation or underemployment of the many more graduates for whom not sufficient or not sufficiently well-qualified jobs would be available. In the 1980s, expectations and empirical findings adjusted to a somewhat blurred state of affairs which neither supported the high hopes of the 1960s nor reinforced the deep sense of crises of the 1970s (Teichler, 1999). Despite the ongoing expansion of higher education, labor markets still are able to absorb graduates and most of them find work and careers providing substantial material and immaterial rewards.

What emerged from further analyses was a mixture of vertical and horizontal adjustments in job placement, changing values, and expectations of what was considered a desirable job for the highly qualified and what was meant by a proper link between higher education and work. Career studies and employment statistics show that the absorption of the growing number of graduates by the labor market has been achieved in a variety of ways: the growth of occupations traditionally filled by graduates, increasing employment in the private sector and the nonprofit sector, increasing numbers of graduates entering mid-level positions and semi-professions, a growth in the (still) small number of self-employed and the (still) small number of graduates in blue-collar jobs, as well as an extension of job-search periods after graduation and initial unstable employment and unemployment. In developed countries, an important component in such adaptations between an expanding higher education system and the labor market has been due to the massive inclusion of women into higher learning. This has led to an increase in the labor market participation of women. Nonetheless, the careers of female graduates still show remarkable differences from those of male graduates with a lower return of investment in education for women.

In the wake of massification, both policy debates and scholarly work thus became more interested in the dynamics of the relationship between higher education and the labor market. It became obvious that certain gaps could not be avoided. Shortages or oversupply of graduates overall or in specific occupations and labor market segments readjust only after some time; adaptations of student choices as well as of the labor markets proceed with time lags (Brennan *et al.*, 1996). All this undermines strong hopes for a perfect forecasting and planning of supply and demand.

Such economic perspectives on the forecasting of the contribution of higher education to the labor market often draw on human capital theory (Becker, 1964) that assumes that highly qualified employees will be preferred by employers and will earn more because of their qualifications that make them more productive. Some empirical evidence could be found for such a claim that continues, however, to be contested. Human capital theory suffers certain empirical shortcomings. It can neither rely on appropriate measures of graduates' qualifications nor on appropriate measure of the qualification demands of the workplace. Instead, research in the tradition of the human capital approach works with proxy variables such as the level of educational attainment (for qualifications acquired) and wages (for contributions to productivity). Further difficulties derive from the fact that higher education also sorts and selects graduates, and that employers hold imperfect information on graduates' abilities and are thus heavily dependent on this function of higher education in labor-allocation decisions. Scholars such as Spence (1973) and Arrow (1973) have pointed out that selection and rewarding of employees take place on the basis of such signals that are assumed to point to the productive capacities of the employee. The labor queue theory (Thurow, 1975) has added to this debate the interesting argument that part of the qualifications required on the job will not even be acquired in (higher) education but will be acquired by training on the job or further training alongside the job. This argument points to the unavoidable fact that higher education will not deliver graduates that perfectly match the needs of the labor market overall or of a specific job. Higher education rather provides the more or less developed foundations for development and refinement of qualifications on the job and throughout the career. These scholarly debates have already pointed to what became in our days a more commonly held insight into the relationship between higher education and the labor market: the match between supply and demand of qualifications is by definition imperfect, only partly transparent and fluid. Graduates thus should hold qualifications of flexible knowledge workers and lifelong learners being able to make contributions to shifting and ever-changing demands on the workplace. Finally, some

scholars have raised doubts on to what extent higher education has an effect on the capabilities and the productivity of its graduates at all. They provide a variation of a theme that credentialists such as Collins (1979) developed earlier. Credentialists argue that higher education is used as a gatekeeper to social mobility and elite reproduction, legitimizing access to privileged positions in economy and society. Again, there is certain empirical evidence to this claim that does, however, not necessarily exclude that higher education also has an impact on the capabilities of its graduates. Research thus points to a mixed state of affairs with elements of empirical evidence for the theories addressed above.

Qualitative Aspects

Since the 1990s, a new process of adjustment and restructuring seems to be underway, that tends to undermine the whole notion of a quantitative match. The perils are no longer seen in diminishing return of investment due to growing competition or in the labor markets being swamped by overqualified and dissatisfied applicants. It is nowadays more frequently underlined that it is the occupational structure and social stratification system itself that has become mobile. This is accompanied by deep structural changes in the way the economy works as well as a perceived individualization of the life-course regime (Beck, 1986). The characteristics of occupations and jobs, the vertical as well as the horizontal division of work, and the needs and reward structures of the employment system continue to be restructured. Learning–working pathways through education, training, and employment tend to be de-institutionalized and re-institutionalized. Quality thus stands for possessing a mixture of skills and knowledge for new and changing configurations. Graduates are expected to be trained for what is increasingly seen to become a market for knowledge workers in constant flux. In addition, the student body has become more heterogeneous due to ongoing massification in terms of social background, age, levels of preparation and work experience, patterns of studying and learning, aspirations, and life chances.

The issue of the relationship between higher education and the labor market and between demand and supply thus gains again in importance. However, the emphasis is less on structural–quantitative relationships and more on the qualitative match between a changing body of students and graduates and ever-changing job requirements and labor markets. In consequence, competences beyond cognitive knowledge play a stronger role in political debates as well as in scholarly work. Terms such as soft skills, key qualifications, practice orientation, and employability signal that higher education is increasingly expected to take more explicit care of competences that go

beyond the codified body of knowledge related to certain disciplines, fields of study, occupations, or professions (Teichler, 1999). Moreover, research on employers' recruitment processes and selection criteria show in fact that they pay less attention to curricula details than to the reputation of certain higher education institutions or fields of studies, professional experiences of graduates during their studies, and the training and socialization of soft skills.

From this point of view, higher education is too youth centered and program oriented as far as the actual and desired clientele is concerned, and relies on the old-fashioned idea that full-time students can appropriately be piggybacked with consistent stocks of knowledge prior to the transition from education to work. Higher education is, thus, expected not only to continue considering fair access according to sociobiographic background, but also to strengthen the overall supply with a highly trained workforce in the sense of the old regime. It is also expected to further diversify structurally and, in terms of conditions of study and courses provided, to devote greater attention to generic competencies and social skills and to reshape its function for a society of lifelong learning, to prepare students for a growing internationalization, and to serve practical learning beyond classroom teaching. In other words, higher education is expected to move from a front-end model to a life-span model of education and training, from curricula to learning pathways.

Certainly, such a vast and inclusive concept of higher education in the knowledge society holds strong appeal but goes by no means uncontested. This is partly so because such an integrated view of the role of higher education in the knowledge society can serve to obscure attempts to define clearly what educational goals should be pursued and who should be responsible for which provisions and actions. It is also unclear what an appropriate balance between cognitive skills and soft skills, between workplace-related competencies and transferable skills would look like (Tuijman, 1999).

Studies among employers point, for example, to the fact that growing expectations as regards soft skills do not necessarily imply that the cognitive domain of knowledge becomes less important. Further signals for the employability rather grow in importance on top of traditional expectations in the cognitive domain. In addition, various studies show that different countries provide distinctive mixtures of qualifications, and that the returns of investment for further specialization or greater flexibility are a topic of considerable debate.

Last but not least, the lack of any satisfactory measure of the abilities and competencies of higher education graduates has thus found increasing attention. The outcomes and policy impacts of research on school effectiveness

and of studies on the qualifications of students in school (e.g., the Programme for International Student Assessment (PISA) study of the Organization for Economic Co-Operation and Development (OECD)) are also stimulating this search for appropriate measures and methods to study abilities and competencies of higher education graduates. This is an area where further conceptual and analytical work is of growing interest. Various projects are undertaken to overcome this situation and to find ways for an objective assessment of the value added by higher education training and experience. This is by no means an easy undertaking but would help to learn more about suggested key qualifications or soft skills, and how they are related to the mix of hard skills and tacit knowledge traditionally provided. Further research on learning outcomes could also link up to labor market studies in order to learn more about the trainability of employability, and the evidence for the recognition, transfer, and portability of skills to and within the labor market. Further insights in this area are also likely to revitalize traditional debates between the human capital approach and the screening hypotheses that were suffering from a lack of reliable measures of graduates' qualifications.

Institutional Embeddedness

Major contributions to the further development of our insights into the (changing) quantity and quality of the relationship between higher education and the labor market have been made by institutionalist approaches. Such a perspective emphasizes the matching problem between higher education and the labor market as the outcome of individual and organizational decision making, shaped by institutional characteristics. Such institutional characteristics determine the opportunity structures for new and old graduates (macro-level) and shape the interactions between graduates and employers (micro-level). Insights into the institutional embeddedness of the relationship between higher education and the labor market and their cross-national variations have benefited a lot from a life-course perspective. Life-course research analyzes the pathways of individuals, social groups, and cohorts as a process rather than as a state. Concepts such as trajectories, transitions, duration, and sequences are employed to identify life-course regimes in cross-national perspectives as well as their change and stability over time.

There is, for example, evidence that the signaling function of formal educational qualifications is more important in job-allocation processes in countries characterized by a high degree of selectivity, stratification, and standardization of higher education (Allmendinger, 1989; Shavit and Müller, 1998). Selectivity points to the reliability of degrees due to earlier selection processes for

access to higher education or certain parts of higher education. Stratification of higher education points to a vertical or horizontal differentiation between institutions or institutional types providing further signals to the employer. Standardization points to the nationwide recognition of curricula and degrees. All these characteristics may allow employers to invest more trust into the reliability of degrees than in countries with a low degree of selectivity, stratification, and standardization of higher education. Systems also differ in the extent to which they have a more academic or a more vocational orientation, the extent to which general education or more specialized training is held as important, the existence of institutionalized links between higher education and employers, or the flexibility of pathways from education to work.

The transition of graduates into work and their further careers are also enabled or constrained by institutional patterns of the labor market (Shavit and Müller, 1998; Müller and Gangl, 2003). Countries differ in the extent to which they offer positions on occupational labor markets that are in principle open for all highly qualified or positions on internal labor markets that are usually filled by internal candidates. The degree of labor market regulation by public authorities, the influence of trade unions on labor market conditions, and the degree of (un)employment protection differ between countries as well and impact on the employment relations of young and old graduates.

The relationship between the demands of the labor market and the supply from higher education is also influenced by structural changes in the labor market and by the way work and career are organized in employment organizations. The most important development concerns the tertiarization of the labor market shifting away from manufacturing and toward service provision. The rise of multinational companies and the flourishing of small- and medium-sized enterprises have changed the labor market for graduates, and they provide a specific mix of demands for their highly qualified employees. Many changes of labor market regulation went in the direction of deregulation and flexibilization even though with different speeds and intensities in different countries. The public service sector traditionally sheltered from market competition became the subject of scrutiny in the wake of new public management approaches. The concept of the transitional labor market points to the assumption that overall expectations on mobility and flexibility of employees are increasing resulting in an overall focus on the employability of graduates and a de-standardization of the life course.

Various lessons can be drawn from empirical investigation into the cross-national variations of the relationship between higher education and the labor market and their change and stability over time. First, transition to the

labor market and the quality of work and career obtained by graduates differ strongly cross-nationally (Teichler, 2007) and differences can partly be explained by the different institutional regimes in higher education and in the labor market. Second, many national systems of higher education have become more stratified in the wake of educational expansion. Growing variation according to different types of institutions, different fields of study programs, different degree levels, and reputation and prestige within formally equal institutions and programs have been observed. Such differentiation has been instrumental in stratifying the growing number of graduates on the labor market. As a consequence, occupational rewards of graduates differ more than in the past and the status-selection function of higher education has become even more important due to its massification. Third, stability and ongoing adaptation rather than dramatic change in the relationship between higher education and the labor market can be observed over time (Shavit and Müller, 1998; Heinz, 1999). Fourth, many studies show that early careers have a lasting effect on later career. They confirm the early career hypotheses that expect that the relationship between early and later career success has changed to a lesser extent than what the proponents of an overall flexibilization of the labor market and a de-standardization of the life course would assume. However, as we all know: what might be a sign of the future to come may not be representative today.

Conclusion

Several insights can be highlighted on looking at the development of research on higher education and the labor market. One is that an automatic and stable link between higher education and certain positions in the employment system cannot be taken for granted, and also that it has never existed from a systematic point of view. In societies where certification plays an important role in job placement, career trajectories, and life chances, the mechanisms through which this occurs and the expectations over how this should occur change. Second, differences among national traditions of training and selecting those who are able to run society are, however, likely to be important and may change only over long periods. Third, when access to higher education becomes more widespread, the growing opportunities for higher education become, at the same time, something of an obligation. The requirements of knowledge economies exert demand for more, and not for less education. In effect, the gap between the highly educated and the lowly educated in terms of income, status, and life chances is likely to grow, while the rewards for the highly educated are likely to become more diversified and negotiable. Educational expansion leads to a further stratification of higher

education that is instrumental in screening and sorting the increasing number of graduates for the labor market. Fourth, the importance of higher education for the labor market is in the combination of a qualification, a certification, and a status-distributive function. Which function prevails is not a question of principle, but an empirical question to specify the institutional contexts under which one or the other function prevails.

Research on the relationship between higher education and the labor market has traditionally been dominated by strong theoretical assumptions built on relatively simplistic models and a limited set of issues taken into account. Such approaches still play their role but are increasingly challenged by more complex research approaches. Growing complexity has been called for by developments on the research frontier as well as by changes in the relationship between higher education and the labor market. The trend toward more complex studies has also been enforced by new methodologies and improved conditions for quantitative research. Last but not the least, beliefs built into certain theories about universal relationships between higher education and labor and universal megatrends are undermined by growing insights into the relevance of time-specific and country-specific institutional settings and dynamics. Growing awareness of the complexity and variability in the relationship between higher education and the labor market has also led to a growing eclecticism as far as theoretical debates are concerned. Theories strongly adhered to in the past have partly lost their simple beauty, but so far, new holistic frameworks, that would sufficiently cover the territory of the more complex research approaches chosen today, have not been able to replace them. This may be disappointing for those who call for a clear-cut and simple diagnosis of the relationship between higher education and work. However, at the same time, it opens windows of opportunity for a stepwise improvement of our theoretical frameworks and empirically validated insights. Research has improved our insights into the institutional embeddedness of individual choices and collective pathways within the educational system and the world of work, the changing structural-quantitative relationships and qualitative dimensions in the relationship between higher education and the labor market. The further systematization and enhancement of this knowledge is unlikely to generate perfect solutions for problems discussed in policy and practice. However, it will provide better information on the opportunities and limits for attempts in shaping the relationship between higher education and the labor market.

Higher Education and the Transformation of Society

P Scott, Kingston University, Kingston upon Thames, UK

Introduction

The expansion of the number of students in higher education and the development of mass higher education systems during the past 50 years have been accompanied by a number of profound socioeconomic (and scientific and cultural) changes. These included the intensification of the democratic revolution (and a deeper process of democratization which has transformed the basis of class society); the completion of the educational revolution (which began in the nineteenth century and reached its climax with the development of near-universal secondary school systems after 1945); individualization (a complex and contradictory phenomenon combining the extension of civil rights – e.g., to universal welfare-state services – with the accentuation of market-led consumerism); the triumph of (mainly scientific and technological) expertise and the more pervasive phenomenon of professionalization which has reached into every nook and cranny of modern society (already apparent in the nineteenth century but reaching its apotheosis in the second-half of the twentieth century); and, most crucially, the development of a post-industrial and services-intensive economy in the many developed countries (which tended to be the same countries that produced the most mature mass higher education systems). The list can be greatly extended – popular culture, mass literacy/media, urbanism, post-modernism, the emergence of risk society.

However, as with all social phenomena, the balance between causality, contingency, and coincidence is difficult to assess. Whether the expansion of higher education has been an important driver of these profound social and cultural changes or simply their consequence is an interesting question – but ultimately no more susceptible of a clear answer than another, more direct, question which is often asked “do rich and developed countries need extensive higher education systems to sustain their economic development, or does economic growth provide a surplus which allows these countries to afford such systems which are desirable for other, non-economic, reasons?” Economists may be obliged to continue to try to answer this question, if only to enable politicians to make rational choices between competing priorities within higher education. But other social scientists may have to limit themselves to the conclusion that the relationship between social change and the development of higher education is open and reflexive, multi-linear as well as multi-lateral, probably irreducible to a series of unambiguous causalities.

One reason for this is simply that on the wider canvass of social transformation, in practical terms, there is not the same pressure to make rational choices between competing priorities as there is in the narrower domain of economic development. But a second reason is that the expansion of higher education has been surprisingly poorly articulated in more theoretical terms. By and large it is a phenomenon that has failed either to develop or to attract a convincing body of social theory. Sociologists, cultural historians, anthropologists, and others have typically preferred to generate their theories, to seek to explain the larger and wider connections between social transformation and cultural and political change, in domains other than their own home territory, the academic system. Only a few, such as Talcott Parsons and Gerald Platt in the 1970s (Parsons and Platt, 1973) and, in a narrower sense, Burton Clark in the 1980s and 1990s (Clark, 1983), have attempted to interrogate the university itself; typically, such efforts have not been sustained in any systematic and scholarly tradition but have remained one-offs, however intriguing. As a result, the big pictures of the links between the expansion of higher education and wider social change have been painted either by policymakers, institutional leaders, and other practitioners or – once again – by economists largely preoccupied by the application of concepts of human capital to understanding the explosive growth of universities and colleges. In recent years, these concepts of human capital have been incorporated within wider theories of economic development within the so-called knowledge society, which may have blunted their sharp economic edge but nevertheless remain limited as general explanations. Higher education, the *habitus* of social theorists, remains a largely theory-free zone.

In this article, the links between higher education and social transformation are considered under five headings: (1) democratic participation – the relationship with the rest of the education system, and the rise of a mass graduate class; (2) civil society – and, in particular, the links between the university and the city; (3) clever cities – the role of modern higher education systems in developing creative communities; (4) knowledge society – the fundamental changes in occupational, and therefore social, structures as a result of the development of post-industrialism; and (5) new patterns of knowledge production, which have reshaped notions of expertise and scientific/technical literacy.

Democratic Participation

In most of Europe, North America, and many other developed regions of the world universal systems of elementary education were first established in the second-half of the nineteenth century. Half a century or approximately two generations later, universal systems of secondary education were established. A quarter of a century (or one generation) later, after 1960, there was in most of these countries a decisive shift away from closed and elite university systems to more open and mass systems of higher educations (Scott, 1995). Although these mass systems did not become truly universal systems until the end of the twentieth century, this sequence depicts the quickening pace of the educational revolution. In some less well-developed regions of the world, the sequence was a little different, as mass higher education systems developed precociously before universal secondary education was achieved.

Two major processes appear to have been at work – a push process which meant that the establishment of much more extensive systems of education for younger age groups inevitably fueled demand for the expansion of opportunities for older age groups (an iron law of chronology so-to-speak); and a pull process because the capacity to participate fully in an increasingly sophisticated society came to depend on higher levels of educational achievement (in terms both of cultural capital and of formal skills and qualifications). These two processes are linked by a third, the complex (and controversial) phenomenon of up-skilling and/or dumbing-down whereby individuals require enhanced skills and superior qualification merely to retain their comparative positions in the occupational structure (and social hierarchy). The extent to which higher education remains, in Hirsch's classification, a positional good remains unresolved – and irresolvable (Hirsch, 1976).

The first process, the iron law of chronology, is well understood. Indeed, it can be measured in the case of the transition from secondary to higher education; the number of secondary school leavers with qualifications that entitle them to enter higher education (whether as of right, as in many continental European countries or as candidates for consideration, as in the United Kingdom, the United States, and Australia) has increased. The major driver of increased participation in higher education in most developed countries has been this increasing pool of eligible candidates. However, this has been a qualitative as well as a quantitative phenomenon. For example, a growing proportion of this increasing pool of higher education entrants has been women; indeed the equalization of participation rates between men and women has been not only a major cause of the expansion of higher education but also a manifestation of a fundamental shift in

gender identities in these societies (the graduate woman became an iconic figure in late-twentieth-century society). Another example of qualitative change has been the changing nature of the higher education systems to which this increasing number of secondary school leavers have gained access; a core of traditional universities has been supplemented by a growing penumbra of other post-secondary education institutions (*Fachhochschulen* in Germany, HBO (higher professional) schools in the Netherlands, as well as the former colleges of advanced education in Australia and polytechnics in England and Wales) while these universities themselves have been transformed into more open institutions.

The second process, the acquisition of the cultural capital necessary to function effectively in a democratic society, is more complex. It has been argued by some scholars that mass, or universal, systems of education make a reduced contribution to social mobility because they provide less scope for the co-option of the best and brightest, of whatever social origins, into elite structures. As a result, their emergence has had conservative, even regressive, effects. However, the contrary (and more convincing) view is that the threshold of active civic participation has been raised as surely as the threshold for effective participation in the labor market, and economy more generally. Mass higher education systems are necessary to provide the means for such threshold participation; without the expansion of universities and colleges over the past half-century, a growing proportion of young (and older) people would have been disenfranchised in sociopolitical terms as well as disempowered in economic terms. However, the growth of a (perhaps predominant) graduate class cannot be regarded as a largely reactive phenomenon, a response to the need to accumulate increasing stores of cultural (and social) capital which has been determined by other forces of social change; mass participation in higher education has itself transformed notions of such capital, changing the rules of engagement between the academic system and society at large for ever.

Civil Society and Urban Culture

Civil society, that crucial layer of institutions which mediates between the citizen/consumer and the state/market, has been to some degree de-populated in contemporary society, although social scientists and commentators are divided as to the causes. Some, typically on the left, blame the *anomie* of the market while others, generally on the right, blame the dependency culture produced by an intrusive welfare state. But they appear to agree that traditional civil-society institutions such as local government agencies, trade unions, and churches (in most but not all countries;

the United States is a notable exception) have been attenuated. Moreover, it is not clear that the civil-society institutions which may have replaced them – the mass media with its celebrity culture on the one hand or new social movements with their shifting allegiances (and unstable institutionalization?) on the other – have the same mediating influence. However, mass higher education systems may be an exception, although universities and colleges are not conventionally regarded as elements within civil society. The emergence of mass graduate populations, bound together by something resembling a common culture (or, at the very least, shared lifestyle experiences) may represent a crucial mediating layer in contemporary societies.

This is most evident in the interaction between the mass university and the modern city, whether the mega-cities of the developing world or the world cities of the developed world (Scott, 2005). Both are key sites of social transformation – and both universities and cities have spread far beyond their spatial boundaries; their normative influence is now pervasive. Although some twentieth-century campus universities were established in semi-rural or small-town locations (in, perhaps unconscious, celebration of the visual and spatial utopianism of nineteenth-century American liberal arts colleges), the university has always been a predominantly urban institution. Nor has this association, historical and contemporary, between the university and the city been purely accidental. The city has always been a site of radical experimentation – in social, economic, technological, and cultural terms. This was true in the classical world, the medieval and early modern periods, the Industrial Revolution – but never more so than under the hyper-urbanizing conditions of contemporary society with its mega-cities/world-cities where the impulses of the market and of mass culture are most keenly and intensely felt (and, consequently, where the need for novel forms of social mediation – such as the presence of large-scale graduate populations – is most necessary). The university has been an equally radical source of innovation – in scientific and intellectual terms. Although there have been quieter, and more quiescent, periods – the eighteenth century perhaps – in the long history of universities, the dynamism of the modern university is not in doubt. It has come to dominate the social landscape through the development of mass higher education systems (and the mass institutions that are so prominent in contemporary cityscapes); and it has an equally commanding role in the determination, and reproduction of, technical and professional expertise.

The histories of both the university and the city (in its widest sense), therefore, demonstrate remarkable affinities – which over time have become more intense (and continue to intensify). Academic life in all its manifestations – from the street life of students, through donnish society and the influence of universities on cityscapes, to their impact on the formation of expert professions and the generation of scientific and technical knowledge – has

always been a major contributor to the emergence of broader urban cultures (which both determine and reflect the social structures of our now predominantly urban, even hyper-urban, societies). The normative structures of city and university were, and are, also similar. Both encouraged the emergence of individualism and secularism, skepticism and rationality which became the key values of modernity (Bender, 1993). Arguably, this dynamic engagement between the city and the university continues even more intensely in the interaction between the post-industrial and consumerist social structures characteristic of the contemporary city and the post-modern (or, at any rate, more febrile and heterogeneous) intellectual cultures on display in the modern university.

Yet, important changes have taken place in the respective positions of the city and the university. The twenty-first-century city, particularly the mega-cities/world-cities, lacks the coherence, organizational and normative, even of the metropolitan cities of the nineteenth and earlier twentieth centuries. A favorite, and revealing, metaphor is of the shopping mall, a post-modern version of the arcades through which the *flâneurs* of the pre-industrial city wandered (Harvey, 1990; Benjamin, 2002). As with civil society, more broadly traditional civic cultures have been attenuated – first, by the rise of the national bureaucratic state which reached its apotheosis in the welfare states of the second-half of the twentieth century; and, more recently, by the impact of free-market and mass-media globalization. As a result, the role played by the city in social transformation, although even more powerful, is also more ambiguous and volatile. Once the university was one among a number of civic institutions, but, by no means the most powerful – and one of a range of ingredients of civil society (the two words, of course, come from the same root). Today, in contrast, the university has become in many cities the dominant civic institution, its role enhanced rather than attenuated by the rise of national bureaucracies, the welfare state, and globalization.

The strength of the university is apparent in pragmatic terms. First, it is typically among the largest employers, and makes a decisive contribution to the economy of the city and its region. Second, it is often an important locus for civic culture, both traditional and experimental – as the provider of theaters, galleries, and museums in its own right; as a corporate patron of the city's own cultural institutions; and as a sponsor, or source, of the audiences that sustain cultural activities and events. Third, the university is an intermediary, or more active mediator, between national (and now global) markets and cultures on the one hand and local contexts and civic environments on the other – or, perhaps more accurately, it has as important a role as financial institutions or mass-media corporations in these interactions (sometimes clumsily labeled glocalization). But the dominant role played by the university in the modern city is also normative. First,

although it plays an increasingly central role in market exchanges, the university is the most powerful intermediary between global and local in the non-market domain, in civil society. Second, the city itself having abandoned its traditional role of articulating the civic, or the public, in the pursuit of global economic success (or lacking the institutions to articulate them), the university has become the primary agent for such articulations. In both pragmatic and normative terms, therefore, the mass university plays an absolutely crucial role in social transformation.

Clever Cities

A particular manifestation of that role is to be found in a phenomenon labeled clever cities, after the work of Richard Florida. He argues that entrepreneurs, wealth-makers of all kinds, social experimenters, and cultural innovators flourish best in creative communities. This is no longer a Bohemian phenomenon largely restricted to artists, although the creative and cultural industries are among the fastest-growing, and most distinctive, sectors in the most dynamic contemporary economies; it also embraces designers, scientists, engineers, bankers, even the public at large (Florida, 2005). So these communities have a double impact. They not only provide a social and cultural milieu, an environment, in which other forms of enterprise, both business and social, flourish, but also create, through the cultural industries, their own powerful forms of wealth generation.

Universities are key to the building of creative communities – and so of clever cities. The influence of universities is felt directly – through the generation of new technologies and the production of skilled graduates. These technologies and graduates, in turn, produce intellectual property of various kinds – patents, spin-out (and spin-in) companies, consultancy capacities – and also cultural property (plays, music, novels, and other cultural artifacts). But the influence of universities is also felt indirectly – because they create the cultural ambience and social infrastructure which creative people value (for example, theaters, museums, schools, even restaurants); in short university cities are also clever cities.

However, the ways in which mass higher education is transforming the social base of these cities are more complex than the socioeconomic (and cultural) impact of traditional universities on cities of the industrial age. In both periods, universities educated future elites, both political and cultural elites, but in particular professional and technical elites. As the urban middle-class in the course of the nineteenth and twentieth centuries succumbed to the twin forces of credentialization and professionalization (or, to put it more positively, came to be determined more in terms of educational attainments and professional skills

and less in terms of social origins), the modern city took on distinctive characteristics – university quarters with a raffish, even Bohemian, quality as well as solid suburbs inhabited by the new university-trained professional classes. Both continue to be characteristic of the social structure of post-modern cities, although the raffishness of university quarters has intensified and professional structures have become both more open and less secure.

But the social impact of the mass university is also more far reaching – and also more volatile. First, mass graduate populations have penetrated more deeply into the urban environment, influencing not only elites but also the general population. As a result, a distinctively graduate culture has become pervasive – and may have ceased to provide such a significant social demarcation (the bartender may well be a graduate like her/his customers). Second, these graduate populations are less rooted. Not simply the elites (international bankers or designers) but the masses are often highly mobile (adding to the ephemeral quality of the post-modern city). This mobility, attributable in part to the development of mass higher education systems, has had a profound effect on housing patterns, employment structures, even the patterning of social life, consumption habits, and leisure pursuits. Third, the creativity which Florida celebrates is produced not simply (or even mainly) by traditional forms of scholarly enterprise, scientific research, and professional practice; it is also produced, often serendipitously, by the contingencies of intellectual playfulness and post-modern lifestyles. Silicon Valley and its worldwide clones are characterized by highly unconventional social and economic structures. The college dropout, the alternative entrepreneurs, the camp-followers of mass higher education – such are the creative people that power some of the world's most significant clever cities.

Knowledge Society

The idea of a knowledge society has gone through a number of intriguing iterations. It began in the 1970s under the label post-industrial society, a relatively unproblematic characterization of the shift from an economy dominated by extractive and manufacturing industries to one in which services, and increasingly symbolic goods, made a more prominent contribution – although Daniel Bell attempted to highlight the social and cultural consequences of this shift (Bell, 1976). This first iteration coincided with the emergence of the first mass higher education systems, initially in the United States and later, and more tentatively, in Western Europe, Latin America, Australasia, and some Asian countries. The expansion of universities reflected, and reinforced, these new occupational structures – both meeting the demand for new kinds of professional workers, predominantly in

services (and at this stage, largely in public services rather than commercial services, which explains the tight association between the welfare state, at its apogee in the 1970s, and the first stages of mass higher education) and also reducing the supply of now obsolescent industrial workers by keeping young people out of the labor market for longer (and, of course, producing the technician and higher-level engineers required for the functioning of increasingly high-technology manufacturing industry).

Later, the knowledge society took on new forms – for example, the network society of Manuel Castells (Castells, 1996, 1997, and 1998) and the risk society of Ulrich Beck (Beck, 1992). The first iteration emphasized the importance of connections and connectivity (powered, of course, by the information and communication technology revolution) – and, at any rate by implication, the relative decline in importance of the institutions which were being connected in these novel and powerful ways; to that extent the idea of a network society captured the process of de-institutionalization, the so-called hollowing-out of government (through privatization), of industry and business (through outsourcing) and even established professions (because of competing notions, and alternative locations, of expertise). The second iteration, the risk society, highlighted the accumulation of uncertainties in a society in which the intensification, and acceleration, of knowledge produced alarming new forms of social and cultural volatility. These more recent iterations of the knowledge society coincided with the maturity of many mass higher education systems, now outputting large-scale graduate populations defined as much by their lifestyle, and social and cultural capital, as by their technical or professional expertise. It is probably not accidental that this period, the 1990s onward, also saw the absorption of formerly distinct systems of higher technical education into these mass systems of higher education (and, in some countries such as the United Kingdom and Australia, the abandonment of the distinction between traditional universities and institutions of professional education).

These policy shifts may reflect significant changes in the articulation between higher education and the social base. Once discrete groups of graduates – social, political and cultural elites; higher professional workers; technical experts; the now more highly educated populace – have tended to coalesce into a less well-differentiated mass (or, perhaps more accurately, once discrete roles have become fuzzier). As a result, the need for special-purpose institutions of higher education, such as universities or (in England and Wales) polytechnics, has diminished. Changes in the structure of higher education, therefore, mirror wider changes in social structures in the knowledge society. Mass higher education systems and socioeconomic structures now touch at several different points – the traditional role played by universities in the

formation of future elites, the re-production of the established professions, and the development of technical expertise (although all three have become more heterogeneous, and even contested, categories for reasons that are discussed in the next section of this article), has been both reinforced and subverted by the growth of graduate culture, that unstable combination of lifestyle preferences and the (at times defensive) accumulation of social and cultural capital needed to maintain positional advantage in a knowledge society.

The conventional view, therefore, that there is a straightforward and comparatively linear relationship between the development of mass higher education and the emergence of knowledge society – essentially, that in a society powered, and pervaded, by knowledge there is a corresponding need for an increase in the number of not only knowledge, that is, technical, experts but also of knowledgeable actors (and that modern higher education systems are near-monopoly producers of both) – is perhaps too simple. Instead, there are multiple, ambiguous, and maybe conflicting relationships. It is as a total phenomenon that mass higher education is contributing to social transformation, as a powerful social fact and cultural presence in its own right, as much as a series of inputs that are contributing to social change such as better-educated citizens or more highly skilled workers – being as much as becoming. Its presence is perhaps more normative than instrumental.

New Patterns of Knowledge Production

One of the most enduring classifications of higher education systems was that devised by Martin Trow (Trow, 1973). He suggested a three-stage process of evolution – elite higher education systems that enrolled up to 10% of the eligible population; mass systems that enrolled up to 40%; and universal systems that enrolled more than 40% (and came to embrace a majority of young people). This classification has been criticized, partly on the grounds that it suggested a tidier linear sequence than was actually the case and partly because it focused on the initial higher education of young adults and therefore failed to take account of the growing phenomenon of lifelong education available to all age groups. Nevertheless, it has remained a useful classification. Indeed, it is tempting to align elite systems with the education of Robert Reich's symbolic workers (Reich, 1991, 2001), the old social and cultural elites dressed in new knowledge society clothes perhaps; mass systems with the training of the burgeoning cadres of knowledge workers (not all necessarily with highly technical expertise), for which the new economy of the late twentieth and early twenty-first century has an insatiable appetite; and universal systems with the development of an

even more extensive graduate culture in which all citizens, and all workers, have become knowledgeable actors.

However, to describe the social impact of modern higher education systems in such a tidy, simple, and (by implication) hierarchical taxonomy may be misleading. Studies of new patterns of knowledge production suggest the need for a more nuanced account of the transformative effects of higher education. For example, it has been argued that the more closed and hierarchical knowledge production systems of the past have been overlaid, if not replaced, by more open and fluid systems (Gibbons *et al.*, 1994; Nowotny *et al.*, 2001). Consequently, it has become more difficult to define the primary (and, therefore, privileged) producers of new knowledge, partly because the complex, interactive, and even reflexive characteristics of innovation in the new economy are now better understood and partly because of the playful and serendipitous quality of creativity in a knowledge society, which has already been discussed. This has important implications for the role of higher education – and, in particular, for traditional research universities. Their primacy may be less marked than is often assumed, for example, in the politically dominant discourse about world-class universities.

Conversely, mass higher education institutions may flourish in more open knowledge production systems and make a greater social impact – first, because they develop the socially distributed expertise needed to empower workers and to enfranchise citizens and transform both into knowledgeable actors; and second, because these institutions are more familiar with notions of diversity and difference (and, therefore, may promote an intellectual flexibility need to manage this socially distributed expertise which is inherently problematical – and often contested as rival expertises clash). However, another implication of the emergence of more open knowledge production systems is that the (social) contextualization of knowledge has become a key attribute not only of its relevance but also its novelty. As a result applied research has been replaced as a category by knowledge produced in the context of application (or even implication – which hints at the creative, even visionary, qualities of post-modern knowledge).

The result could be to erode the organizational base of all higher education institutions, even the most open (in terms of intellectual traditions and research practices) and accessible (in terms of their social constituencies), as they confront more competition from other knowledge institutions (indeed, in a knowledge society it becomes axiomatic that all institutions must become to some degree both learning and knowledge-producing organizations). In turn, this could compromise their capacity to shape the social landscape as decisively in the future as in the past. At the very least, the relationship between higher education and social transformation (which, of course, was always mediated through other institutions, notably the

labor market) is likely to be dependent even more on higher education's interdependences with other knowledge institutions – thereby reflecting the importance Castells attaches to networks and connectivity.

Conclusion: Looking to the Future

The relationship between higher education and social transformation – and, in particular, between mass higher education systems that first emerged in the 1960s in the United States and have now become the dominant global model and the emergence of a knowledge society (and the new economy, equally a global phenomenon) – is difficult to reduce to a small number of simple formulas. But two general conclusions may perhaps be possible conceptually as well as institutionally:

1. The first is that the relationship has become more intense and more direct. Mass higher education systems help to shape their societies more powerfully than the elite systems of the past – not simply quantitatively, because many more people are embraced within these systems, but also qualitatively, because social structures are both more finegrained and more volatile (and higher education plays a more active role in determining not only the division of labor but also the distribution of cultural capital).
2. The second conclusion is that the relationship is more complex, even problematical. Straightforward linear producer models no longer adequately describe the social impact of higher education, whether in research or teaching. More reflexive models of the engagement between higher education and society are needed. Mass graduate culture, socially distributed expertise, playful creativity, open innovation systems, and other key characteristics of contemporary society, most certainly can be traced back to the influence of modern higher education systems. But attempts to delineate these relationships more precisely are likely to fail – not simply, for empirical reasons, because of the lack of research and paucity of data (there is a super-abundance of both, particularly the latter), but mainly for structural reasons because these systems are now so interwoven that they cannot be disentangled.

Quality Assurance in Higher Education – Practices and Issues

D Dill, The University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Academic accreditation – Assessment of an institution's or a program's capacity for quality with a binary judgment about the attainment of threshold academic standards.

Academic audits – Assessment of the processes institutions use to assure themselves that their chosen standards are being achieved.

Academic standards – The specific levels of knowledge, skills, and abilities that students achieve as a consequence of their engagement in a particular academic program.

Culture of compliance – Institutions' investment of time and effort to satisfy external assessors rather than on active efforts to assure and improve academic standards.

External examining – Assessments by external peers of the performance of students on subject examinations.

External academic quality assurance – Supra-institutional policies and practices whereby the quality of higher education institutions and programs are assured.

National graduate examinations – Nationally designed and administered exams in all major subject fields for university graduates.

Internal academic quality assurance – Policies and practices whereby academic institutions themselves monitor and improve the quality of their education provision.

Market regulation – Consumer sovereignty in which informed student choice of academic programs helps assure academic standards.

National qualifications frameworks – Broad descriptors of learning outcomes specific to each level of academic degrees.

Professional regulation – Producer sovereignty in which academics themselves are principally responsible for defining and enforcing academic standards.

State regulation – State sovereignty in defining and enforcing academic standards.

Student experience surveys – Surveys of students' or graduates' experiences in their academic programs known to be associated with effective learning.

Subject assessments – Systematic evaluations of the quality of delivered performance of study programs with emphasis on curriculum, teaching, and program relevance to graduates and the economy.

Subject benchmarks – Publicly defined academic content and threshold standards for each subject field.

The Emergence of New Quality-Assurance Practices

At the close of the twentieth century, the national policy frameworks for higher education institutions underwent substantial reforms. In the emerging global economy, advanced human capital has become a crucial factor in economic development and a central component of a nation's competitive advantage. Consequently, many countries are shifting from elite to mass systems of higher education (Trow, 2005).

The combined impacts of globalization and massification have radically altered the traditional relationship between the state and institutions of higher education and motivated policymakers to seek new means for assuring academic quality in higher education (World Bank, 2002). First, the global demand for skilled human capital encouraged changes in the degree frameworks of many countries as policymakers sought international recognition of the credentials granted by their country's higher education institutions. These new degree frameworks also encouraged a rapid proliferation of new academic programs in many countries, thereby testing established national practices for assuring academic standards. Second, the rapid growth of higher education systems has provided incentives for the development of private institutions, including cross-border franchise and virtual universities, which have posed novel challenges to national systems of external quality assurance (QA), particularly those based upon central control of public institutions. Third, the competitive forces unleashed by globalization and massification have required institutions of higher education to become more responsive to rapidly changing labor markets and to student program interests. Consequently, institutions in many countries

have sought increased flexibility and autonomy from traditional state QA regulations so that they can react more swiftly to changing social demands by establishing new academic programs, reconfiguring existing programs, and eliminating outdated programs. Finally, the rapidly expanding social demand for higher education has been caused in large part by students' desire to achieve the increasing private benefits available to individuals with higher degrees. The empirical reality of the growing private benefits of academic degrees has altered the traditional debate about higher education finance, encouraging many countries to require students and their families to pay a larger share of higher education costs. Consequently, the new practices of external QA also seek to respond to public concerns that institutions provide educational value for money.

This dramatically altered environment of institutions of higher education helped reveal the inadequacy of both the traditional internal and external practices for assuring academic standards (Brennan and Shah, 2000). Therefore, in their search for a national framework that will encourage innovation in academic programs while maintaining and improving academic standards, policy-makers are experimenting with many innovative forms of academic QA.

The first government experiments with new QA practices occurred predictably in the US, an early exponent of mass higher education. Concerned with evidence of declining academic standards in public education, the majority of US states, in the early 1980s, adopted regulations requiring that publicly supported universities develop explicit plans for assessing student teaching (Dill *et al.*, 1996). Subsequently, new national QA policies were also introduced in France (1984), the United Kingdom (1985), and the Netherlands (1985) (van Vught and Westerheijden, 1993). The French government was primarily interested in reducing its dysfunctional QA bureaucracy, the government in Great Britain sought to achieve a better linkage of higher education with the labor market, while the Netherlands adopted a new QA framework in association with an innovative approach to

steering universities. The developments in these pioneering countries were then diffused to other countries in Europe, Asia, and eventually around the globe.

The traditional national frameworks for external QA varied from country to country, but had generally followed three modal forms: the European model of central control of QA by state educational ministries, the US model of decentralized QA combining limited state control with market competition, and the British model in which the state essentially ceded responsibility for QA to self-accrediting universities (Dill, 1992). In the UK, up until the actions by the Thatcher government in 1981, the assurance of academic quality in the publicly supported university sector was delegated to the academic profession itself, which monitored and assured the standard of university degrees through collective mechanisms such as the external examiner system. In contrast, ministries of education on the continent were much more active in setting standards for universities. They established and monitored regulations on university admissions, academic appointments, program curricula, and endpoint examinations. In the US, as higher education rapidly expanded following World War II, the federal Congress explicitly adopted a market-based approach to academic QA as a supplement to the existing tradition of state licensing and voluntary institutional as well as program accreditation. During the 1972 re-authorization of the Higher Education Act, members of the Congress argued that providing federal, financial assistance directly to students rather than to institutions was the most efficient and effective means to both equalize opportunities in higher education and harness market forces for enhancing academic quality.

Table 1 outlines representative external QA practices organized by the locus of authority over academic QA. Professional or self-regulation clearly assumes producer sovereignty in which academics themselves are principally responsible for defining and enforcing the rules and norms assuring the quality of academic provision. As noted, this places greatest emphasis on traditional voluntary practices carried out by professional bodies

Table 1 External assurance of academic quality

<i>Locus of authority</i>	<i>Professional (self) regulation</i>	<i>State (direct) regulation</i>	<i>Market regulation</i>
Practices	Professional accreditation and licensure Voluntary institutional accreditation External examining	National qualifications frameworks Subject assessments State-conducted accreditation Academic audits Performance-based funding or contracting National examinations or surveys	Commercial information provision, for example, institutional or program performance data, assessments, and rankings

including accreditation of academic programs and institutions by professional associations as well as collective professional practices such as external examining. State or direct regulation of academic quality assumes the sovereignty of the state in defining and enforcing academic standards. The new QA instruments emphasized by the state include the definition of academic degree frameworks, policies introducing new assessment practices such as academic audits and/or subject assessments designed to maintain and improve internal QA practices, state-conducted accreditation of programs and/or institutions, performance funding and contracts, and finally, regulations influencing the public provision of academic information such as state-mandated exams or surveys. For the market to work effectively as a means of assuring academic standards, it is necessary for students and their families to achieve effective consumer sovereignty through informed choice of academic programs. QA practices associated with this perspective include commercially produced rankings and student guides designed to provide academic quality information to students.

Several key points can be derived from these simple distinctions. First, a number of QA practices such as accreditation or academic audit are essentially generic processes that can be conducted voluntarily under the auspices of academic professional organizations such as the American Board of Engineering and Training (ABET) or the European University Association (EUA), or can be a requirement of national policy carried out by agencies established by or affiliated with the state. Similarly, quality rankings can be produced by the academic profession as in the world university league table published by the Shanghai University, by the state as in the UK subject assessments, or by the private sector as in the commercially produced rankings of the *London Times* or the *US News and World Report*. Second, while it is often argued that professional self-regulation or market forces represent serious alternatives to state regulation of academic standards, the reality is that professional or market-based QA practices are usually highly dependent upon the state for their effective functioning. If professional self-regulation or market forces are to successfully protect the public interest in the assurance of academic standards, they must be reinforced by law or formally recognized and/or subsidized by the state. For example, the current influence of voluntary accreditation in the US derives almost entirely from the fact that the national government utilizes institutional accreditation to determine college and university eligibility for federal student aid. Similarly, more valid commercial rankings such as those of the *Guardian* in the UK or the *Good University Guide* in Australia are highly dependent upon government subsidized or produced data on universities. In short, effective professional self-regulation and/or market regulation are best understood as alternative state instruments for

assuring academic quality. The challenge confronting all nations is to design a policy framework that effectively and efficiently utilizes the forces of the state, the academic profession, and the market to assure academic standards.

An Assessment of External QA Practices

The sections that follow review the primary new practices of external academic QA and the issues they raise for higher education.

National Qualifications Frameworks

In response to the changing environment of higher education, a number of countries, such as Australia and Ireland, have adopted new national qualifications frameworks (Young, 2003). The cross-national Bologna framework of bachelors, masters, and research doctoral degrees, the Dublin Descriptors, and the UK Graduate Standards Program can also be understood in these terms. The initial rationale for these frameworks was to provide international recognition for academic degrees to aid in attracting foreign students as well as to help in placing program graduates in the global market. However, by providing broad descriptors of learning outcomes specific to each level of academic degrees, academic qualification frameworks also provide some potential reference points for external QA practices (McInnis, 2005).

A more refined example of degree frameworks is the UK subject benchmarks program (Williams, 2005). The massification of higher education has also produced many new professional or more vocational university programs for which clear agreement on academic content and student learning outcomes is often lacking. In response to a growing concern about the comparability of academic standards across academic programs, the UK systematically created subject benchmark committees to publicly define appropriate academic content and threshold standards at the level of each subject field. Over a 5-year period, the UK committees developed subject benchmarks for programs enrolling the vast majority of first-level students.

Some policymakers clearly hoped and some academic staff clearly feared that national qualifications frameworks and subject benchmarks would become a regulatory device for assuring the fitness of purpose of academic degrees. While the new frameworks do play a role in external QA, the fact that the higher education component of these frameworks and benchmarks is usually defined by academic staff means that the frameworks' impact on academic standards is limited and indirect. In the UK, the impact of subject benchmarking proved more formative and developmental than regulatory (Williams, 2005) – helping to define and legitimize new academic

subjects, generating discussion about appropriate academic standards at the subject and university level, as well as helping to strengthen internal university processes for new course approvals and academic QA. Similarly, the most significant contribution that qualifications frameworks make to an overall national QA system is to help encourage a focus on student learning outcomes rather than course content in national debates about academic standards.

Quality Assessments

One of the most significant changes in national QA frameworks at the end of the twentieth century was the emergence of the evaluative state (Neave, 1988). Many national governments initiated and/or subsidized the creation of new agencies and practices designed to assess quality in existing higher education programs and institutions. The new assessment practices included academic audits, subject assessments, and new forms of academic accreditation.

During the 1980s, the majority of the US states adopted assessment regulations designed to encourage public institutions to place greater attention on the improvement of student learning. However, these regulations delegated implementation responsibility to institutions, the institutional responses were not externally assessed, and the regulations had little measurable impact on academic quality (Peterson *et al.*, 1999). Similarly, traditional institutional accreditation in the US was criticized for being too comprehensive in its scope, overly focused on input criteria rather than policymakers' concerns about academic standards, and insufficiently transparent in that accreditation reviews are not required to be made public (Dill *et al.*, 1996). Existing voluntary program accreditations did not assess the education programs in which the majority of students were enrolled, accrediting primarily professional fields. Under mounting pressure from policymakers concerned about declining academic standards, all of the institutional accreditation agencies adopted student assessment as one of their standards for review and several accreditation agencies introduced new accreditation review processes. However, after several decades of experimentation, a United States Department of Education (2006) report concluded that US-style voluntary institutional and program accreditation were still inadequate mechanisms for assuring the quality of student learning.

Outside the US, new forms of quality assessment, including subject assessments, academic audits, and innovative approaches to accreditation, were mandated by many countries for all publicly supported institutions of higher education. Each of these practices adopted a similar sequence of activities – an institutional self-study, an external peer review, and a public report of findings – but the focus of each practice differed. Subject

assessments, as implemented in countries such as the UK, the Netherlands, and Denmark, involved systematic evaluations of the quality of delivered performance of study programs with emphasis on curriculum, teaching, and program relevance to graduates and the economy. In contrast, academic audit as implemented in countries such as Australia, the UK, and Hong Kong, focused on the processes that institutions use to assure themselves that their chosen standards are being achieved, what in Sweden is usefully termed education quality work. Accreditation, as implemented in Europe, is similar to US accreditation in its assessment of a program's capacity for quality with a binary judgment about the attainment of threshold academic standards. However, the European practices differed in their focus on study programs rather than institutions, in their comprehensive coverage, and in their attention as well to the effectiveness of program QA activities.

All three of these new external assessment practices had the effect of encouraging dialog and collaboration among academic staff regarding the improvement of student learning and assurance of academic standards within academic institutions (Kehm, 2006; Massy, 2005; Stensaker, 2004). This is not a negligible impact given the increasing incentives in all of higher education for academic staff to invest time and effort in research. However, if overly focused on external control rather than institutional responsibility for improvement, these assessments can encourage a culture of compliance in which institutions invest time and effort on developing policy documents and erecting quality infrastructure to satisfy external assessors rather than on active efforts to assure and improve academic standards. External subject assessments and program accreditation are also very costly to mount and sustain over time. Their focus is exclusively on the subject level and, therefore, these assessments also provide limited incentives for the overall institution to develop an effective internal QA process. Audits by contrast are much less costly, applicable to all types of institutions, and provide some of the same incentives for communication and collaboration on the improvement of teaching and learning. However, the potential positive impacts of academic audits may be limited if poorly designed, for example, by too comprehensive an assessment that includes other than core educational processes, or by focusing too much on QA documentation rather than on empirical evidence regarding the validity and reliability of internal processes for assuring academic standards.

The evolution of external examining in the UK, a professional external QA practice, illustrates a number of issues involved with quality assessments (Lewis, 2005). Of the many external QA practices, external examining, as conducted in the UK and some Scandinavian countries, most clearly assesses academic standards. External examiners traditionally assessed the actual performance of

students on subject examinations used to award honors degrees in UK universities. External examining emerged in early nineteenth-century England as a professional practice and was explicitly encouraged in subsequent university charters. However, the practice was not regulated or codified until, under pressure from the government to assure academic standards, the committee of vice chancellors and principals published the first code of practice in 1986. Subsequent research revealed that only a minority of universities were following these professional standards, challenging academic assertions on the effectiveness of the practice (Warren Piper, 2004). Government regulations were then introduced requiring summaries of university external examining reports to be made public and the governmentally supported UK Quality Assurance Agency (QAA) incorporated specific precepts on external examining into their academic audits of each university, thereby encouraging greater equivalency of practice across institutions. However, the widespread adoption of modular instruction and continuous assessment in much of UK higher education over the last decades has lessened the ability of external examiners to actually compare academic standards within a subject field. Instead, external examiners now perform the function of assessing the validity and reliability of the overall assessment regime in a particular subject.

Information

A third means of external QA is information provision. The development of performance indicators to help assure academic standards has become an important external QA practice in many countries (Cave *et al.*, 1997). Initially performance indicators were designed by policymakers to inform government funding, often in association with new higher education financial instruments such as performance-based funding or university performance contracts. As higher education has become more competitive nationally and internationally, indicators of academic quality have increasingly been published by government, academic, nonprofit, and commercial entities to better inform student choice of an educational program. Many policymakers also believe that informed student choice is an influential means of external QA. While government subsidies of higher education in every country are predicated on the belief that the educational value added by higher education programs produce beneficial outcomes for society, these social benefits are difficult to gauge directly, therefore external QA utilizes proxy measures of academic quality. These include: more immediate outcome measures such as graduate placement, salaries, and satisfaction with education program; output measures such as student test scores, completion rates, and marks; and various process measures such as student engagement.

Outcome measures, such as graduate placement and salaries, are informative and generally valid quality

information for potential students and could also be valuable general indicators of effectiveness for academic programs if used by institutions. Readily available output measures such as student marks or graduation rates may be unreliable indicators of academic quality because they can be increased by lowering academic standards. For this reason, performance-based funding or contracts, which are usually based upon available input, process, and output measures, have proven to be an inadequate instrument for assuring academic standards (Jongbloed and Vossensteyn, 2001) and need to be supplemented by government mandates on quality information provision and external quality assessments. While common graduate exams exist in certain professional fields, such as medicine or teaching, and have been utilized in association with external assessments by professional accrediting agencies in the UK and the US to improve academic standards, common exams do not exist in all subjects. Brazil attempted the most ambitious experiment in mandated common subject exams (Schwartzman, 2004), developing nationally designed and administered exams in all major subject fields for graduates of both public and private universities. The exams provided influential performance information, but could not effectively assess the actual value added by an academic program. Under strong political pressure from the universities, the exams were modified to a voluntary survey of a sample of graduates, thereby diminishing the validity and reliability of the performance information provided. Both Australia (graduate skills assessment – GSA) and the US (collegiate learning assessment – CLA) are experimenting with less costly and more easily administered tests of generic skills for first-level students. While these tests could provide a general indicator of the educational value added by institutions, the generic content of such exams might encourage the lowering of academic standards and in any event is unlikely to help inform academic staff about the means of improving academic standards in specific educational programs.

The limitations of traditional output measures and common exams or tests necessitated the development of common surveys of student experience in Australia and the US as a means of academic QA and these are spreading to other countries. The Australian course experience questionnaire (CEQ) surveys graduates' perceptions of teaching quality, skills learned, and their satisfaction with their education in their academic program (Harris and James, 2006). The US national survey of student engagement (NSSE) asks currently enrolled students to report on experiences in their educational program known to be associated with effective learning (Ewell, 2005). While generic instruments, both these surveys are based upon systematic research on effective teaching and student learning and therefore offer more valid and informative indicators of academic quality for potential students as well as academic staff.

Overall, the validity of public information on academic quality has become a controversial issue in higher education. Quality rankings by commercial publications often rely upon information gleaned from reputational surveys, input measures such as student test scores or financial resources, and indicators of research quality all of which have questionable validity as predictors of effective student learning (Dill and Soo, 2005). These rankings have become highly influential on academic behavior, often encouraging institutions and programs to invest time, resources, and effort in improving their rated reputations rather than in the challenging education quality work necessary to actually improve academic standards (Brewer *et al.*, 2002). More valid and useful academic quality information and rankings have been produced by not-for-profit entities such as the Center for Higher Education Development (CHE) in Germany, as well as the NSSE and National Research Council's (NRC) assessment of research doctoral programs in the US. A critical determinant of the legitimacy of academic quality information is government policy, which may subsidize the development and provision of more valid quality information as in the case of the NRC doctoral surveys in the US and the Australian graduate survey, and/or mandate publicly supported universities to participate in more valid surveys and rankings as in the case of the NSSE and CHE rankings.

Publicly available information on academic quality plays an important role in assuring academic standards, but ironically its import may be greater for internal than external QA. International research on student choice suggests that quality rankings and ratings influence the educational decisions of a relatively small segment of the student population, primarily those of high ambition and achievement (Dill and Soo, 2005). The education choices of most students are influenced by a wide variety of educational, social, and personal factors, which suggests that the individual decisions of even well-informed potential students are unlikely to be a strong influence on the assurance of academic standards within academic institutions. The more significant role of quality information is therefore likely to be its development and use by academic staff as part of institutional efforts to assure and improve academic standards.

Summary

The growing importance of human capital to the economic and social development of contemporary societies mandated the massification of higher education and subsequently motivated a search for new methods of assuring and improving academic standards. All countries, therefore, are seeking an effective national framework for academic QA that will likely include an appropriate classification of academic degrees, the provision of valid and reliable

information on academic quality, and some efficient means of external assessment designed to assure that institutions of higher education have in place effective internal QA processes. Degree frameworks and subject benchmarks can contribute to external QA by helping to redirect public and academic debate about academic quality from curricular issues to socially beneficial learning outcomes. In addition, some type of state-mandated external assessment of internal QA practices seems warranted, since traditional professional practices appear inadequate in the new environment of higher education. Centralized control of academic quality by state education ministries is impractical in mass systems. Professional practices such as voluntary academic accreditation in the US and external examining in the UK have noted limitations, and academic audits of internal QA in a number of countries have clearly revealed that these institutional practices can be improved. Comprehensive program accreditation practices, such as those being experimented with in Europe, can help assure the attainment of threshold academic standards following the adoption of a new degree framework. However, over time, the high cost and limited focus of regular program accreditations as well as subject assessments appear difficult to justify and sustain. National quality-assessment practices seem to be evolving out of necessity toward the adoption of some form of external academic audit of internal QA processes. Developing effective academic audit processes will therefore likely be a continuing and important challenge for the field of academic QA (El-Khawas, 2005). Finally, the public provision of valid and reliable information on academic quality will be a critical component of national QA frameworks. While commercial publications provide an increasing amount of information to the public on academic quality, they have limited incentives to publish rankings that will actually help maintain and improve academic standards. The development and public provision of valid and reliable indicators of academic quality therefore is best understood as a pure public good, which must be subsidized by the government.

The Role of Accreditation of Higher Education Institutions

J S Eaton, Council for Higher Education Accreditation, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

Defining and Describing Accreditation

Accreditation refers to examining and affirming the quality of a higher education institution. While there is significant variation in the use of the term among countries, many would agree with the description of accreditation offered by the United Nations Educational, Scientific and Cultural Organization (UNESCO): “(Accreditation is)... the outcome of a process by which a governmental, parastatal or private body (accreditation agency) evaluates the quality of a higher education institution as a whole, or a specific higher education programme/course, in order to formally recognize it as having met certain predetermined criteria or standards and award a quality label” (Sanyal and Tres, 2007: 6).

Whether called audit, evaluation, quality assurance, or accreditation, five characteristics are common to the quality-affirming efforts across many countries. These are the development and application of accreditation standards, self-reviews undertaken by colleges and universities, peer reviews of institutions, judgments by an accreditation body using the standards that have been developed, and awards of accredited status.

Accreditation standards are established either by an accrediting organization itself or in cooperation with the institutions and programs that are accredited. The standards focus on the resources, processes, and results associated with institutional efforts with regard to teaching and learning, governance and finance, among other areas. Standards are periodically reviewed and revised.

Self review by an institution is undertaken in the early stages of an accreditation review. It is usually based on the accreditation standards or, in some instances, more generally on individual institutional mission and goals. The self-review and accompanying documentation is sent to the accrediting organization for its consideration.

Peer review refers to an examination of the self-review by colleagues in higher education or a specific profession. This takes place through scrutiny of the self-review documents, usually accompanied by a visit to the institution. Review teams are composed of higher education colleagues and, increasingly, also include individuals from, for example, the business sector, students, or the international community. The peer-review process culminates in a report to the accrediting organization.

The accrediting organization, through its decision-making body, uses the self-review and the peer report to make a judgment about whether and to what extent an

institution or program meets the accreditation standards. These decision-making bodies are usually composed of academic administrators and faculty, sometimes accompanied by public members.

With regard to awards of accreditation, a decision-making body may act to grant accreditation, deny accreditation, or ask the institution to undertake some additional work to achieve accreditation. The length of accreditation periods varies from a few years to ongoing accredited status, provided that the institution sustains an effective system of internal quality review.

Accreditation status may be granted for an indefinite period or require periodic renewal.

Most accreditation bodies are owned and operated by governments, although they exhibit degrees of freedom from the government in a number of ways. They may, for example, be only partially funded by government and receive funds from other sources such as universities. Although established by government, these bodies may be governed, at least in part, by the university community. The United States is a conspicuous exception, where all accreditation organizations are private (nongovernmental) organizations.

The Values That Drive Accreditation

Accreditation is based on a core group of values about how colleges and universities are to operate. While this varies in some measure from country to country, commitment to these certain values is frequently expressed. They buttress the work of accreditation that, in turn, reinforces these values in an institutional setting.

A core value related to accreditation is the importance of institutional mission. An institution's statement of mission describes the range of its activity, for example, degree level, selectivity, curricula, governance, and intended student population. Most systems of accreditation use mission as the point of departure for judging the quality of institutional performance. In the accreditation review, the institution is typically held accountable for carrying out its mission, but not for activities that fall outside this range.

A second value is institutional autonomy, the importance of responsible freedom of action at the institutional level as essential to assuring quality. This value is grounded in the view that the faculty and academic administrators of a college or university are best positioned to make academic decisions such as determining curricula and setting

learning standards. While a number of countries are still sustaining systems in which government decides curricula, admission criteria, and faculty hiring, there is a growing international dialog about the need and desirability of institutional autonomy.

A third value is academic freedom or the importance of sustaining independent intellectual inquiry in the teaching and research of faculty. The tradition of faculty as maintaining and defining this academic space as they carry out their responsibilities has been essential to knowledge development throughout the world. As with institutional autonomy, the commitment to academic freedom is often carried out alongside considerable government authority for academic decisions affecting colleges and universities.

The Roles of Accreditation

Accreditation carries out several roles that are vital to students and society. Among the most important are accreditation's work to (1) assure threshold quality and quality improvement in colleges and universities, (2) serve as a reliable authority on quality for students, government, and the public, and (3) assist with student mobility through easing both recognition of degrees and transfer of credit.

For colleges and universities, accreditation is a useful external review that enables an institution to affirm its quality and create paths to improving quality. If successful in achieving accreditation, an institution has a quality stamp, a significant indicator to students and society that it has undergone external review which confirms that it meets threshold-quality expectations.

Accreditation serves as a reliable authority for both the public and private sectors that fund higher education institutions (e.g., government, private foundations, and alumni donors). Accreditation plays the role of confidence-builder. Without the accredited status, it is quite difficult, if not impossible, for an institution to either obtain sustained funding for its operation or maintain the confidence of these funders in the work of an institution.

Accreditation assists with student mobility and recognition of qualifications. Accreditation is one assurance of the value of a degree as well as a factor in the recognition of degrees across institutions and countries. Accreditation is also a significant factor in transfer of credit or students attempting to move credits earned at one institution to another, usually in the course of earning a degree.

There are other roles that accreditation plays. For example, quality assurance is sometimes seen as a means to assure equity in higher education, providing for high quality along a range of institutions, whatever the income level of students who attend. The accreditation process is sometimes considered from a social-justice perspective, with concerns that the process not be used to reinforce

undesirable social stratification. Higher education is often viewed as essential to reinforcing social responsibility, ethical awareness, and citizenship and these characteristics are included in concepts of quality that accreditors review.

Change in Higher Education and Implications for Change in Accreditation

The significant changes that higher education is experiencing in many countries are having a considerable impact on accreditation. Three changes are especially dominant: the expansion of access, internationalization of higher education, and heightened accountability to the public.

Expansion of Access

Both developed and developing countries are experiencing significant growth in higher education attendance. Many countries have constructed mass higher education systems, enrolling anywhere from 25 to 40% of the college-going age cohort (Altbach, 2007). The Organization for Economic and Cooperative Development (OECD) countries saw a doubling of the proportion of adults with higher education qualifications between 1975 and 2000 (*The Economist*, 2005). An estimated 133 million students were enrolled in higher education in 2004 (Sanyal and Tres, 2007), depending on whether part-time as well as full-time students are included and how individual countries define higher education. This is up from an estimated 90 million in 2000 (Garrett, 2007).

The unprecedented expansion of access is driven by a range of factors. The diminution of manufacturing employment and the rise of knowledge and service employment dominate more and more national economies, intensifying the need for higher education. Students need at least some higher education in order to obtain jobs and assure upward mobility in the workforce. In many countries, the level of education is closely tied to social success and perceptions of personal accomplishment. Beyond education for work, it is vital that countries also sustain the important traditions of knowledge development and intellectual inquiry.

International competition and cooperation are putting pressure on more and more countries to assure their populations measure up to workers in other countries. Finally, the increase and expansion of trade agreements as well as technology that enables businesses to quickly develop a worldwide workforce has also put pressure on countries to improve access to higher education.

Access through distance learning

Distance learning has been around for many years, mainly in the form of correspondence courses. The nature of distance learning varies among countries for reasons

related to geography, culture, history, and current capacity for technology. In all instances, however, students are separated, either by time, location, or physical proximity, from the institutions and faculty offering instruction. Twenty-first-century distance learning is an electronically driven, synchronous, or asynchronous and web-based enterprise. It has emerged as a significant enabler of access. The Internet has had a most profound impact on the provision of distance learning, allowing providers to invent themselves at will.

An estimated 7 million students are enrolled in distance-learning offerings (Garrett, 2007). Some countries, such as Kenya and Jordan, import distance learning; others such as Malaysia have significant in-country capacity. Yet others, such as the United Kingdom, Australia, and the United States, are major exporters of distance learning (Middlehurst and Woodfield, 2005). The growth of reliance of distance learning has been particularly significant in countries such as Turkey, China, Japan, India, and Israel, where some of the largest distance-learning providers are located. As distance learning is readily accessible even without the development of campuses or a faculty, it has become part and parcel of mass higher education, instantly international and capable of rapid changes (Altbach, 2007).

Access through for-profit providers of higher education

For-profit enrolments are a subsection of the complex privatization of higher education that is going on worldwide. The emerging for-profit activity is large scale, career oriented, degree granting, aimed at a mass market, and competitive with traditional higher education. At this time, there are few countries in which for-profit, degree-granting higher education exceeds 5% of total enrolments (Garrett, 2007a). In the United States, a traditionally hospitable for-profit higher education environment, 2 million of the 16–17 million students in colleges and universities attend for-profit institutions (JBL Associates and Wilson, 2007). An estimated 5 million students are enrolled in for-profit operations worldwide (Garrett, 2007).

For-profit providers are expanding rapidly in countries such as China, India, and regions such as Latin America. Particularly, the US-based publicly traded for-profit operations such as the Apollo Group, DeVry, Laureate, and Kaplan are actively engaged in international expansion. The for-profit focus is primarily on training, credentials, and employment. International for-profit higher education relies on both local and electronic delivery, cooperative initiatives with local higher education providers in other countries, and special initiatives for short periods of time such as summer programs (Levy, 2006).

Degree mills, dubious or bogus providers of higher education, are the dark side of for-profit higher education. The rogue operations, offering degrees and other credentials for considerable sums of money but requiring little if

any educational experience, are causing considerable concern for many countries, especially those that import higher education. A provider is likely to be a degree mill if, in addition to the characteristics mentioned above, it employs few if any faculty, has a name that is similar to a well-known traditional institution, sells credentials online, and provides no evidence of accredited status.

While there is considerable discussion about the problems caused by degree mills, few countries to date claim to have adequate laws and effective practices to fully protect students, employers, and the public, although considerable efforts are underway to address this. In the United States, for example, federal legislation has been introduced that would define degree mills and make the use of fraudulent credentials a crime. A number of states, as well, are introducing or strengthening their laws with regard to degree mills. Central to the effectiveness of these efforts is the capacity to distinguish degree mills from other, quite legitimate for-profit providers.

Impact on accreditation

The expansion of access to higher education in country after country has resulted in increased pressure to establish, expand, or restructure accrediting bodies. Accrediting organizations are being asked to assure the quality of a significantly massified and more diverse higher education enterprise. Since 1991, the number of countries with fully operational accreditation systems has grown from 11 to 60 (Lewis, 2005). As traditional institutions develop new programs, students and the public want the same kind of assurances about the quality of these new offerings as with more mature programs. As branch campuses are developed to serve more and more students, the public wants to be similarly assured. The internationalization of higher education as a means to expand access has been part of this pressure as well.

A number of countries have passed new legislation or revised current law to address the quality of their expanding and diversifying higher education systems. For example, Japan amended its School Education Act in 2002 and initiated a new accreditation scheme in 2004. All public and private universities, junior colleges, and colleges of technology have to be accredited by an organization authorized by the national government (Yonezawa, 2005). In the same year, China's Ministry of Education merged accreditation, regular institutional assessment, and selective assessment into a single policy package and in 2004, a quasi-governmental quality-assurance agency was established (Sanyal and Tres, 2007).

Portugal's new degree law, launched in 2006, provides a legal framework for a national accreditation system (European Network for Quality Assurance in Higher Education, 2006). In South Africa, the higher education quality committee was established in 2001 to carry out three mandated roles of accreditation of programs, audit of institutions,

and quality promotion and capacity development. This has resulted in a strengthened focus on quality and the application of a qualifications framework across a coordinated system (Council on Higher Education, 2004).

With regard to distance learning, more and more accrediting bodies are developing capacity to review these operations. They have put in place new standards or applied current standards to address synchronous and asynchronous learning environments, free-standing distance-learning providers, or blended instruction that is a combination of distance and site-based delivery. India, for example, has established a distance-education council specifically for its open universities and distance-education system. The quality assurance agency (QAA) for higher education in the United Kingdom has a statement of good practice that is applied to distance learning as well as site-based institutions (Sanyal and Tres, 2007). In the United States, review of distance learning has been incorporated in the ongoing accreditation reviews of colleges and universities and one US accreditor, the distance education and training council, reviews only distance-learning providers.

For-profit providers of higher education are, in some countries, subject to the same scrutiny as nonprofit operations. In other countries, there is little capacity or infrastructure to acknowledge and thus address these providers, the result being an essentially unchecked and blossoming enterprise, operating alongside government-regulated higher education. Legitimate apprehension and concern about degree mills are driving out careful attention to legitimate for-profit providers. To the extent that for-profit operations are accredited, the apprehension and concern are diminished. In the United States, for example, more than 2500 for-profits have earned accreditation from a reliable accrediting organization.

Accreditation is often a first-line defense against for-profit degree mills in a number of ways. Institutions that have achieved accredited status from reputable accreditors constitute a *de facto* positive list of responsible institutions on which students and the public can rely. A number of degree mills seek accreditation and fail to achieve this status, thus remaining outside the sphere of what are generally considered legitimate higher education institutions. Accrediting organizations, working with organizations such as UNESCO or OECD, are playing a significant role in creating greater international awareness and enhancing capacity to identify degree mills. Going forward, accrediting organizations, working with institutions, government agencies, and business, can develop effective practices and other means to enhance public awareness and understanding of how to identify and avoid degree mills.

Internationalization of Higher Education

According to one UNESCO estimate, 3.84 million students were studying abroad in 2002 (Sanyal and Tres, 2007).

In the 1990s, the United States has seen growth in international students from Korea, China, and Japan, (Altbach, 2006). As of 2005–06, 564 766 international students were enrolled in US colleges and universities. (Institute of International Education, 2007). More recently, there has been considerable growth in the number of foreign students in England, Germany, and France as well (*The Economist*, 2005).

In response to this enrolment growth, the international activity of colleges and universities is expanding rapidly and has taken several forms. More institutions are entering into partnerships with colleges and universities outside a home country. More institutions are moving unilaterally to operate internationally, either through offering programs in another country or establishing new campuses or even freestanding institutions. Faculty exchange programs, a staple of international activity, have grown significantly. In some instances, developing countries are inviting foreign institutions to come to them as an alternative to sending students abroad. This is the case in Singapore, Dubai, and Qatar (*The Economist*, 2005). Distance-learning operations, as well, are increasing the extent of international activity.

Impact on accreditation

All of this activity has resulted in pressure on accreditation to operate internationally as well as nationally. In country after country, accrediting bodies are developing capacity to review programs established for student exchange, partnerships among institutions that cross national boundaries, and institutions establishing operations in other countries. The QAA of the United Kingdom, for example, reviews all overseas activity of UK institutions (Middlehurst and Woodfield, 2005). In Australia, all offerings of providers are examined, wherever they are carried out, by the Australian universities quality agency (Sanyal and Tres, 2007).

US private, nongovernmental accrediting organizations are now exporting accreditation. As US institutions expand internationally, accreditors are required to expand their work to other countries. Some US accreditors actively seek significant additional international engagement through accrediting non-US institutions and programs. As of 2005, 43 of the 81 recognized accrediting organizations were active in 96 countries, accrediting 710 operations (Council for Higher Education Accreditation, 2006). While growing slowly, the international activity of US accreditors raises a number of issues. As the only country that is, at present, free to export accreditation, what are the appropriate means by which to do this? Can the fundamentals of US accreditation, closely intertwined with US higher education that is different in a number of ways from higher education in many other countries, avoid a kind of academic colonialism – shaping academic policies in other countries (Altbach, 2006)?

Accreditation is taking on a regional character in the service of an internationalizing of the higher education enterprise. The European Bologna Process, a comprehensive initiative involving 46 countries, provides one example of attention to assuring quality through a regional regulatory framework. European standards and guidelines for quality assurance were adopted in 2005. A register of European higher education quality-assurance agencies has been developed and is in the implementation stage (European University Association, 2007). The purpose of the register is to provide for peer review of quality-assurance bodies.

Other regional efforts include the Ibero-American Network for the accreditation of quality in higher education established in 2003. The network is made up of quality-assurance agencies, government organizations, and associations of higher education institutions in Latin America and Spain. Its efforts are focused on development of national quality-assurance mechanisms, including assistance with development of technical staff for quality-assurance agencies. It also promotes regional efforts (Lemaitre, 2006). The Arab states have been promoting quality assurance at regional and national level, with regional efforts underway since 2003 to establish the Arab states quality-assurance network and the Arab society for quality assurance in education. At a national level, this includes mechanisms for quality assurance and accreditation (Sanyal and Tres, 2007).

Multinational organizations have been active in this area as well. UNESCO initiated a global forum on international quality assurance, accreditation, and recognition of qualifications in 2002, establishing a significant arena in which governments, institutions, and accreditation and quality-assurance bodies can address quality-related issues. The forum's work includes a major capacity-building effort, especially for developing countries as well as efforts to establish an information portal to provide a central international source for information about reliable higher education institutions and accreditation and quality-assurance providers in each country. UNESCO and OECD published, in 2005, *Guidelines for Quality Provision in Cross-Border Higher Education* to assure quality across national boundaries as international activity in higher education continues to expand.

Heightened Accountability to the Public

Across the globe, governments are concerned to make higher education institutions more accountable to the public. Two expectations define their efforts: increased calls for evidence of student achievement and demands for greater transparency. The similarity of expectations across countries is striking and related to the internationalization of higher education as well as expanded access.

In many countries, evidence of student achievement is being addressed through the development of student

learning-outcome indicators and identification of expected student competencies. Australia, various provinces in Canada, England, South Africa as well as Europe, and a number of other nations and regions, for example, have developed qualifications frameworks, seeking to link degree levels with student achievement in specific skill areas. The European effort, the Dublin descriptors, is multinational and identifies capacities that are to be associated with degrees at the bachelors, masters, and doctoral levels (Lewis, 2005). In Hong Kong, incorporating additional attention to student achievement has been central to policy discussions related to the ongoing work of its publicly funded universities and a comprehensive qualifications framework has been developed as well.

Accountability has dominated federal policy discussion in the United States during the past 2 years. There is little current interest in qualifications frameworks, but there is increasing emphasis from both state and federal governments to develop a common set of institutional performance indicators or expectations of student achievement. Institutions themselves are pressed to provide more information about performance and student achievement on websites and in official print documents. This has been accompanied by a number of federal and state associations of higher education institutions that have recently taken significant steps to expand their attention to both performance indicators and student achievement.

Transparency, demands for readily accessible and easily understandable information to the public about quality, is routinely part of accountability conversations. Institutions are called upon to provide information, for example, about graduation rates, job placement, transfer, and entry to graduate school. There is much discussion about rankings and mechanisms that allow for comparison among institutions as additional means of addressing the public interest in greater accountability. Less of this work has taken place through accreditation bodies, but has been pursued by governments, universities, or the commercial sector.

There is considerable debate about whether or not rankings provide useful information about quality; nonetheless, these lists attract a good deal of attention. These include the national rankings of *US News and World Report* in the United States and the *Times Higher Education Supplement* in the United Kingdom and the international academic rankings of world universities at Shanghai Jiao Tong University. To address some of the issues and concerns surrounding rankings, an international group of professionals issued, in 2006, the Berlin principles that provide a framework to approach and improve ranking systems (Institute for Higher Education Policy, 2007).

Impact on accreditation

A number of accrediting organizations in various countries have standards that require institutions to

develop expectations of student-learning outcomes and provide evidence that these expectations are realized. In the United Kingdom, the QAA has subject benchmarks for more than 40 program areas (Lewis, 2005). In the United States, expectations to address student outcomes have been embedded in the standards of all recognized institutional accreditors since 1992.

Accrediting organizations in many countries are expected to enforce qualifications frameworks. In addition, accreditors are pressurized to provide comprehensive information about their reviews of institutions. As of 2005, 46% of accrediting organizations made their reports public, with 52% keeping the reports private (Lewis, 2005).

There are also international calls for accrediting bodies to address both outcomes and transparency. In addition to the UNESCO/OECD *Guidelines*, two statements on sharing higher education quality across borders have been developed by the American Council on Education, the Association of Universities and Colleges of Canada, the Council for Higher Education Accreditation, and the International Association of Universities, urging institutions and accreditors to address both of these areas (Council for Higher Education Accreditation *et al.*, 2005, 2006). The *Guidelines of Good Practice* of the international network of quality assurance agencies in higher education includes attention to transparency as well (2006).

Summary

Accreditation of higher education is a quality-affirming process that, in many countries, includes the creation of accreditation standards, institutional self-review, institutional peer review, judgment about achieving accreditation, and award of accredited status. Just as the process of accreditation is similar across countries, both the values and roles of this enterprise are similar as well. Accreditation builds on the key values of institutional mission, institutional autonomy, and academic freedom. It plays major roles with regard to assuring threshold quality and quality improvement, serving as a reliable authority on quality to students and society and assisting with student mobility through recognition of qualifications and transfer of credit.

Major changes in higher education in many countries are also driving changes in accreditation. Higher education is experiencing a significant expansion of access with the internationalization of colleges and universities and demands for heightened accountability to the public. To accommodate these changes, accrediting bodies are expanding in numbers as well as enhancing and diversifying their capacity in order that these emerging key features of higher education are effectively examined for quality and quality improvement.

Universities and Regional Development*

J Goddard, Newcastle University, Newcastle upon Tyne, UK

Introduction

Across the globe, universities and local communities are discovering each other and more and more partnerships are being established based on a growing appreciation of shared interests. This article explores the drivers behind such engagement from both the university and local-community perspectives, the barriers to effective working, and how these barriers can be addressed at the institutional, local, and national levels.

The article draws heavily on an Organization for Economic Cooperation and Development (OECD) review on supporting the contribution of higher education institutions to regional needs and which involved case studies of 14 regions across 12 countries. Following the OECD approach, this article links two hitherto separate areas of enquiry, namely that concerned with the economic, social, and cultural development of localities in the round (cities and regions) and the university as a key institution in civil society. It therefore considers how groupings of local interests in business and the wider community can reach in to universities in their area and how universities can reach out and engage with these groupings.

Inevitably, a short high-level article cannot pay adequate attention to important differences between countries, universities, and localities. The nature of engagement between universities and their local communities is highly contingent on institutional and local-development trajectories and national policies toward higher education and the governance of cities and regions. The reader is therefore referred to the OECD case study reports which reveal universities and regions at various stages on this journey of discovery (or re-discovery) and how in the process they are seeking to overcome all manner of barriers to engagement.

The Regional-Development Drivers behind Community Engagement

Post World War II, regional policy in many OECD countries emphasized the need for intervention by the nation state to reduce disparities between regions. Public

intervention took the form of financial support for established industries and the attraction of mobile investment in order to absorb surplus labor. There were also measures to equalize living standards between regions, including standards of primary and secondary education.

Significantly, higher education did not enter into the panoply of regional-policy interventions. Many European universities which had developed to serve traditional industries during the later part of the nineteenth and first-half of the twentieth century were subsequently incorporated during the 1960s into national systems of higher education. In this process, their local ties were weakened. However, in the United States, individual states did support public universities in serving the needs of their territories, building on the land-grant tradition established in the nineteenth century. Indeed, state investment in higher education to tackle industrial decline in New England and to attract new federal investment in areas facing structural adjustment in agriculture in California laid the foundation for subsequent high-technology corridors such as Route 128 and Silicon Valley. In Canada and Australia, where a federal structure of government was established, higher education played a key role in the development of the cities which were the gateways to the individual states, for example, laying the foundations for the so-called sandstone universities in each of the state capitals of Australia. In Australia, regional problems were (and remain) essentially problems of underdeveloped city hinterlands and rural areas. Outside of the so-called developed world, the priority of nation building around national capitals contributed to rising regional disparities with national universities being one of the magnets for internal migration.

The European post-war consensus around the need for state intervention to reduce core/periphery regional disparities broke down during the 1970s. This was associated with the onset of structural adjustment problems and the rejection of the post-war Keynesian models of economic regulation. The emergence of so-called rust belts linked to traditional industries such as coal and steel, heavy engineering, and textiles which were now facing competition from newly industrialized countries and the related decline of mobile investment seeking lower-cost sites within industrialized countries, undermined the basis of redistributive regional policy.

In response to the crisis, the emphasis on territorial and industrial policy switched toward indigenous development

* Based on Goddard, J. and Puukka, J. (2008). The engagement of higher education institutions in regional development: An overview of the opportunities and challenges. *Journal of the Programme on Institutional Management in Higher Education* 20(2). OECD (2008) *Special Issue: Higher Education and Regional Development*. With permission from OECD.

focused on small and medium-sized enterprises (SMEs) with a particular emphasis on the role of innovation in raising their competitiveness.

This shift of emphasis opened the way for links into the research base in local universities. It also coincided in the US with the passing of the Bayh-Dole Act in 1980 which empowered universities to commercialize their own intellectual property. During the 1980s, a growing body of academic literature underpinned the case for local or bottom-up public intervention in the supply side of the local environment supporting (or inhibiting) business innovation. Studies of the so-called third Italy indicated that networks of traded and untraded interdependencies between SMEs could provide a fertile environment for innovation in traditional industries outside established urban agglomerations. Whereas in Italy these networks did not involve universities, the experience of Silicon Valley in California and Route 128 in New England assumed totemic significance in relation to the possibility of creating new industrial districts or regenerating older districts through strong links with research-intensive universities.

Moving into the 1990s, the range of supply-side factors that regional policymakers deemed to be influencing economic performance widened. Most significantly, education and skills and the tacit knowledge gained through work-based learning became embodied in the concept of the learning region. This had resonances with the growing appreciation that innovation is not necessarily a linear process and could involve close interaction between producers and users, interactions which were best conducted face to face. Moreover, the role of students and graduates in what might be termed knowledge transfer on legs and establishing the social relations between researchers and the business in which they work became increasingly apparent.

During the 1990s, these perspectives began to be formally adopted in public policies to foster the development of industrial clusters rooted in particular places. The concept of the industrial cluster recognized that innovation is seldom isolated but systemic with the industrial cluster acting as an innovation system. Clusters, in this instance, could encompass strategic alliances of universities, research institutes, knowledge-intensive business services, bridging institutions and customers. Cluster success required and encouraged flows of talented individuals, including students and graduates, and the creation of vibrant and exciting places.

Within the cluster, universities could assume an entrepreneurial role while firms developed an academic dimension. Emphasis was placed on a spiral model of interaction where a number of channels feed into the innovation process including research links (the creation of new knowledge), information transfer (selling existing knowledge), and people-based transfer (students and staff) as well as spin-offs. In this model, specialized centers and cluster discourse could provide a focus for both

higher education institutions (HEIs) and the business community. It could involve embedding engagement in the core business processes of both HEIs and industry.

Throughout the OECD, there is now a convergence of innovation and territorial-development policy. This is placing new demands on universities as innovation policy becomes more comprehensive. There is increased emphasis on education and training, employability, the quality and skills of the workforce, and lifelong learning. People and human resources are being brought into focus. There is recognition that initiatives to foster innovation and competitiveness need to take account of challenges of urban and regional variations in unemployment, poverty, and exclusion in a multicultural society. There are also aspirations to establish and foster creative and enterprising places where people and companies want to locate. Thus, many towns and cities have been inspired by reflections on the new creative class and the global competition for talent which has led to increasing investment on place marketing and the branding of cities as nice places to live.

In summary, regional policy which was redefined and narrowed down to technological innovation policy is now in the process of being ever broadened as other fields of policy are given an innovation signature and more agents and levels of government (city, regional, national, and international) are drawn into the process of building innovative capabilities. From a rather narrow focus on high technology and manufacturing industry and the private sector, attention has been widened to include social and organizational innovations and business, consumer, and public services.

This broadening of regional policy has wide-ranging implications for the expectations placed on universities by cities and regions. They are now expected to participate in public and private partnerships and contribute to balanced region building. Whereas previously attention was focused on universities as a source of high-technology innovations and new knowledge-based industries, these are now beginning to be regarded in a broader perspective, encompassing the whole social fabric of which universities are part. For example, the new emphasis on social innovation, tourism, the creative industries, and welfare widens the academic domains relevant to community engagement from science and technology and medical faculties to the arts, humanities, and social sciences.

In summary, and for those agencies charged with city and regional development, universities are: major businesses generating tax and other revenues; global gateways in terms of marketing and attracting inward investment in the private sector; generators of new businesses and sources of advice to existing businesses; enhancers of local human capital through graduate retention and professional updating of the existing workforce; and providers of content and audience for local cultural programs.

Universities, particularly in highly centralized states, can also be key local agents able to bring together within the territory different national interests in science and technology, industrial performance, education and skills, health, social inclusion, and culture.

The Higher Education Drivers behind Engagement

The longevity of universities as key institutions in the evolution of civil society is linked to their adaptability to changing circumstances, while maintaining key elements of continuity (such as the global connections which characterized the medieval foundations). The emergence of the Humboldtian University in nineteenth-century Prussia was linked to the professionalization of science, the requirements for specialized infrastructure to support it and to underpin, at a distance, the development of the state.

The principle of at a distance is important because in many respects, the research university that evolved in continental Europe during the nineteenth century can be described as a denial of place. This is because the ideal of scientific enquiry embodied in the modern university is to strive for universalism. Scientific claims to truth were deemed to be irrespective of time and place and the university had to have a mission that transcended its actual location. Indeed, the notion of the university as a detached site for critical enquiry, exchange of ideas, and advancement of knowledge for its own sake has been of vital importance to the creditability and legitimacy of the institution.

The nationalization of science and education during the twentieth century further enhanced the detachment of universities from places. Due to their importance to nation building, universities were no longer expected to rely on the patronage of churches, town councils, and local elites. They now received their core funding from national governments and in return trained the cadres for the civil service and national corporations and the professions such as law, medicine, engineering, and architecture. They were to contribute to new national identities and the cultural spirit which underpinned the nation-building process. All of this was based on a compact whereby the university rendered services to the state in return for a degree of institutional autonomy in terms of internal governance.

Part of the American higher education system, however, developed in a different direction. Land-grant universities, which in the first instance promoted agricultural development, were regionally embedded people's universities based upon widening access to education and service to the community.

The second part of the twentieth century witnessed a massive expansion of public investment both in research

and development and higher education. This had a profound impact on the universities that had emerged in the previous century and their engagement with regions. The expansion of higher education typically took place outside the established universities which were regarded as too inflexible to meet the demands for new skills emerging in the workplace and from communities where they were not present. Thus, we now speak of HEIs not just universities. The higher education map of most countries has been colored in incrementally with a diverse set of institutions. Many of the new institutions built on previous foundations, typically with limited tradition of research (such as teaching and nurse-education colleges), and many of them have been given a specifically regional mission.

In some countries, this geographical dispersal of higher education has formed part of a conscious policy seeking to preserve the spatial distribution of the population and to achieve balanced regional development by addressing regional disparities. It has included also the objective of improving regional access to higher education. This has translated into policies to establish new HEIs in various regions, for example, in Norway, Sweden, Finland, Japan, and Mexico. However, in many countries dispersal of higher education has followed a simple logic of higher education expansion modified by political lobbying. This is not just a top-down phenomenon. Towns and cities have lobbied for their own university.

The consequence is that many OECD countries have a highly diversified system of higher education with complex mixes of universities, polytechnics, regional colleges, and vocational-training institutions. The regional role has sometimes served to differentiate among the various types of institutions. In Finland and Portugal, for example, universities are considered to have a stronger national and international role while polytechnics are assumed to focus on their regional role.

In many countries, the distribution of universities is not necessarily structured to meet the challenge of balanced regional development in a highly competitive global economy. So, while disadvantaged regions may possess locally orientated HEIs, these are often more geared toward upgrading the existing industry and less equipped to build a new knowledge-based economy.

The expansion of public investment in research in science and technology inside and outside of universities has likewise had an impact on the issue of regional engagement. This expansion has largely been driven by ministries of science and technology and in many cases has taken place in public research laboratories outside higher education, characteristically in the hinterlands of capital cities. At the same time, universities were able to compete for research funding from research councils operating at arm's length from government. In these councils, the academic community has had a major influence

via peer review in a manner that has preserved the autonomy of their institutions and their distance from the state. This peer-review process has often reinforced the position of the longest established institutions, typically in capital cities, thereby reinforcing regional disparities.

During the 1990s, this model for the organization of public research began to break down as governments began to demand a more immediate economic return for investment in the science base. A key challenge has been to remove barriers and bottlenecks between scientific research and industrial innovation. The institutional division of labor which implied that research was carried out in isolation from the context of application was perceived as a problem when science policy was morphing into innovation policy. In this process, HEIs as institutions, as well as the individual academics who work within them, have been expected to become more active players in the so-called triple helix of government, business, and HEI relations.

Industrial policy and science and technology policy have thus been converging toward a common innovation policy which in some countries explicitly or implicitly embodies a strong territorial dimension. Research-intensive universities have been surrounded by science parks and a host of special-purpose organizations established to support close cooperation with industry. In some instances, these have served to buffer the institution from external pressures and instead of facilitating links, these have operated as filters or merely served as display windows toward the universities' political environment. But increasingly, universities are expected to take the lead and to rearrange the structures so that the promotion of entrepreneurship and knowledge exchange form part of the academic heartland of research and teaching. HEIs are now expected to contribute to economic development by: creating new sectors through spinning out businesses backed by research; attracting and retaining global businesses in the region through the availability of quality research links and the supply of well-trained graduates; assisting with the diversification of established businesses in their production of new products and services; and upgrading existing mature industries through assistance with incremental product/service innovation and improvement in industrial/business processes.

This science-driven model nevertheless overlooks many features of regional development to which universities can directly and indirectly contribute. It neglects the contribution of broad-based teaching and learning to the enhancement of regional human capital. Service industries provide most regional jobs and the majority of graduates take up employment in financial, legal, and other professional services. Some regional services will be traded nationally and internationally and use the skills of graduates to develop new products, some of which will also be provided to regional high-technology-based

businesses. These businesses may in turn require non-scientific graduates, for example, with a business-school background to assist in activities such as marketing. Other important nonmanufacturing sectors recruiting graduates are the cultural industries and tourism which can serve to attract and retain creative people within the region, including those working in high-technology businesses and HEIs themselves. Moreover HEIs are creators of, and venues for, cultural and social activity.

HEIs also make a considerable contribution to public services, particularly health and education; these services play a role in economic development not least as regions with wide internal social disparities less likely to be attractive to leading-edge investors in the global knowledge economy. Finally, as environmental sustainability moves up the political agenda, it is becoming increasingly apparent that HEIs could have a key role to play through research, teaching in public education, and in building sustainable communities. All of these latter roles highlight the public service responsibility of HEIs as distinct from the more private focus of the science-driven model.

In summary and in terms of economic drivers, HEIs are seeking: local support for their global aspirations in research and student recruitment; increased student enrolments from the local population; additional income from services provided to local businesses through consultancy and professional training; and last but not least the indirect benefits of a local environment that can attract and retain creative academics and motivated students. At a higher level, regional engagement is an outward and visible sign of the third or public-service role of higher education and through which the institution can demonstrate its contribution to civil society. Through such endeavors, HEIs are able to provide concrete evidence of the value that higher education and research adds to public investment in it.

National Policy Barriers to Regional Engagement

In most OECD countries, higher education policy does not include an explicit regional dimension. Ministries of Education characteristically act as champions of the role of higher education and research in meeting national aspirations in terms of scientific excellence and advanced education of high quality for its own sake.

The seemingly more mundane task of applied research and development and meeting skill needs in the local labor market may be left to lower tiers in the education system, such as tertiary/community colleges. In some countries, the boundaries between the levels of higher education have become blurred. Examples include the designation in 1992 of polytechnics in the United Kingdom as universities, the designation of selected colleges in

the Netherlands as universities of professional education (now universities of applied sciences), and the creation of universities of applied science in Finland (formerly polytechnics).

Characteristically, the newer institutions do not have a well-established tradition in research or the infrastructure to support it and have to work hard with limited resources to build a national, let alone an international, profile traditionally associated with university status.

An important point to note in relation to regional engagement is that longer-established HEIs have developed and grown in locations that broadly follow the national-settlement hierarchy. These locations are quintessentially larger cities with the most prestigious institutions located in or around the capital city. In contrast, the newer institutions, often with a specific remit to serve particular territories, tend to be more geographically dispersed.

To what extent has the process of rolling out of higher education across national territories been part of conscious national policies to use higher education as an instrument in regional development? The answer depends on the definition of development and the extent to which this has been a task laid upon HEIs by their funders in central government. It is widely accepted that the challenge of raising competitiveness via research-led innovation is now at the heart of regional policy. However, it is clear that supporting excellent research in all regions has not been an objective of higher education policy. Even when engagement with business and the community has been recognized and laid upon HEIs as a duty as in all the Nordic countries, it has been very much a third task, not explicitly linked to the core functions of research and teaching. Nor, in most instances, is this task specifically funded or linked to regional development.

Turning to science and technology policy, there are growing pressures to ensure that public investment in this area has an economic impact. Consequently, there is an increasing convergence between research policy and other policies designed to support business innovation. But notwithstanding the growing recognition of the importance of organizational and social barriers to innovation, most top-down science and innovation policies continue to have a high-technology and manufacturing-industry focus and neglect the contribution of the arts, humanities, and social sciences to new ways of working and servicing the creative industries. Recent decades have therefore witnessed the establishment of centers of science-research excellence to support industrial innovation and which focus on newly emerging high-technology fields such as biotechnology, nanotechnology, and information and communication technology (ICT). But the policies underpinning such centers often fail to recognize that much innovation is neither science based nor radical, but incremental in nature and taking place in SMEs.

National innovation policy driven by ministries of science and technology also does not as a rule pay regard to the role of teaching and learning in knowledge transfer from the research base. Work-based learning schemes which usually involve regional links between employers and HEIs are designed to enhance graduate employability and not as specific tools to improve regional business competitiveness. A notable exception in this regard is the UK's knowledge transfer partnership scheme under which postgraduates undertake projects in companies which are usually local. However, this is not explicitly a regional scheme.

While most OECD countries have active national-labor-market policies led by the ministries of labor or their equivalent, the focus is chiefly on intermediate and lower-level skills and the unemployed, not those associated with higher education. At this level, it is assumed that the market (i.e., demands from students and employers) will work effectively without intervention. National employer-led associations for particular professions (e.g., lawyers, architects, and civil engineers) often play a key role in regulating supply and maintaining quality. Only in areas where the state remains a major provider of public services, most notably health, does the government undertake a planning role. While the market for intermediate and lower-level skills may be local and therefore require a strong spatial dimension, it is assumed that the market for high-level skills is national and international. Therefore, there is no case for intervention at the intermediate or regional level.

For these reasons, there appears to be little engagement by research-intensive universities in the development of human capital at the regional level, particularly as it relates to the skills required by knowledge-intensive businesses growing on the support of links with the research base. In contrast, newer and vocationally oriented institutions are usually committed to upgrading skills in the established industrial base.

The cultural domain is another area where the role of universities in contributing to city and regional development is not widely acknowledged in national policy. Universities are often owners or custodians of cultural assets displayed in their own museums and galleries. Their music, arts, and drama departments directly and indirectly contribute to the vibrancy of their cities through performance and related activities. In some countries, support for the arts and heritage does have a regional dimension and embrace higher education, but this is an exception rather than a general rule. Increasingly, universities are finding it difficult to support such activities out of their core teaching and research budgets and are seeking support from regional sources to maintain expensive facilities and activities. At the same time, the fast growth of the creative industries is shifting the focus to new enterprise formation by graduates of creative arts, design, and media.

Barriers in Regional Structures and Governance

Although many regions across the OECD are looking to universities to contribute to their economic, social, cultural, and environmental development, the capacity of city and regional public authorities to reach into higher education is often constrained by a wide range of factors. At the most general level, the public governance of territory operates within closed boundaries. Local and regional governments are responsible for administratively defined areas and these are usually linked to unambiguous political mandates. By contrast, research-intensive universities cannot have a mandatory geographical sphere of influence; indeed, such institutions operate at the local, regional, national, and international scales. Some lower-tier HEIs do have a specific regional mandate but it is increasingly less likely to be enforced by national, regional, and local governments with the institutions competing for students and contracts wherever these can be obtained. So, the delimitation of its region is a challenge for many universities.

Local government in many OECD countries is highly fragmented with individual municipalities having limited powers and resources to engage in economic development generally, let alone with higher education. In some countries, municipalities pool resources across several units and/or establish joint development agencies with a responsibility to work with universities in the combined area. At the next level of aggregation (or disaggregation of the national governance system), some countries have politically powerful regional authorities with a specific mandate to support higher education in their region. This is the case in the Spanish autonomous regions and the Provinces of Canada. In highly centralized countries like the UK, the national government has devolved some powers to the countries of Scotland and Wales including some aspects of higher education. Within England, special development agencies in each of the ten regions have been established by the central government. These agencies have some autonomy and are increasingly seeking to mobilize HEIs in support of economic development even though higher education remains a central function.

In attempting to engage with some level of government between the national and local and even when there is a specific regional administrative structure in place, universities often face challenges of intraregional competition for their attention. Relating to the specific municipality in which they are located is one thing – serving a multitude of locations across a broader region with several centers of population is another. Multi-campus solutions raise questions of dilution of resource and partnerships between several HEIs across a region and can be very demanding of senior-management time and energy.

Finally, identifying who speaks for the private sector in relation to what higher education has to offer can be

challenging, especially in regions without a strong private sector research and development base. In strong and dynamic regions, there are often well-developed private sector networks that are plugged into higher education and articulated through chambers of commerce. But in weaker regions, the SME sector is often inchoate and there are not well-developed industrial clusters. In such regions, branches of national and international companies can lack the autonomy to engage with universities for the development of new products and services and to provide placements for students and jobs for graduates.

In summary, the environment for universities to engage in regional development across OECD countries is highly variable. Where the governance and business structure is poorly developed and where there is no strong regional leadership, it is often necessary for HEIs to not simply respond to regional needs but to set the development agenda. Whether the HEIs are able to do this depends on their own governance, leadership, and management.

Barriers in the Governance, Leadership and Management of HEIs

Regional engagement is a challenge for universities, particularly for longer-established institutions organized around academic disciplines and along a supply-driven agenda. Most universities recognize the importance of teaching quality and research excellence and link these qualities to the cross-cutting roles of vice rectors (as distinct from the disciplinary roles of deans and heads of department). However, the integration of teaching and research within the disciplines to deliver regional impact is seldom recognized.

The all-embracing nature of regional engagement implies that this is a task for the head of the university. He/she can integrate the function and disciplinary areas and represent the corporate view of the institution externally. In many cities and regions, rectors and vice chancellors are key members of local elites, participating in many forums. At the same time, individual academics or other staff members may be active as business or social entrepreneurs in projects supported by the city and region. But in many instances, there is little connection between the high-level engagement of the senior management and the actions of individual academics. Indeed, the customs and practices of the institution may act as a barrier to more systematic engagement across the institution.

There are numerous institutional barriers particularly within research-intensive universities. First and foremost is the lack of incentive to individuals. Few institutions recognize regional engagement as one of the grounds for academic promotion; this is characteristically based around research excellence as reflected in peer-reviewed

publications with an occasional nod toward innovative teaching or academic management.

Second, resources to support the development of ideas (proof of concept) into products, services, or public policies are often not available let alone translational research facilities to build prototypes or test drugs. Third, intellectual property can also be a major source of conflict between the academic and his/her institution even where the national legislative environment is favorable.

Fourth, continuing professional development for small businesses and the community does not easily fit into conventional full-time teaching programs and can require evening and weekend teaching, eating into time for research and scholarship. Finally, problem-solving research and development for local SMEs (who may have difficulty in formulating their needs) can be very time consuming and diversionary from what are regarded as core activities.

How far are these barriers to institutional mobilization, in support of regional development, a function of traditional forms of institutional governance and how far are they a matter of the underfunding of the third task? The evidence from the OECD countries suggests that it is a combination of both factors.

Enhancing the development of more entrepreneurial universities is becoming an objective of new higher education policies in many countries. Some OECD member states, for example, the Netherlands, Austria, the United Kingdom, and Denmark, which have embraced new public management principles, have replaced collegial forms of governance and management (i.e., elected rectors, deans, and heads of departments) by a system of stronger and more overt managerial roles undertaken by appointed vice chancellors or rectors and heads of faculties. However, while governments recognize that more leeway needs to be granted to higher education managers, reducing the burden of regulation does not necessarily proceed at a fast pace.

In many OECD countries, universities still have limited autonomy (in contrast to the autonomy of the academic staff) in terms of their mission, academic profile, program offer, and management of human resources and infrastructure. In particular, the ability of the university to exercise control over its estate can be a key asset in supporting engagement with city and regional development but as this is a significant financial-resource responsibility, it is often retained by the central government.

Where governance of universities has not been changed, the national government has often looked to new institutions, notably polytechnics, to address the regional-development task. Such institutions characteristically are strongly managed. The internal mechanisms which mobilize the institutions to support the region are well tuned using a variety of performance measures. However, these institutions characteristically lack a strong research base capable of transforming a regional economy

as distinct from improving the existing industrial base. In these instances, delivering the higher education capacity that has both global reach and local engagement may require strong collaboration with research-intensive universities – a further challenge for the leadership.

Reference to the entrepreneurial approach is not to imply that this is the appropriate model to ensure that a university actively engages in regional development. An institution with greater freedom of action may well pursue the achievement of international status rather than local utility. The challenge for academic leaders wishing to build a locally engaged and globally competitive institution is to manage the tensions arising from the different rationalities embedded within higher education. The key task is to produce a synthesis through which the institution not only responds to regional needs but also becomes a motor for regional development by mobilizing a strongly independent academic heartland. Indeed, with the right institutional and civic leadership, partnership with the local community can become a crucible within which more dynamic and open universities can be forged, both responding to and shaping developments in the wider society.

Universities' Engagement with Society

D Watson, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Until the advent, in the late twentieth century, of company or for-profit universities, all university institutions grew in some way from the communities that originally sponsored them. These acts of foundation varied according to a range of local circumstances, in time and location. Many such founding commitments have been transformed – positively and perversely – over the ensuing years, but the familiar image of a university as somewhat separate from its community – as, for example, an ivory tower – is curiously unfaithful to the historical record.

This article explores the foundation and subsequent history of types of institution around the world from the perspective of their relationship with the community, civil society, and the state, before attempting a contemporary assessment of who can claim to own the university enterprise, and with what implications.

Foundations

Most university foundations had an immediate element of service to the community in their agreed mission and purpose. The idea of responsiveness to social priorities was much more central to the founding goals of their institutions than many subsequent generations of university leaders and members have come to believe. There is a pattern here, as set out in the following stages of establishment of universities. Stephen Lay's *The Interpretation of the Magna Charta Universitatum* provides an excellent overview of these developments culminating in the proposal that "an expectation of public service could be written into the Magna Charter and thus become a guideline for university administration" (Lay, 2004: 18–71, 109).

The early foundations were specialist communities such as the late medieval colleges for poor scholars in England (Oxford and Cambridge), and for urban professionals (such as Bologna and Paris in continental Europe). Three centuries later, a similar trajectory was followed by the American colonial seminaries (many of which subsequently became expensive private schools in the United States, including the heart of the Ivy League). Lay points out that what distinguished all of these foundations from their ancient predecessors was the presumption of independence from the state, or what has subsequently become termed autonomy.

After a further fallow period, the next significant wave of foundations took place in the mid- and late-nineteenth century. These grew similarly out of perceived social and

economic needs, but in the radically different context of industrializing societies. Examples are the great Victorian and Edwardian Civic universities in the UK and the Morrill Act-inspired Land Grant universities of the American West and mid-West, leavened by specific, primarily research-based institutions on the German Humboldtian model, such as Johns Hopkins.

It is often helpful to go back to the founding acts or charters to see what was intended. The illustration below is of extracts from the royal charter of what is now the University of Sheffield. Note the emphasis on practical knowledge, as well as the sense of place (**Case study 1**).

In the next wave of development, the mid-twentieth century saw the establishment of local authority-based public systems of higher education, as in the English polytechnics, the Scottish central institutions, and American state systems (of which the archetypes are Wisconsin and the Californian Master Plan). These were equally specifically tied to expectations about relevant education and training, with a new element of ensuring both access by groups previously underrepresented, and progression. In many societies, the result was to create what came to be known as binary systems of higher education – a group of traditional university institutions contrasted with a more local, apparently more locally accountable, and apparently more responsive pattern of provision. Around the turn of the twenty-first century, this juxtaposition posed real dilemmas for policymakers dealing with the advent of mass higher education. Those with binary systems felt that they had run their course; those without them felt that the only way to re-inject mission diversity was to try to create a polytechnic-style counterpoint to unresponsive autonomous universities; others who had tried the change decided they needed to change back.

These were followed by late-twentieth-century experiments in curriculum, pedagogy, and a further drive toward accessibility (such as, notably, the pioneering of open access, or admission of adults without formal qualification by the UK's Open University and New York's City College system, and their imitators around the world). At the same time, nations began to establish the mega-universities, as analyzed by John Daniel, making use of open and distance learning (ODL) technologies to speed up participation, and to cut costs. The Indira Gandhi National Open University, founded in 1985 had 1.4 million enrolments in 1996, and the Islamic Azad University had 1.2 million. The notion of community interest is thereby dramatically expanded.

Case study 1

Extracts from the Charter granted by Edward VII in 1905, to convert the University College of Sheffield (founded 1836) into the University of Sheffield

To provide for:

- Instruction and teaching in every Faculty.
- Such instruction in all branches of education as may enable students to become proficient in and qualify for degrees diplomas associateships and certificates in arts pure science applied science commerce medicine surgery law and all other branches of knowledge.
- Such instruction whether theoretical technical artistic or otherwise as may be of service to persons engaged in or about to engage in education commerce engineering metallurgy mining or in other industries or artistic pursuits of the city of Sheffield and the adjacent counties and districts.
- Facilities for the prosecution of original research in arts pure science applied science medicine surgery law and especially the applications of science. (University College Charter, 1905: Paragraph 14).

However, even the experiments in ODL built upon traditional foundations. In 2007, the University of London's external degree scheme (which celebrated 150 years of such business in 2008) supports 43 000 students in 183 countries.

Finally, the latter part of the twentieth and beginning of the twenty-first centuries have seen significant action on the frontier activity between compulsory education, optional tertiary provision, and the initial rungs of higher education. Examples are the UK phenomenon of higher education in further education and the vitally important American Community College network: the former, especially in the provision of intermediate qualifications such as the higher national certificates and diplomas and foundation degrees, and the latter through 2-year (when taken full-time) associate degrees. The latest descriptor of activity in this borderland is that of dual sector provision.

These latter two waves of developments illustrate that as communities have changed – most recently in response to global communications – not only have existing universities had to respond, but also the acts and intentions of foundation of new institutions have also adapted.

Communities, Civil Society, and the State

The big question that then arises is about how universities as institutions fit into the structure and function of public life. Various theoretical models are available, and one of the most influential conceptualizations in modern political philosophy can be used. Writing in Prussia in the early nineteenth century (a decade after Humboldt's founding of the University of Berlin), Hegel saw a rising standard of

collective identity, behavior, and self-realization through three circles: the family and community (or what he called ethical life), civil society, and the state. The intermediate point – of civil society – he described as follows in *The Philosophy of Right* (1821):

In the course of the actual attainment of selfish ends – an attainment conditioned in this way by universality – there is formed a system of complete interdependence, wherein the livelihood, happiness, and legal status of one man is interwoven with the livelihood, happiness, and rights of all. On this system, individual happiness etc. depend, and only in this connected system are they actualized and secured. . . . (para. 183) (Knox, 1952: 123).

For Hegel, the Prussian State was an ethical end-point, a proposition which it would be hard to defend today:

The state is the actuality of the ethical idea. It is ethical mind *qua* the substantial will manifest and revealed to itself, knowing and thinking itself, accomplishing what it knows and in so far as it knows it. The state exists immediately in custom, mediately in individual self-consciousness, knowledge and activity, while self-consciousness in virtue of its sentiment towards the state finds in the state, as its essence and the end and product of its activity, its substantive freedom (para. 257) (*Ibid.*: 155).

The contention here is more modest: the university occupies a critical role within civil society. According to Michael Edwards of the Ford Foundation, “as a concept ‘Civil Society’ speaks to the best of us, and calls upon the best of us to respond in kind” – and so should the university (Edwards, 2004: 3). There is a corollary: when it becomes over-identified with the political interests of the state, it has probably lost its way. The sticking point is well-articulated by Michael Daxner, former president of Oldenburg University and post-war European Union (EU) education commissioner in Kosovo. “East of Vienna,” he has said, “the role of universities is in society-making, not state-making.” Universities are needed, he says “because of our dangerous knowledge.” At a conference of the European University Association and the American Council of Education in 2004, he went on to explain how this priority can easily become masked:

No wonder that most of the harmonizing structures in higher education refer to pure scholarship, administration, government, and institutional autonomy, whereas the basic notions of the university as the ‘lead institution’ in civil society – republican legitimacy, democracy, and citizenship – are rarely included in modern concepts of academic freedom, or treated only nominally in the mission statement of universities (EUA/ACE 2004: 64).

The notion of dangerous knowledge – that is of being critical as well as supportive of activities across civil

society leads to moral injunctions for both states and their universities. How do these work in practice? In a work on *Managing Civic and Community Engagement*, it has been suggested that universities relate to their communities in three main ways (Watson, 2007: 132–141).

First-Order Engagement

First-order engagement arises from the university simply being there. One of the primary roles for universities is to produce graduates who go to work (perhaps in areas completely unconnected with those they have studied); who play their parts in civil society (where the evidence suggests they are likely to contribute more than if they had not been to university); who have families (and read to their children); who pay their taxes (and return a proportion of their higher-than-average incomes as graduates through progressive taxation); and who support their universities through gifts and legacies. An analysis of national cohorts in the UK summarized in the work by Schuller *et al.* (2004) on *The Benefits of Learning* has securely established that graduates are not only wealthier, but also happier, healthier, and more democratically tolerant than their non-graduate peers.

Also, in this first domain, universities guard treasures (real and virtual) in their museums, galleries, and archives. They provide a safe place for the exploration of difficult issues or challenging ideas. They also supply material for a branch of popular culture (the campus novel, film, and television series).

Together these features add resonance to the university as a social institution in its own right: at its best, a model of continuity and a focus of aspiration for a better and more fulfilled life; at its worst, a source of envy and resentment.

First-order considerations also imply that universities should strive to behave well, to be ethical beacons. Universities can choose to behave well or badly in a number of different directions, in relation:

- to applicants (and their families);
- to students (and their sponsors);
- to staff (of all kinds);
- to the local community (or neighbors);
- to the institutions of civil society (as above);
- to investors and supporters (the stakeholders discussed below);
- to government (in their role as a commentator and contributor to policy, as well as a deliverer of a public service);
- to global citizenship (e.g., by progressive engagement with political, economic, social, and environmental issues); and
- to groups of other higher education institutions (locally, regionally, nationally, and internationally).

Some of the sticking points include the following. Universities can offer misleading promotion and advice, to staff, students, and potential students, about their real performance and intentions. As powerful institutions they can undermine and intimidate their members, their partners, and their clients. They can perpetuate self-serving myths. They can hide behind specious arguments (narrow constructions of academic freedom, *force majeure* and the like). They can displace responsibilities, and blame others. They can fail the stewardship test (e.g., by not assessing and responding to risk, by cutting corners, or by failing to safeguard their assets). They can be bad neighbors. Above all, they can fail to tell the truth to themselves at least as easily as failing to tell the truth to others.

Second-Order Engagement

Second-order engagement is generally structured and mediated by contracts. In this domain, the university produces graduates in required disciplines and professional areas (whether directly or indirectly required to do so). It responds to perceived needs for particular skills, or for professional updating, or to more general consumer demand for courses in particular subjects. It supplies services, research and development, and consultancy at either a subsidized or a for-profit rate. The university may run subsidiary businesses – some as spin-outs or joint ventures, others in the service sector of entertainment, catering, conference-organizing, or the hotel business.

Also, in this domain, the university is often an important local and regional economic player. It supplies employment – from unskilled occupations to the highly skilled. It provides an expanded consumer base, as students and staff are attracted to the institution and its locality. The university offers a steady, well-indemnified customer for goods and services. It is a source of development, such as of buildings, amenities, office space, and green spaces, although this has its downsides, like controversy over planning, car-parking, congestion, or studentification (the perceived takeover by temporary student residents of streets and neighborhoods, as well as the potential displacement of local residents from low-paid jobs).

The first domain affects the second in some complex and significant ways. The university, as a kind of moral force, is expected to behave better than other large organizations (which are similarly concerned about the bottom line).

Third-Order Engagement

Third-order engagement relates to commitments between the university and its members.

Universities are voluntary communities: around the world, they are rarely part of the compulsory educational

infrastructure of the state. Thus, they should not be regarded as agents of the state in creating citizens or subjects. This is not to say, following the precepts of first-order relationships, that universities do not play a role in ensuring social cohesion, in promoting community solidarity, and in problem-solving for policymakers and practitioners of all kinds.

University members have a similar set of obligations as individuals; this is the dimension of academic citizenship. To be a full member of a university requires more than completing basic, obvious tasks. For traditional academics, this has meant collective obligations: to assessment, to committee membership, and to strategic scoping. There is a growing body of literature about such professional academic practice.

Since the late twentieth century, such practice has been recognized as no longer belonging exclusively to the ranks of the faculty. The teaching, research, and service environments are increasingly recognized as being supported and developed by university members with a variety of expertise (e.g., finance, personnel, estates, libraries, and information and communications technology), each with their own spheres of professional competence, responsibility, and recognition.

At the heart of academic citizenship is the concept of membership. As consumers, students have entitlements and expectations. Both students and staff have responsibilities, along with all of their rights, within the community. Such responsibilities include the following:

- a special type of academic honesty, structured most clearly around scientific procedure;
- reciprocity and honesty in expression, for example, avoiding plagiarism by accurately and responsibly referring to other people's work within one's own;
- academic manners, such as listening to and taking account of other people's views;
- self-motivation and the capacity for independent learning, along with learning how to learn;
- submission to discipline (most clearly in the case of assessment – for both assessors and the assessed);
- respect for the environment in which members of the college or university work; and
- adherence to a set of collectively arrived at commitments and policies (on equalities, grievances, harassment, etc.).

Who Owns the Modern University?

According to the conventions of corporate governance, organizations are governed in the interests of either shareholders (the institutions, groups, or individuals who own the shares – and expect dividends) or stakeholders (the individuals and groups, including the staff – whose interests might

be affected by aspects of the organization's performance). To the frustration of several commentators, most universities are neither shareholder nor stakeholder institutions. On one end of a spectrum, institutions with the university title may be wholly for-profit institutions, especially in jurisdictions where the title is relatively unprotected by law. At the other end, they may be unmediated emanations of the apparatus of the state. However, in the vast center-ground, they are unashamedly *sui generis*, with, as Lay says, institutional autonomy lying at the heart of the conception of the modern university.

In these circumstances, who owns the university (or pieces of it) or thinks that they do? There are several potential candidates.

The state, directly and indirectly, is invariably a major funder. It will also claim to represent the people's share by investing the proceeds of taxation. However, attempts to co-opt universities into politically influenced national priorities is, as Daxner warns, dangerous. Nor is it likely to work. Early results from a 15-country project on the role of universities in the transformation of societies would urge caution on the more aggressive advocates of higher education and the national interest. Brennan *et al.* (2004) find, in general, a relatively weak role for higher education in stimulating economic change, complex and contradictory influence on political change, and a social role that is at least as much about reproduction as about transformation.

Other big investors may be other public services, the professions, business, and employers, including through sponsorship and purchase of student places. The professions are a particularly interesting case. They were in at the beginning of the modern European university (law at Bologna; theology at Paris), and they played their part in the nineteenth- and twentieth-century expansion of the system (science and technology in the civics – especially engineering throughout the Commonwealth, and beyond – and more recently the addition of health professions to the traditional formation of doctors of medicine).

Then there is the public more generally, especially as refracted through the media. There are contrasts between cultural roles of universities and colleges in different national contexts: in the United States, they are more loved and respected than may be deserved; in Australia and the UK, they stimulate more opprobrium than is objectively fair. This picture may, however, be changing, as US higher education is hitting – almost for the first time – a combination of cuts in public subsidy, consumer resentment, and consumer debt.

So far, the various communities which interact with and within the university have been outlined.

But probably most important in the historical sense are the members of the university. Here a degree of detachment and self-knowledge is required. As Gordon Graham concludes his study of *The Institution of Academic Values*,

“when it comes to debates and disagreements about their own affairs, universities are as prone to self-protecting flights of unreason as any other institution” (Graham, 2005: 280).

To describe all these as stakeholders is by no means straightforward. Stakeholder, is one of those words which has almost exactly the opposite meaning now, since when it was originally coined. The stakeholder used to be the person who held the coats – and the prize-money – while the fight was on; the notion was one of scrupulous disinterest. Stakeholders need to understand that if they are to live up to the modern designation (as having invested something themselves), they have to put something at risk. A rigorous stakeholder analysis from the perspective of the university would throw up some surprising results. Questions that arise include the following: whose are the stakes on the table (really) in the sense of sharing risk? And who can most effectively (i.e., legitimately as well as logically) claim to hold the third party stake (the celebrated people’s money) on behalf of the community as a whole? The politicians would like to claim the latter is theirs – through democratic validation – although they too can fail the stewardship test.

The Challenge of Engagement

What are the implications of this analysis for universities in the early twenty-first century? One response, as set out in Iacobucci and Touhy’s *Taking Public Universities Seriously* has been to try to establish systematic compacts between universities and all of their stakeholders, including the government (Iacobucci and Tuohy, 2005: 11–19). The UK’s National Committee of Inquiry into Higher Education (the Dearing Committee of 1996–97) tested this approach – some would say to destruction (Watson, 2007: 18–28).

Another response has been to rediscover the role of universities and colleges as fully engaged members of their communities. An emphatic lead has been taken here by the Association of Commonwealth Universities (ACU). According to the Association of Commonwealth Universities (ACU), “engagement is [now] a core value for the university.” In the Association’s widely circulated consultative paper (published as *The Idea of Engagement: Universities in Society*), this proposition was revealed as follows:

Engagement implies strenuous, thoughtful, argumentative interaction with the non-university world in at least four spheres: setting universities’ aims, purposes and priorities; relating teaching and learning to the wider world; the back-and-forth dialogue between researchers and practitioners; and taking on wider responsibilities as neighbours and citizens (Bjarnson and Coldstream, 2003: 312–313).

Case study 2

The Talloires Declaration (2005)

- Expand civic engagement and social responsibility programs in an ethical manner, through teaching, research and public service.
- Embed public responsibility through personal example and the policies and practices of our higher education institutions.
- Create institutional frameworks for the encouragement, reward and recognition of good practice in social service by students, faculty, staff and their community partners.
- Ensure that standards of excellence, critical debate, scholarly research and peer judgement are applied as rigorously to community engagement as they are to other forms of university endeavor.
- Foster partnerships between universities and communities to enhance economic opportunity, empower individuals and groups, increase mutual understanding and strengthen the relevance, reach and responsiveness of university education and research.
- Raise awareness within government, industry, charitable, not-for-profit and international organizations about higher education’s contributions to social advancement and well-being. Specifically, establish partnerships with government to strengthen policies that support higher education’s civic and socially responsible efforts. Collaborate with other sectors in order to magnify impacts and sustain social and economic gains for our communities.
- Establish partnerships with primary and secondary schools, and other institutions of further and higher education, so that education for active citizenship becomes an integral part of learning, at all levels of society and all stages of life.
- Document and disseminate examples of university work that benefits communities and the lives of their members.
- Support and encourage international, national and regional academic associations in their efforts to strengthen university civic engagement efforts and create scholarly recognition of service and action in teaching and research.
- Establish a steering committee and international networks of higher education institutions to inform and support all their efforts to carry out this Declaration.

In similar vein, in September 2005 Tufts University brought together leading figures from universities across the world at their conference center in Talloires, southwest France. The meeting resulted in a draft declaration on the civic roles and responsibilities of higher education which has attracted signatories from around the world, and which is now being used to design systematic interventions, for example, on literacy (**Case study 2**).

These are serious challenges for the leaders and managers of higher education institutions. They can absorb some lessons from history. Without a sense of obligation to the spirit of its foundation, university communities will find it hard to develop and adhere to a core set of values underlying strategic choices.

There are some lessons from the needs of civil society, especially through partnerships of various kinds. This is the necessary moving picture against which the institutions

need to test their plans. It is also the context for what Donald Kennedy has eloquently described as academic duty.

And there are some lessons about restoring the traditional role of universities in the special circumstances of a globalized knowledge economy. The post-Enlightenment project of a liberal higher education requires constant reinvention to meet new needs. In the process of its early twenty-first century reinvention, engagement is indeed a core value.

Introduction

There are more entrants to higher education today than at any time in the past. Higher education (HE) has, in fact, evolved from an elitist pursuit into a mass system. By 2020, 40% of the global workforce will be knowledge workers, with a need for tertiary qualifications. The World Bank, which in the 1980s and the 1990s privileged basic education, is now of the view that for countries to achieve sustainable economic development, the age-participation rates (APRs) in HE must be in the region of 40–50%. With access to HE being less than 10% of the relevant age group in South Asia and sub-Saharan Africa, this key concern is being addressed by most developing countries. Malaysia plans to raise its APRs to 40% by 2010. The Government of Trinidad and Tobago plans to see an APR of 60% by 2015, while the Jamaican government expects to raise the APR in tertiary education to 30% by the same time. India has since announced the establishment of one central university for each of its 28 states and its intention to raise the APRs to 15% by 2012 (Daniel *et al.*, 2006: 17–23). Can existing institutions cater to the rising demand? Dhaka University, Bangladesh could only enrol 10 000 of the 80 000 applicants in 2000, while in Kenya only 9000 of the 40 000 qualified students could be accommodated in the public university system (Kapur and Crowley, 2008: 16).

As building brick-and-mortar institutions is not a viable option for most countries, especially developing ones, the search for alternative approaches will continue. Even though distance education has been in existence for over 150 years, it is only in the last 40 years that its growth has been phenomenal and it has emerged as a viable supplement and serious alternative to the formal system. In Africa, there was only one open university in 1988; today there are four. India has nearly six million students in its 14 open universities and 126 dual-mode institutions.

The emergence of new information and communication technologies (ICTs) offered the right tools to reach out to people irrespective of their location and specific circumstance. Time and space ceased to be barriers to education. This unprecedented demand for growth has led to the evolution of new institutional structures, flexible and innovative teaching and learning styles that have transformed the traditional approaches to education. The role played by open and distance learning (ODL) is a key element in this metamorphosis.

Distance Education and Open Learning

Distance education is the delivery of learning or training to learners who are separated, mostly by time and space, from those who are teaching and training. As learners and

teachers are separated by time and space, some kind of technology or media must be used for communication between them.

The term open learning describes policies and practices that permit entry to learning with as few barriers as possible. For example, when the Open University in the UK was created in 1969, it based its claim to be open by abolishing all academic prerequisites for entry. Potential learners did not have to show any evidence of having been to school or passed any examinations. Once they start, they have to work hard to pass courses and continue – but there are no barriers to starting.

But the Open University was not open on some other dimensions. Students could not enrol unless they were aged over 21, so there was an age barrier. They had to study at a prescribed pace, between fixed dates for starting and finishing, so there was a barrier of time. On the other hand, when seen from the perspective of Athabasca University in Canada, that did not have an age barrier and allowed students to start a course at the beginning of any month and take as long as required, the UK Open University did not appear to be particularly open.

Open learning, then, is a relative term but it does express the ambition of an institution to remove those barriers to learning that are particularly restrictive in its own environment.

While distance education refers to the methodology by which the learners are reached, open learning refers to the philosophy underlining open entry and access to learning opportunities. Though the two are conceptually distinct, distance education and open learning are often complementary. Opening up learning without introducing some elements of distance education is not always possible and introducing distance education inevitably opens up learning in new ways for many people.

Hilary Perraton has pointed out that the term distance education captures the economic imperative of gaining benefits of scale, low-cost, and consistent quality, whereas open learning evokes the political imperative of widening access.

For this reason, it is customary to bring these two terms together in the expression open and distance learning or ODL. New terms, however, have evolved to designate forms of ODL that include more than just print and paper. For instance, e-learning, online learning, and virtual learning refer to learning with a variety of media, not just computers. Other terms in currency include m-learning; multimedia education, technology-mediated learning, and technology-enhanced learning. Another recent name that reflects the growing trend of mixing ODL with conventional face-to-face teaching is flexible learning.

The Evolution of ODL

Initially, distance education catered to children in remote locations with no access to school and to adult learners

who had missed the opportunity for higher education for one reason or another. Today, distance education is seen as a cost-efficient and effective tool for providing education and training at all levels and for a variety of disciplines and professions. Developments in ICTs have made it possible to make effective pedagogic interventions for providing unlimited flexible learning options to several constituencies of learners. In the process, distance education is emerging as an effective tool not just for education but for development generally.

When Britain introduced a universal postal system, the penny post, in the middle of the nineteenth century, Isaac Pitman offered postal tuition for a course in shorthand almost immediately and correspondence education was born. It began as a private commercial venture and correspondence education has always retained a strong commercial component, even though governments and public universities also began offering traditional education programs through correspondence in the late nineteenth century. The UK University Correspondence College (1887) was set up to support external students to prepare for the University of London's external degree. Early correspondence-course providers included Illinois Wesleyan University (1874), Queen's University in Kingston, Ontario, Canada (1889), the university extension department of the University of Chicago (1891), and the University of Queensland in Australia (1911). In the 1920s, a range of universities and other tertiary-level institutions offered programs solely at a distance, including a number of Soviet all-union correspondence polytechnics (Rumble and Koul, 2007: 11).

As the name implies, correspondence education usually involved mail going in two directions: the school mailed instructional texts to the students; each student mailed back assignments which would be corrected and commented on by a tutor and returned to the student. Holmberg (1977), called this process a guided didactic conversation, a pillar of good distance-education practice.

For over a century, until the second-half of the twentieth century, correspondence education brought great benefits to large numbers of people. This contribution was never properly recognized, partly because it involved individuals learning privately and partly because the correspondence schools were mostly private enterprises. This combination, private individuals dealing with private companies, was also the explanation for the abuses that gave correspondence education a bad name and caused a backlash against it in the 1960s.

The Rise of the Open University

The University of South Africa (UNISA) started its distance-education operations in 1946 and was interracial even

during the apartheid years. It is highly rated in South Africa and is one of the world's mega-universities.

But it was the establishment of the UK Open University (UKOU) in 1969 that led ODL to expand phenomenally in the 1970s and 1980s. Two trends came together in the 1960s to initiate a revolution that brought together open learning and distance education in an explicit manner and dramatically increased the impact and effectiveness of ODL. First, the 1960s was a time when most governments gave high priority to expanding education at all levels. Second, it was a time of effervescence and enthusiasm for communications technology. Television was seen as far too important to be limited to entertainment alone and the UKOU used it creatively to lead a revolution in bringing education to the masses.

Throughout history, education has been constrained by the iron triangle of quality, access, and cost. If access is increased, there is the danger of lowering quality. If this is to be avoided, then the costs would have to be raised. ODL is revolutionary because it does allow, through division of labor, specialization, and economies of scale, to reconfigure the access–quality–cost triangle. Access can be increased, quality can be improved, and costs can be cut, all at the same time.

But this is by no means an automatic process. While research shows that there is no significant difference between distance education and traditional classroom instruction in relation to student outcomes, there are still the issues of quality and the recognition of qualifications that need to be addressed constantly.

Harnessing the mass media to higher education enabled the UKOU to excel in all three dimensions and reshape the triangle. It immediately became the largest university in Britain. Independent rankings of the quality of the teaching programs in UK universities put the Open University in fifth place out of 100 institutions. Cost studies conducted by the UK government show that whichever way the calculations were done, the total cost of the Open University degree was substantially less than that in conventional institutions.

ODL is revolutionary because it does allow, through division of labor, specialization, and economies of scale, to reconfigure the access–quality–cost triangle. Access can be increased, quality can be improved, and costs can be cut, all at the same time. That was the message of the Open University; something that had never happened before in the history of education.

Mega-Universities

It was not surprising that numerous open universities came to be established thereafter in many countries across the world. Most of them soon became popular enough to register enrolments of over 100 000 students each. Notable among them are those in India, Indonesia, Iran, Korea,

Pakistan, Spain, Thailand, and the US. These new open universities, along with some older institutions in China, France, and South Africa came to be known as mega-universities. In 1999, there were 11 such universities in the world with a collective enrolment of about three million students (Daniel, 1996). Today, the number of mega-universities has doubled, among them figure the following:

- Allama Iqbal Open University, Pakistan;
- Andalu University, Turkey;
- Athabasca University, Canada;
- Bangladesh Open University, Bangladesh;
- *Centre National d'enseignement à distance*, France;
- China Central Radio and TV University, P.R. China;
- City College of San Francisco, USA;
- Dr. B. R. Ambedkar Open University, India;
- Indira Gandhi National Open University, India;
- Korea National Open University, South Korea;
- Madhya Pradesh Bhoj Open University, India;
- Netaji Subhash Open University, India;
- Open University, UK;
- Payame Noor University, Iran;
- Shanghai TV University, P.R. China
- Sukhothai Thammathirat Open University, Thailand;
- *Universidad Nacional de Educacion a Distancia*, Spain;
- *Universitas Terbuka*, Indonesia;
- University of Maryland University College, USA;
- University of Phoenix, USA;
- University of South Africa, South Africa;
- Yashwantrao Chavan Maharashtra Open University, India.

Dual-Mode Institutions

In all countries, conventional educational institutions, most notably at university level, are adding ODL activities to their face-to-face teaching and becoming dual-mode institutions. Australia has many such institutions: Deakin University, Monash University, and University of Southern Queensland. The University of Delhi has a large campus of open learning with student enrolments in the range of 150 000. The University of South Pacific and the University of West Indies are multimodal institutions and cater to both face-to-face and distance students on a regional basis.

However, it is not only campus institutions which are introducing distance education. Dedicated distance-education institutions such as the Open University of Hong Kong are offering face-to-face classes. In Canada, the single-mode ODL institutions in Québec and British Columbia, the *Télé-université* and the Open University of British Columbia, have been merged with conventional institutions.

E-Learning is gradually seeping into education at all levels and contributing to the trend of flexible education.

By 2006, in a typical American college or university, one fifth of all continuing and professional-development courses were being conducted online (Kapur and Crowley, 2008: 32–33). With 81% of face-to-face institutions in North America offering blended learning options, it is clear that there is an increasing convergence of distance and face-to-face education.

Key Features of ODL

Compared to campus-based institutions, open universities are large enterprises that require careful planning, efficient organization, and effective management to carry out a variety of operations that include the design and development of learning materials, their production, distribution and delivery, and the mobilization of physical and intellectual resources across wide geographical areas. Due to this basic feature, distance-education systems are sometimes referred to as an industrial form of education. They can involve thousands of faculty members, students, academic counselors and tutors, and staff at headquarters and in distant and far-flung learning centers. Necessary organizational and administrative components include clear statements of vision, purpose, and objectives; an integrated strategy for program development that includes curricula, teaching and learning, policies for students, tutors, and other staff; materials production and distribution; learner support systems and student assessment. Some of the critical success factors are:

1. *Self-instructional learning materials.* The key to the academic strength of an open and distance-education system is the learning materials around which its programs and courses are designed and delivered. As the learning process takes place at a distance from the teacher or the institution, interactive pedagogic processes are built into them and the materials are therefore, called self-instructional. Preparation of self-instructional materials is a complex professional skill that requires specialized training. Teams of specialists that comprise subject experts, media professionals, graphic designers, editors, and reviewers generally develop these materials. Extensive participation of both in-house and external experts ensures the quality and authenticity of the learning materials on which most open universities and dual-mode institutions build their academic reputation.
2. *Effective student support services.* Excellence of materials alone does not assure the quality of the outcomes. Just as important as the preparation of the materials is the effectiveness of the delivery systems that connect the students with their institutions. Most open universities and distance-education institutions need to develop extensive and intensive support services, both to help

students with the process of learning and with the new experience of being a distance learner. The challenge is that student support is inherently more labor intensive than simply using technology to allow students to learn independently. Student support through people does not have the same potential for economies of scale. Therefore, the fundamental dilemma in designing a distance-learning system is to ensure a good balance between using technology so that students can learn independently and using tutors so that they can be well supported.

3. *Logistics and administrative support.* The success of ODL systems depends mainly on the learning environments in which they operate. Creation of an effective learning environment is based on several factors – technology choices, learner preparedness, the design and development of the learner support systems, and the commitment of the leadership. Technology choices must be made only after scanning the environment to determine a variety of factors that include: the form of telecommunication that is within the reach of potential learners; the policies of governments that support and strengthen the applications of emerging technologies in educational development; the technology infrastructure that the ODL provider is able to create and maintain; as well as the type of programs that the institution can provide within the context of its mission and resources. An understanding of the learner's needs and characteristics can help integrate the chosen technology with the design of the program and is quite central to the success of any ODL operation. Any weaknesses in any of these links in the chain can have major consequences for the system as a whole leaving it with frustrated students, demotivated staff, and the loss of credibility.
4. *Networking.* A critical success factor in most ODL systems today is the ability of the provider institution to mobilize both physical and intellectual resources from a variety of sources for the design, development, and delivery of its programs. Networking with suitable institutions that are well-known in their areas of competence not only reduces institutional costs, but also ensures the quality of the teaching–learning transaction. The networking arrangements often extend to the acquisition and adoption or adaptation of learning materials, collaboration with major media houses to produce and deliver technology-supported and technology-enhanced learning packages, and at the purely local level, the support of the existing educational institutions to function as learning centers. As the theory–practice integration assumes critical importance, collaboration with the world of work is fundamental to the success of all education. For a variety of reasons, ODL institutions are well suited to implement industry–academy partnerships to foster this collaboration.

New Trends

The following trends will impact the development of ODL in the twenty-first century:

1. *ODL in the time of e-learning.* The most important trend today is e-learning. A feature of the history of education, going right back to the invention of the blackboard in 1850, is that each new technology is hailed as the harbinger of an educational revolution. Such claims were made for radio, film, television, programmed learning, and computers, and have been made abundantly for online communication.

Education, like many other areas of human life, was swept up in the dot.com frenzy of the late 1990s when some prophets argued that the Internet would be the only vehicle for education in the future. Studies show that e-learning has so far failed to deliver on these extravagant claims.

E-learning shares some of the features of correspondence education and, like correspondence education, attracts many private sector players. At its best, it enables a much more sustained guided didactic conversation than was possible with the postal service. At its worst, it allows digital diploma mills to take students' money before closing down their website and putting their profits in the bank.

The Internet is not, and probably never will be, a mass medium – even if the day comes when everyone is connected to it. Telephone is not radio, even in well-connected communities. Internet learning alone cannot have the mass impact on access that was achieved with the mass media of broadcast and print. This partly explains why the pure Internet learning operations that were launched during the peak of the dot.com frenzy have either disappeared or broadened out to take a multimedia approach.

In the last 10 years, the most exponential growth in ICTs has been in the area of mobile telephony. By 2010, there will be 2.5 billion mobile users in the developing world (Atkins *et al.*, 2007). A recent study at the University of Pretoria (UP) indicates that of about 14 000 teachers, mostly located in rural South Africa, who are enrolled in its distance-learning programs, only 1% have access to e-mail; but 99% own cell phones. The UP first began by using cell phones to provide administrative support and then academic messages. Through this personalized intervention from the university, students became more motivated than before and were satisfied with both the administrative and academic support provided (Hendrikz *et al.*, 2006). The implications of this development for the way we teach and learn are enormous.

2. *Open education resources (OERs).* The last 5 years have seen tectonic shifts in how technology is being used in education. Thanks to the prestige of the Massachusetts

Institute of Technology (MIT), the open courseware movement, based on the principle of sharing the knowledge contained in faculty lecture notes, marked the first generation in a movement to make knowledge our common wealth. The online course materials of the UKOU were the second generation as existing self-instructional materials were made freely available in online format. The third generation is collaborative course development as exemplified by the wikiEducator, a course-authoring tool being used to develop materials for the Virtual University for Small States of the Commonwealth (VUSSC) and many other projects. In this phase, the focus is shifting from this courseware is mine to this courseware is for (open) mining (Atkins *et al.*, 2007). The open education resources (OER) movement is largely based on four principles: (1) encouraging mass ownership rather than elitism; (2) acknowledging faith in everyone's inherent capability to self-organize; (3) enlisting amateurs as producers of content; and (4) promoting collaboration for the common good.

Content development is resource intensive and the OER movement provides a unique opportunity to developing countries to access global knowledge flows. Bernard and his colleagues carried out a meta-analysis of hundreds of studies in which distance-education students were treated in different ways. They distinguished three types of interactions: student–content; student–student; and student–teacher. They then analyzed all the studies to find which type of interaction made the greatest difference when it was increased. The results were very clear. Increasing student–content interaction had much the greatest effect; with student–student interaction coming next and student–teacher interaction last. Within this context, the importance of content cannot be underestimated. In the coming years, there will be a greater need to collaborate on free content development and sharing resources (2008). The open university of the twenty-first century will adopt and adapt existing content rather than create it.

3. *Cross-border higher education (CBHE).* In 1975, there were 600 000 international students globally. This figure quadrupled to 2.7 million in 2004. Existing unmet demand opens the door for cross-border tertiary education and there are at least 50 providers, registered and unregistered, in Jamaica alone. The number of cross-border providers in India increased from 27 in 2000 to 114 in 2004 (Daniel *et al.*, 2005). This is a growing business because of the general growth in interest in international education, because of demand from working adult students, who cannot travel abroad to study except for short periods, and because countries like Australia, as they approach saturation in imported students, are exporting the courses instead. The future of distance learning

across borders lies in partnership. Partnership is a sound principle because it helps develop an indigenous capacity for distance learning in the country concerned and because partnering with a local institution, that is credible or committed to becoming credible, can provide access to much larger numbers of students and can facilitate relationships with the national authorities.

National governments are grappling with the issue of diploma mills, online providers, and the recognition of foreign qualifications. Quality will be a key requirement of cross-border distance education.

4. *The diversity of the new learner.* The characteristics of the twenty-first century student have changed. Half the world's population (6.5 billion) is under 20 years with two billion teenagers in the developing world. In countries such as Malaysia and Pakistan, approximately 65% of the population is under the age of 30, while over two-thirds of the tertiary-education students in Singapore are over the age of 25 (Kapur and Crowley, 2008: 7). Today, a HE student may be anywhere between 18 and 50 years of age. Then there is the traditional young learner between 18 and 24 years.

There are relatively more women in HE today. Ghana, Kenya, Uganda, and Tanzania offer incentives for women candidates by offering lower admission cut-off points even as female enrolments in Africa compare unfavorably with other developing regions. In Bangladesh, women account for 34% of all enrolments in public and 17% in private institutions. In Brunei Darussalam, women at the tertiary level outnumbered males by 32% in 2004 and the trend continues (Kapur and Crowley, 2008: 53).

The new learner is a digital native, a twenty-something, who takes to technology as a fish to water. This is in contrast to the digital migrant (Prensky, 2005), the adult who has adopted technology relatively late in life. The digital native is a multitasker who can perform several tasks at the same time. The new learner can be the adult who needs continuing professional development combined with full-time employment. S/he would have little time for synchronous instruction. Such an academic customer is on the rise in both developed and developing contexts. The new learner belongs to a very diverse constituency and has a range of needs that the traditional institution thus far has never known.

Distance education has always dealt with a diverse range of learners and as conventional institutions grapple with this challenge, open universities and distance-education institutions will assume a leadership role in pedagogic design and delivery.

Key Issues

From the experience of the last four decades, it is clear that ODL will be an important element of future education and

training systems across the world irrespective of the stages of the economic, political, and social developments within countries. While in the educationally advanced and resource-rich countries, ODL provides a more convenient learner-driven model of education, in the developing countries, challenged by inadequate resources, ODL is a cost-effective option and can reach out to larger numbers without major constraints of time and place. The following issues, however, need to be addressed:

1. *Role of ODL in national systems.* There is a lack of clarity about the role of ODL in national systems. In several cases, it is perceived to be an alternative to the formal system leading to comparisons with respect to policies, processes, resource allocations, and performance outcomes. ODL suffers in such comparisons as the formal system usually dominates most national systems with ODL relegated to a secondary status. Is it a supplementary system? Yes, because the formal system does not have a real alternative. New colleges and universities will continue to be established throughout the world, and students will continue to enrol in them. The key challenge is that they will never be able to meet the rising demand. ODL supplements the efforts of the formal system.
2. *Graduation rates.* There are several instances of ODL systems that have taken off with great promise and potential. Some of them have indeed emerged as leading mega-universities measured by the size of the enrolments. However, there have also been instances of a disconnect between promise and performance. Wider access is not synonymous with success. Success is reflected in the outcomes measured in terms of the ratio of graduates to enrolment, the time taken to complete a program, the ratios of retention and drop-out, and the response of the market to the graduates. Graduation rates from some of the high-enrolment open universities are disproportionately low.
3. *Recognition of qualifications.* Recognition of qualifications is just as important as the performance levels. ODL degrees and certificates need to enjoy the same status and recognition for the purposes of employment and further studies as conventional systems both within national jurisdictions as well as globally. Provisions need to be made in the national policies for according the necessary equivalence to ODL qualifications and to ensure that students who have graduated from this system are treated at par with students from conventional institutions. Fortunately, sustained efforts are being made by international agencies to build a consensus among countries on the recognition of ODL qualifications. While research shows that there is no significant difference between distance education and traditional classroom instruction in relation to student outcomes, there is still a perception barrier to be

overcome, in order for this mode of education/training to be utilized to its fullest potential universally.

4. *Research.* What is the nature of research that open universities conduct? There are open universities that are engaged in disciplinary research with considerable success. The UKOU is rated high among British universities for excellence in research. But there are many open universities that struggle with a variety of challenges. Some of the more commonly reported impediments are inadequate technology infrastructures, lack of human capacity, deficiencies in planning and management and inadequacies of teaching and learning resources. It would be worthwhile for the ODL institutions systematically to record their experiences in all aspects of the implementation of their programs and activities to create a strong database that could support in-depth studies to draw useful lessons from. Such an effort could also help develop a body of best practices, identify strategic issues, analyze learner response and experiences, design effective support systems for different learning environments, and appropriate student-assessment procedures and practices. Research into these aspects would give ODL institutions a leadership position in improving the quality of mainstream tertiary institutions.
5. *Technology and the developing world.* The development of ICTs has been uneven across the globe. The increasingly symbiotic relationship between ODL and technology is likely to disadvantage developing countries in the short term. While technologically advanced countries will benefit from advances in technology and develop more cost-effective pedagogies, developing countries will continue to use older technologies. There will be a need to focus on the ways to close this digital and pedagogic divide.

Conclusion

Crisis often generates creativity and innovation. Innovations are not necessarily spectacular initiatives. They can be minor modifications or adaptations of known practices and methods to get over challenges and obstacles in specific situations. It has now become possible to transform verbal information into visual communication. It is possible to study synchronously or asynchronously. The consequences of this transformation are more far-reaching in education than in most other areas of human endeavor. They impact the traditional notion of the classroom, the teaching profession, the pedagogy, the design of the curricula, and the learning experience. Engaged as they are with every aspect of these emerging trends, the ODL systems can, through systematic and

systemic research, provide valuable insights into the unfolding universe of a new, but not fully defined, world-education order.

Introduction

This article discusses the discipline of professional development for the learning and teaching roles of staff in the higher education sector. Internationally, the terms used to describe this activity include academic development, learning and teaching development, education development (ED), and faculty development. The terminology is contested and somewhat divides along US and UK/Commonwealth lines with faculty development the preferred US term. In this article, we use the term ED to refer to “developmental activities informed by the discipline of teaching and learning in higher education. This discipline is underpinned by research into university teaching and learning” (Fraser, 2005: 5). We have chosen to use this term rather than the older term of academic development because it reflects the reality for those working in the area from both central development units and within faculties. While ED staff have the remit to work with academics to improve the quality of teaching, we are as likely to be working with staff from the library, computing technology, student services, and the disability and equity office, as with academic staff. We also prefer the term because it encompasses the work that we do to develop academic policy, implement legislative requirements, and carry out pedagogic research, as well as the work done to develop the quality of curricula, assessment, evaluation, and teaching delivery.

In this article, we discuss ED from the perspective of our combined experiences of working in the discipline in Australia, North America, and the United Kingdom.

The Context

ED takes place in what has been described by Barnett (2000) as the age of supercomplexity. The pace of change in higher education is extraordinarily rapid and futures are uncertain. Internationally, drivers for change in the sector are: the shrinking of government funding sources while accountability measures increase; the increase in student diversity and numbers; demands by Generation Y (Gen Y) students for more flexibility in their access to education and the speed of that access; globalization adding increasing complexity and competition; government agendas driving curricula increasingly toward

vocationalization; information and communication technologies (ICTs) which are finally ubiquitous within universities with their potential to store and create information and foster new forms of communication; and changing conceptions of the nature of knowledge itself (Gibbons *et al.*, 1994). All these factors have disrupted traditional conceptions of the academic role, away from content transmission to learning processes. The consequence is a necessary expansion in the knowledge base of academic (and professional) staff: they must be ‘double professionals’ – discipline and education specialists. ED’s concerns are with this second profession, spanning psychology, sociology, systems theory, communications theory, cross-cultural studies, curriculum and education theories, and epistemology as well as legislative requirements, for example, in relation to international students.

The seeds of ED were sown internationally in the 1960s and 1970s, coinciding with both the beginning of mass participation in higher education in the developed world and the student activism of that time. In North America “students demanded the right to exercise some control over the quality of their undergraduate learning experience, by such means as evaluating their teachers’ performance in the classroom. At the same time, economic recession and the concomitant decline in [academic] mobility and opportunities for renewal contributed to new interest in [education development] and instructional improvement” (Sorcinelli *et al.*, 2006: 2–3). Barbara Falk (University of Melbourne), credited with founding ED in Australia, recalls that “it was a time [in the later 1960s] when students were turning against their university. They had moved from turning their indignation on public issues to criticising the institution Actually the student movement was instrumental in focusing people’s attention on teaching and learning” (Lee *et al.*, 2008: 28). Universities were called to task “about the curriculum and quality of teaching” (Lee *et al.*, 2008: 10, 11). In the 1970s, dedicated ED positions and units emerged in several universities in the UK, North America, Europe, and Australasia, although it was not until the 1990s that significant numbers of ED units were established. By the 1970s and 1980s, higher education teaching and learning (T&L) societies and associations were founded, such as the UK Staff and Education Development Association (SEDA), the Canadian Society for Teaching and Learning in Higher Education, the American Professional and Organizational Development Network in Higher Education,

and the Higher Education Research and Development Society of Australia (HERDSA). Annual higher education T&L conferences and journals dedicated to higher education T&L were established.

Yet ED remained piecemeal across the higher education sector. Ling *et al.* (2009) report that the organization of ED “occurred idiosyncratically within individual institutions, resulting in a diverse, context-specific and volatile set of models and practices” (Ling *et al.*, 2009: 17). The 40-year history of ED allows us to add another observation: as with any emergent field of knowledge, individual and often inspirational university staff such as Barbara Falk in Australia, Ruth Beard in the UK, Chris Knapper in Canada, and William Bergquist and Steven Phillips in the USA shaped the form that ED took in specific institutions, adding to the idiosyncratic nature of ED approaches and models.

By the late 1990s however, the UK Dearing Report (NCIHE, 1997), the Australian West Report (1998), and the crisis in funding for postsecondary education in the USA ushered in a resurgence in government interest in the quality of teaching and learning in higher education. This interest coincided with the seminal work of Boyer and colleagues on the scholarship of teaching and paralleled the burgeoning of research in organizational learning and organizational change processes, in itself a consequence of another emergent discipline, that of management (Rossiter, 2007). With this came accountability and quality-assurance demands, generally tied to funding initiatives. As students contributed more to the costs of their education, government concern shifted strongly to the consumer of education, the student. Universities needed to demonstrate systematic improvement in support for learning and teaching, and at least minimal development programs for staff. Performance review schemes, derived from the literature in management, and setting achievement goals in teaching as well as research and service, further prescribed academic roles.

The new millennium witnessed the introduction of national quality-assurance agencies (UK Quality Assurance Agency, the Australian Universities Quality Agency); national teaching quality indicators such as the Course Experience Questionnaire (CEQ) in Australia, and the US National Survey of Student Engagement; the development of national standards for higher education teaching, such as the UK National Professional Standards Framework for Teaching and Supporting Learning in Higher Education; the development of national higher education T&L institutes such as the UK Higher Education Academy, the Australian Learning and Teaching Council and the New Zealand Ako Aotearoa; stronger teaching reward and recognition schemes, for example, the Canadian Society for Teaching and Learning in Higher Education 3M Fellowships, and the Ako Aotearoa Teaching Excellence Awards; and the introduction of contestable national T&L

funding schemes, for example, the Australian Learning and Teaching Council grants and the UK Teaching Quality Enhancement Fund (TQEF).

With international interest in higher education T&L growing, ED became more systematic at institutional and sector levels. In the next section, we explore ED models and approaches.

ED Models and Approaches

By 2000, the majority of universities in the UK, Australia, and North America had constituted a central ED unit, although models and approaches varied, both between institutions and between countries.

Models

Hicks (1999) analyzed education development units across Australia in terms of their location within the university (centrally or faculty-based), and their activities in terms of disciplinary-based or generic. His paper describes four models of academic development in late twentieth century Australian universities:

1. the central model, characterized by a strong central unit and usually with minimal local discipline activity accompanied by little activity and responsibility at the local level;
2. the dispersed model with more activity at the local level;
3. the mixed model, of central and discipline-specific activities “with separate resourcing, potential duplication and a significant lack of coordination” (Hicks, 1999: 17); and
4. the integrated model with systematic and established collaborative processes.

The predominant model was the central unit providing generic programs and activities. In the UK, Gosling (2006) reported that universities tended to use a hub-and-spoke model in which a central ED unit worked closely with ED staff distributed through the faculties. The arrangements varied significantly between universities in terms of relationships, secondment, workload allocations, and role definition.

Approaches to ED

ED can be described in terms of both models and approaches. The latter refers to the work of ED staff: their activities, interventions, relationships, and networks. Sorcinelli *et al.* (2006) describe US ED approaches

(referred to as faculty development) from 1950 to the turn of the century in terms of four ages: scholar; teacher; developer; and learner. According to Sorcinelli *et al.*:

1. "In the Age of the Scholar (1950s and early 1960s) the term *faculty development* referred primarily to practices for improving scholarly competence" (Sorcinelli *et al.*, 2006: 27).
2. In the age of the teacher (mid-1960s through 1970s), ED focused on teaching development in which an "... earlier interest in behavioristic research on college-level teaching was superseded by an interest in research and practice related to the development of teaching skills and competencies, as well as the design of teaching development and evaluation programs" (Sorcinelli *et al.*, 2006: 3).
3. "In the Age of the Developer (1980s), faculty development broadened to address curricular issues, faculty needs at different career stages, and collective as well as individual faculty growth" (Sorcinelli *et al.*, 2006: 3).
4. In the age of the learner (1990s) "student learning rather than teaching took center stage ... Student diversity ... also called for a greater range and variety in teaching and learning methods, skills and sensitivities" (Sorcinelli *et al.*, 2006: 3, 4).

The UK and Australian literature, summarized by the Ling *et al.* (2009), suggests two main approaches to ED from the 1960s to 2000: teacher-focused and learner-focused.

Teacher-focused

ED staff worked primarily with voluntary academics, individual staff with a particular interest in teaching, via university-wide workshops or one-to-one-consultations. As in North America from the mid-1960s through the 1970s, the focus of ED work during this period was primarily on the improvement of individual teaching skills, "... teaching in different teaching contexts (e.g., lectures, tutorials, laboratories and so on), and for assessing students' work" (Ling *et al.*, 2009: 23).

Learner-focused

During the 1980s and 1990s the seminal phenomenographic research of Marton *et al.* (1984) and Bigg's (1999) work on enhancing student learning led to a focus on student learning research:

A deeper understanding of this interplay of teacher, context, student and curriculum has led to the development of more integrated conceptual models of teaching and learning that now play a major role in shaping the efforts of academic developers (Ling *et al.*, 2009: 23).

ED in the Twenty-First Century

While teacher and learner-focused approaches still form a significant part of ED work, different approaches to ED have emerged since the turn of the century. Sorcinelli *et al.* (2006: 4) in US argue that "with the new millennium faculty development has ... entered ... the Age of the Network". They argue that with the expansion of academic roles and the increase in sessional staff which in turn puts more administrative and management pressure on fewer full-time staff, more collaboration between all staff, academic and professional, is required.

Ling *et al.* (2009) report that since the turn of the century two other ED approaches have evolved: organization-focused and sector focused.

Organization-Focused

The turn of the century saw significant government regulation of higher education teaching quality. Universities were required to develop university teaching and learning strategic and implementation plans and performance indicators. Publications such as Ramsden's (1998) *Learning to Lead in Higher Education* focus "on the quality of organisational leadership, organisational structures that develop quality, scholarship that includes the ideas of reflection, informed critique, evaluation and development ... He squarely places the responsibility for academic development onto academic leaders" (Reid, quoted in Ling *et al.*, 2009: 23).

Sector-Focused

With specific reference to the UK and Australia, the Ling *et al.* (2009) that the first decade of the millennium saw "sector-wide initiatives stemming from government investigations into higher education and established and sustained by hitherto unprecedented amounts of government funding" specifically focusing on learning and teaching (Ling *et al.*, 2009: 23). These initiatives include:

1. National quality-assurance agencies, which audit individual institutional processes to ensure higher education standards and quality, such as the UK Quality Assurance Agency, and the Australian Universities Quality Agency.
2. National T&L agencies, such as the UK Higher Education Academy (HEA), the Australian Learning and Teaching Council (ALTC), and the New Zealand Ako Aotearoa, have unprecedented funding for supporting higher education T&L.
3. National funding bodies. The Australian Learning and Teaching Performance Fund, while controversial, rewards institutions for learning performance outcomes

measured against national benchmarks. The UK Teaching Quality Enhancement Fund supports T&L development at the institution, sector, and individual level.

4. National Teaching and Learning Standards, for example, the UK National Professional Standards Framework for Teaching and Supporting Learning in Higher Education.
5. National peak representative bodies and professional associations. In Australia, the Council of Australian Directors of Academic Development (CADAD) and the Australasian Council of Open, Distance and Elearning (ACODE) operate at the sector level, hosting and commissioning projects of significance to the sector and working with other national organizations to promote and support higher education T&L. The UK Heads of Educational Development Group and the Canadian Educational Developers Caucus play a similar role to CADAD.

The Ling *et al.* conclude that:

Academic development units typically concurrently engage with all four approaches – teaching oriented, learning-oriented, organisationally-directed, and response to system-level initiatives – in complex and dynamic configurations and arrangements peculiar to their institution (Ling *et al.*, 2009: 25).

All these factors have converged to position teaching professional development for higher education staff as critical in the adaptation of universities to the new millennium.

In his review of the ALTC in Australia, Lee Dow (2008: 4) argues “there is little doubt that the learning and teaching function of Australian universities has gained greater prominence in recent years, there is more respect for good teaching among many academic staff on most campuses of most universities, and the measures of student satisfaction with their learning and teaching experiences appear to have increased overall”.

Despite national initiatives, and the call by some for the professionalization of higher education teaching (Dearn *et al.*, 2002), academics in 2009 are still typically employed on the basis of disciplinary research strengths. ED is carried out in an ambivalent environment: national policy and programs promote and value good teaching, yet the prestige of institutions is judged on research performance and productivity, and research grants gain greater recognition for academics at the institutional level. The next section considers the challenges for successful ED.

Challenges

Aging Demographic and Workforce Structures

The aging demographic of academic staff in Northern America, the UK, and Australia represents a significant

challenge to the sector in the coming decades (Mills *et al.*, 2006). Hugo's (2005) studies on the aging demographic of Australian academic staff, and belated responses to succession planning by management suggest two immediate challenges for ED: the reluctance of existing staff in later age brackets to engage fully with less transmission-based pedagogies and the potential of Web 2.0 technologies in teaching, and the imperative to expand ED for the influx of new staff expected within the next decade. A further challenge is the dramatic increase in numbers of sessional staff (Ling *et al.*, 2009; Sorcinelli *et al.*, 2006), who are often also practising professionals in nonteaching fields such as accounting, nursing, and management. Such staff are employed for several reasons: they permit a university to decrease labor costs; increase staffing flexibility when enrolments fluctuate; and, because they bring professional and real-life experience to their teaching, give relevance to students in their educational programs. However, they pose difficulties in terms of ED, since they often work outside usual academic contact hours, making workshop timing a major issue, and they may be less inclined to consider development necessary in what is essentially a poorly paid and part-time work role.

Vocationalization of Curricula

The issue of the relevance of curricula to engage students poses a further dilemma for ED: work-integrated learning (WIL) has emerged in the past decade as a means of improving the work-readiness of graduates, and as a corollary of the trend to more vocational programs in universities. In consequence, a larger share of teaching is done at the workplace, under the supervision of experienced professionals who do not often see mentoring or student supervision as central to their role. Universities have not responded quickly to the additional complication of this off-campus teaching, in terms of their quality control over workplace supervisors, or the ED of such ancillary staff.

New Technologies

Although new technologies have given affordances to teaching approaches unimaginable even 30 years ago, such as videoconferenced lectures, podcasting, and teaching blogs, all concerning the physical separation of teacher from student and student from class, a major contributor to the complexity of ED in the contemporary and future university is the very nature of new technologies, its capacity to fragment the academic role and dissipate the authority of the teacher. Many ED units include training in technologies as a major component of their work, infusing technical skills with pedagogy. This places ED staff in the awkward position of dancing with the devil of technology as Katz (1999) argues, since they are by fiat supporting

extended use of technologies which many staff see as subverting their role.

Students themselves appear ambivalent about the use of newer technologies in teaching. Prensky's (2001) arguments regarding digital natives (Gen Y students who have grown up with ubiquitous computing and mobile devices) versus digital immigrants (those who came late to computer devices) seem convincing: the natives demand that academics use these new tools with as much ease as they themselves do. Yet, more robust research (such as Krause *et al.*, 2005) reveals both that natives are less competent and confident in their use of ICTs for learning than Prensky argues, and that they often resent the use of their spaces (FaceBook and MySpace) for educational purposes.

Further, the very ease of cut-and-paste research for assignments has created yet another domain of activity for ED: educating staff about assessment that discourages/prevents plagiarism of this sort, and educating students about academic integrity in a surrounding culture which places no virtue on originality.

Theoretical Perspectives

One of the principal challenges in learning and teaching in higher education is a lack of consensus on its theoretical underpinnings. At all levels of education studies, multiple disciplinary inputs (from sociology, psychology, systems theory, history, and philosophy) are crucial to understanding and practice. In higher education, however, the influence of these disciplines in teaching practices has persistently clashed with discipline-centered arguments, around tribes and territories. Nor has education as a broad discipline been assisted by the evolution of, and overlap in, psychological theories pertinent to learning and teaching. Behaviorist approaches still dominate our classroom practice, as expressed through observable learning outcomes, at the same time as new discoveries in neuroscience inform our understanding of learning, and as constructivism urges a teaching approach that builds on students' existing knowledge, skills, and motivation. The edubabble jargon peculiar to education studies – and of postmodernist and critical theory in the social sciences – has also been unhelpful in professional development for learning and teaching. The lack of an authoritative coherent theoretical core for learning and teaching frustrates many discipline-strong academics, especially those in the hard sciences, when they engage in ED.

Accredited Higher Education Learning and Teaching Programs

One component of the efforts to focus more intently on learning and teaching was the establishment of formal award programs in higher education teaching generally

at graduate certificate level. The efficacy of such courses in improving student learning has been widely contested, most particularly by Knight *et al.* (2006), and as heatedly defended by ED staff (Dearn *et al.*, 2002). In practice, they attract few academic staff unless mandated, yet are essential to credibility in the development of the double professional.

Structural Instability

As the idea of the university has shifted over the past 20 years, and ED encompasses an ever-increasing repertoire of responsibilities, the models adopted by individual institutions have fluctuated between those outlined by Hicks (1999). One consequence of what appears to be regular restructuring of ED units has been high turnover among directors of ED units, with resultant instability in learning and teaching leadership. A more intense focus on learning and teaching systematic policies and processes has, paradoxically, made ED a tenuous profession, occupying an uncertain space between senior management and staff, developing and promulgating policy designed to standardize quality in learning and teaching, to a workforce historically resistant to uniformity. The disparate nature of ED within institutions, and this instability, has made it difficult to measure the value of ED units in enhancing learning and teaching performance, as discussed below.

ED Futures

The futures of ED are as varied as the ways in which ED operates and is configured in individual universities. In spite of that qualification, we believe that ED success over the next decade depends in large part on the achievement of the following: development and adoption of key ED performance indicators; the national and international collaboration of higher education staff on projects to address sector-wide ED issues and challenges as is the norm in other disciplines; the distribution of ED roles throughout institutions and the development of staff in these roles; and the professionalization of ED staff and leaders.

Key ED Performance Indicators

The work of ED staff is mediated through their colleagues who work directly with students, or through the development of policies and procedures designed to improve learning environments and student engagement with the university. Because of this mediation it has been difficult to directly measure the impact of ED work on student learning.

In spite of these difficulties, the demonstration of the impact of ED is of critical importance to the sector. Just as the demonstration of the quality of teaching was inevitable with greater accountability demands from government, the sector is increasingly demanding that the impact of the work of ED is measured. A project to develop ED key performance indicators was started in Australia in late 2008 and is expected to be completed in 2009. It is likely that international collaboration on the development of ED key performance indicators would be of value to the sector.

International and National Collaboration in ED

While there has been a long tradition of staff exchange between the UK and Australia in ED leaders (Ramsden, Trigwell, and Prosser), ensuring some commonality in sector emphases in promoting learning and teaching, and some cross-fertilization via associations such as the International Society for the Scholarship of Teaching and Learning (ISSOTL) and the International Consortium for Educational Development (ICED), globalizing trends will demand more collaboration at national and international levels.

National collaborations are well underway through the auspices of agencies such as ALTC and the HEA. Embryonic international relationships are also being established by the same agencies, but it will require robust effort to foster initiatives that will meet ED needs in transnational issues such as professional development for sessional staff, and training in information technology (IT) for teaching. The question of academic standards at a global level will also require international collaboration of an order of magnitude above the efforts of Bologna.

Distributed ED Roles

To effect the changes in teaching quality and standards and student access that twenty-first-century societies and governments demand, the work of ED needs to be the responsibility of many positions distributed across the university in collaboration with a central ED unit. This hub-and-spoke model allows for central (hub) expertise in all areas of ED to be accessed by (usually) discipline-focused staff (spokes) located in the faculties. Discipline-based ED roles include faculty deans/associate deans T&L, T&L champions or advocates, course coordinators, and externally funded teaching project staff.

While the distributed configuration of ED provides a useful approach to achieve institution-wide T&L improvement, the issue of a lack of ED experience and expertise undermines this approach, unless more systematic initiatives are undertaken to professionalize ED.

Professionalization of ED

The quality of ED is as good as the experience and expertise of the staff fulfilling the roles. While the sector increasingly relies on staff with ED skills and knowledge to lead disciplinary, interdisciplinary, institutional, and sector improvement of T&L, an urgent issue for universities is the struggle to find staff who are experienced and skilled in ED, teaching scholarship, and leadership. Whether in full- or part-time roles, many learn on the job (frequently as managers on short-term contracts) and yet the ED role is a highly specialized profession in its own right.

Currently, relatively few university teaching staff in distributed ED roles have a professional qualification in T&L or in T&L leadership. Most make the transition from being a discipline specialist to a role that includes ED on the basis of their interest and enthusiasm for learning and teaching. These staff have considerable experiential knowledge but many lack a theoretical understanding to underpin their practice. They are often expected to lead significant changes and innovations in their university/faculty/school but have little strategic planning experience and the expertise and management skills needed to effect change.

The processes by which staff in ED leadership roles learn to be strategic and to take a broad sectoral view of teaching and learning are not yet well documented. It is critical for the sector that this role is supported and developed through a scholarly and evidence-based approach to their professional development. Further research into pathways into the profession, the theoretical understanding needed for working successfully in ED roles, and effective models for ED professional development are needed.

Conclusion

The next decade will see yet more structural changes in the university sector in response to financial stringency, digital technologies, and government demands for more flexible pathways between technical and further education, and higher education. We expect that the role of ED will continue to be to work through all levels of the institution (individual, department/school/faculty, and across the institution) and potentially across the sector to improve T&L quality, learning environments, and student engagement with the university. We have argued that to do this work effectively staff with ED roles need to be both centrally based and distributed throughout the institution and that those staff need to engage in professional development specific to the profession of ED.

In addition to addressing these imperatives, we believe that T&L leadership at the deputy and pro-vice-chancellor levels is critical to the success of institutional ED.

Just as, accountability and role-specific professional development are needed for teaching and ED, the same is true for those in Deputy Vice Chancellor (Academic/Education/T&L) roles. Further research is needed to determine ways in which leadership at this level can be most effective.

Effective Use of Technology in Teaching and Learning in HE

D Laurillard, Institute of Education, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Blended learning – A mix of conventional and digital technologies for learning and teaching.

Conversational framework – Laurillard's representation of the minimum requirements that any learning environment should provide to support the complete learning process, embracing the learning experiences of instruction, construction, experimentation, discussion, collaboration, production, and articulation, as a unified way of challenging both conventional methods and learning technologies.

E-learning – The use of any digital technology in support of teaching and learning.

Learning Activity Management System (LAMS) – An online interactive tool for designing sequences of learning activities using standard individual and group learning tasks.

Learning object repositories – Websites offering access to peer-reviewed online teaching and learning materials, for mainly college-level and HE curricula.

Technology enhanced learning (TEL) – A more recent term than 'e-learning', which has the same meaning.

Virtual learning environment (VLE) – An institutional-level software application to be developed software application to support teaching transactions online, for example, curriculum plans over a period, access to content, scheduling, information on assignments, assignment-handling.

Effective Use of Technology in Teaching and Learning in HE (D3)

Introduction

Until the widespread availability of personal computing in the 1980s, the general technology used for teaching and learning in higher education (HE) had been confined to audio-visual formats such as overhead projectors, audio-cassettes, video, slides, and tape-slide systems. The central aim was to improve the delivery of lectures. Toward the end of this earlier period, educational technology as a discipline began to develop a wider scope to include the

study of teaching methods more generally (McKenzie *et al.*, 1970), and bring a critical methodology to ways of improving all forms of teaching and learning. This brought a greater emphasis on the importance of the evaluation of effectiveness, and a focus on how educational technology affected the learners' work and performance. The discipline was eclectic in its methodologies, borrowing from the natural sciences to set up control studies of the differential effects of a technology or method in comparison with traditional approaches, and from qualitative methods in the social sciences to carry out interviews and observations of the learners' experience of the technology.

In the mid-1980s the development of personal computers and institution-based digital communications networks gave individual faculty members their own access to computer power. Students could rarely afford personal access, but benefited from the IT suites set up in many university departments, libraries, or central resource areas. The surge in business and domestic use of personal computing toward the end of the twentieth century, fuelled by lower hardware costs, the arrival of the worldwide web, cheaper communications technologies, and consumer-oriented entertainment software such as games and music, meant that, increasingly, students had personal and portable access to computers and the Internet.

The interactive personal computer, offering multimedia and online access to communications and content, brought all forms of traditional educational technology and teaching methods together in digital form. The development, in the space of two decades or so, of the extraordinarily rich opportunities for the technological enhancement of teaching and learning was too rapid for educational research to keep pace with it. The R&D methodologies and pedagogic theories of traditional educational technology did not have time to mature to the robust and rigorous research discipline needed for such an explosion of innovation. The funding required for installation and maintenance of hardware, the development of software, and the need to ensure that it was a universal amenity, not just for an elite few, was high. This meant the funding for research and development, and for the training of faculty staff, was rarely commensurate with the expenditure on hardware.

The result was rapid but uneven development, across all the developed countries, of a wide range of uses of digital technology to support teaching and learning in HE, as educationists struggled to work out how best to exploit each new technological opportunity for the benefit

of learners. The discipline of educational technology began to focus on the potential advantages of each new digital technology that became available – multimedia, hypertext, artificial intelligence, the Internet, the web, mobile/cell phones, email, computer-based conferencing, simulations, animations, multiplayer games, virtual worlds, blogs, wikis, podcasts, user-generated design tools, social networking sites – exploring what uses might be made of them in the service of different aspects of teaching and learning. Research methodologies and pedagogic theories drew on ever wider antecedents, as the field developed and members of more discipline areas became engaged in the problem of how best to use digital technologies to improve teaching and learning in HE.

To provide some focus in this nascent, but rapidly growing field, an analysis of the effective use of technology for teaching and learning can be structured around its role in the curriculum, in learning, and in teaching, complementary to the other articles in this section, but providing also a contrasting perspective on teaching and learning in HE.

The Effective Use of Technology in the Curriculum

The academic curriculum in many universities is determined in part by the faculty staff, with courses derived from their areas of expertise. As research responds to innovation and change, so courses follow. However, faculty also respond to a variety of other influences on the curriculum.

There has always been a close link between higher education and the requirements of professional work, and this tends to influence the inclusion of high-level transferable skills, such as problem-solving, information analysis, learning to learn, and communication in general, rather than specific content. Where students personally pay a high proportion of the costs of teaching, HE behaves more like a consumer-oriented business, and works to attract students by offering high-demand courses, especially in business and IT, thereby creating a further pressure on the curriculum. The role of government varies in different countries but, wherever it does play a role, universities are urged to respond to the requirements of the knowledge society and provide graduates with the IT skills they will need in all walks of life, no matter what their discipline qualification. The expectations of graduate skills are therefore strongly affected by the increase in technology in research, in culture, and at work.

Technology also affects the content of what is learned. It has such a powerful effect on how knowledge is being developed, negotiated, represented, and disseminated, that it will continue to affect the curriculum, whether it is academically, vocationally, or personally motivated. The online availability of data sets in science and social science enables students to analyze more authentic and complete

data; software used as tools of the trade in research and business, such as data analysis, computer-aided design, text analysis, and data mining, come into the curriculum of courses whose graduates need to compete in the modern workplace.

Global communications technologies have now begun to move the curriculum beyond the institution toward a potential global curriculum. In 2002 MIT made the first web-based offering of their curriculum with the Open Courseware Initiative, by making lecture notes available to all (Lynch, 2003). While this does not make the MIT learning experience accessible to all, as this is defined primarily by the on-campus experience, it does make public the detail of the curriculum being learned by their students. The material is available to other universities or individuals to use as they wish, but its mere availability helps to define what the curriculum is in a particular field. The UK Open University launched a similar initiative, OpenLearn, in 2006, with two significant developments from the original idea: (1) the courseware made available was designed for distance learning students, not as lecture materials and (2) an additional lab space provided the means for the material to be negotiated and adapted, making the curriculum organic, rather than static (Lane, 2008). In both cases, an important use of open teaching resources is likely to be through teachers using them to enhance their own courses and teaching. Students will use them for individual study, and many will no doubt benefit in a way that would not otherwise have been possible, but mere access to the material does not yield a university education. An open teaching resource is the modern equivalent of the public library. The effectiveness of the online learning experience is highly dependent on the interactive nature of the material and the personal support also provided (Littlejohn and Pegler, 2007).

There has been some speculation that the internet would make it possible for students to study at many different universities, simply by accessing their materials online, a truly market approach. However, the learning experience provided by a university is not simply the transmission of information given – the relationships between teachers and students are critical, as is the coherence of the curriculum. This would be lost in a supermarket model of higher education. Students are not able to act like consumers, precisely because they are learners, putting their trust in the quality of the institution and its staff.

In the early years of the twenty-first century, there have already been several examples of universities making curriculum materials available through the Internet. The trend will probably continue and, as teachers increase their use of other teachers' materials, the process will tend to develop a common global curriculum, with much greater commonality between the courses on offer. However, as the textbook market demonstrates, an increasing volume of material tends to create pressure for a more clearly differentiated curriculum as universities compete more

aggressively for students in a global market for higher education. An online curriculum, providing economies of scale across a widespread student audience, can enable specialist subjects to survive despite relatively low local demand. At a time when many universities were closing classical language courses, the UK Open University was able to aggregate the interest across the country to build a viable distance learning course. Global online access to higher education should enable scholars and teachers to build a highly differentiated online curriculum.

Technology affects what students need to learn, independently of the academy, because its impact on society, work, and research affects what must be studied in all disciplines, defining the skills and knowledge graduates need. It also provides access to extensive digital libraries that constitute the information and ideas that are available to be explored and studied. Technology also enables teachers to exchange and use each others' materials, and this in itself will affect the development of the curriculum. The effective use of technology in any context, however, is primarily dependent on the reflective practice of the academy, and its willingness and ability to innovate.

The Effective Use of Technology in Learning

Learning through instruction

Digital technologies emulate a very wide range of traditional educational technologies and delivery channels, all of them relevant to higher education because they concern the engagement with and manipulation of information, and the social processing of information as knowledge and practice. The personal computer enables the user to engage with text, photography, sound, film, video, and computational models of real-world systems. Together with the Internet it also provides the digital equivalent of the printing press, postal services, public libraries, the telephone, radio, and television. Software tools and environments provide the digital equivalent of writing, debating, literature searching, data analyzing, system modeling, film editing, painting, and designing – there is a long list, and tools relevant to university study continue to be further developed.

Throughout the history of higher education, all the traditional forms of information and communications media and technologies have been used to improve the experience of student learning – blackboards, books, slides, laboratories, libraries – as supplements to the delivery of the subject by the teacher, and the interpersonal dialogs between teachers and students. Digital technologies are capable of emulating all these, but add further value by bringing them together in a personal machine, with personal control over many aspects of their use and organization. Since the advent of wide access to personal computing, the higher education community has looked for ways to exploit the opportunities offered by digital

technologies. The expectation is that they should be capable of enhancing student learning to a far greater extent than the traditional forms.

The early work in the United States on instructional design, analyzing the conditions of learning (Gagné, 1970, 1997), sought to improve on traditional teaching by building interactive programs that could be used by individual students, going at their own pace, rehearsing them in concepts, examples, and illustrative exercises, using the limited static graphics of the time (Merrill, 1994). The early learning theorists had emphasized the importance of knowledge of results, or feedback as an essential component of the learning process, and this has always been embedded within teaching and learning of any kind, as fundamental to pedagogy. The interactive computer offered exactly this capability. However, the type of feedback on offer was usually limited to multiple-choice questions, easily handled by a computer, and commonplace as an assessment method. This essentially instructional use of learning technologies has been the most prevalent, especially in professional training, and in foundational courses in higher education. Didactic forms of teaching continue to dominate e-learning, through many of the open teaching resources, digital libraries, and learning object repositories, together with the continuing widespread use of multiple choice questions as the main form of interactive feedback. An alternative instructional approach used computer modeling to represent the behavior of a human tutor, as a branch of artificial intelligence, and built intelligent tutoring systems (Brown and Burton, 1978). This approach fell out of favor as it could not compete with the explosion of web-based resources, which were easier to develop and closer to the experience of most academics, being similar to writing texts.

Learning through construction

Around the same time a more experiential approach to the use of technology exploited the capability of computers to model systems, and used interactive simulations, where learners could input parameters to a computer model and see the effect on graphical or pictorial output (McKenzie *et al.*, 1978). Intelligent tutoring systems and simulations were both pursued as strands of development within the field, and were represented in the national R&D programs set up to develop the field of technology enhanced learning, although they never dominated.

An importantly different approach within this genre, which gained wide acceptance from its early inception, was the idea of constructionism within a digital environment. Pioneered by Seymour Papert at MIT, and influenced by Piagetian psychology, it embodied the theory that we learn complex concepts and ideas best by constructing representations that use them (Papert, 1980; Papert and Harel, 1991). The best-known example is turtle geometry, where learners have to guide a digital turtle using turn, move, and repeat instructions, and angle and

distance parameters. The trace of the turtle's journey illustrates what it takes to draw a triangle, and other more complex geometric forms. The student learns about angles and the geometrical properties of triangles through giving the turtle the sequence of instructions that construct the triangle. An important part of the theory is the production of a public representation of the learner's idea that can be shared with other learners. The idea was applied to other areas of higher education, such as physics, but it had most impact at school level, in many different countries (Hoyle and Noss, 2003). The fundamental concept of learning through construction is applicable across a wide range of discipline areas, at all levels of learning. Thirty years on, the concept has been implemented as NetLogo, a modeling tool that allows learners to set up and investigate models of the behavior of systems such as population growth, electrical circuits, and climate change, wherever a computational model is possible (Gilbert and Troitzsch, 2005).

Learning through discussion

Before the arrival of communications technologies, individualized instruction – making the learner active, and providing individualized feedback – was seen as the principal value of digital technology. During the 1990s, the Internet and the Web spread quickly within higher education to provide a different kind of value – offering both wide access to digital assets (text, audio, images, animations, simulations, videos), and communicative access to people (synchronous and asynchronous, one-to-one and one-to-many, text, audio, and video). These new capabilities offered the possibility of digital emulation of a much wider range of learning activities – information searching and handling, presentation of ideas, dialog, discussion, and debate. The clear beneficiaries were the distance learning universities, now able to emulate academic discussion at a distance (Harasim *et al.*, 1995; Mason, 1994), and the first major software applications for higher education, such as the First Class conferencing system, were developed. Campus universities were also quick to adopt, as it enabled them to reach part-time and work-based students. Networking was quickly seen as one of the most important applications of the technology (Castells, 2001). As it relied on the construction of knowledge through discussion among the participants, this use of the technology was most obviously aligned with the idea of the social construction of knowledge (Scardamalia and Bereiter, 1994).

Digital communications environments, developed to support group and community discussion in business and leisure, could emulate aspects of face-to-face communication quite successfully. However, the structure of the communication made an important difference to the success of the communication for teaching purposes. The form of discussion in a university refectory is different from the form of discussion in a tutorial – both can be

highly educational, but they have different kinds of learning outcomes. Educators had to rediscover the rules of good pedagogy in these new kinds of communication environments. One clear strand of development focused on the online version of the tutorial, and developed guidelines on how to prepare and moderate asynchronous group discussion (Salmon, 2003). Another focused on the online version of the seminar, where learners collaborated to develop knowledge, and the online environment is structured to encourage the sharing, critiquing, and negotiation of ideas (Crook, 1996; Koschmann *et al.*, 2002; Scardamalia and Bereiter, 2006). This focus on the social aspects of learning led researchers to return to the work of Vygotsky, and the socio-cultural theory of learning as a form of social action (Vygotsky, 1978).

Learning through collaboration

In more recent years, with wider access to broadband in the home and the workplace, users began to want to do things with the technology themselves, not just receive information from others. This led to a much greater emphasis on the development of user tools, enabling individuals to create their own web pages, computer-aided designs, and virtual environments, providing the means for construction as a learning method, to be more widely available. With all the digital capabilities now available, it is possible to emulate practically any traditional teaching method – the seminar, the guided field-trip, the experimental laboratory, the drama studio, the role-play simulation – and developers of e-learning can potentially call on a much wider range of pedagogic theory. The emergence of what is often called social networking enables a community to build, share, and re-use each others' materials – in the leisure context: text, music, photographs, and videos. This means that digital environments now enable learners to collaborate in the building and sharing of representations of their ideas in a variety of media.

Commercial online games have taken the lead in developing highly interactive virtual reality environments. The capability of the technology now goes well beyond the capacity of the educational community to keep pace with exploiting the software developed for other communities. Virtual reality, serious games, and dynamic modeling environments are being explored by commercial companies for educational applications, but the market tends to be sought at school level, rather than from the more specialist communities in higher education. It is unlikely that universities will be able to exploit the full potential of digital technologies for learning, until the development of such games becomes affordable outside the leisure market. University students will certainly continue to use them for their own purposes, and possibly, sometimes, for self-directed learning.

E-learning Pedagogies

Much of the recent research and development literature on e-learning has appealed to pedagogic theory to support the argument for a particular technology application (Alexander *et al.*, 2006; Conole and Oliver, 2006; Garrison and Anderson, 2003; Jonassen and Land, 2000). The field of student learning has in recent decades developed an analysis of what it takes to learn that focuses on learning as an activity by the student, rather than learning as an effect induced by the act of teaching. Since the initial link between behaviorism and programmed learning, and the early development of instructional design, the key theoretical developments in student learning have continued in the Dewey tradition of experiential learning (Dewey, 1938), emphasizing the importance of the learner being active, learning through making, experimenting, exploring, and the social aspects of learning through structured forms of discussing, articulating, and reflecting (Entwistle and Tomlinson, 2007). Every learning technology application can be linked to a pedagogic theory that demands what it provides. **Table 1** provides some examples.

Technology has something to offer every pedagogic theory, from instructional design to constructionism, to situated learning, to social constructivism. The relationship is essentially a post hoc rationalization, however. Technologies are developed for markets other than education – defense, manufacturing, commerce, leisure – and education finds uses for them. Therefore, this technology-led approach to the enhancement of learning is inevitable and productive, as innovations and new opportunities inspire teachers to invent new ways of using them in their teaching. However, alongside this enthusiasm for exploiting new opportunities there has also been a concern to lead innovation from an understanding of what it takes to learn, bringing a critical approach to how technology should be used, and a concern with ensuring that it be effective (Laurillard, 2002). The conversational framework built on research on student learning, and

borrowed the ideas of Conversation Theory (Pask, 1976), to represent the minimum requirements that any learning environment should provide to support the complete learning process. It was designed to embrace the learning experiences of instruction, construction, experimentation, discussion, collaboration, production, and articulation, as a unified way of challenging both conventional methods and learning technologies. Blended learning is the useful term used to describe the judicious mix of the two (Garrison and Vaughan, 2008).

The effectiveness of these different uses of technology for the quality of the learning experience has usually been evaluated with respect to the particular application in a particular learning context, such as a course or subject topic. Use of control groups is not very common, partly because when used, they continued in the educational technology tradition of demonstrating no significant difference, and partly because the value of the technology was often precisely in its innovation, which had no counterpart in conventional methods (Ehrmann, 2002). Evaluation of effectiveness typically takes the form of demonstrating through learner feedback that the application is seen to be enjoyable and beneficial, but the most compelling evidence of effectiveness is found in those studies that use qualitative data, such as comparisons of learners' written output, or quotes from learners about their experience of the learning environment afforded by the technology (Conole and Oliver, 2006).

Use of Technology for Flexible Study

There are two distinct types of role that technology can play in enhancing higher education from the students' point of view. One is its role in supporting the learning experience, as discussed above. The other is its role in extending the ways in which learning is undertaken, which could be referred to as the study experience, that is, enabling flexible study.

Table 1 The relationships between pedagogic theory and technology applications

<i>Pedagogic theory</i>	<i>Learning technologies</i>	<i>Examples</i>
Instructional design	Interactive programs able to select learning material according to performance, graphical displays, automated checking of multiple choice questions	Interactive teaching systems (Merrill, 1994; O'Shea and Self, 1983)
Constructionism, Experiential learning, Situated learning	Simulations, system models, and virtual environments offer an emulation of investigative or experimental learning experiences	Simulations and virtual worlds (Gilbert and Troitzsch, 2005; Harper <i>et al.</i> , 2000; Luckin and du Boulay, 1999)
Social constructivism, activity theory – that learning is a product of social interactions and the use of tools	Social software, such as conferencing systems, wikis, where contributors build a consensual representation of knowledge, bringing students into the activity of negotiating knowledge	Computer-Supported Intentional Learning Environment, CSILE (Engeström, 1999; Scardamalia and Bereiter, 1994) and HE applications of activity theory (Jonassen and Rohrer-Murphy, 1999; Scanlon and Issroff, 2005)

The traditional modes of study in higher education are campus-based, face-to-face, time-limited, teacher-paced classes. These constraints, which effectively excluded part-time or working students, were overcome by the distance teaching universities to provide home-based, correspondence, asynchronous, self-paced study (Bates, 2005; Daniel, 1996). The distance teaching universities could not easily match the library and laboratory facilities of the campus, so this provision was either limited to what could be delivered at a distance, or covered by occasional short study periods on a campus. As innovations in digital technology offered ways of emulating all these aspects of study – synchronous and asynchronous communication, access to digital libraries, and virtual laboratory environments – both distance and campus universities took advantage of them. All universities could now offer flexible forms of study to attract part-time, home-based, and work-based learners. This was a valuable development at a time when higher education was being pressed to find ways of widening participation (Bates, 2005; Castells, 2001; Collis and Moonen, 2001).

With the much wider availability of computing technology in all universities by the beginning of the twenty-first century, and the realization that it could emulate many aspects of the transactions between teachers and learners, the next major software application to be developed for HE was the virtual learning environment (VLE). Modeled on the traditional description of learning and teaching transactions – teacher plans curriculum over a period, delivers content, arranges tutorials, specifies assignments, returns assignments – the approach of the VLE was teacher-oriented, rather than being based on the requirements of learners, and was valued mostly for its administrative features, enabling faculty staff to post assignments and course documents (Dutton *et al.*, 2004).

The effectiveness of information and communications technologies in support of students' study experience is highly dependent on the extent to which the organizational context has adjusted to the presence of technology. It should not simply be an add-on, but properly embedded in the planning and conduct of courses, and the information, advice, and guidance to students. All the studies mentioned in this section above stress the importance of organizational structures. In particular, Bates proposes the SECTIONS framework (Bates and Poole, 2003) involving the following criteria by which institutions can test their implementation of e-learning:

Students – who are they, what do they need, and to what extent do they have technology skills?

Ease of use – how accessible is the technology for all groups of learners?

Costs – what is the cost structure (fixed and variable costs) of each technology, and the unit cost per learner?

Teaching and learning – what kinds of learning and instruction are needed? What are the best technologies for supporting T&L?

Interactivity – what kind of interaction does the technology enable?

Organizational issues – what are the organizational requirements, and barriers? What changes in the organization need to be made?

Novelty – can the use of the technology be sustained over the long term? Will initial capital costs be followed through with recurrent maintenance costs?

Speed – how quickly can courses be mounted and materials changed?

In this and other books on implementation, effectiveness of the technology is not evaluated simply as a general property of the technology, which would make no more sense than it would to test the effectiveness of books or lectures in general. Empirical studies are used instead to clarify the contextual conditions and design features that ensure the effectiveness of particular technologies, for particular educational ends.

Effective Use of Technologies for Teaching

The teacher's perspective on the use of technology derives to a great extent from their approach to teaching. If teaching is understood as a way of transmitting their own knowledge to the mind of the learner, to caricature one extreme, then faculty staff will use digital technology to deliver resources, much as they would deliver lectures and books. These teachers are well served by the VLE, described above. Unfortunately, although it has been widely implemented as a solution to the problem of making e-learning available, the VLE does not typically challenge higher education staff to develop new approaches to teaching and learning (Zemsky and Massy, 2004).

On the other hand, to the extent that teaching is seen as a way of facilitating the development of students' high-level skills through the vehicle of a particular field of study, then lecturers want to take advantage of the interactive, communicative, and collaborative capabilities of the technology. However, innovative teachers, even those well supported by a university's learning technology unit, find little time in a busy schedule to learn how to innovate with e-learning. It is least time-consuming to make use of communication environments, where students manage their own peer learning, and digital libraries, where students manage their own investigation and discovery learning. These teachers need learning design tools that make it easy for them to build a learning environment in which their learners can be active in pursuit of their study and learning. Few such tools are currently available. One example that is attracting attention in several countries is the Learning Activity Management

System (LAMS), an online tool for designing sequences of learning activities using standard individual and group learning tasks (McAndrew *et al.*, 2006).

The use of technologies for teaching will be more effective when teachers can more easily engage in designing their application to learning. The tools of teaching they are familiar with are blackboards/whiteboards, slide presentations, lecture notes, books, moveable desks, field trips, laboratories, and libraries. Here they have a reasonable degree of control over what and how their students learn, sometimes supported by technical staff. Designing their teaching with digital tools and resources requires either technical support of the kind that takes away their control, or a steep learning curve. One current trend may be an indication of how this could change. The development of repositories of learning objects is providing faculty staff with the means to share and build on each others' teaching materials. One example, the Multimedia Educational Resource for Learning and Online Teaching (MERLOT) provides peer-reviewed online teaching and learning materials, for most of the HE curriculum, through a website available internationally (MERLOT). While the majority of early submissions were primarily text-based materials, the number of more interactive examples is growing. This kind of development alongside the open education movement, dominated by MIT in the United States and the Open University in the United Kingdom, brings to the academic teaching community the means to become true scholars of teaching, able to critique, improve, and share teaching ideas. Their best pedagogy is no longer an evanescent abstraction, but is captured for the benefit of others in digital form.

This supply of teaching materials is not yet matched by demand. Faculty staff prefer to build their own, without reference to others' ideas, in stark contrast to their behavior in their research fields. However, if the learning object repository trend is matched by the further development of the learning design tools trend, then there may yet be a flourishing exchange of ideas and innovations in the practice of e-learning by the academic community.

Studies of online courses have used surveys to try to discover the extent to which e-learning achieves cost-effectiveness, but the results are largely inconclusive, due to the immaturity of most implementations, and the complexity of the analysis (Bates, 2005; Boyer, 1997; Garrett and MacLean, 2004; OBHE, 2003; Twigg, 2003). The best evidence comes from institutional studies where the organization has set out to achieve cost effectiveness through the innovation, and has managed and monitored costs of all aspects of the implementation (Bates, 2005; Twigg, 2003).

Concluding Points

Developments in digital technologies over the last few decades have repeatedly offered opportunities to emulate

traditional forms of teaching and learning and, by integrating them, and operating at scale, have extended their potential to contribute to all aspects of higher education. However, the changes have been so rapid that scarcely has the potential of one technology been understood than another offers even greater promise. The main developments in e-learning have therefore tended to be technology driven.

Educators and scholars have found ways of using digital technologies to facilitate

- learning through instruction;
- learning through construction;
- learning through discussion; and
- learning through collaboration.

However, typically, the pedagogic theory is brought in to fit what the technology offers. It may then direct the design of the application, but it never drives technology development.

This will continue, because technology attracts massive investment, and responds to the powerful drivers of the business and leisure markets, whereas pedagogy develops slowly, unnourished by investment. The field of e-learning, whether research, development, or practice, is immature and fragmented. It needs a clear and robust pedagogic theory, capable of withstanding the allure of technology developments that do not serve learner understanding, and of challenging the technology to develop what learners actually need.

There is some promise in the trends of development of tools and resources by higher education, for higher education, that now go beyond the administrative tasks to generate learning object repositories and learning design tools. These new capabilities could generate a genuine scholarship of teaching, emulating the rigor of scholarship in research.

Technology development will continue, and students in HE will continue to use it extensively in all parts of their lives. Some of this use is likely to extend to their learning, but in a self-directed way. Faculty staff will use technology extensively in their research, and to the extent that research and teaching are synergistic, this will benefit their teaching.

However, innovation in e-learning, driven by pedagogic imperatives, and focused on improved learner understanding, is not likely to be a major force in HE until it is linked to the broader strategic aims for the quality and reach of teaching and learning, at the highest levels in universities.

Facilitating Students' Success – Student Support and Learning Resources in Universities

E Woodberry and C Barnes, University of New England, Armidale, NSW, Australia

© 2010 Elsevier Ltd. All rights reserved.

Context

This entry examines the role of student support services in promoting success in university study. Such services have been a feature of higher education systems worldwide for decades. However, their critical importance has not always been recognized. This situation has changed as a consequence of the transformation of the higher education sector since the early 1990s.

The international shift from elite to mass higher education has greatly increased the demand for student support services. Newer entrants to universities often lack the academic literacy skills higher education programs require. The rapid growth in distance education programs has also affected demand, as learners at a distance typically require greater support than those in traditional programs. This need is most acute in online learning, where additional assistance is often necessary to allow students to cope with new technologies.

Growing emphasis on accountability has also played a part in the renewed interest in student support services. Employers, taxpayers, and governments are now more demanding in terms of educational outcomes, attrition rates, and graduate skills. Other factors have been the commercialization and internationalization of higher education in many industrialized countries. Competitive pressures and the growing importance of foreign student income have made many institutions far more sensitive to the needs of students as consumers. It is no longer possible for universities in Western countries to be complacent about student outcomes.

Equally significant has been the change in teaching philosophies. Even those students enrolled in traditional on-campus programs are exposed to fresh challenges as newer forms of learning grow in popularity. Although intended to mitigate the perceived inadequacies of traditional pedagogies, newer active-learning methods, particularly those based on advanced technologies, demand much more of students, particularly in terms of information literacy. Student services have an important role to play in facilitating student adjustment to state-of-the-art teaching environments.

What Does Student Support Entail?

Student support usually involves a range of nondiscipline-based services that provide guidance and tuition tailored to

each student and at every point in the student's academic progress. Effective student support programs include opportunities for students to access: pre-enrolment guidance, career counseling, work-ready programs, course advising, orientation sessions, basic literacy and numeracy programs, study skills tuition, academic literacy instruction, library skills tuition, information literacy training, technical support, personal counseling, disability support, and advocacy.

This list is not exhaustive, representing only some of the range of student support programs typically provided in a major university in an industrialized country.

Academic Support

History

Academic support programs in higher education have a much longer history than is often recognized. Modern programs are based on a tradition that dates back at least as far as the early college preparation courses offered at the University of Wisconsin in 1849. By the 1950s, writing courses for freshmen were common in community colleges in the United States of America. From these early beginnings, effective academic support has emerged as a critical element in institutional and program success. Academic support is now seen as crucial to improved learning outcomes, student fulfillment, and higher completion rates.

Early research into academic support programs is often associated with the work of John E Roueche in the United States community college sector during the late 1960s and 1970s. Roueche and his colleagues at the University of Texas at Austin emphasized mastery of learning as a core concept in academic support. This idea took the form of highly structured, performance-based instruction in which frequent testing was used to measure learning and to provide feedback. Although a behaviorist, Roueche favored varied teaching approaches. These included class discussions and group projects. Roueche also argued that academic support programs should involve a personal counseling component. Many of Roueche's insights have been confirmed by later investigators.

Although early research provided a significant body of knowledge, progress in the field since the 1970s has been uneven. Academic support programs, particularly in the United States, initially took the form of remedial

education: tuition in reading, writing, and basic mathematics skills. The initial prevalence of deficit models meant that such services were often accorded low priority as a research topic and were starved of resources in practice. As delivery was often contingent on a range of local circumstances, much research was in the form of 'how to do it' case studies. This emphasis hampered efforts at the development of generalized theory. However, considerable progress was made during the 1980s in the United States in terms of developmental education, an approach that introduced topics such as study skills and time management.

New Theoretical Perspectives

In more recent decades, deficit models have lost ground. Research outside the United States has led to a richer understanding of the importance of academic support programs. The success of first-year students in adjusting to university study is less often taken for granted. Stresses associated with an unfamiliar learning environment, social isolation, and inevitable disappointments are recognized as potentially affecting all new learners, not only weaker or under-prepared students. Another factor has been growing awareness that students require more explicit instruction in academic culture. Academic literacies research has challenged the assumptions that the discipline-specific genres are self-evident, or that student acculturation through simple exposure to university practice is easy or natural. There has also been a growing acceptance of the point that learning outcomes and completion rates are affected by teaching quality. Academic support services are required to remedy deficiencies in teaching as well as flaws in learning. Although this point was made by Roueche in the 1970s, it has taken three decades for the decision-makers in the higher education sector to come to terms with realities long apparent to generations of students.

Approaches

Academic support services are currently delivered through a range of delivery mechanisms. These include traditional lectures, self-paced workbooks, peer-led study groups, group tutorials, one-to-one counseling, computer-based training (CBT) packages, Web-based tutorials, audio tapes, video tapes/DVDs, podcasts, and blogs and wikis.

Although each of these approaches has yielded positive results, some should not be used in isolation. When used alone, CBT packages do not generally result in satisfactory learning outcomes. The effectiveness of traditional lecture format relative to more student-centered, active learning approaches has also been questioned in the academic support context.

Information Literacy

Importance

Student training in information literacy (IL) has, for many years, been recognized as a crucial element in student support. This is an area in which librarians and other information specialists can offer a significant contribution, particularly when working in conjunction with specialist academic staff. The teaching of information skills (particularly when tailored to a specific subject or discipline) provides a long-term benefit to students and assists in reducing attrition and promotes life-long learning.

History

The work of the American scholar Zurkowski (1974) is usually seen as the starting point for modern concepts of information literacy. Growing US interest in IL during the late 1980s led to the *Final Report* (1989) of the American Library Association (ALA) Presidential Committee on Information Literacy. This report is now seen a milestone in the development of IL and it is still highly influential. By the mid-1990s, IL concepts had spread well beyond the United States, leading to curriculum changes in universities in the United Kingdom, The Netherlands, South Africa, and Australia.

The 1990s also saw the development of a range of theoretical frameworks. Kuhlthau's Information Search Process (ISP) model emerged in 1993 (Kuhlthau, 1993). This has proved to be one of the most significant theoretical interventions in the IL field, and has been applied to IL research and practice in universities in many countries. Other crucial theories include Bandura's (1997) theory of self-efficacy, and Kapitzke's critical IL model (Kapitzke, 2001). Librarians and educationalists in this decade have also explored the implications of older theoretical perspectives, such as Bloom's taxonomy of educational objectives (Bloom, 1956), to IL instruction.

The release of a number of comprehensive IL standards marked the growing maturity of the IL field in higher education. The most important of these was the *Information Competency Standards for Higher Education* (2000) issued by the US Association of College and Research Libraries (ACRL, 2000). The ACRL document provided the basis for the *Information Literacy Standards* (2001) published by the Council of Australian University Librarians (CAUL, 2001). In its position paper *Information Skills in Higher Education* (1999), the UK Society of College, National and University Libraries (SCONUL, 1999) provided a list of seven headline skills and a model for IL. These three documents have provided a framework for the development of nation-level IL initiatives in many countries. The ACRL standards alone have been translated into upwards of 15 languages, including French, German, Italian, Finnish, Japanese, Spanish, and Chinese.

The strategic importance of IL on the Anglo-American model of information skills is currently acknowledged by universities across Europe, North America, and other parts of the industrialized world. This is the case even in Eastern Europe, where IL has taken a different trajectory for many years. The systematic incorporation of IL instruction into curricula across all levels of university study is increasingly seen as the ideal. There is growing recognition that effective IL instruction cannot be separated from discipline-related content or from assessment. The implication is that successful IL requires collaboration between academic staff, university administrators, librarians, and other information professionals. In addition, agreement grows that IL is best taught through problem-based learning and other forms of authentic, student-centered instruction. This consensus is far from complete, but few educators in the industrialized world would now see IL instruction in isolation or give it a low priority.

Progress in higher education institutions in the developing world has been uneven. IL initiatives are often hampered by the lack of technology, resources, trained personnel, and infrastructure. Despite efforts by UNESCO and the International Federation of Library Associations (IFLA) to raise awareness of IL issues worldwide, progress has been limited. South Africa is a notable exception. Recent developments in other developing nations, such as the People's Republic of China, also give grounds for optimism.

Approaches

In the early 1990s, most libraries taught IL using more-or-less traditional methods. These included library tours, printed pathfinders or subject guides, self-paced workbooks, subject-specific lectures, face-to-face tuition, and telephone support for distance learners.

Whatever the mode of instruction, the emphasis was on library orientation and specific tools, such as the online public access catalog (OPAC). Course-related instruction was often limited to students in specific subjects or those faced with particularly difficult assessment tasks. Little weight was placed on transferable skills.

These older methods have not been superseded or entirely replaced. In universities in many parts of the world, they remain standard. They are now only part of a wider range of instructional modes. Some modes, like the greatly emphasized on hands-on instruction (as opposed to the traditional lecture format), or the use of Web-based subject guides, represent evolutionary, rather than revolutionary, change. More striking has been the proliferation of technology-driven modes, many of which are in their infancy.

Universities, and in particular university libraries, are testing the use of technologies such as the following to assess their usefulness for information literacy: podcasting,

screencasting, bulletin boards and email lists, virtual chat, instruction by SMS, blogs and wikis, and Web-based tutorials.

Emphasis has also shifted from tools-based instruction toward tuition designed to ensure that students make effective use of information they find. The Web has resulted in an information-rich environment in which responsibility for assessment and evaluation now falls primarily on the user.

There is also greater recognition of the fact that information literacy is a worthwhile goal in itself, as demonstrated in the Graduate Attributes programs prevalent in Australia at the turn of the twenty-first century. While instruction based on textbooks or collected readings still has a role in university education, particularly in developing countries, the increasing availability of online information has shaped teaching strategies. The trend in many industrialized countries is toward learning strategies in which students learn through engagement with an ever-increasing range of information resources, often those which they would use in the workplace. Enthusiasm for problem-based learning (PBL) is one factor in this development.

The ideal is articulated as a situation where IL learning is embedded into the curriculum at all levels. In this model, IL instruction is designed through collaboration between librarians and academic staff.

Instruction takes the form of specific assessment tasks that involve a structured, systematic search for information. Although widely recognized as desirable, this approach has often proved to be difficult to realize in practice.

The creation of Web-based packages providing generic IL instruction is often seen as a cost-effective alternative. These are relatively easy to build and do not depend on academic collaboration. They can also incorporate interactive exercises, self-assessment tools, and online tests. Although such packages are useful, their generic nature means that they fall short of the ideal. Despite this drawback, they are increasingly popular and a handful have achieved an international reputation, having been translated or adapted into a number of languages. Examples of Web-based IL programs with an international profile include TILT (USA) and eSKILLS UNE (Australia).

Learning Spaces

The revolution in information technology in the 1990s, simultaneous with the availability of information resources in electronic form, had a major impact on university libraries. The necessity to provide the technology to support access resulted in university libraries redeveloping themselves as institutional access points for digital resources. The inevitable convergence of these trends

led to the emergence of the concept of Information Commons, which included not only equipment but also new services required to support students in access and utilization of the technology and the resources. Lippincott (2006) defines the underlying philosophy of the Information Commons as one of providing users with a technology-rich space where students can access, manage, and produce information all at the same workstation.

History

One of the earliest examples of an Information Commons was the facility established in 1994 by the Leavey Library at the University of Southern California. In the intervening period, the Information Commons concept has been employed at university libraries in countries such as Australia, Canada, Malaysia, New Zealand, South Africa, and the United Kingdom. Early best-practice examples were at the University of Calgary and the University of Guelph in Canada, with later developments such as the Kate Edgar Information Commons at the University of Auckland and the University of Otago in New Zealand, significantly expanding the concept.

Developments

Recognition that the design of space impacts on learning emerged as a significant issue in the late 1990s. Bennett (2003) identifies the fundamental changes that occurred during this period as recognition of the social dimensions of learning, and the revolution in information technology. Design of learning spaces was challenged by a change in student requirements, the pervasiveness of information technology, the emergence of e-learning technologies and an increased understanding of learning. Research carried out by Oblinger (2006) for Educause in the United States, the Joint Information Systems Committee (JISC, 2006) in the United Kingdom, and the Canadian Association of Research Libraries (CARL, 2005) develop the concept of learning space design and its application for academic support services.

Responding to the demand from students for increased variety in spaces and technologies, the Information Commons concept was further developed to that of a Learning Commons. Lippincott (2006), in *Linking the Information Commons to Learning* defines the purpose of the Learning Commons as being to enhance student learning and scholarship. The Learning Commons concept recognizes that libraries need to respond to changes in teaching practices and student demand not only for social space and technology access but also for access to academic support personnel, technology-enabled shared facilities for project work and group study purposes. In practice, the Learning Commons provides an integrated work environment for students

with technologies and spaces that support learning theory principles; they are student centered, support a range of flexible learning methods, and provide a single point of access to support services.

The commons personnel can include advisors in writing, numeracy, academic literacy, library, information skills and information literacy, together with assistance in the utilization of the technologies and associated software. The technology-rich environment of the commons requires that students have immediate access to technical support staff for troubleshooting and advice. The scope of the learning commons can also include consultation spaces, rooms for group work (such as peer-led study sessions), and electronic classrooms to support the delivery of academic support programs.

Early examples of Learning Commons developments are the University of Queensland Ipswich campus in Australia and the Learning Centre at the Glasgow Caledonian University in Scotland.

The Learning Commons ideal extends beyond the idea of a dedicated physical space, which supports on-campus students, to online support services. An example is the Learning Commons at the University of Guelph, which incorporates a very extensive Web site including self-paced instruction modules, multimedia resources, and interactive self-assessment tools. The future of student support services lies with strategies that make best use of the possibilities inherent in the latest generation of educational technologies within a physical space and online.

Student Support in Distance Education

History

Student support programs for distance learners have a long history. The first universities to provide correspondence tuition to their own learners were in North America, beginning with the Illinois State University (1874). The University Correspondence College (1887), a British provider, was perhaps the first to offer distance learners a well-thought out program of student support. The University Correspondence College was a private institution providing support to nonresident students intending to sit for University of London degrees. It ran classes in London and Cambridge, offered residential schools, published its own textbooks and offered tuition by correspondence. The University Correspondence College anticipated the comprehensive student support systems associated with higher education in the late twentieth century.

The methodical approach of the University Correspondence College was very much the exception. For most of the twentieth century, distance learners in higher education were largely dependent on informal support from partners,

families, and friends to overcome the frustrations and loneliness of study by correspondence. This situation changed in the early 1970s, when the Open University in the United Kingdom revolutionized distance higher education through the concept of supported open learning.

Open University learners enjoyed study skills advice, telephone support, face-to-face tutorials, and a network of local resource centers, in addition to tuition by correspondence. One of the strengths of the Open University program was 'continuity of counseling'. Students were assigned a personal tutor-counselor who provided support and advice throughout their degree. The Open University also made use of broadcast media as well as high-quality print materials.

During the 1980s and 1990s, the Open University provided a model for many single-mode distance providers. Although the Open University system remained a standard of excellence, not all of the 'second-generation' universities had the resources to provide the same level of support to distance students. In fact, the Open University itself was forced to modify its program in 1997, in part due to the need to control costs.

Another competing model in these decades was the University of New England (1955), an Australian institution that pioneered dual-mode distance education in the 1960s. Dual-mode instruction was based on the principle that on-campus and distance students should be taught by the same academic staff. Student support mechanisms at the University of New England included telephone counseling, face-to-face tuition at residential schools, audio tapes, and broadcast radio. However, the standards of student support at dual-mode institutions were dependent on a range of institutional factors. In parts of the developing world, dual-mode institutions found their ability to provide effective support constrained by inadequate resources and the often rudimentary state of national infrastructures.

New Approaches

As in other areas in higher education, the 1990s represented a period of renewal for student support services. Universities had previously experimented with a range of technologies for supporting distance students as independent learners. These included telephone counseling, audiotapes, television, radio, video, computer disk, CD-ROM, and written materials. Technological changes and cheaper telecommunications made it possible for distance education providers to go beyond this goal: to facilitate the involvement of distance students in collaborative, social learning. Initially, the creation of online learning communities involved the use of email or bulletin boards, often through commercial learning management systems such as WebCT and Blackboard.

More recently, universities have looked toward Web 2.0 technologies to provide an improved level of student support for distance learners. A growing number of universities have built student portals, which offer rich functionality and access to a personalized range of electronic resources. Many administrative functions have been moved online, reducing delays and providing students with instant access to information on enrolment and course progression. New technologies – blogs, wikis, and podcasts – provide opportunities for the innovative delivery of student support services.

Glossary

Academic culture – Represents the deeply embedded, historically transmitted traditions, myths, values, and expectations that are peculiar to academic occupational life and work.

Academic freedom – Typically refers to the unencumbered search for truth, freedom for academics to undertake research and publication in their specialist fields and to teach without any restrictions in their area of expertise.

Academic values – Are those strongly held beliefs and principles that guide academic work and life. Three such values or 'tenets of faith' in academia are academic freedom, collegiality and professional autonomy.

Collegiality – In academia refers to the active participation of faculty in academic and democratic decision-making, the professional sharing of ideas, as well as the mutual support and sociability it offers. Collegiality derives from the 'community of scholars' ideal which reflects the dominant ethos of the medieval guild – collegial decision making by a body of equals in an unhierarchical and collaborative enterprise.

Research-led teaching and learning – Implies a close relationship exists between research, teaching, and student learning. It holds that as teachers are at the forefront of knowledge they need to be actively engaged in scholarship and research, teaching, and learning must be evidence-based and curricula designed that reflect a research-based approach to learning.

Introduction

Like all social entities, the world of academia possesses a symbolic dimension – an academic culture that, unlike institutional structures, cannot be visibly or diagrammatically depicted, but can only be inferred from the values and expectations of academic faculty who reside there. The potency of academic culture and its impact on the life

and work of faculty and their institutions should never be underestimated. Three integral tenets of faith peculiar to this culture, which influence significantly the core business of higher education and its organizational arrangements, are those of academic freedom, collegiality, and professional autonomy.

Academic freedom and professional autonomy in teaching, research, and publication are two forcefully defended values of academic culture. These are, however, in danger of being eroded as faculty values and norms in many countries come under considerable pressure to conform to changes wrought by demographic, economic, social, and technological developments (Honan and Teferra, 2001: 183). Traditional collegial practices are also under threat as progressive corporatization and managerialism take stronger hold in higher education institutions (Kreber, 2006: 6). Measures taken to conform to these pressures impact on the core business of higher education institutions and the way teaching is carried out. Growing competition and financial constraints mean that professional decisions are now becoming financial ones, forcing institutions to increase the attractiveness of academic programs to potential clients (Anderson *et al.*, 2002: 54). Competition also leads to institutions increasingly defining their distinctive approaches to teaching and learning (Zubrick *et al.*, 2001: ix).

In addition, pushing for change are the significant influences of massification and diversification of the student body in higher education, the changing role of research in knowledge economies, societal demands for lifelong education, and changing labor-market needs (Evans, 2002; Enders, 2004; Kehm, 2007; Harman, 2008). In such fast-changing environments, themes of growing interest in higher education are how best to safeguard and sustain the integrity of academic culture while simultaneously providing quality teaching and learning.

Attention, in this article, is directed to core values and expectations enshrined in a deeply entrenched academic culture that influence the teaching role of faculty, student learning, and the organization of higher education institutions. Of further interest are external pressures impacting on higher education institutions that have modified the teaching role and placed the integrity of deeply rooted faculty values and expectations under increasing strain.

Faculty Values and Expectations: Core Components of Academic Culture

Academic faculty represent the embodiment of a distinctive culture as they uphold and sustain deeply held traditions, myths, values, and expectations that are peculiar to their occupational life and work. These cultural traits are historically transmitted, cumulative, deeply embedded and not easy to turn-off at will. The thicker the culture, the more potent is the culture's influence (Harman, 2002: 97).

The most deeply embedded values and expectations shared by academic faculty are those of academic freedom, collegiality, and professional autonomy. Creativity, critical appraisal by peers (a sacred cow of academia), and integrity in teaching, research, and scholarship also form integral elements of academic culture. The influence of this culture on teaching, learning, and the organization of higher education institutions is pervasive.

Academic freedom – the most forcefully defended value – refers to the unencumbered search for truth, freedom to undertake research and publication in scholars' specialist fields, and to teach without any restrictions in their area of expertise. Another interpretation sees academic faculty as public intellectuals who should have the freedom to express their views in any public forum without fear of retribution or censure (Altbach, 2007: 24) – a value that has been eroded significantly over the last 20 years with the “crushing of the dissident voice” in heavy managerialistic institutional contexts (Anderson *et al.*, 2002: 57).

Collegiality – the active participation of faculty in academic decision making, the professional sharing of ideas, as well as mutual support and sociability (Anderson *et al.*, 2002: 47–48) – is another strongly defended value which does not sit easily alongside managerial styles and structures that exclude faculty from decision making in nonacademic areas. Collegial, democratic decision making is based on the principles that intellectual authority derives from the disciplines and truth is no respecter of status and hierarchy. As a value, collegiality derives from the community-of-scholars ideal which reflects the dominant ethos of the medieval guild – collegial decision making by a body of equals in an unhierarchical and collaborative enterprise.

Professional autonomy – closely related to academic freedom – represents the ability of academics to exercise their professional judgment about what they teach and research and is another strongly defended value. Growing competition, financial constraints, and accountability are, however, eroding this autonomy, as noted earlier. This autonomy–accountability tension is a ‘perennial concern’ in higher education as external bodies demand tighter control over higher education (Altbach, 2007: 20).

Faculty Values Guiding Teaching and Learning

The teaching role typically encompasses communicating via traditional face-to-face interactions and technological means, preparation of lesson content, curriculum development, individual consultations with students (real and virtual), postgraduate supervision, provision of feedback to students, and assessment of their learning. Faculty values and expectations that have a marked influence on this teaching role are identified in the sections that follow.

Research-Led Teaching and Learning

Good teaching which draws on disciplinary expertise, professional experience, and is continually revitalized by research and scholarship, is valued for fostering quality learning outcomes (Australian Vice-Chancellors' Committee (AVCC), 2002a: 1). This value implies a close relationship exists between research and teaching. It holds that teachers are at the forefront of knowledge and are actively engaged in scholarship and research, teaching and learning must be research-led, and curricula designed that reflect a research-based approach to learning (Anderson *et al.*, 2002; Kreckel, 2002; Jenkins *et al.*, 2003; Harman, 2005). Research-led teaching is seen to inform practice, encourage inquiry/problem-based learning, provide up-to-date knowledge on curriculum content and development, and inform teachers better on how students learn effectively and how particular teaching methodologies encourage deep learning. This implies that knowledge imparted by faculty needs to be evidence based and teachers must make decisions about curriculum, teaching pedagogy, and modes of assessment on the basis of well-informed research and scholarship. Thus, teachers must be intellectually engaged as learners who acquire knowledge and improve practice through research and scholarship that augments research findings (Brown, 2002: 5).

While arguments persist over how close the relationship is, or needs to be, between teaching and research (Hattie and Marsh, 1996; Elton, 2001; Scott, 2007) and while some teachers are clearly not active researchers, a strongly held value is nevertheless that students should be taught by experts in their respective fields of research. Problems typically experienced by institutions with teachers who are nonresearchers are that those who do not engage in research often use outdated knowledge, are limited to merely using knowledge generated by others, and are constricted in scope and range of teaching skills. These problems are highlighted in the report, the Boyer Commission on Educating Undergraduates in the Research University (1998: 1–2), which argues that the teacher-as-researcher or scholar-teacher moves from a base of original inquiry

and that students should be taught by those who discover, create, and transmit insights about subjects in which they are the experts.

Deep Learning Versus Surface Learning

Another strongly held value is that good teachers encourage deep learning which builds on the intrinsic interests of the learner, is inquiry/problem-based, and seeks the interrelationship of new knowledge with existing knowledge. Surface learning (memorizing or rote learning) is discouraged as this method merely encourages passively storing and processing information rather than synthesizing, evaluating, and analyzing. Work that values teacher as facilitator, learner, and educative leader and adopts an interactive mode of teaching that encourages problem solving, will ultimately be more successful in ensuring deep student learning. The Boyer Commission on Educating Undergraduates in the Research University (1998: 1) adds that inquiry-based learning possesses an element of reciprocity – faculty learn from students (the learner–teacher concept) as students learn from faculty.

Higher education reform agendas, in many transition economies, place significant value on improving teaching, learning, and assessment methods. In Vietnam, lecturers are being urged to move from passive to interactive teaching modes that encourage active participation of students and to ensure their teaching is research-led. The former Minister of Education and Training emphasized recently that interactive teaching and problem-based learning increase learners' participation and their ability to work in teams, and adapt to their jobs and future careers. The teaching principle is promoted as “teaching how to learn” and “learning how to learn” (Ministry of Education and Training (MOET), 2005: 18).

The Move to the Learning Paradigm

As the workplace that graduates will enter is vastly different now than even a decade ago, the modern college or university is increasingly encouraged by external constituencies to strengthen undergraduate and postgraduate education by shifting from an emphasis on instruction to an emphasis on learning (Barr and Tagg, 1995; Rice, 2006). The greater value placed on learning devalues the instructional (didactic) paradigm exemplified by the passive transmission of information in lecture-discussion format where faculty talk and students listen – a form that does not encourage deep learning.

Focusing on the learner rather than the teacher leads to new expectations for how faculty will enact their roles. Rice (2006: 16) talks of the need for the unbundling of the traditional role – a change that poses a serious challenge to the holistic conception of the teacher–scholar ideal rooted in a collegial culture where peer review and

self-monitoring are the norm. Faculty members now need to know how to support and advise students, how to facilitate learning through applying a range of innovative learning processes, and be able to link learning with life experiences and service in the community.

Stress on learning opposed to teaching is seen mostly as a problem in research universities. In Germany, for example, it is argued that the teaching function has remained faithful to the Humboldtian tradition, but the learning function is less clear. The traditional Humboldtian concept of concentrating on teaching the elite students that would somehow elevate the pedestrian rest is an idea that is not seen to be viable any more (Kreckel, 2002). It is now argued that effective teaching not only assists students less well prepared for university, but also provides those imbued with the consumer-rights ethic better value for their investment.

One implication for institutions of higher learning still holding to the instructional paradigm is that in the context of diminishing resources alongside the ever-increasing quest for quality, they are faced with a real dilemma – how to increase quantity and quality of outputs without a corresponding increase in resources.

External Pressures Impacting on Values and Expectations Guiding Teaching and Learning

The New Political Economy of Higher Education

A number of major changes impacting on teaching and learning in many higher education systems are encapsulated in the literature under ‘the new political economy.’ According to Rich (2006: 37), these changes include:

- erosion of public funding;
- escalating costs in the face of public fiscal stringency;
- restraint sought on increasing fees and tuition;
- increase of political and ideological intrusiveness, for example, managerialism and growing corporatization in a more profit-driven environment;
- changing expectations of students influenced by user choice and the emphasis on students as customers/consumers;
- professional standards dictated by outside control, for example, by government regulation rather than by disciplinary norms;
- globalization of economies and research systems, intensification of international competition (free trade), and the rise of new information technologies;
- erosion of academic freedom to determine curriculum content and standards and methods of teaching; and
- greater accountability on access, cost containment, and learning outcomes.

In this climate, faculty feel the pressure from both top-down and bottom-up; from administrators reacting to market forces and from students demanding new styles of presentation (Hagner and Schneebeck, 2001: 2). Moreover, the core value of academic freedom is seriously threatened (Altbach, 2001: 205).

Technological Advances

The impact of information and communication technologies (ICTs) that liberate learning from constraints of time and space has revolutionized traditional forms of teaching. Teaching is continually being challenged with emphases on borderless education using e-learning, with online interactive teaching modes, to meet the developing needs of a more diverse student population globally and locally. Traditional face-to-face delivery modes are now challenged by more flexible multimedia approaches which add value to lifelong and distance learning and expand the webs of learning available in a global context.

As technology advances and increases in off-campus teaching and flexible delivery modify the teaching role, teaching faculty are now expected to be up to speed with these developments and adapt accordingly. Implications are that teaching must adapt and ongoing training for faculty needs to be provided if quality teaching and learning, curriculum design, and assessment practices are to result.

Resulting from the impact of the digital revolution, a typology of faculty is offered by Hagner and Schneebeck (2001: 3–5). The predominant types comprise:

1. The *entrepreneurs* characterized by a high level of commitment to quality teaching and learning, work that tends to be idiosyncratic, and a preference to use their expertise to solve their own instructional problems.
2. The *risk averse* characterized by a commitment to quality teaching but a lack of technical expertise, fear that current success in teaching will not translate into new teaching environments, and a need for significant levels of instructional support.
3. The *reward seekers* whose motivation is tied to reward structures and who see adoption of technology-based teaching as a way to advance careers.
4. The *reluctants* characterized by computer illiteracy or a firm belief that traditional learning models are superior, that new technology may have adverse effects on teaching evaluation, and change is fearful.

Implications of the above four categorizations are that institutions need to know their faculty-mix before beginning any transformation or e-skilling processes (Hagner and Schneebeck, 2001: 5). The fact that so much more new information is being generated and disseminated more quickly than ever before highlights the need for faculty to continue to acquire new skills, develop new

mindsets and practices, expand their knowledge bases throughout their careers, and possess a capacity for continuous learning.

Massification and Diversification: Demand for New Skills

Apart from signaling the need for greater resources and different organization and governance modes, mass education access has meant a marked growth of nontraditional students oriented toward gaining useful skills and knowledge. This growth demands adjusting teaching to serve a greater range of students with diverse needs, aspirations, and academic talents (Trow, 2000: 323). Concerns are that outdated knowledge and ivory-tower curricula repeatedly stifle creative thinking and fail to produce students who can apply academic knowledge to real-life situations.

With increasing diversity of students' needs (especially of mature-age learners) has come new education packages that offer convenient, quality, and low-cost courses. In response to these demands, many higher education providers now offer certificates and short courses that are particularly attractive to adults who face changing employment demands or wish to explore personal interests (Austin, 2002: 122).

Importantly, the knowledge economy is generating a need for emerging skills and knowledge to replace outdated knowledge that has not, earlier, been part of higher education curricula – skills such as initiative and enterprise, information literacy, planning and management skills, capacity for lifelong learning and self-learning (learning how to learn), flexibility in order to adapt to jobs yet to be envisaged, and skills useful for working in multidisciplinary contexts. As the integration of work and learning is now so critical in knowledge economies, employers are increasingly demanding researchers who can integrate knowledge across traditional disciplinary boundaries and demonstrate industry readiness when they graduate. Many universities have now adopted integrative doctoral programs that provide graduates with skills that are transferable to a range of different work contexts (Harman, 2004: 387–388).

The Economic Imperative

Government economic agendas and user-choice ideology, in many countries, have impacted profoundly on teaching values and expectations in higher education systems as the relationship between learner and teacher is becoming more like that of consumer and producer (Bjarnson, 2001: 97). A vice-chancellor of a leading British university argues that university teaching is changing from a tradition based on craft to a model based on industry, where the emphasis is more on developing skills for economic purposes (Bjarnson, 2001: 86). Likewise, students who develop

skills for more instrumental ends have been characterized by Cunningham *et al.* (2000: 3) as earner-learners and just-in-time learners (similar to just-in-time manufacture) who will be able to apply what they have learned immediately in the workforce.

The possibility of mix-and-match courses from a variety of institutions and corporate providers gives the student-as-consumer (Bjarnson, 2001: 89) tremendous power to determine the content and direction of study. Such practices tend to erode the long-held traditional value of teaching for intrinsic worth and self-development. However, the emphasis on continuing professional development and postgraduate provision in professional areas such as law, computing, information technology (IT), business and management, engineering, and languages suits the concept of borderless education.

Building Learning Societies

Emphasis on the value of lifelong learning indicates that teaching and student learning should be focused on the needs of tomorrow (Commonwealth Department of Education, Science and Training (DEST), 2002: ix) as well as on the short-term future. Lifelong learning is particularly valued in developing countries. The Vietnamese Government, for example, acknowledges that there is a need to build a learning society where every effort should be made by all educational institutions to create opportunities for lifelong learning (Ministry of Education and Training (MOET), 2005: 8).

That building learning societies ultimately leads to citizens enjoying a better quality of life and that developing new learning and research skills enhance considerably a nation's development and standard of living, are reinforced by the World Bank. Knowledge and advanced skills are seen to comprise critical determinants of a country's economic growth and standard of living. Learning outcomes are transformed into goods and services and greater institutional capacity, a more effective public sector, a stronger civil society, and a better investment climate result. High-quality, merit-based, equitable, efficient higher education teaching and research are stressed as essential components of this transformation. All countries, whether industrially based or in transition, are seen to benefit from the dynamic of the knowledge economy (The World Bank Group, 2005: 1).

Accountability Demands

Indicators that measure the quality of teaching and learning outcomes are now well established in many higher education systems. Accountability has also become more prominent as new providers with little experience in higher education enter the scene, especially where quality is seen to be threatened.

Implications of accountability are that teaching faculty need to be aware of more formalized procedures that institutions have put in place for measuring learning outcomes and comply with these. Graduate attributes resulting from skills learnt during the undergraduate years are one form of measures used to assess institutional teaching and learning capacity. In Australia, the Review Committee on Higher Education Financing and Policy (West Committee, 1997) suggested seven attributes that a first-degree graduate should have on exit: the capacity for critical, conceptual, and reflective thinking; technical competence and an understanding of the conceptual and theoretical elements of their fields of specialization; intellectual openness and curiosity and an appreciation of the interconnectedness and areas of uncertainty in current human knowledge; effective communication skills in all – reading, writing, speaking, and listening; research, discovery, and information-retrieval skills, and a capacity to use information; multifaceted problem-solving skills and the capacity for team work; and high ethical standard in personal and professional life, underpinned by a capacity for self-directed activity. Encouragingly, the Committee went on to add, "Above all else, however, the successful graduate must be captivated by a love of learning" (West Committee, 1997: 47).

In the UK, in the same year, the Dearing Committee (National Committee of Inquiry into Higher Education (The Dearing Report, UK), 1997) came up with four graduate attributes: communication skills, numeracy, the use of IT, and learning how to learn. In such contexts, expectations are that faculty will work toward ensuring that these standards are met.

Implications for Higher Education Institutions: New Initiatives in Teaching and Learning

It is well acknowledged that good teachers impart the art of and the thirst for learning and unlock the potential of their students who, in turn, will ultimately have an enormous impact on the future cultural and economic life of a nation. In this respect, aspirations of institutions of higher learning have changed little over the centuries (Commonwealth Department of Education, Science and Training (DEST), 2002: v). What has changed, however, is the way that many institutions are now set up to ensure that quality teaching and student learning prevail and are rewarded. Teaching and learning plans are now firmly embedded in most institutional plans and the requirement to demonstrate quality teaching now forms a key element of most tenure and promotion-seeking faculty. Teaching and learning centers that aim to facilitate the highest quality of student learning by instilling into faculty the ability to manage effectively the design, presentation, teaching, and assessment of the subjects for which they are responsible are now part and

parcel of most universities. These centers are typically based on values that support scholarship, research-led teaching, lifelong learning, problem-based learning, e-learning, self-learning, and professional and personal growth through critical reflection and self-evaluation (Australian Vice-Chancellors' Committee (AVCC), 2002a: 2).

Other initiatives now also acknowledge that quality teaching in higher education needs to be identified, recognized, and rewarded. For Australian universities, there is now an explicit separation of teaching and learning funding streams from research streams – changes that will have long-term significance (Dearn, 2006: 39). These changes have been marked by establishment of the Carrick Institute for Learning and Teaching in Higher Education (now the Australian Learning and Teaching Council) to support excellence in teaching and learning, the Awards for University Teaching Scheme, and the Learning and Teaching Performance Fund. To be eligible for the last-mentioned benefit, universities must satisfy the Commonwealth Government that they have met certain minimum standards for learning and teaching.

British higher education has also seen funding initiatives to introduce accredited teaching programs, e-learning, and centers of excellence in teaching and learning. For example, in 2004, the Higher Education Academy was created with the specific intent of providing institutional support for enhancing the learning experience. It acts to provide the sector with access to research, and develop and fund pathfinder projects and networks which bring faculty from different disciplinary groups together with senior institutional managers (Ramsden, 2007: 37). Additionally, some universities in the UK are creating different kinds of teaching and learning centers as the production and imparting of knowledge created within the academy, typically characterized as Mode 1, is no longer seen to be solely the responsibility of universities. Mode 2 knowledge – generated from a variety of sources which transcend traditional boundaries and is more applications generated – now questions the monopoly of Mode 1 (Bjarnson, 2001: 94).

In some transition economies, various policy instruments have been used by the World Bank (2002: 104) to stimulate performance and enhance the quality and relevance of teaching in higher education institutions. These include well-designed competitive funds, accreditation mechanisms, and management and information systems.

A good example provided by the Bank of a successful competitive fund to develop teaching programs is The Engineering Education Fund in Egypt which transformed the traditional engineering degree into more applied programs that link closely with industry. In Jordan, a similar fund is available to teachers in science and technology fields and an operations manual has been devised. In addition, Brazil, Mexico, and Venezuela are developing human capital in science and technology through

competitive funding. In all these funding programs, international peer review experts play a prominent role in assessing the quality of proposals.

In Vietnam, strategies to upgrade the knowledge of teaching staff in universities have been adopted by the Ministry of Education and Training. These include training-abroad programs and relationship building between universities in the same region and overseas so that teachers might experience practices in other universities and other countries. The World Bank is also establishing different kinds of cooperative ventures between universities in transition economies. This encourages universities to expand bilateral cooperation in their regions by co-sponsoring courses, student exchanges, and lecturers sharing their experiences across national and international boundaries (Harman, 2005).

Concluding Comments

While a healthy new culture of professionalism in teaching – similarly termed the scholarship of teaching and learning (Hatch, 2005) – has emerged in higher education, many factors aiding this development have impacted on the values and expectations to which academic faculty traditionally subscribe. The modern academic workplace is now characterized by the move to near-universal student access, greater student diversity, the impact of the digital revolution, globalization, changing economic and societal expectations, tighter competition, greater demands for accountability, new forms of governance with growing corporatization, expanding faculty workloads, industrial demands, and a new labor market for faculty. Austin (2002: 123) adds that fiscal constraint, the emergence of new institutional types, the introduction of postmodern ways of knowing, and dramatic shifts in the nature of faculty appointments have all impacted on the core business of higher education. Most of these changes have been met with institutional responses that now place greater emphasis on the quality of and more distinctive and innovative approaches to teaching and learning at both undergraduate and postgraduate levels.

Implications are that the newly developed teaching and learning culture needs to be sustained with a coordinated effort by institutions in areas of quality control, staffing and teaching quality, and more innovative curricula. Research activity of teaching faculty also needs to be strengthened and their knowledge continually updated. As one professional higher education body stresses, if high-quality learning outcomes are to be achieved, institutions of higher learning need to possess a teaching and learning culture that acknowledges the value of teaching, promotes scholarly inquiry and reflection, provides opportunities for professional development of faculty in their disciplines as well as in teaching methodology,

has supportive policies and practices that attract faculty with a strong commitment to effective teaching, and is able to promote or reward faculty for teaching excellence (Australian Vice-Chancellors' Committee (AVCC), 2002b: 10).

Importantly, however, as higher education institutions respond to changing environmental pressures that continue to threaten traditionally held faculty values and expectations and, ultimately, the core business of higher education, institutional managers have a special responsibility to uphold the integrity and independence of teaching faculty and to foster, nurture, and safeguard those enshrined values and expectations that undergird the very essence of the academic enterprise.

Flexible Learning in Higher Education

S Alexander, University of Technology Sydney, Sydney, NSW, Australia

© 2010 Elsevier Ltd. All rights reserved.

The term flexible learning was largely unknown prior to the 1990s, became a buzzword in higher education during the 1990s, and has largely been replaced by other terms, such as blended learning, over the course of the 2000s. This article provides an overview of the context in which flexible learning became one of the driving forces of higher education during the 1990s, its successes and consequences, and the changing language of the discourses over the last decade.

In this article, the term flexible learning is taken to represent a range of approaches to meet the varied needs of students in contemporary social contexts. The needs of students include independence in terms of time and location of learning, and the availability of some degree of choice in the curriculum (including content, learning strategies, and assessment). The approaches taken to meet these needs include the use of contemporary information and communication technologies to support a range of learning strategies, and other learning strategies such as learning contracts.

Flexible Learning and the Context of Higher Education

Although the term flexible learning began to emerge in higher education discourses during the early part of the decade, its high watermark was the mid- to late 1990s. It was no accident that time period coincided with the release of the first popular web browser, NCSA Mosaic, in 1994. The subsequent rapid adoption of the Internet gave rise to predictions of the end of higher education as we knew it, and in its place, the emergence of new providers such as private, online, for-profit institutions, and media and communication organizations. It was widely believed that these providers had ready access to content which could be beamed out to students all over the world who would learn about theories firsthand from those who had conceived them.

Others, such as Cunningham *et al.* (1997), studied the potential for this new era of higher education to be realized, but concluded that “the ‘threat’ of communication networks had been overstated” (p. 207). Despite this, the apprehension remained and indeed underpinned much of the activity of the particular discourse where the term flexible learning was used interchangeably with the use of information and communication technologies.

During that period there were many who believed that higher education was in crisis, based on a number of factors including:

- the move to mass higher education;
- escalating costs of provision; and
- lack of access to education.

Thus, the arrival of the Internet was very attractive to university administrators such as Daniel (1997) who wrote that “technology provides the most fertile ground for growing these key ingredients of university renewal: lower costs and unique attractions” (p.14).

Flexible Learning: Toward a Definition

The *Oxford Dictionary* (2005) reports the word flexible as being derived from the Latin word *flexibilis*, from *flectere* meaning to bend. Its definitions include “to be easily modified to respond to altered circumstances” and “capable of bending easily without breaking.” Both of these meanings are relevant to the descriptions in this article about the ways in which flexible learning has evolved as a consequence of the changing circumstances in which higher education found itself operating during the 1990s, and the ways in which it has been implemented without breaking the higher education system.

Despite the fact that there has been much discussion about flexible learning in the higher education community, this discussion has invariably focused on the meaning of the term itself, rather than its implementation. The consequence has been that a shared understanding of what it means in practice has not evolved. This imprecision has contributed to its status as a mantra in higher education (Cloonan, 2004), where different stakeholders ascribe meanings to suit their own purpose. Vice-chancellors, for example, were said to be enthusiastic about flexibility in learning and teaching because of “a perception that flexible delivery is more effective and efficient in terms of getting teaching resources to students” (Bigum and Rowan, 2004). Managers and politicians are said to focus on “effectiveness and efficiency and cut price solutions to the delivery of a service” (Nunan, 1996: 2), while some faculty see it as a path to improving the experience for their students and/or as a path to certain promotion, as its use is deemed to have the approval of management. Thus, as expressed very well by Edwards and Nicoll (2000: 130)

“flexibility in higher education is not a single phenomenon but has a range of possible meanings and practices.”

Notwithstanding the lack of clarity around a shared meaning, there has been almost universal acceptance of flexibility as a positive attribute – good for students as well as good for the university. As a result, references to flexible learning in the strategic plans of universities and/or its teaching and learning plans and policies became common during the 1990s.

The next section discusses the range of meanings of flexible learning, the first of which is of flexible learning as synonymous with the delivery of education through the use of new information and communication technologies.

Flexible Learning as Flexible Delivery

This definition, the emergence of which coincided with the development and release of multimedia-capable computers and the Internet in the early 1990s, focuses on the mode of delivery as the most important aspect of flexible learning. At its most minimal, the term flexible delivery is taken to mean any form of delivery where students have a choice of study mode (Roberts, 2001: 22). This is said to give students choice of location of study (as the course materials are delivered to them), and time at which they study, thus widening access to higher education. The design of the materials may also facilitate students’ control of learning through choice of media (e.g., text vs. video), and pathway through the content.

It was also common to associate the use of flexible modes of delivery with traditional distance-education practices where flexible learning has replaced distance education as a means of “servicing the needs of geographically distant or remote students” (Kirkpatrick, 1997: 160).

As well as the focus on the delivery of course materials, for some there has been an assumption that flexible delivery means the use of advanced learning technologies (Kirkpatrick, 1997; Roberts, 2001; Sadler-Smith and Smith, 2004; Collis and Moonen, 2002).

Information and Communication Technologies

The development and release in the early 1990s of multimedia-capable computers and the Internet came at the very time when the crises of higher education were being widely discussed and thus became the catalyst for many of the changes that ensued. University administrators and academics alike were attracted, as many commentators noted, like moths to the flame to use of the new technologies which were seen as the panacea to the contemporary issues they faced.

In one the largest initiatives of its kind in the world in higher education, the UK government provided

significant funding for the Teaching and Learning Technology Programme (TLTP) with the aim of “making teaching and learning more productive and efficient by harnessing modern technology” (Teaching and Learning Technology Program, 1996). In Australia, successive national government committees, such as the Committee for the Advancement of University Teaching (CAUT) and the Committee for University teaching and Staff Development (CUTSD), offered grants to institutions for the development of projects to improve teaching and learning. Although not specifically targeting the use of new information and communication technologies, the reality was that a significant proportion of the projects submitted involved the use of the new technologies.

Early developments in the use of new technologies for flexible learning included the development of CD-ROMs (CD-ROM, compact disk, read-only-memory) containing course materials in the form of lecture notes, databases, animations, simulations, and collections of still and moving images, and sounds. Some of the learning materials were said to be interactive when there was a degree of learner choice through, for example, following hypertext or hypermedia links, and through multiple-choice selections on screen. Other programs used more sophisticated interactive multimedia software to provide that user choice. Although still in use today, especially in locations where the Internet is unavailable, slow, or unreliable, CD-ROMs have largely been replaced by the Internet as a delivery mechanism.

From the late 1990s until the present day much of the focus of higher education’s use of the Internet has been through the deployment of specialized software variously referred to in different countries as Course Management Systems, Virtual Learning Environments, and Learning Management Systems. These tools have become almost ubiquitous in higher education institutions in First World countries. Although this software had its origins in developments in computer-mediated conferencing in the mid-1970s, it was rarely used outside conventional distance-education higher education institutions until the mid-1990s. Early commercially available software included FirstClass, Lotus Notes, Top Class, Blackboard, and WebCT. More recently, there has been a significant move toward the adoption of open-source software such as Moodle and SAKAI.

Those tools have been supplemented by more recent technological developments such as the mobile phone (including the iPhone), Personal Digital Assistants (PDAs), and Personal Access Devices (PAD), which, when used with ubiquitous wireless communications with high bandwidth, enable what is now known as m-learning or mobile learning. Students may use these devices to access new mobile versions of Learning Management Systems, and to download and listen to or watch podcasts (audio recordings) and vodcasts (video recordings) of lectures

available on Internet sites such as iTunesU and YouTube, thus facilitating access to content at a time and location convenient to them.

Some universities have opened up the content of their courses to anyone with Internet access. The most famous of these is the Massachusetts Institute of Technology (MIT) OpenCourseWare initiative which, at the time of writing, has 1900 courses available online complete with syllabi, course materials, assignments, and in some cases, videos of lectures.

The degree of interactivity afforded by the earlier technologies was minimal compared to that available in the late 2000s. The rapid adoption of social networking tools such as Facebook, LinkedIn, Twitter, and MySpace have provided opportunities for the proliferation of user-controlled networks of 'friends' sharing photos, videos, blogs, and personal profiles (Mason and Rennie, 2008). Third-party tools, such as Flickr (photos) and del.icio.us (social bookmarking), can be integrated with personal profiles. Students form special-interest groups (which share common pages and message boards and may be private or public) within social networking sites which, in the higher education context, are used for diverse activities such as group homework problem solving, and general academic support. However, tempting it is for universities to make use of these sites, students express a strong preference to be left alone within them (Aleman and Wartman, 2009). Each of these tools does, however, support learning which is time and location independent.

In addition to the growing use of these Web 2.0 tools, there has been the increased sophistication of virtual worlds software (such as Second Life) which enables learners to inhabit computer-generated worlds using a computer-generated self known as an avatar. While some higher education institutions have reproduced real-life classrooms in which lectures take place, others have taken the opportunity to design qualitatively different learning experiences for students.

Effectiveness of Information and Communication Technologies for Flexible Delivery

Early evaluations of the effectiveness of these innovations found some evidence of benefits of the use of these new technologies to higher education. In a large-scale national study of 104 projects, the majority of which had developed computer-based learning/interactive multimedia products, Alexander and McKenzie (1998) found that for students there was some evidence in some projects of:

- improved quality of learning;
- improved productivity of learning;
- improved access to learning; and
- improved student attitudes to learning.

Examples of positive learning outcomes which resulted from students' use of information-technology (IT)-enabled projects included:

- opportunities for students to interact with others to gain a more sophisticated and global understanding of complex international political issues;
- improved understanding of concepts which students are known to have difficulty with in a range of disciplines, through the use of interactive multimedia animations, simulations, and microworlds;
- enhanced communication between part-time students and their lecturer, through the use of the Internet;
- the acquisition of information, such as language learning, where a high component of factual recall is required; and
- the facility for students to assess their own learning of concepts, through computer-based qualitative and quantitative assessment modules.

The benefits for faculty involved in the projects were found to include: job satisfaction flowing from the improved learning of their students; an improved understanding of student learning, student needs, and difficulties; an improved understanding of their own discipline area; enhanced enthusiasm for teaching; and, for some, an increase in their own personal profile.

For departments or faculties, the major benefit was the faculty development opportunities afforded by faculty member's participation in the projects. This sometimes led to significant change in teaching approach in areas other than the designated project, as faculty developed enhanced understanding of learning and teaching. For some departments, the project outcome helped faculty to cope with decreased resources, without a commensurate decrease in the quality of teaching. Finally, the teaching profile of some departments was raised as a result of external recognition of the innovation.

The study emphasizes the fact that it is not the presence of information and communication technologies by itself that accounts for enhanced learning, rather it is the design of the learning experience, the support of the learners undertaking that experience, and the students' perception of the context in which they learn.

In a more recent study of the use of lecture recording technologies used across four universities, Gosper *et al.* (2008) report that students perceive the following benefits of lecture recording technologies in improving their learning: picking up on things they missed in class; to revise for exams; to revisit complex material, ideas, and concepts; and to work through material at their own pace.

Faculty have expressed two main concerns around the use of these lecture recording technologies: that students would not pace their use of these technologies, resulting in the need to cram learning at the end of the semester,

and/or that they would stop coming to lectures. This fear was somewhat confirmed by the Gosper *et al.* study in their report that only approximately 50% of students listened to the recordings on a regular basis and almost 40% listened to several weeks at the one time. Of the students who no longer attended lectures, as reported in the study, 68% said they had chosen not to attend because they could learn as well from the recorded lectures as they could from the face-to-face lectures.

Critique of Flexible Delivery

Alongside the benefits ascribed to flexible delivery using the information and communication technologies discussed above, there are also significant challenges. First and foremost, there remain, despite the rhetoric about the high levels of IT literacy of generations X and Y, whole cohorts of students who do not have sufficient levels of IT literacy to access the course materials. Adequate technical support is essential to these learners in achieving successful learning outcomes.

A second factor is that of students reporting insufficient time to devote to the course. Mason (2001) famously proclaimed that “time is the new distance,” since lack of time, rather than long distance, has become one of the primary reasons that students withdraw from courses. The self-discipline required to undertake a course that has been delivered to the door is far greater than that required by students whose attendance requirement at face-to-face lectures serves as a time-management strategy. It is often only the experienced learners who have the time-management skills to undertake such self-directed study, yet the majority of students in the higher education system are undergraduates, who have come directly from high school, and who are studying full time.

A third critique has centered around the degree to which information and communication technologies are in fact innovative. Many authors have pointed to the long-term existence of books and papers which have for many years facilitated learners’ access to the content of learning in a way that is time and location independent. These authors also point to the fact that learners have control over the order in which they read printed material, thus facilitating learner control over the content of learning that is held up as a unique feature of information and communication technologies. Others, such as Alexander and Boud (2001), argue that the potential for the use of information and communication technologies to enhance learning has been lost because faculty have, by and large, simply used the new technologies to automate existing didactic practices. Much of what passes for innovation in learning is little more than lectures that have been turned into podcasts and vodcasts, and textbooks which have been repurposed as websites with electronic page turning for example.

The view of flexible learning described above which equates flexible learning with the use of technologies for flexible delivery of teaching/learning has been criticized for being a particularly narrow view of flexible learning. It does, nonetheless, remain a prominent discourse in both everyday discussions and promotional literature.

There are, however, other views of flexible learning which are discussed below.

Flexible Learning as an Educational Philosophy and a Political Position about Education

Another view of flexible learning differs from that of flexible delivery because it foregrounds the students’ learning and their experience of education as paramount, rather than the features of the delivery mechanisms as have been described above. As Nunan states:

Part of the attraction of flexible learning for many educationists is the belief that it enables students to use desired learning strategies which involve them in constructing meaning, and thereby educationists link the term with student centred learning, self-directed learning, activity learning, problem based learning . . . and the like. (Nunan, 1996: 5–6)

While the above definition focuses on particular views of learning as underpinning the design of flexible-learning strategies, others focus on providing options for students. In this view, students, rather than faculty, choose the dimension of learning from a range of options.

Flexible Learning as Providing Access and Democratization of Processes of Teaching and Learning

This view of flexible learning relates to democratization of learning by improving access to higher education, thus challenging the power relationships said to exist between teachers and learners (Nunan, 1996: 1). Those who now have increased access to higher education include people who live in geographic locations which do not have physical universities. It also includes a significant group for whom, despite living in reasonable proximity from a university, work and family commitments or illness and disability previously precluded their attendance on campus. A positive consequence of increased access is a corresponding increase in diversity of the student body.

Having gained access to higher education, this group is said to no longer be subject to learning which is teacher centered, having opportunities instead to control and direct their own learning.

Flexible Learning as a Set of Strategies in Response to New Challenges in Teaching and Learning and Changing Student Needs

The challenges of higher education that are said to be new include: a decrease in traditional sources of funding for many higher education institutions; evidence that students are undertaking longer hours of paid work to finance their studies; and increased numbers of students seeking to change careers.

The response of many higher education institutions to the decrease in traditional sources of funding has been to increase class sizes. This does not necessarily lead to a less personalized learning experience for students, however, as faculty draw upon many contemporary innovations in learning and teaching strategies to offer a degree of flexibility in content and assessment of learning, and to provide individualized feedback.

There is mounting evidence that the availability of podcasts and vodcasts has made it easier for students who are unable to attend class because of work commitments to continue their enrolment. The same students also make use of the range of tools (e.g., discussion boards) which form part of the learning management systems which have now become ubiquitous.

For those students seeking a change of career, flexible learning can be designed to provide an experience which is tailored to their individual needs, which takes account of their background and existing knowledge, and which can be undertaken in a workplace. The majority of these students are more mature in age, more experienced as learners, and bring with them much existing knowledge. These learners may take advantage of flexible strategies such as individual learning contracts (affording a degree of learner choice of both content and assessment), and work-integrated learning opportunities.

A Critique of Flexible Learning

The major criticism of flexible learning centers on its alleged flexibility. Releasing students from the need to attend regular on-campus classes, and instead making it possible for them to learn at their own pace using flexible learning strategies transfers the time-management responsibility entirely to students, some of whom are not yet able to cope with this degree of flexibility. Less-experienced (and usually younger) students have not yet learned to pace their learning, often leaving the majority of activities to the last week/s of semester. This results at best in learning which is not as deep as it might otherwise have been, and at worst in stress and failure. Some argue the case for more inflexibility in learning for such students (Edwards and Nicoll, 2000),

where this term is not necessarily assigned a negative connotation.

Similarly, giving students the responsibility for negotiating the content of learning places them in a situation where they are said to require the symbolic-analytic literacies of “interpretation, analysis and communication of information – as well as capacities of critique, problem-solving, flexibility, teamwork, communication and self-direction” (Edwards *et al.*, 2002: 202). Learners who develop these are said to go on to become flexible lifelong learners.

A second significant area of critique lies in the particular discourse that equates flexible learning to the use of information and communication technologies. For some, the mere presence of these technologies somehow magically improves the learning experience. Often, however, they merely automate existing teaching practices such as lectures in the same way that earlier innovations were seen as automations of previous technologies (e.g., the telephone was conceived of as an automated telegraph). As noted earlier however, it is the design of the learning experience using the technologies that accounts for any improvements in learning rather than the presence of technologies.

Although the problems have now largely been resolved, the early years of flexible learning using information and communications technologies involved significant technical problems for many aspiring students. Problems included lack of bandwidth, unreliable networks, difficulties loading specialist software, and printing failures, to name just a few. For those who did not have access to adequate technical support, access to higher education was inflexible.

From Flexible Learning to Blended Learning

In recent times there has been an increase in use of the term blended learning such that its boundary with flexible learning has now become blurred. Early uses of the former suggested a simple combination of face-to-face learning experiences with online activities. More recently, however, the term has evolved to include dimensions which embrace both individual self-paced and collaborative learning activities, structured and unstructured learning experiences, and blending of both custom and off-the-shelf learning content (Khan, 2007: 7). The goal is to use these blends to create flexible learning experiences for students.

Exhibiting further similarity to the evolution of flexible learning however, there appears to be no single agreed definition of blended learning. In their review of over 300 studies of blended learning Sharpe *et al.* (2006) noted that “Although difficult to define, the term ‘blended learning’ is finding acceptance among higher education staff. We suggest that the advantages of the term include its poor definition – which allows staff to negotiate their own

meaning – the implication of the protection of face to face teaching, and the implication of designing for active learning.”

Conclusion

Students have much to gain from the new order of higher education where they need no longer sit passively in lecture theaters and tutorials at a time that suits the university, learning content that has been determined in the absence of considerations of what they already know, using approaches that lead to memorization rather than deep understanding of content, nor be assessed in ways that have no parallels with the world of work they are about to enter. Likewise, students, who have previously been unable to access higher education for a range of reasons, are now able to do so.

The significant expertise that has developed in the design of learning experiences, both face to face and online, means that there is the potential for a high-quality learning experience for all who seek out higher education.

Innovation in Teaching and Curriculum Design

J M Dearn, University of Canberra, Canberra, ACT, Australia

Innovation in Higher Education

Higher education is usually known more for its traditional approaches to teaching and curriculum than for innovation. However, recent years have seen a widespread change, both in what is taught in universities and colleges and how teaching takes place. The pressure for change has come from two main drivers. First, a growing realization that traditional teaching methods are relatively ineffective for many students, and second, the changing demands being made on higher education resulting from the changing nature of work and knowledge, the changing nature of the student population, and the emergence of new information and communication technologies. Notable developments have been the growth of academic-development units in colleges and universities which have been established to support staff in their teaching and promote educational innovation, the proliferation of books and resources on teaching methods, and the emergence of national institutions devoted to supporting innovation in higher education.

Nevertheless, despite the diversity of approaches to both teaching and curriculum design now seen in higher education, the view persists, that higher education has been slow to respond, at least in relation to changes that have taken place in other community sectors.

Recent national reviews of higher education systems have made a clear connection between higher education, and both economic growth and social development and have called on higher education to greater embrace innovation. The Australian 2002 national review of higher education, *Higher education at the Crossroads*, stated “We need a system that produces graduates who can think critically and have adaptable skill sets as well as technical expertise. In many ways, that will require significant transformation of approaches to curriculum and pedagogy to stimulate and stretch students and accommodate their varying needs” (Department of Education, Science and Training, 2002: 14).

The USA 2006 national review of higher education, *A Test of Leadership: Charting the Future of U.S. Higher Education*, also commented on the importance of higher education saying “And for the country as a whole, future economic growth will depend on our ability to sustain excellence, innovation, and leadership in higher education” (Spellings, 2006: 1). The review concluded that “Too many of our colleges and universities have not embraced opportunities to be entrepreneurial, from testing new

methods of teaching and content delivery to meeting the increased demand for lifelong learning” (Spellings, 2006: 4–5) and “Institutions as well as government agencies have failed to sustain and nurture innovation in our colleges and universities. The commission finds that the results of scholarly research on teaching and learning are rarely translated into practice” (Spellings, 2006: 15). Any understanding of innovation in teaching and curriculum design in higher education must consider not only the changing demands being made on higher education by government and employers, but also the way these forces are interpreted, acted on, and disseminated within the academy.

Innovation and the Importance of Context in Higher Education

While there is evidence of considerable change occurring in higher education, the concept of innovation is complex. For example, what is designated an innovation could be a general educational concept, such as the social construction of knowledge, which could be implemented in a variety of different ways in different teaching contexts. On the other hand, it could be a new procedure, such as a laboratory process in a science class, which needs to be implemented prescriptively. Furthermore, it needs to be agreed whether it is enough for an idea to be new for it to be called an innovation or whether it also has to be shown to be effective in achieving its stated objectives. Even if a new idea is effective in achieving its objectives, it can be argued that it needs to be adopted by somebody other than the person who first introduced it, to be designated an educational innovation. Higher education is replete with examples of innovations that have not gone beyond the original developer. A particular problem is that many educational innovations are dependent for their effectiveness on the particular context within which they are implemented, be it the individual teacher, the discipline, or the type of institution. Even innovations that have been shown to be highly effective in one particular context may not work in another.

Even the concept of new is problematical. For example, a teaching practice such as case-based teaching would be considered innovative in an undergraduate science program but is a commonplace approach to teaching in graduate law programs. Similarly, what would be considered innovative teaching in a traditional university might

be a common practice in a newer institution. To add yet another layer of complexity, for each of these types of innovation, the change can be regarded as novel or an adaptation or modification to an existing innovation.

The importance of context for innovation is also seen in cross-cultural comparisons where approaches to teaching and what is regarded as appropriate pedagogy and curriculum vary markedly between different countries. Finally, it is worth noting the importance of context at the level of the individual where the adoption of a familiar approach to teaching might be seen for some individuals as highly innovative. In part, this will reflect their underlying beliefs or perspectives about teaching and learning. There is a diversity of different models of teaching perspectives but the typology developed by Daniel Pratt will serve as an example. His model recognizes five different teaching perspectives based on the underlying beliefs and values held, implicitly in most cases, by teachers, which he labeled as transmission, apprenticeship, developmental, nurturing, and social reform. What approaches to teaching and curriculum design are implemented by individual teachers, and consequently which will be regarded as innovative, will depend in part on the particular perspective of their own teaching.

The contextual nature of innovation in higher education does not negate the usefulness of the concept but it does mean that judgments about whether a change is innovative can only be made in the context of the discipline, the type of institution, the culture, and the teaching perspective of the individual teacher as well as what the innovation was attempting to achieve. However, despite these problems, the persistence of the concept of innovation in discussions about higher education is indicative of both the level of change occurring in our colleges and universities and, more importantly, the need for change.

Types of Innovation in Higher Education

It is useful to recognize different types of innovation in higher education. First, some innovations attempt to improve the quality of student learning outcomes based on new ideas emerging from our understanding about the nature of learning. Second, innovations may be aimed at developing qualitatively new types of learning outcomes, reflecting, for example, the changing nature of work and society. Third, innovations may be attempting to increase access to higher education by different groups of students. Fourth, innovations may have as their aim the amelioration of adverse external factors such as the reduced availability of funding or increased class size. Finally, innovations may be focused on exploiting the potential of new information and communication technologies, the Internet being a prime example. Indeed, the impact that technology has on higher education is so great that for

many, educational innovation is synonymous with using educational technology.

These different types of innovation are not, of course, mutually exclusive. For example, an attempt to cope with increased class size by making students more independent of the teacher for their learning might, if somewhat fortuitously, improve the quality of student-learning outcomes. Similarly, teaching innovations using information and communication technologies are opening access to higher education to students who had previously been unable to attend regular classes on campus.

Innovations in higher education take many forms, each with their own issues related to support dissemination. Andrew Hannan and Harold Silver in their book *Innovating in Higher Education: Teaching, Learning, and Institutional Cultures* proposed a number of different types of innovation including those initiated by individuals, those initiated by discipline associations or professional bodies, institutional initiatives, and systemic initiatives responding to system-wide policy changes. The way innovations are perceived, disseminated, taken up, and implemented will differ in each case.

Innovation, Lone Rangers and Systemic Change

Innovation in higher education has for a long time been the province of individuals, the lone rangers, to quote Tony Bates' memorable term, a reflection of the particular culture of higher education where individual academic staff typically enjoy a relatively high level of autonomy over both what they teach and how they teach. However, the recognition-and-reward systems found in colleges and universities typically favor achievements in research rather than teaching, and staff wishing to introduce teaching and curriculum innovations frequently encounter significant barriers and even opposition.

There have, of course, been notable examples of successful innovations being introduced by individuals and as Hannan and Silver (2000: 32) note "It seems that innovators will take on extra work, learn new skills, court unpopularity with other staff and take risks with their own careers so long as they feel that by doing so they can improve the quality of their teaching, and/or, if they feel that circumstances are such that they have no choice but to depart from their old methods to cope with new demands."

However, even effective innovations have a poor record of being adopted by other people and being sustained in the absence of the original innovator. This has led in recent years to a recognition that in order to bring about sustained change, innovations need to be adequately funded, linked to the strategic goals of institutions, have the support of senior management, and be

supported by effective leadership and change management processes. The need for a more systemic approach to innovation was recognized in the influential 2002 US report *Greater Expectations: a New Vision for Learning as A Nation Goes to College* by the Association of American Colleges and Universities which noted “The academic world . . . as the repository of accumulated knowledge, functions as a conservator, slow to change in fundamental ways. Thus, new ideas appear as pockets of innovation, taking root at the margins of institutions, and maintaining themselves by the patient effort of a few dedicated individuals. These innovations only slowly permeate the mainstream” (American Association of Colleges and Universities, 2002: 19). The report concluded “The next step is to create from these isolated innovations a comprehensive movement for change across the higher education landscape” (American Association of Colleges and Universities, 2002: 12).

Initiatives such as the Australian Learning and Teaching Council, the Higher Education Academy in the UK, and Pew Foundation in the USA are examples of attempts to introduce large-scale system-wide sustainable change.

The Scholarly Basis for Teaching Practice in Higher Education

While there exists a considerable body of research literature on learning and teaching in higher education, it is largely disconnected from classroom practice, a reflection, in part, of the lack of any required systematic preparation for the teaching role in higher education. A notable recent development in higher education is the emergence of discipline-based initiatives such as those of the UK’s Higher Education Academy, the Carnegie Foundation, and the Australian Learning and Teaching Council where there is a recognition of the critical role played by disciplinary cultures in teaching and the different approaches to knowledge creation and inquiry in different disciplines and professions. There is no doubt that university or college teachers steeped in the traditions of their disciplinary field, be it physics or law, will respond more positively to initiatives aimed at improving student learning if these are framed within the culture and language of their discipline.

However, despite the many initiatives that are taking place to better support the development of teachers and teaching in higher education through staff-development programs and reward schemes such as fellowships and prizes, much teaching practice is still based on the individual teacher’s own personal experiences and falls far short of what might be regarded as evidence-based practice. In particular, there is a dearth of studies that critically evaluate the effectiveness of different teaching practices or interventions on student learning. One of the most

interesting and effective recent developments in higher education has been the introduction of what is called classroom assessment developed by Tom Angelo and Patricia Cross. Classroom assessment involves teachers investigating what and how their students are learning as teaching takes place, typically through short questions given out at the end of each class, as opposed to seeing the outcomes of student learning at the end of teaching when there is no longer the opportunity to change teaching practice. An interesting recent variant of classroom assessment is the use of electronic feedback or polling systems in the classroom which can provide immediate feedback to the lecturer as the class progresses. Combined with other teaching approaches, such as peer instruction, this can make for a very powerful learning environment focused on student learning that can be used even in large introductory undergraduate classes. A good example of this approach is the work of Eric Mazur in introductory physics classes.

Classroom assessment can be seen as a part of a growing interest in classroom research and the scholarly underpinning of teaching in higher education, reflecting Boyer’s designation of the scholarship of teaching as one of the four types of scholarship within the academy. It is still early days, but the growing interest in what is being called the scholarship of teaching and learning (SoTL) has the potential to strengthen and enhance teaching practice in universities and colleges and, while not being pedagogic research as such, offers an effective approach for improving student learning.

A Focus on Student Learning

Perhaps the most significant idea that has influenced innovation in teaching and curriculum design has emerged from the realization that teaching as an activity does not always lead to learning, or at least the learning that was intended by the teacher. As Thomas J. Shuell explained “If students are to learn desired outcomes in a reasonably effective manner, then the teachers’ fundamental task is to get students to engage in learning activities that are likely to result in their achieving those outcomes . . . It is helpful to remember that what the student does is actually more important in determining what is learned than what the teacher does” (Shuell, 1986: 429).

The implications of this proposition are significant and together with the work of educational researchers, on student approaches to learning, such as Keith Trigwell, Michael Prosser, Paul Ramsden, Noel Entwistle, Roger Säljö, and Ference Marton, underlie the major shift of focus from teaching to learning that underpins much of the innovation that has been undertaken in higher education in recent years.

A work that has been particularly influential in changing educational practice in higher education is *From Teaching to Learning - a New Paradigm for Undergraduate Education* by Robert Barr and John Tagg. In it, they describe the shift from what they call an instruction paradigm of higher education to a learning paradigm. Under the instruction paradigm, knowledge is seen as being transferred from teachers to students and there is a focus on covering content. Under the learning paradigm, the role of the teacher is to facilitate students construct their own knowledge and there is a focus on student learning and understanding.

The term active learning, above all others, best represents the type of innovations that reflect the shift in perspective from the instruction paradigm to the learning paradigm of teaching. The term, which was popularized by Charles Bonwell and James Eison, is used to describe anything that students do in the classroom other than passively listening to an instructor talk and is one of the principles in the very well-known *Principles of Good Practice in Undergraduate Education* of Arthur Chickering and Zelda Gamson.

Active learning activities are many and varied and have been implemented in a wide diversity of contexts including traditional large lecture theaters. Typical approaches include introducing into the classroom activities like writing, brainstorming, think-pair-share, problem solving, role playing, games, and debates, approaches which not only require a high level of student interaction but also provide students with immediate feedback on how effectively they are learning. The systematic use of these techniques is seen in teaching approaches such as inquiry-based learning, case-based learning, problem-based learning, and scenario-based learning. These learner-centered approaches to teaching allow students to integrate theory and practice and apply their knowledge and skills while engaging with issues and problems. While initially popular in medical curricula, inquiry-based approaches to student learning are gaining wide acceptance across the disciplines.

Student Approaches to Learning

While much of the research that has been conducted into student learning in higher education remains unknown to university and college teachers, the research on student approaches to learning has had a major impact. Studies on how students approach their learning has revealed one of two basic patterns. Students who adopt a surface approach to their learning focus only on the memorization of information, treat assessment tasks as an external imposition, and are unreflective about their purpose or strategy for learning. On the other hand, students who adopt a deep approach to learning have an intention to understand,

examine the logic of arguments, vigorously interact with the content, and relate new ideas to previous knowledge. The consequences of these two approaches are profound since a surface approach to learning is associated with a limited retention of knowledge and a failure to recognize key ideas, distinguish principles from examples, or gain an overview of a topic.

These two approaches to learning clearly describe characteristics that most teachers in higher education would wish to either enhance or reduce. However, in contrast to what is sometimes thought, surface and deep are not characteristics of students themselves but describe the way students interact with teaching in a particular context. A given student may adopt a surface approach to his/her learning in one teaching context and a deep approach in another. Significantly, research has shown which characteristics of a teaching environment are associated with students adopting one approach or another. For example, the characteristics associated with students adopting a deep approach to their learning include a strong motivational context where there is ownership of learning by students, where there is a high level of learner activity, and where there are interactions with other students through discussion. These findings can be used as the basis for developing a wide range of innovative and effective approaches to teaching.

The Curriculum in Higher Education

Depending on how the curriculum is defined, it can be seen to have a number of dimensions – not only content but also structure and planned student experiences. However, in marked contrast to teaching, the concept of curriculum, *per se*, has received relatively little attention in higher education. One of the few recent books on the curriculum in higher education by Ronald Barnett and Kelly Coate begins “Higher education is ever more important to increasing numbers of people. And yet, despite all this growth and debate, there is very little talk about the curriculum. What students should be experiencing is barely a topic for debate. What the building blocks of their courses might be and how they should be put together are even more absent from the general discussion. The very idea of the curriculum is pretty well missing altogether” (Barnett and Coate, 2004: 1).

In 1985, the Association of American Colleges report, *Integrity in the College Curriculum*, put it even more bluntly, “As for what passes as a college curriculum, almost anything goes” (Association of American Colleges, 1985: 2). The *Imaginative Curriculum Project* of the UK’s Higher Education Academy is a notable exception. This project takes a broad view of the curriculum and sees the concept as including what is to be learned, why it is to be learned, how it is to be learned, and when it is to be learned.

However, irrespective of what is included under curriculum, the most important distinction to be made is the curriculum as planned versus the curriculum as experienced by the learner.

The notion of a set of overall learning outcomes applying to the extended period of study typical of the undergraduate degree is widely held in higher education. Learning in universities and colleges has traditionally taken place over an agreed time period, typically 3 or 4 years for an undergraduate degree. Within this time period, learning occurs with a rhythm determined by the institution consisting of classes during the week, teaching weeks over a semester or term, and semesters or terms over a year. In Europe, there is currently an attempt to standardize the time periods over which learning in higher education takes place under what is known as Bologna process where the bachelor, masters and doctoral cycles are to take 3, 2, and 3 years respectively.

At the same time, we are currently seeing the emergence of very different models of teaching where learning can be compressed or fragmented and more under the control of the learner often facilitated by information and communication technologies. One can see these developments, often described as flexible learning, as a move to a model of student-centered just-in-time learning and away from the traditional just-in-case model of higher education. Even within traditional models of higher education, the increased modularization of units of study and the increasing tendency for students to combine study with work is resulting in a more fragmented and a less-integrated learning experience. The impact of these developments on the achievement of the traditional learning outcomes of higher education remains to be seen.

Curriculum Design in Higher Education

If the notion of the curriculum in higher education is problematical, this is even more the case for curriculum design where whole-degree programs and their constituent parts are planned. As the influential American Association of Colleges and Universities 2002 report *Greater Expectations* put it “The fragmentation of the curriculum into a collection of independently “owned” courses is itself an impediment to student accomplishment, because the different courses students take, even on the same campus, are not expected to engage or build on one another. Few maps exist to help students plan or integrate their learning as they move in and out of separately organized courses, programs, and campuses. In the absence of shared learning goals and clear expectations, a college degree more frequently certifies completion of disconnected fragments than of a coherent plan for student accomplishment” (American Association of Colleges and Universities, 2002: 10).

A powerful idea that is influencing teaching and curriculum design in higher education is that of constructive alignment proposed by John Biggs. The basic concept is that there should be alignment of (1) the intended learning outcomes, (2) the learning and teaching activities designed to facilitate those learning outcomes, and (3) the ways in which the learning is assessed. This might sound like common sense, but in many cases the particular pedagogy used by a teacher, such as a lecture, is inappropriate for facilitating development of the intended learning outcomes and the assessment tasks given to students do not address the learning outcomes. For example, if an intended learning outcome is related to the skills of learning to work as a member of a team, then the teaching must involve practice at working in a team and the assessment of this learning must directly involve an assessment of capacity to work in a team. Ensuring alignment between learning outcomes, pedagogy, and assessment, is emerging as one of the most effective approaches to improving learning and teaching in higher education which has traditionally put great emphasis on didactic instruction and written exams.

The increasing role of information and communication technologies in both the preparation and delivery of teaching materials has introduced an element of enforced curriculum design though not always within the context of a coherent explicit educational model.

Innovation at the Level of the Whole-Degree Program

Teaching models such as problem-based learning, case-based learning, and collaborative learning used in individual units of study can become the central feature of teaching for the whole-degree program or even institution. However, teaching innovations at the level of whole-degree program are much harder to implement than innovations at the level of the unit of study. Degree-program initiatives require considerable coordination and planning, something often hard to do given the high level of autonomy and independence that characterizes the work of most teachers in higher education who typically have a higher degree of ownership of individual subjects. Yet, it is the learning outcomes of the whole-degree program that are the most significant aspects of higher education from the perspective of the student. Alverno College’s pioneering work on integrating curriculum and assessment at the level of the whole institution is a notable exception and shows what is possible.

The learning outcomes of whole-degree programs are usually expressed as a set of graduate attributes including those relating to generic communication, critical thinking, and interpersonal skills as well as discipline-specific knowledge. However, there is often a considerable gap between the rhetoric and reality in terms of ensuring

that the graduate attributes are actually developed and assessed. In addition to teaching models *per se*, whole of degree curricula have characteristics such as depth and breadth, integration, and the level of general education and interdisciplinarity. Concerns about the lack of integration across undergraduate programs have led to initiatives such as capstone courses where students have an opportunity to integrate and apply knowledge gained over previous years of study.

Employability, and specifically the curricula and pedagogies that support the development of the knowledge, skills, and attitudes needed for employment, have proved to be powerful models for teaching and curriculum design. However, the skills and attributes considered to be needed in the modern workplace comprise a long list. Peter Knight and Mantz Yorke's book *Learning, Curriculum and Employability In Higher Education* lists a total of 39 such skills attributes that should underpin an undergraduate curriculum focused on employability:

1. *Personal qualities.* Self-awareness, self-confidence, independence, emotional intelligence, adaptability, stress tolerance, initiative, willingness to learn, and reflectiveness.
2. *Core skills.* Reading effectiveness, numeracy, information retrieval, language skills, self-management, critical analysis, creativity, listening, written communication, oral presentations, and global awareness.
3. *Process skills.* Computer literacy, commercial awareness, political sensitivity, ability to work cross-culturally, ethical sensitivity, prioritizing, planning, applying subject understanding, acting morally, coping with complexity, problem solving, influencing, arguing for and/or justifying a point of view or a course of action, resolving conflict, decision making, negotiating, and team work.

Clearly mapping of all of these to an undergraduate curriculum and ensuring they are all aligned with both pedagogy and assessment, together with required disciplinary knowledge, is a daunting task. Recent developments in this area have included introducing work-integrated learning into undergraduate degree programs, such as internships, and putting greater responsibility on students themselves to document their acquisition of their knowledge, skills, and attitudes, including extracurricular activities, through portfolios.

In contrast to programs that focus on employability, a significant curriculum innovation in undergraduate education in recent years has been the development of research-led teaching, together with similar approaches such as research-aligned teaching and research-enhanced teaching. These models attempt to create a strong nexus between teaching and research in undergraduate teaching by introducing students not only to current research in the discipline but also ensuring their learning is aligned with the methods of inquiry and research characteristic of

the discipline. This approach to the curriculum has been taken up, in particular, by research-intensive universities and is consistent with the recommendations of the well-known 1998 report of the Boyer Commission *Reinventing Undergraduate Education: a Blueprint for America's Research Universities* and can involve, in some teaching models, undergraduate students engaging in real research themselves. Engaging with real research problems using disciplinary-based inquiry is not only an effective way for students to learn the inquiry skills of their disciplinary area, but is also highly motivational.

Innovations Aimed at Exploiting the Potential of New Information and Communication Technologies

New information and communication technologies have been the focus of much of what is viewed as innovation in higher education in recent years. Developments such as the Internet are providing access to higher education to students who would otherwise be unable to attend universities and colleges in ways that have transcended the traditional models of distance education. However, the new technologies, in particular the capacity to store, access, and share vast quantities of information, are also transforming what it means to learn and to teach in higher education. Universities and colleges no longer have a monopoly on the possession and distribution of information and this presents a major challenge to the authority of knowledge and the concept of authorship. Moreover, mobile technologies mean students can access information from just about anywhere, which is challenging the traditional role of the classroom and lecture hall and is giving a new meaning to the concept of internationalization.

Aside from the issue of information access, information and communication technologies are impacting on the process of learning itself, giving rise to the concept of e-learning. The ability of students to customize the information they receive, process it in a way and at a speed they themselves control, and the ability to review it when they want, stands in marked contrast to the one-size-fits-all approach of traditional higher education where students are forced to learn at the pace and style of the particular teacher they have. Moreover, technologies are making it possible for students to explore their ideas through dynamic simulations and receive immediate feedback on their learning. Many of the different technologies that facilitate learning are being integrated into commercial learning-management systems that have become the foundation for many university and college teaching programs.

Information and communication technologies such as the Internet are relatively recent in terms of their application to higher education and there is a tendency to equate any use of technology in learning and teaching as

an innovation. However, the effectiveness of many of these approaches to teaching remains to be determined and indeed there is a considerable debate about how such effectiveness can or should be determined. Some concerns center on the lack of face-to-face interactions between both teachers and their students and among students. Recent years have seen a growing interest in online collaboration and social-networking tools and Web 2.0 technologies such as blogs and wikis offer the potential for a high level of interactivity and a rich learning experience. It must be remembered that students now entering higher education, the so-called digital natives, see the Internet in all of its manifestations as an integral part of their lives. Nevertheless, for many students and teachers, face-to-face interactions remain an important, if not the central, feature of the higher education experience and recent years have seen the emergence of the concept of blended learning which combines features of both face-to-face and online learning.

Productivity of University Faculty Staff

S Kyvik, NIFU STEP, Oslo, Norway

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Publishing of papers and books is the principal means of communication of new ideas and results of scientific and scholarly enquiry. It is through the exchange of published knowledge that science makes progress. However, publication is also the principal means of career advancement and scientific reputation for individual university staff, and, increasingly, a means for funding of new research projects and research environments. In the competition for research funding and individual rewards, the number of publications has become an important parameter of scientific productivity, quality, and success. Through the introduction of performance-based funding of universities and university departments, being a productive researcher is no longer only an individual matter, but also a matter for the collectivity of staff members.

Over time, three trends in publication patterns stand out as particularly visible: the number of publications per academic staff member has increased, co-authorship has become much more common, and, worldwide, the scientific article in an English-language journal has enhanced its position as the dominating type of publication.

The increasing publication pressure has led to a significant rise in the number of published papers and books by individual faculty members. This is not only due to more productive researchers, but probably also due to a tendency to fragmentation of data presentation in several shorter, but strongly related papers, and to the publishing of slightly different versions of basically the same paper. The frequent complaints about these side effects from journal editors and referees have not had much impact on the publication system. The number of scientific journals is constantly growing, publishers invent new book-series to earn more money, and report-series are established by universities themselves, so that virtually every manuscript eventually might be published somewhere.

The large increase in the rate of co-authored publications as well as in the number of co-authors is related to fundamental changes in the science system itself as well as to changes in the steering and funding of research. The augmentation of joint authorship of scientific papers is a reflection of the trend toward collaboration in research; a development that can be traced back to the beginning of the twentieth century in the natural sciences, and which later accelerated in those disciplines where research projects are dependent on contributions from different researchers with complementary knowledge and skills to

make progress. The trend toward more co-authorship is also determined by another aspect of the organization of research. Over the last decades, more and more weight has been put on research programs, initiated by national and cross-national authorities and research councils, and in all fields of science. This way of organizing research usually presupposes collaboration between scientists that, in turn, leads to more co-authored papers by an increasing number of authors per paper. Finally, the increase in co-authorship is related to the pressure on universities and individual staff members to document results in the form of published output. In the competition for research, funding, and individual rewards, the number of publications has become an important parameter of success. The social importance of becoming a co-author of scientific papers has subsequently increased.

Measurement of Publication Productivity

The number of journal articles is the most widely used measure of publishing productivity. The reason is simple: journal articles are indexed in various databases and are relatively easily accessible for measurement or assessment purposes. Moreover, in most disciplines, they are presumed to reflect the production of new knowledge or research productivity. There are, however, four major problems related to this measure.

First, each article does not represent an equal contribution in quantitative terms. The information contents of journal articles vary enormously. This is not so much due to variation in the number of pages or words, as to differences in the density of information (Seglen, 1996).

Second, few databases include all relevant scientific and scholarly journals. In those databases that aim at international coverage, there is an English-language bias in the journals that are indexed, and a considerable number of national journals as well as newly established journals are not included.

Third, the author list of most journal articles counts several names. It is not evident how this problem should be dealt with. The main problem is how much credit each co-author should be attributed. The various authors are seldom equal contributors to an article. On the one hand, plain paper counts obviously favor those who have their names attached to many articles. On the other hand, attributing fractional counts to each author according to the number of authors might disfavor those contributors

that are first authors. One way of dealing with this problem has been to give credit to first authors only. However, customary practices within or across different disciplines as to the ordering of names among joint authors do not exist. In some articles, the first author is the primary author; in others, the authors are listed alphabetically; still others use different conventions.

Fourth, the publication pattern differs considerably between fields. The number of publications per academic staff member is higher in the natural and medical sciences and technology than in the social sciences and the humanities. This is partly due to the concentration on article production in the former fields and the larger emphasis on books in the latter fields, and partly due to less frequent co-authorships in the social sciences and in particular in the humanities. In order to deal with the problems of skewed coverage of publications in the journal-indexing databases, simple publication counts, or more refined weighting procedures have been developed to account for different types of publications. Scanning the research literature in the field reveals however that no agreement exists on the appropriate weighting that should be assigned to various types of publications.

In spite of these methodological problems, publication counts make sense as a rough measure of the output of scientific enquiry. Publication productivity would, however, be a dubious measure on scientific output if high productivity could be proven to correlate with low quality and vice versa. There is, however, general agreement among scholars that if one examines larger groups of scientists as opposed to individuals, there is a positive – albeit not perfect – correlation between high numbers of publications and the significance and impact of the authors as deemed by their colleagues. The conclusion is, therefore, that the more productive researchers will, in general, contribute more to the stock of knowledge than the less productive scientists. This tendency can, moreover, be explained theoretically; those scientists who receive recognition for their publications are encouraged to continue to publish, while those whose work is not regarded as important are likely to become discouraged and less productive. Nevertheless, there are differences between academic staff members; some manage to publish a lot of low-quality work, while others publish few, but excellent, papers or books. Productivity measures are accordingly insufficient means to gauge the scientific standing of individual scientists and scholars.

Productivity Differences Between Faculty Members

There are large individual productivity differences among faculty members in all university systems. A relatively

small percentage of staff accounts for a disproportional large share of the published output. During the time since Lotka (1926) formulated his inverse square law on productivity, which says that the number of scientists producing n papers is proportional to $1/n^2$, several attempts have been made to test the generality of this law. According to Lotka, about one-half of all papers are produced by 6% of all researchers and nearly one-quarter by 1%. This law obviously overestimates the number of papers produced by the most prolific researchers. Nevertheless, many studies have confirmed that highly skewed patterns of productivity exist in scientific publishing. This skewed pattern is shown to apply to all university disciplines (Kyvik, 1991), and seems to be insensitive to a variety of time frames (Pao, 1985). A study of tenured faculty members in research universities reports that the most prolific 20% of the staff produced 50% of the total number of publications, and that this pattern was stable over a 20-year period (Kyvik, 2003). This skewed distribution applied to the natural and medical sciences, technology, the social sciences, and the humanities, indicating a remarkable regularity in individual productivity differences independent of time and discipline.

Explanations for Productivity Differences

Many explanations have been put forward to explain the large differences in publishing activity among academic staff members, of which the following are the most common.

Abilities

There seem to be only few studies on the relationship between individual abilities and scientific productivity, and these inquiries indicate a very weak, if any, positive correlation. The conclusion which may be drawn on the basis of present knowledge is that high intelligence quotient (IQ) may be a prerequisite for becoming a scientist, but that differences in measured ability within this group of people do not determine subsequent levels of performance.

Time and Energy

A number of studies report only a weak correlation between time spent on research and scholarly output. However, the splitting up of a work day such that it is difficult to have uninterrupted time for research appears to be a widespread problem among tenured faculty. Some individuals appear to cope with this more easily than others. Differences in the organization of a working day and the ability to concentrate on research in spite of interruptions can, therefore, be just as important as the total time spent on research.

Resources

Research is often expensive with regard to equipment, materials, travels, and assistance. Those scientists who have large resources at their disposal will be in a better position to be productive researchers than those who have scarce resources. A number of studies report a positive, although relatively weak, significant correlation between financial support and published output.

Communication

It seems to be widely accepted that having close contacts with other researchers stimulates productivity. There are informal networks, or so-called invisible colleges that have the leading scientists within disciplinary specialties as members, and where information is exchanged, people are invited to take part in collaborative projects, and invited to submit papers for publication as book chapters or journal articles. Communication may create intellectual synergy between individuals through the cross-fertilization of ideas. This process may, in turn, generate new insights or perspectives that individual researchers – working on their own – would not have grasped. There is some scattered evidence that networking with colleagues enhances publication productivity.

Collaboration

It is a well-known fact that collaboration in research has become gradually more common as evidenced by the increase in co-authored publications. The reasons for the enhancement of research collaboration are a mixture of related factors; internal scientific reasons, science-policy initiatives, individual motivations, and improvements in communication facilities. Many scholars and policymakers seem to assume that research collaboration enhances publication productivity, because division of labor and the joining of specialized skills may enable researchers to increase their efficiency. In addition, much collaborative research of academic staff is done as supervisors of doctoral students and materializes in co-authorship. On the other hand, there are transaction costs associated with working with others, and, for a variety of reasons, collaboration does not always live up to expectations (Lee and Bozeman, 2005). Despite this, there is some evidence suggesting that collaboration in itself enhances productivity in research, even when corrections are made for the number of co-authors.

Environmental Location

Even though we know relatively little about under what circumstances organizational variables will affect research productivity, there is still some scattered evidence that organizational context influences research performance. The average quality of academic staff in a university

department, and values and norms related to the level of publishing activity seem to affect an individual staff member. There is some evidence that academic staff who change institutional location after some time conform with the characteristics of that context, independently of previous productivity. On the other hand, the effect of group size and department size on publication productivity is unclear. Different studies report various tendencies, indicating that size in itself has no significant effect on publishing productivity.

Cumulative Advantage and Disadvantage

These various explanations of productivity differences are not mutually exclusive but have been integrated in the theory on cumulative advantage and disadvantage in science. According to this theory, the skewed pattern of publication productivity is the result of the way the scientific reward system operates (Merton, 1968; Cole and Cole, 1973). Minor differences between scientists early in their careers accumulate to produce substantial differences in productivity over time. This process can be viewed as consisting of two feedback loops in which recognition and resources are intervening variables (Allison and Stewart, 1974). Scientists who have been recognized as having made significant advances will be motivated to maintain or increase their recognition by additional publications, and will be influenced by their colleagues' expectations that they repeat or exceed those achievements. Beyond these direct effects, recognition usually implies increased access to resources which facilitate research. In contrast to this picture of spiraling success, the scientist who publishes little or whose work is not recognized is likely to become discouraged with research.

The cumulative advantage theory has been widely accepted as the best explanation of why there are such large productivity differences among individual scientists. The theory has, however, obvious weaknesses (Kyvik, 1991). One objection is that accumulative advantage (resources, rewards, etc.) will not necessarily lead to higher productivity. For some academic staff, the utility of using more time on academic administration or professional work will be regarded as more advantageous for their future career prospects than persistent efforts in research. Another objection is that accumulative disadvantage will not necessarily lead to lower productivity. Some faculty members find scientific work personally enjoyable and continue publishing even though their publications are not recognized as worthwhile by their colleagues. For others, publishing papers is a self-legitimizing act as researchers, even in the absence of rewards. Nonetheless, the cumulative advantage and disadvantage theory is attractive as an explanation of the large differences in productivity between scientists.

Age and Productivity

Many studies report that, in general, publication activity declines with increasing age and that old academic staff are less productive than their middle-aged colleagues. There appears to be a curvilinear relationship between age and number of publications. Productivity reaches a peak when scientists are in their 1940s, depending on scientific field, and then declines. We can distinguish between six different hypotheses which all suggest reduced publishing activity with an aging academics staff (Kyvik and Olsen, 2008).

The Utility-Maximizing Hypothesis

According to this hypothesis, academic staff will pay less attention to research with increasing age because the expected utility of time dedicated to research diminishes (Diamond, 1984). Investing time in other university tasks – for example, administration – or in work external to universities can be seen as more effective ways of increasing one's prestige and/or income.

The Seniority Burden Hypothesis

Another possible explanation for the decline in research productivity with increasing age is that the more experienced academic staff are, the more duties they are expected to engage in – administrative work, evaluation tasks, supervision of postgraduate students, professional work in relation to the discipline and the community, etc. Seniority and experience bring about an accumulation of tasks and duties that reduce the time available for research (Zuckerman and Merton, 1972).

The Cumulative Disadvantage Hypothesis

According to this explanation, the average publishing productivity of a cohort declines with age because those who are not rewarded for their research gradually lose the motivation for new achievements (Cole, 1979a). As they continue to publish, some find their work rewarded and go on to be even more productive. In addition, professional recognition leads to greater possibilities for access to economic resources, research assistants, and membership in international research networks – all of which have positive effects on productivity. Others, who are treated indifferently by their colleagues, and who receive negative responses to their work, may gradually lose their motivation and the possibilities to keep their productivity at a high level. The older a cohort of researchers grows, the less motivated an increasing share of the cohort will be to keep up high publication rates.

The Age Decrement Hypothesis

Another hypothesis is that older scientists, on average, function on a lower intellectual and physical level than their younger colleagues. While there is probably very little age decrement up to the age of 60 in intellectual abilities and skills that do not require fast responses or are not affected by reaction time (Schaie, 1975), older scientists are less creative than younger researchers, and they are also exposed to age-related physical problems and illnesses which may hamper or slow down their engagement in research.

The Obsolescence Hypothesis

According to this explanation, the speed of the introduction of new research technology has had different consequences for the younger and older generations. While the oldest cohorts of scientists were trained in methods and equipment neither sufficient nor relevant for new scientific breakthroughs, the younger generations have access to the latest theory, methodology, and equipment in their doctoral work. Thus, the skills of old scientists do not necessarily decline, but rather become obsolete (Price *et al.*, 1975).

The Intellectual Deadlock Hypothesis

A final assumption is that older academic staff are not able or willing to reorient their research toward new scientific or social problems. There is a tendency among scientists to pursue research problems which were important in the early days of their career, making their research irrelevant to new generations of academics who possess a fresh point of view on how to solve a problem as well as on what problems ought to be studied (Stephan and Levin, 1992).

There are, however, several methodological problems related to the study of age and productivity. In general, it is extremely difficult to measure the impact of aging on human behavior because observed results can be influenced by three different effects (Riley *et al.*, 1972): First, by pure age effects – that is, of physical and mental changes related to the aging of the body and the mind. Second, by generation effects – that is, that different age groups have had different life experiences, and the reason why people of different ages differ on a given characteristic may be due to the fact that they belong to different generations, rather than because they differ in age. Third, by period effects – that is, that norms for appropriate behavior might have changed over time, and resources available for job performance may be quite different at different time periods. In practice, these effects intermingle, making it difficult to disentangle the impact of aging from generational and situational effects.

Gender and Productivity

Virtually all studies that have examined scientific publishing among men and women scientists have found that men are more productive than women. Cole and Zuckerman (1984) refer to more than 50 studies in various fields which show that men on average publish 40–50% more papers than their female counterparts. Even though a number of studies have attempted to explain the large differences in scientific productivity between male and female researchers, there is disagreement about the reasons for this difference. Various explanations have been proposed to account for this difference. One important reason is differences in academic rank. Full professors are more productive than associate professors, who in turn are more productive than assistant professors. As there are relatively fewer women in senior positions, the difference in productivity between ranks has consequences for the average productivity of male and female staff. However, even when controls are made for rank, productivity differences persist. Thus, it has been claimed that women are less integrated into professional networks than are men, and that they are accordingly less motivated or enjoy fewer opportunities to be productive. It has been contended that women have less academic confidence than men, and that they have poorer access to economic resources for doing research. Some argue that women use less time for research than do men, either because they are less motivated to spend most of their time on research, or because they are not able to use as much time for research as are men due to stronger commitments in teaching, supervision, and administrative work – duties that have clear parallels with women's roles as caretakers. In addition, women often interrupt their research careers because of childbirth and have more caring responsibilities than do men. These different explanations have also been integrated into the cumulative advantage and disadvantage theory. If women do less well than men on a number of such indicators, productivity differences are likely to reflect different cumulative effects for men and women over time.

The two most commonly used explanations for gender differences in publication productivity when controlled for academic position are that women are not as well integrated in scientific networks and collaborative research as are men, and that women are hampered by childbirth and child-care.

Networking, Collaboration, and Productivity

The probably most widely used explanation for gender differences in productivity is that women in male-dominated universities have problems in integrating into important informal networks (Reskin, 1978; Cole, 1979b;

Fox, 1991). This is thought to be the case in the department as well as in relation to the research community as a whole. The reasons are that women are a minority, and that men communicate best with men. Many men might also avoid working closely with women – either because they or their spouses fear that a sexual relationship could develop, or because they want to avoid the gossip of their colleagues. Several studies show that researchers who have wide professional contacts with colleagues publish more than those who do not. There also is some evidence that teamwork in itself enhances productivity in research. If women are excluded from important networks so that their opportunities for collaboration in research are thus restricted, their publishing activity may be adversely affected. The research literature has not, however, produced consistent evidence that women are less integrated in informal professional networks or in collaborative research than men.

Motherhood and Productivity

The other principal explanation for gender differences in publication productivity is that women have interruptions in their research career due to childbirth and also have more caring responsibilities than do men. Various studies report inconclusive results. Some studies indicate that women with children publish more than do childless women and thus suggest that women's lower productivity cannot be due to maternal responsibilities (Cole, 1979b; Cole and Zuckerman, 1984). Other studies show that when children's age is introduced as a variable, maternity leave and child-care turn out to be important determinants for women's publishing activity. One study reports that while women tenured faculty with children under age 6 were almost 60% less productive over a 3-year period than were their male counterparts, and women with children in the age range 6–10 were 30% less productive, there were virtually no differences between men and women whose children were all older than 10 years (Kyvik and Teigen, 1996). This indicates that maternity leave greatly reduces women's scientific productivity temporarily, but child-care in itself also affects the publishing activity of women. Other studies report that gender, family characteristics, and publication productivity are complex relations that go beyond being married or not married, and the presence or absence of children (Fox, 2005).

Conclusion

Research done on scientific and scholarly publishing indicates that productivity patterns among university staff are remarkably similar across different countries and time-periods. There are large individual differences; a relatively small share of a given researcher population

accounts for the majority of publications. Men publish on average more than women, there are differences between various age groups, and the higher the rank, the more productive is the average faculty member. No single explanation can account for these differences. Even the theory of cumulative advantage and disadvantage – which aims at integrating the various inequality-causing processes into a coherent explanation – falls short in explaining the skewed productivity patterns, although it is a fruitful theoretical abstraction.

Promoting Effective Student Learning in Higher Education

K Trigwell, University of Sydney, Sydney, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Conceptions of learning – Students ways of thinking about what learning is – e.g. memorising or developing personal meaning.

Deep approach to learning – Students main intention in learning is to develop personal understanding.

Effect size – A number between 0.0 and 1.0 used to gauge effectiveness, with numbers around 0.2 being small, 0.5 being medium and 0.8 being large.

Interventions – Introduction of education practises designed to improve teaching/learning.

Learning environment/climate – The context in which learning is experienced.

Phenomenography – A way of mapping variation in ways of experiencing a phenomenon.

Self-efficacy – The degree of confidence students have in being able to tackle requirements.

Self regulation – Students ability to monitor and adapt their learning.

Surface approach to learning – Students main intention in learning is to satisfy assessment requirements.

Threshold concepts – Those areas of subject content that, having been mastered, open the field to greater understanding.

Effective student learning is learning that prepares students for the present as well as for an unknown future. While it must include passing courses and the acquisition of skills and key concepts, it needs to be more than that. In a major UK study on student engagement and high-quality learning, the Enhancing Teaching–Learning (ETL) Environments research team describes desired student outcomes more in terms of ways of thinking and practicing in the discipline or professional area (Hounsell *et al.*, 2005). Ways of thinking and practicing “capture the richness, depth and breadth of what the students could learn through engagement with a given discipline or subject area. It rests on a secure foundation of subject knowledge and understanding and could also encompass subject-related skills, conventions and practices for communicating within the subject, and salient values and attitudes.”

Research on what promotes effective learning in higher education has, for the last 30 years, been dominated by

two quite different schools of thought. One has its origins in Europe, is now known as the Student Approaches to Learning (SAL) perspective, and is focused on seeing learning from the point of view of the experience of the students (Marton *et al.*, 1997). From this perspective, promoting effective learning is about helping students experience a supportive learning environment. The other has its origins in the USA, is now known as the Self-Regulated Learning (SRL) perspective and has developed principally from top-down psychological conceptualizations (Pintrich, 2004). From this perspective, promoting effective learning is about changing students’ ability to teach themselves.

A recent variant on the two dominant research conceptualizations is the work on observations from the widely adopted National Survey of Student Engagement (NSSE) in North America (e.g., Kuh, *et al.*, 2005). In focusing on broad environmental factors associated with student engagement these studies complement the two research areas outlined above. Finally, while the student is at the center of these three areas, teaching and the teacher are seen to play a crucial role in promoting effective learning in all of them, including the minimizing of barriers to learning.

In the notes that follow, the key elements from each of four research fields (SRL, SAL, student engagement, and higher education teaching) are presented. There is overlap between the fields. Indeed they share two concepts considered to be fundamental in effective learning. The first is the assumption that students construct their own knowledge and that this construction may not always be consistent with teachers’ ways of knowing. Therefore, effective learning is more likely when students are provided with the opportunity to be active learners, and both students and teachers are able to monitor learning outcomes through the learning process. The second is that students’ prior academic learning is one of the strongest predictors of academic achievement. Students who have had previous success tend to continue to have success. Promoting effective learning means being aware of students’ prior learning. Despite these commonalities, each of the four fields also address a different aspect of what is a very complex education system, and an understanding of what promotes effective learning in higher education would not approach completeness without the inclusion of all four.

One area of research that is considered to be important in understanding student learning has not been included in this entry. Students’ personal and contextual characteristics

are related to academic achievement, but they are not normally seen as amenable to much change after late adolescence.

SAL Perspective: Promoting Effective Learning Through Changes to Students' Perceptions of Their Learning Environment

From the relational perspective of this research, students adopt qualitatively different approaches to learning according to their perceptions of their learning situation. This situation is a relationship between the learning context and the student (Marton *et al.*, 1997). An approach, either deep or surface, is not fully either a characteristic of the student or the context. A student's approach to learning can change with their changing perceptions of their learning situation (Ramsden, 2003).

In adopting a deep approach to learning, the students' intention is to understand ideas and seek meanings. They have an intrinsic interest in the task and an expectation of enjoyment in carrying it out. They adopt strategies that help satisfy their curiosity, such as making the task coherent with their own experience, relating and distinguishing evidence and argument, looking for patterns and underlying principles, integrating the task with existing awareness, seeing the parts of a task as making up the whole, theorizing about it, forming hypotheses, and relating understanding from other parts of the same subject, and from different subjects. Overall, they have a focus on the meaning in the argument, the message, or the relationships but they are aware that the meanings are carried by the words, or the text, or the formulae (Prosser and Trigwell, 1999).

In adopting a surface approach to learning, students see tasks as external impositions and they have the intention to cope with these requirements. They are instrumentally or pragmatically motivated and seek to meet the demands of the task with minimum effort. They adopt strategies which include: a focus on unrelated parts of the task, separate treatment of related parts (e.g., principles and examples), a focus on what are seen as essentials (factual data and their symbolic representations), the reproduction of the essentials as accurately as possible, and rote memorizing information for assessment purposes rather than for understanding. Overall, they would appear to be involved in study without reflection on purpose or strategy, with the focus of that study being on the words, the text, or the formulae (Prosser and Trigwell, 1999).

Students who adopt a deep approach to learning are more likely to engage in learning that lasts than students who adopt a surface approach to learning. The early research studies showing that students who adopt a deep approach to learning are more likely to have a higher-quality learning outcome than those adopting more

surface approaches (Marton *et al.*, 1997) has been repeated in numerous contexts. Deep approaches to learning are effective learning processes.

Promotion of effective learning, from this relational perspective, is about establishing a learning environment perceived by students to afford more of a deep approach to learning and less of a surface approach to learning. In studies of the relations between perceptions of the learning environment and approaches to learning, five factors associated with the variation in approach have been identified:

1. teaching that fosters active and long-term engagement with learning tasks;
2. academic goals and standards that are clear to students;
3. assessment that discourages recall or the application of trivial procedural knowledge;
4. workloads perceived by students to be appropriate (not so heavy that in-depth exploration is stifled, but not so light that the work is not challenging); and
5. choice of learning tasks.

To assist curriculum designers and course administrators to continuously improve the learning context, a quantitative instrument (Course Experience Questionnaire, Ramsden, 2003) has been developed to gauge students' perceptions of their learning context.

In more recent studies involving analyses using structural equation modeling, and in the ETL project (Hounsell *et al.*, 2005), the associations between these environmental factors and approaches to learning have been confirmed. Several new factors have also emerged. For example, the drop in frequency of small-group meetings brought on by financial savings and increased participation in higher education has affected students' approaches to learning. In the current context, supporting individual learning and studying may enhance effective learning. While feedback to students on their progress was originally seen as being a part of a good teaching environment, there is a growing literature that suggests this as a major factor in its own right, and that immediate feedback, given in a personalized way, such as through discussions, can assist in promoting effective learning.

In designing supportive teaching–learning environments, however, it is also crucial to see these as interacting systems, in which even one element that interferes with high-quality learning can have damaging effects.

SRL Perspective: Promoting Effective Learning Through Changes to Students' Ability to Teach Themselves

A central tenet of the SRL perspective is that learners can potentially monitor, control, and regulate certain aspects

of their own cognition, motivation, and behavior as well as some features of their environment (Pintrich, 2004). Students who do self-regulate their learning are more effective learners than those who do not. The characteristics of those who self-regulate their learning include:

1. A familiarity with and knowledge of how to use a series of cognitive strategies (e.g., repetition, elaboration, and organization) which help them to attend to, transform, organize, elaborate, and recover information.
2. A knowledge of how to plan, control, and direct their mental processes toward the achievement of personal goals (meta-cognition).
3. Evidence of a set of motivational beliefs and adaptive emotions, such as a high sense of academic self-efficacy, the adoption of learning goals, the development of positive emotions toward tasks (e.g., joy and enthusiasm), as well as the capacity to control and modify these, adjusting them to the requirements of the task and of the specific learning situation.
4. Ability to plan and control the time and effort used on tasks and knowledge of how to create and structure favorable learning environments, such as finding a suitable place to study and help-seeking from teachers and class mates when they have difficulties.
5. Evidence of greater efforts to participate in the control and regulation of academic tasks, classroom climate, and structure (e.g., how one will be evaluated, task requirements, the design of class assignments, and organization of work teams) when the context allows it.
6. Ability to put into play a series of volitional strategies, aimed at avoiding external and internal distractions, in order to maintain their concentration, effort, and motivation while performing academic tasks (Montalvo and Torres, 2004).

In a framework for classifying the different phases and areas for regulation, Pintrich (2004) describes a temporal matrix involving four phases, from forethought, planning and activation, to monitoring, to control, and, finally, to reaction and reflection. He sees each of these phases as being applicable to cognition, motivation/affect, behavior, and context. In cognition, for example, the students set specific goals for learning, are aware of progress toward those goals, have the ability to change directions if the strategies are not working, and make cognitive judgments on how they did. In motivation/affect, regulation would include attempts to regulate beliefs such as self-efficacy, goal orientation, task value, perceptions of task difficulty, and personal interest, as well as controlling emotions such as fear and anxiety. In behavior, regulation is focused, for example, on effort, control, time management, and help-seeking strategies, while regulation of context is about control of the environment. While the latter would not have been thought possible even 30 years ago in higher education, the

growth of student-centered teaching approaches, where students are asked to make a greater input into processes, has meant that students do have influence over some aspects of the environment.

Self-regulators treat learning as an activity that they develop proactively rather than mere reactive processes stimulated by their reactions to teaching. Each process of self-regulated behaviors can be taught by parents, teachers, classmates, etc.

From this perspective then, the process of promoting effective student learning involves teaching the students to become more effective self-regulators of their learning. This is normally achieved through interventions embedded in the context of normal subject-matter teaching, and in which teachers play a crucial role.

Different types of intervention have been reported. Since the main objective is meta-cognition, the current emphases are on self-reflective practices and on instruction designed to scaffold the students' development. To develop awareness and control of their learning, students must engage with and practice using a range of skills, know how they are used, know why one strategy is best used at one time rather than another, and know what effects the adopted strategy is having on learning. Modeling by the teacher of the key processes – planning, controlling the process, outlining the relevant sources, and reviewing what has been done – provides students with observable examples, and direct teaching of the self-regulation strategies are both fundamental starting points. However, it is the students who must engage in practice, in self-monitoring, and with the social support systems to achieve the levels of competence needed to self-regulate their own learning.

The development of ways of measuring the effectiveness of the interventions has not kept pace with the development of the explanatory frameworks behind the current thinking. Both the Learning and Study Strategies Inventory (LASSI) and the Motivated Strategies for Learning Questionnaire (MSLQ) were designed before the many dimensions now considered to be a part of the SRL framework were identified. In including many of these dimensions, the latter is probably still the best quantitative instrument available.

While many learning-to-learn programs fit comfortably within the descriptions in this section, there are some, for example, those focused on developing specific skills such as reading, or on the development of mnemonic skills that do not. Simpson *et al.* (1997) note in a review of academic assistance programs that these programs have continued to flourish for a variety of reasons, one being that many university students are not self-regulated learners. They describe program models as being based on either a generic or embedded approach. Generic interventions are usually conducted outside of the teaching context (e.g., development of note-taking skills).

In a comprehensive meta-analysis of the effects of learning skills interventions on student learning Hattie *et al.* (1996) use effect size to gauge the effectiveness of a range of intervention programs in terms of students' academic performance, change in study skills, and affective changes. The conclusions they draw from the meta-analysis are consistent with the conclusions in the literature at the time: the interventions are associated with increases in student performance, in study skills, and in affect and are effective most of the time. The effects are greatest on performance (effect size 0.57) and least for study skills (0.16). They conclude that the typical study skills package is not as effective as metacognitive and contextualized intervention, but it is significantly better than nothing. However, they also found that these effects are not uniform across the educational sectors. Of the 51 studies analyzed by Hattie and coworkers, 21 were from university or adult-learning contexts. Effect sizes from the university subsample, for performance, study skills, and affect are 0.27, 0.19, and 0.68, respectively. In terms of performance and study skills, these are small effect sizes, and such interventions cannot be considered to be major contributors to enhancing student learning. The moderate effect size for affect suggests that the interventions may change students' attitudes to their work, and as noted in the notes above on self-regulated learning, students' attitudes are related to aspects of their performance.

Student Engagement: Promoting Effective Learning Through Alignments of Student Support within the Educational System

Kuh *et al.* (2005) have used the idea of students' self report of their engagement in their college life as a proxy for effective learning. Drawing on results from the National Survey of Student Engagement (NSSE), their major conclusion is that what is needed for the promotion of student success (greater engagement) is a holistic approach, as the responsibility lies with just about everybody in the college system, including the students. This includes the governing board, president, provost, teachers, and others in the classroom context, the context outside the classroom, and the administration. The key, however, is not the inclusiveness of this array, but an overall plan aimed at organizing for student success that involves alignment or congruence between the various elements that are included and the sustainability of these initiatives.

Kuh and colleagues describe nine key areas, and strategies within each, identified from the practices of colleges where students report high levels of engagement. Taken together as an aligned and sustained process, adoption of these nine suggestions may lead to more effective learning:

1. *Feature student success in the institutions enacted mission.* Have a vision of what is to be accomplished with undergraduate programs, clarify and translate the mission into plain language, ensure that the espoused mission is enacted, senior leaders champion undergraduate education, and that multiple missions are balanced.
2. *Make talent development a central tenet of philosophy.* Establish high expectations, know your students, set performance standards for students consistent with their preparation, provide generous amounts of constructive feedback, balance academic challenge with adequate support, use pedagogic approaches to complement learning approaches, and encourage student-faculty interaction that benefits student learning.
3. *Cultivate an ethic of positive restlessness.* Steer organization toward continuous improvement, use data to inform decision making, remove less-effective programs and support high-priority initiatives, and put someone in charge.
4. *Put money where it will make a difference to student engagement.* Invest in: (a) activities that contribute to student success, (b) faculty members who are doing the right thing, (c) teaching and learning centers, and (d) opportunities that allow students to apply what they are learning in ways that benefit others, as well as consider a budget model that privileges student learning processes.
5. *Feature diversity inside and outside the class.* Use a multi-faceted, aggressive approach to diversify personnel, and ensure that diverse perspectives are represented in the curriculum.
6. *Attract, socialize, and reward competent people.* Align the reward system with the mission, pick leaders who are right for the times, recruit faculty who are committed to student learning, emphasize student-centeredness, make room for difference, and ensure high-quality student support services.
7. *Encourage collaboration across functional lines and with community.* Encourage cross-functional activity that leads to student success, tighten links between academic and student affairs, harness expertise of other resources, make governance a shared responsibility, and form partnerships with local community.
8. *Lay out the path to student success.* Draw a map for student success, front load resources to smooth the transition, align the physical environment with institutional priorities and goals for success, teach newcomers about the college culture, create a sense of specialness about being a student here, and develop interventions for under-engaged students.
9. *Reculture the institution for student success.* Identify cultural properties that are obstacles to student success, and expand the number of cultural practitioners on campus.

Promoting Effective Learning Through Teaching

Teaching strongly features as a medium through which effective learning can be promoted in both the SAL and SRL perspectives and alignment of teaching conceptions with the rest of the educational system is essential for student engagement.

A set of teaching qualities generally agreed by researchers to be essential for the promotion of student learning have been summarized by Ramsden *et al.* (1995) as follows:

1. Good teachers are also good learners, for example, they learn through their own reading, by participating in a variety of professional development activities, by listening to their students, by sharing ideas with their colleagues, and by reflecting on classroom interactions and students' achievements. Good teaching is therefore dynamic, reflective, and constantly evolving.
2. Good teachers recognize the importance of context, and adapt their teaching accordingly; they know how to modify their teaching strategies according to the particular students, subject matter, and learning environment.
3. Good teachers encourage deep-learning approaches, rather than surface approaches, and are concerned with developing their students' critical thinking skills, problem-solving skills, and problem-approach behaviors.
4. Good teachers set clear goals, use valid and appropriate assessment methods, and provide high-quality feedback to their students.
5. Good teachers show respect for their students; they are interested in both their professional and their personal growth, encourage their independence, and sustain high expectations of them.
6. Good teachers demonstrate an ability to transform and extend knowledge, rather than merely transmitting it; they draw on their knowledge of their subject, their knowledge of their learners, and their general pedagogical knowledge to transform the concepts of the discipline into terms that are understandable to their students. In other words, they display what Shulman has termed "pedagogical content knowledge."
7. Good teachers display enthusiasm for their subject, and a desire to share it with their students.

The last two of the seven focus on an area which has to a large extent been overlooked in learning enhancement – the subject-matter understanding of the teacher.

An essential element in promoting effective learning is the minimizing of barriers to learning. Reducing students' perceptions of the environmental factors affording a surface approach, and developing students' self-regulated learning skills to enable them to take control of their learning, are ways this is achieved in the SAL and SRL perspectives,

respectively. However, there are three other types of barriers that teachers must address; conceptions of learning, conceptions of knowing, and conceptions of understanding.

Adult students vary in the ways they conceive of learning (Marton *et al.*, 1997). Six qualitatively different conceptions have been constituted from interview studies:

1. learning as a quantitative increase in knowledge;
2. learning as memorizing;
3. learning as acquiring facts, skills, and methods that can be retained and used as necessary;
4. learning as making sense or abstracting meaning;
5. learning as interpreting and understanding reality in a different way; and
6. learning as changing as a person.

Students who do not conceive of learning as described in conceptions 4, 5, or 6 have difficulty adopting a deep approach to learning. Promoting effective learning means raising students' awareness of the higher-level conceptions.

Students' conceptions of knowledge, or ways of knowing, have also been found to be barriers to learning (Perry, 1970). Many students, when first encountering a new study area, see knowledge in absolute terms. Something is right or wrong, or black or white. A diversity of views may be acknowledged, but the diversity exists because insufficient study has been done to find the right answer. As students develop, they recognize that because knowledge is relative and socially constructed there will be a diversity of views. In the final phase of development, students make a commitment to a view in preference to other views, based on their own analysis of the evidence available. Students may be prevented from engaging in effective learning if they do not conceive of knowledge in the more relativistic ways.

Early research in science education focused on identifying the misconceptions that students might have about science. The presence of misconceptions was considered to be a factor preventing many students from achieving the scientific forms of those conceptions, and effective teachers were considered to be those who could change those conceptions. Much of the focus of science-discipline-based education journal articles has been on ways of organizing complex scientific knowledge in ways to make it easier for students to learn. More recently, phenomenographic studies of subject matter in a range of disciplines have revealed the variation in the way a group of students experience that subject matter. Phenomenography is the empirical study of the limited number of qualitatively different ways in which a group experiences a phenomenon. These differing experiences are characterized in terms of categories of description, logically related to each other, and forming hierarchies in relation to given criteria. The categories of description corresponding to those differing understandings and the logical relations that can be established between them constitute the main

results of a phenomenographic study (Marton and Booth, 1997). Some categories or ways of experiencing subject matter are found, through this approach, to be more a part of effective learning than others. The logical relations between the categories that constitute an outcome of this process also provide a means through which variation in the quality of student learning might be addressed.

Teachers also have a crucial content-related role in identifying and dealing with troublesome knowledge and threshold concepts (Hounsell *et al.*, 2005). Threshold concepts seem to serve as portals, opening up previously inaccessible ways of thinking about certain aspects of a subject – a transformed way of understanding without which the learner cannot progress. While they are considered to be transformative, and, once understood, provide a gateway to previously hidden interrelatedness, they are, like troublesome knowledge, a barrier to learning until that threshold is crossed.

Student Attrition from Higher Education Institutions

Glossary

Student attrition – This concept is variously measures, but most often by student persistence from year to year and from course commencement to course completion.

Student survival – The OECD calculates this rate by determining the ratio of the number of students who graduate from an initial degree during a reference year to the number of new entrants to that degree n years beforehand, with n being the number of years of full-time study required to complete the degree.

Although estimates of its incidence and perceptions of its gravity vary from one national higher education system to another, student attrition from higher education is universally regarded as a matter of serious educational concern. Some indication of its extent is provided by a recent estimate of the Organization for Economic Cooperation and Development (OECD) that as many as 30% of all students who commence undergraduate degree programs fail to complete them within a reasonable period of time (OECD, 2006: 51). In some countries, most notably the United States, the rate is closer to 50%.

The empirical literature on the topic is voluminous. Not surprisingly, in view of the high rates of student attrition experienced, much of this literature comes from the United States. The United States is also the main source of relevant theoretical models. Preeminent among these is Tinto's model of student departure from higher education in which a student's failure to integrate with the social and academic environment of a higher education institution is identified as the main cause of student attrition.

This article addresses various aspects of student attrition: how it is measured, how it is explained, how it might be addressed, and what it costs. It focuses on attrition from undergraduate degree programs, this being the main area of attention in most of the relevant literature.

Measuring Student Attrition

Student attrition is variously measured. These measures address student persistence from year to year and from course commencement to course completion. Ideally, they would take into account the incidence of deferments

and of transfers between courses and institutions, but often they do not. Estimates of attrition may be inflated if deferments, that is, periods of approved interruption of enrolment, and if transfers, that is, leaving one course for the purpose of undertaking another at the same or at a different institution, are not taken into account.

The most common estimates of student attrition are those based on measures of year-to-year persistence at the same institution. These are typically calculated for students in their first year of undergraduate studies, when student attrition is highest. In Britain, a higher education statistics agency calculates year-to-year continuation rates for all full-time first-degree entrants to higher education. These rates are relatively high: as many as 87.7% of all full-time first-degree entrants to higher education in 2003/2004 continued their studies at the same institution in 2004/2005, and a further 2.8% of entrants transferred to another higher education institution in 2004/2005 (HESA, 2006, Table 3a). The year-to-year attrition rate from higher education for this cohort was, therefore, 9.5%, although even this estimate may be inflated because it does not take deferments into account. Of note from the British data is that some higher education institutions, generally the more selective ones, had year-to-year attrition rates of less than 5%, while others had rates of attrition between 20 and 30%. This kind of institutional variation is replicated in most countries.

In Australia, the Department of Education, Science, and Training also calculates year-to-year persistence rates for entrants to undergraduate courses. Although not as high as in Britain, these rates are relatively high: 78.8% of all commencing undergraduate domestic students in 2002 continued their studies at the same institution in 2003 (Lukic *et al.*, 2004). When allowance was made for the impact of 1-year deferments, the annual continuation rate increased by about 10 percentage points. The year-to-year attrition rate when adjusted for 1-year deferments was, therefore, about 12%. This estimate would be further reduced if institutional transfers were taken into account.

It is interesting to compare the British and Australian rates with persistence rates for the United States. Berger and Lyon (2005: 25) report that, based on estimates for 2000 produced by the American College Testing Program, only about three-quarters of all freshmen at 4-year institutions return to their studies the following year. At more selective institutions, the average continuation rate was 92%, while at less-selective institutions it was only 65%. The availability of open-access higher education opportunities in the

United States impacts considerably on these rates. Year-to-year persistence rates for freshmen at these institutions were in the order of only 50%.

International comparisons of attrition rates are interesting, but there are many data limitations. Apart from the fact that these comparisons are possible only for those countries that publish attrition data, the main problem is that the measures adopted are rarely exactly the same. Estimates of attrition are also significantly affected by whether or not part-time students have been considered, and, if they have been, by the relative size of the part-time student population. Attrition among part-time students is generally well above that for full-time students.

Student attrition rates may also be estimated on the basis of course-completion data. An example is the OECD's annual estimate of student survival rates for member countries. These rates are calculated, using cross-sectional data, by determining the ratio of the number of students who graduate from an initial degree during a reference year to the number of new entrants to that degree n years beforehand, with n being the number of years of full-time study required to complete the degree (OECD, 2006: 57). In 2004, most OECD countries recorded survival rates close to the average of 70%, but some, notably Japan, Ireland, and Korea, had rates that were markedly above the average. Others, notably Mexico, New Zealand, and the United States, had rates markedly below it. Student-survival rates for systems with stable enrolment patterns, that is, those that show neither expansion nor contraction in total enrolments, provide a reasonable basis for international comparisons, but there is a significant error component in these estimates because of (1) possible double-counting of course commencements, due to transfers; and (2) underestimation of completions, due to extended deferments.

Completion rates calculated using longitudinal data, that is, data derived from tracking higher education entrants through to course completion, generally provide a more realistic impression of student attrition. Astin and Oseguera (2005) calculated the award-completion rates of a large national sample group of students in the United States who were surveyed in 1994 when they were in their first year of college. By 1998, only 36% of students had completed a bachelor's degree award. By 2000, however, 58% of students had completed an award. Completion rates need, therefore, to be considered over realistic periods of time that allow for the normal incidence of interruptions to studies.

Completion rates calculated using longitudinal data also allow for consideration of the impact of institutional transfers. In an Australian investigation by Martin *et al.* (2001), entrants to undergraduate programs in 1992 were tracked through to 1999, by which time 64% of students had completed an award from their university of first enrolment. When their progress in terms of whether or

not they had ever completed an award from any university was calculated, however, 72% of students were estimated to have completed an award. The difference was attributable to the incidence of institutional transfers.

Student attrition is assuming increasing political significance in many countries, and so too, therefore, is its measurement. Any government subsidizing higher education is likely to interpret any instance of student attrition as representing inefficiency in the use of scarce resources. However, the fact is that not all student attrition represents inefficiency. Students often transfer from courses and institutions for sound reasons, and interruptions through deferment may in many instances be beneficial to future academic progress. It is attrition that results in long-term dropout from higher education that should be of most concern. Curiously, this form of student attrition is not well indicated by most conventional measures of student attrition.

Explaining Student Attrition

Tinto's (1975, 1987, 1993) interactionist theory of student attrition dominates the various theoretical formulations advanced to explain student attrition. Developed during the 1970s and 1980s, this theory proposes that premature student departure from a higher education institution is a voluntary behavior prompted by feelings of isolation as a consequence of the failure to integrate with the new social and academic environment of the higher education institution. This process is said to be longitudinal in nature. At the time of admission, a student's decision to withdraw may be directly affected by individual characteristics, including motivation, ability, family background, and prior experiences of education, but, more likely, these characteristics will impact on two types of commitment, the student's commitment to the institution and the student's commitment to the goal of graduating. These commitments may, however, be strengthened or weakened over time as the student embarks on the process of assimilating to a new social and academic culture. Difficulties experienced in integrating with the social culture will weaken the student's commitment to the institution, while difficulties experienced in integrating with the academic culture will weaken the student's commitment to the goal of graduating. Over time, the combined strength of these commitments will largely determine whether the student persists or withdraws.

Although remarkable in terms of its influence, Tinto's model has been found to be deficient in a number of important respects. Empirical support for its key propositions is reported from the United States to be partial in the case of residential universities, and problematic in the case of commuter universities (Braxton *et al.*, 2004: 20). Its inability to accommodate the influence of significant external community groups (e.g., families, neighborhoods,

and secondary schools), the organizational attributes of colleges and universities, individual psychological processes, and general economic forces, including student finances and financial aid, on student attrition has also been identified (Braxton, 2000: 259). The model remains, however, a landmark in the relevant literature.

Other significant theoretical formulations include those of Bean and Astin. Bean's model, which is explicitly psychological in nature, proposes that student attrition is effectively the product of attitudes and psychological processes, the impact of which may be intensified as a consequence of interactions with the academic, social, and organizational conditions of a particular higher education institution environment (Bean and Eaton, 2000). In this model, incentives and opportunities for persistence play an important role through their impact on individual attitudes and psychological dispositions.

Astin's model, also psychological in orientation, focuses more on the specific importance of student involvement with studies and academic life (Astin, 1984). According to Astin, what matters is the amount of time spent by a student attending to studies, being on campus, interacting with academic staff, and engaging with student organizations and activities. As in Bean's model, academic, social, and organizational conditions are seen to impact on student persistence, but, in Astin's theory, their importance derives from the extent to which they stimulate and support a student's propensity to be fully involved in the academic experience.

These formulations, and Tinto's in particular, have been characterized as assigning too much responsibility for persistence to the ability and willingness of students entering higher education to assimilate what for many will be a completely new and quite challenging environment. In recent literature, calls have been made for higher education institutions to adapt more to the cultural attributes of their new students. Thomas (2002: 431), for example, argues that: "If a student feels that they do not fit in, that their social and cultural practices are inappropriate and that their tacit knowledge is undervalued, then they may be more inclined to withdraw early." Zepke *et al.* (2006: 588) invite consideration of the ways in which "institutions accept and recognize diverse learners' goals and cultural capital, and adapt their mores and practices to accommodate these in a learner-centred way." These arguments are underpinned conceptually by Bourdieu's conception of the importance to academic success of cultural capital: "the importance of cultural experiences is regarded as a driver of inequalities which ultimately lead to limited and restricted opportunities for higher education" (Longden, 2006: 176).

A substantial proportion of the literature on student attrition is not, however, overtly concerned with theory. The range of possible explanatory variables considered in many empirical studies is often eclectic in nature, reflecting local interests, as well as characteristics and

constraints of particular data sets and methodological approaches. An implication of this diversity is that generalization is more difficult.

In one investigation (referred to earlier), Astin and Oseguera (2005) analyzed data on degree completions by more than 50 000 undergraduates at 262 colleges and universities across the United States who commenced undergraduate studies in 1994. Using multivariate statistical methods, they examined the ability of selected individual characteristics (e.g., gender, high school grades, standardized test scores, parental-education levels, involvement with athletics), environmental contingencies (e.g., living in a residence hall, financial support, working off-campus), and institutional characteristics (e.g., institutional selectivity, public, or private status) to predict degree completion within 6 years of course commencement. The investigation pointed to the strong independent predictive ability of high school grades, institutional selectivity, and residency in a student hall. Oversleeping and a tendency to miss classes and appointments were also found to be independently significant in affecting degree completion – in these cases in a negative way.

In another investigation, Yorke and Thomas (2003) sought to identify the conditions most likely to impact on institutional success in reducing student attrition. They employed a case-study approach involving interviews with senior management at six higher education institutions in Britain that had performed unexpectedly well in achieving high-retention and completion rates for students from backgrounds not strongly disposed to academic success. Their investigation was informed by a comprehensive literature review (Thomas, 2002) that identified seven areas of interest: academic preparedness, the academic experience (teaching, learning, and assessment), institutional expectations and commitment, academic and social match, finance and employment, family support and commitments, and institutional support services. No blueprint for success was identified, but the conditions considered most likely to impact positively on student retention were: a positive and supportive institutional climate, an emphasis on support leading up to and during the first year of studies, an emphasis on formative assessment in the early phase of programs, recognition of the importance of the social dimension in learning activities, and a willingness to respond to changing patterns of students' engagement in higher education.

In yet another empirical investigation, Long *et al.* (2006) employed multivariate statistical analysis of national survey data, together with a thematic analysis of students' written comments, to examine the reasons for first-year undergraduate students in Australia in 2004 not proceeding to the second year of their studies in 2005. Various possible contributing factors were considered. A striking feature of the results was that, although 28.7% of the students surveyed did not continue in 2005 in the course they had commenced

in 2004, only 13.7% of all students had, in fact, withdrawn from studies in 2005, with almost one-half of these indicating an intention to return to studies after a short period of interruption. Most first-year course attrition was, therefore, simply the result of course transfers, within and between institutions. The investigation also found that students who dropped out from university studies (even if in some cases for no more than a 6-month period of deferment) were likely to be older, to be studying part-time, and to be unlikely to nominate a clear reason for having enrolled at university in the first place. Older students who dropped out were more likely to report conflict in balancing study requirements with full-time jobs and family commitments, while younger students who dropped out were more likely to report a change in direction or the need for a break from study.

Student attrition from higher education is a complex phenomenon. As Long and colleagues report, even the students themselves find it necessary to point to combinations of factors when trying to explain why they do not continue their studies. However, enough is known to be able to identify some key conditions that affect the incidence of student attrition. These include: a student's involvement with and commitment to a particular course of study, a student's ability to commit sufficient time to studies, a higher education institution's commitment to making its courses exciting and rewarding for students, a higher education system's academic selectivity, and, for groups less well represented in higher education, the generosity of provisions for financial support to students.

Addressing Student Attrition

It is widely agreed that policies seeking to address student attrition should have as their focus the creation of conditions for success by all students, rather than being concerned solely with improving retention. Yorke and Longden (2004: 132) argue, for example, that: "A policy focus on student success in higher education through teaching, learning and assessment, and through institutional support services, is likely to lead to better retention than a focus on retention itself." The problem is that an exclusive focus on retention is too limiting, and may even result in outcomes that are incompatible with broader policy objectives. One of the surest ways of improving student retention would be by restricting access to higher education to students with superior levels of academic ability and motivation. Yet, in most systems, such a policy would be inconsistent with a commitment to increasing youth access to higher education and improving the social representativeness of the student population.

The literature on student attrition contains an impressive array of suggestions on how to create conditions for success by all students. Yorke and Longden (2004: 134–147) provide what is possibly the most succinct account of the

various measures proposed. They group these measures according to whether responsibility for their implementation rests with the individual student, the higher education institution, or the higher education system. Students are said to have responsibility for being adequately informed about their course of studies, for developing effective ways of learning, for responding appropriately to any initial lack of academic success, and for anticipating reasonably the extent to which their studies may be adversely affected by financial and lifestyle risks. Higher education institutions are said to have responsibility for selecting students wisely, for informing students fully about course requirements, for giving students a sense of belonging to the institution, for ensuring that students have appropriate and effective support services, for ensuring that academic staff are capable in performing their teaching duties, for creating an academic culture that is supportive of a high quality of student learning, for ensuring that first-year students receive particular support, and for responding sympathetically to adverse events in students' lives. Higher education systems are said to have responsibility for ensuring that good teaching is highly valued, for implementing system-wide quality-assurance processes, for seeking to ensure that financial support systems are as straightforward as possible, and for ensuring that policies intended to support participation by designated student groups are not contradicted or undermined by other policy initiatives.

Tinto (2005) has recently proposed a model of institutional action to enhance student success in higher education. He identifies five conditions in universities that, in the light of insights from research, are of greatest importance. These are: the seriousness of an institution's commitment to the importance of student success, especially among low-income and underrepresented student groups; the extent to which an institution creates an educational setting in which students are required to achieve high academic standards; the adequacy of an institution's provision of adequate and effective forms of academic and social support for students; the effectiveness of an institution's monitoring and feedback arrangements for informing students about progress in their learning; and the institution's success in engaging students with the academic and social culture of the institution.

It is evident that Tinto attaches great importance to the role higher education institutions might play in affecting the conditions for student success. Over recent years, higher education institutions do appear to have become primarily responsible for student success in higher education, but they are not solely responsible. As Tinto (2005: 321) himself points out, first-year students typically spend less time on their studies than is considered necessary for successful learning. Their commitment and expectations in relation to their studies are not always amenable to influence by higher education institutions. Student success is affected also by external conditions beyond the control

of individual higher education institutions. It is evident in many countries that, on average, students feel compelled to engage for longer periods than ever before in paid employment during study semesters. Beyond a certain level, this engagement impacts adversely on student success, regardless of anything higher educational institutions can do (Long and Hayden, 2001).

Costs of Student Attrition

Student attrition generally incurs cost. The most costly form of attrition is long-term dropout from higher education, but even course transfers have a cost impact on individual students, their higher education institution, and the public (if public subsidies are involved). Cost for the most part can be calculated in financial terms, but some forms of cost, particularly opportunity costs and psychological costs, are not readily measurable in financial terms.

Various attempts have been made to calculate the cost of student attrition. Yorke and Longden (2004: 11) provide examples from Britain of different ways in which these calculations can be performed. Using data from 1999, they estimated the cost of student attrition to be of the order of 3–4% of the public funding allocated to undergraduate higher education. However, whether this cost represented wastefulness depends on what the prior expectations were. These expectations are often not well articulated by governments, except in response to a public outcry.

Students and higher education institutions also incur financial costs as a consequence of student attrition. The scale of these costs will depend on the extent to which public subsidies have been provided. Costs incurred by students who discontinue are generally in the form of fees and study-related expenses incurred, while costs for institutions as a result of discontinuation are generally in the form of upfront expenses incurred in the expectation that students would complete their courses within a reasonable time period.

Students, higher education institutions, and the public also incur opportunity costs as a consequence of premature departure from higher education. These costs are rarely calculated in financial terms, but their impact may well be significant. Full-time students who do not realize the benefits of graduating from higher education generally forego possible paid employment during the period of their enrolment in higher education. Higher education institutions and the public also incur an opportunity cost in that the student will in many cases have tied up a place in higher education that another student could possibly have utilized more effectively.

The psychological costs of student attrition are the most difficult to measure, and they are also the most emotive. The disappointment and loss of self-esteem associated with

dropout may be overwhelming, as in the case of a student who reported that: "My family did not talk to me for a long time; they said I'd let them down. They had huge expectations of me; I was the brightest one; the first in the family to go to university" (quoted in Yorke and Longden, 2004: 7). However, it is also the case that students may perceive certain benefits in having participated in higher education, even if they did not achieve course completion.

Concluding Remarks

Student attrition takes various forms, including course and institutional transfer, deferment and long-term dropout. There is rarely a single reason for it, and its consequences can vary greatly in terms of their seriousness. Responses to it require a focus on the broad range of conditions that affect student success.

Student attrition provides an early warning sign of possible problems in a higher education institution, and, more broadly, in a higher education system. Adverse changes in its incidence may well indicate the need for increased attention to be given to key conditions affecting the quality of student experience. These conditions include the extent to which students are engaged by and committed to their courses, have been effectively selected for the courses they seek to undertake, and have sufficient financial support to enable them to have the time required for their studies. Higher education institutions inevitably bear much of the responsibility for addressing these conditions, but students also have responsibilities, particularly in terms of the earnestness of their personal commitment to academic success. So too does the public, particularly concerning financial support, because it is the public that ultimately benefits from having a highly educated population.

The form of student attrition that is of most concern is long-term dropout. The incidence of this form of attrition is lower than headline estimates of attrition based on persistence and completion rates would suggest. Its seriousness should not, however, be diminished. The individual and social costs of long-term dropout may be substantial, and the fact that it occurs more often among student groups whose backgrounds are characterized by social and educational disadvantage should be of additional concern.

Finally, to return to an earlier theme, the differences between systems in terms of the incidence of student attrition are striking. The reasons for these differences have not been able to be explored in this article, but then neither are they examined in much detail in the literature on student attrition. This area is one worthy of further exploration, particularly concerning how policies seeking to widen access to higher education can be effectively integrated with policies that seek to reduce the incidence of student attrition.

University Students' Experiences of Higher Education

C McInnis, PhillipsKPA, Richmond, Australia

© 2010 Elsevier Ltd. All rights reserved.

The student experience refers generally to the broad range of academic, extracurricular, and social activities that involve students during their time at university. The nature and extent of involvement varies for groups and individuals. The term is often used in a more specific sense to refer to aspects of the student experience of teaching and learning such as course design, curriculum organization, instruction, and learning with others, inside and outside the classroom. The first-year experience is a distinctive area of study in its own right that considers issues such as the transition of students into higher education, especially the adaptation and adjustment of those moving directly to university from secondary school. Universities and researchers also refer to the total student experience. This emphasizes the interrelationship between the various elements of university life that result in an experience, and outcomes, for students that is assumed to be something greater than the sum of the parts.

This article reviews developments in the study of the student experience over the last decade or so, and is focused on undergraduates. Among the issues discussed are: whether, and to what extent, the student experience as traditionally defined is still meaningful or indeed viable; the ways in which research and policy is responding to the changes in the nature of the student experience; and the extent and significance of global convergence in student lives.

The student experience is more difficult to define now than it was in the 1960s and 1970s, not least because of the far greater number of students now enrolled in universities. This inevitably brings with it considerably more diversity in student backgrounds, daily lives, and expectations. Renewed interest as to what constitutes the student experience and how it is changing has been further generated by the pressures of market competition and accountability on universities, major changes in the ways students go about learning, and new external social and economic pressures on student lives. Moreover the dimensions of the student experience multiply when national contexts are examined and compared.

In Europe, research and policy in this area is more strongly focused on the social and economic conditions of student life. For example, the Euro Student project gives little attention in its surveys to student perceptions of their experience or the patterns of their behavior related to study habits and engagement (Euro Student, 2004). It emphasizes the relationship between the culture of different disciplines, the time demands or workload, and the extent to which

courses are regimented. Synthesizing culturally bound surveys from eight countries inevitably smooths out some major points of distinction in the assumptions and beliefs about the ways students live and the nature of their experience. A view implicit in the surveys is that student perceptions of their personal experience are unreliable and of limited interest.

In France, the National Observatory of Student Life developed by the Ministry of National Education aims to examine all aspects of student life. Its comprehensive triennial survey is focused on the impact of living conditions, experiences, and perceptions on study patterns and outcomes. The elements of the French student experience considered significant include: the level of independence from parents; the relationship between paid work and study; student expectations as to what they will gain from the experience; and factors that might inhibit learning.

The complexity and multiplicity of student types and roles are currently challenging established research, policy, and practice for governments, universities, and academics. Traditional notions of a campus-based experience and the university as a cohesive learning community preparing undergraduates for citizenship and the workplace are being tested in most developed countries. Universities around the world are under pressure to adapt to significant changes in student needs and expectations while maintaining core values concerned with the holistic development of students.

Types and Purposes of Studies

Studies of the student experience range considerably in scope and methodology. They include: investigations of national trends by way of large-scale surveys quantifying student self-reported behaviors; qualitative strategies aimed at uncovering the everyday realities of student life; and, less common, longitudinal studies of cohorts as they move through their undergraduate programs. The purposes of the studies include contributing to theory and practice in higher education, informing national policy, providing indicators of institutional performance, quality assurance, and marketing. There is a substantial gray literature from institutional research (Harvey and Drew, 2006). These studies gather data for strategic planning and improvement purposes although they are often the basis for journal publications and continue to add to what Clark characterized in the 1970s as a relatively massive but trivial literature

(Clark, 1973: 9). Thirty years later Terenzini and Reason observe that the literature overall is: "... highly segmented, even atomistic, and virtually atheoretical. With rare exceptions (e.g., Astin, 1998) studies focus narrowly on individual programmatic interventions or overlook the wide variety of influences shaping an outcome" (Terenzini and Reason, 2006: 1).

The expectation that institutions should enhance the student experience has generated new demands to monitor student behavior and satisfaction. There has been a proliferation of studies from government, research institutes, and institutions. In addition, research is routinely commissioned to assess the quality of student life for marketing purposes. Studies of student life have also grown at the institutional level as part of the quality-assurance process. Partly in anticipation of external pressures to provide evidence of student satisfaction, and partly to anticipate and deflect criticism, many universities are now generating quite sophisticated pictures of student lives to inform their policy and planning. Until recently, this has been more prominent in the Anglophone countries, but has now become an almost inescapable feature of university strategic-planning initiatives in most developed systems.

The main thrust of the research considered in the discussion here has been toward establishing whether the university contribution to student life is more substantial than providing the basic elements of instruction and delivery of curriculum content. Despite evidence of diversity, the prevailing models of student life from the US assume an optimal level of student engagement with the university or college in a campus-based environment. These include the assumptions that a positive student experience is unlikely to occur in a social vacuum; that learning in a group is critical to the quality of student life; and that there are important learning outcomes from university beyond the mastery of subject matter.

The US is the most significant source of systematic and comprehensive scholarly work on the student experience. The substantial US research literature is in part a product of the deeply embedded belief that undergraduate education ought to be intensively student centered. What students do in college and what that means for them and America's future is a common theme. The key issues generating research and policy most recently have been focused on the need to improve the quality of the student experience set against an apparent drift away from the levels of student engagement that characterized the undergraduate experience for previous generations. Over the last 5 years or so, there has been a wave of internal reviews of undergraduate programs in US universities and colleges to counter the perceived loss of focus and direction. This is particularly the case for large research-intensive institutions. Most institutions involved in the reviews have attempted to clarify and reassert core values about the

importance of the undergraduate years while adapting to the changed realities of student lives and priorities.

Models and Theories

There is a strong tradition of psychological and sociological theory and research on the student experience. The origins of this work can be found especially in models of adolescent and institutional socialization. In their comprehensive review of US studies, Pascarella and Terenzini (2005) examine the range of theories and models of student change in two broad families: developmental theories and models that focus on individual growth; and, college impact models that study change that result from institutional characteristics. Research in the first group draws from fields such as psychosocial theories of student development and cognitive-structural theories. In the second group, the somewhat eclectic sociologically oriented studies tend to identify and evaluate several sets of variables presumed to influence one or more aspects of change (Pascarella and Terenzini, 2005: 18). The variable sets include environmental factors such as the academic and social climate created by faculty and students on a campus.

A typical model works from a chronological sequence of major points in student life. Pre-entry attributes of students are included to account for diversity in student readiness and relative fit with the institution. In these models, the formation of a student identity through interaction with peers and teachers sits alongside academic performance as central to the experience, and the overall attributes gained on graduation combine to represent a holistic outcome. Notwithstanding the view that institutions should bear considerable responsibility for the quality of the student experience, most models assume that students share responsibility for their choices and level of commitment.

Pascarella and Terenzini (2005) chose to organize their review around outcomes for students rather than, for example, attempting to isolate the discrete influences on the student experience. Of the six critical questions they pose regarding available evidence on the impact of university on students, three are particularly pertinent to this discussion: the evidence that different kinds of institutions have a differential influence on student change; the evidence on the effects of different experiences in the same institution; and the evidence that a collegiate experience produces conditional, as opposed to general, effects on student change or development. The latter concerns the extent to which these experiences are conditioned in their influence by the different characteristics of students (Pascarella and Terenzini, 2005: 9). While much of the research in this area has focused on differences in gender, racial, or social background, there has been an increasing

interest in key characteristics of students in relation to their personal priorities and choices about the nature and extent of their commitment to university study.

The broad findings that have informed the search for optimum undergraduate learning environments include the following: the greater the engagement in academic work/academic experience the better the knowledge acquisition and general cognitive growth; effective strategies for engagement are those that are based on increasing active learning, including peer teaching and individualized systems of instruction; wide cognitive impact comes from academic experiences that purposefully provide for challenge and integration; and student learning shows an unambiguous link to teacher classroom behaviors. The two most salient dimensions are the skill levels of teaching, and the nature of the course structure and organization. In summary, effective learning in the undergraduate experience occurs when educational settings are designed and delivered on the assumptions that learning is holistic rather than segmented, and that opportunities are created for active student involvement.

Social Dimensions of the Student Experience

Beyond these fundamental elements of effective learning environments, there is increasing acknowledgment that the social aspects of the student experience inside and outside the classroom, whether constructed or accidental, mediate learning in ways that have a profound influence on student outcomes. Pascarella and Terenzini (2005) demonstrated that the interaction between students, and between academics and students, outside the classroom makes a highly significant contribution to the cognitive and personal growth of students. Likewise, the overall nature of the learning climate of an institution has direct and positive outcomes on student achievement. One of the unequivocal conclusions from their review of the literature is that the outcomes of undergraduate education are largely determined by individual effort and involvement in the academic, interpersonal, and extracurricular offerings on a campus. However, the authors also make the crucial point that it is therefore all the more important to focus on the ways in which an institution can shape its academic, interpersonal, and extracurricular offerings to encourage student engagement (2005: 602). This is explored by a UK project on the organizational mediation of university learning (2005–2007) that represents a significant shift in the established UK research on teaching and learning (Brennan and Jary, 2005). Supported by the Higher Education Academy (HEA), the study aims to show how university learning “is affected by the way courses are organised, by the places in which it is happening, by the people one is

learning alongside, by the reasons people have for studying, by the other things that are going on in their lives” (Brennan and Jary, 2005: 3). As with a number of recent studies, it is partly motivated by the need to balance the tendency in the research on teaching and learning against the overemphasis on the significance and impact of instruction and curriculum content on student outcomes.

Importantly, the UK project distinguishes between the collective experiences of students within an institutional/organizational setting (the curriculum, student culture, and so on) and the personalized experiences of individual students in those settings (e.g., study method and reasons for study). A third dimension, the parallel experience, refers to the amount and nature of paid work, domestic life, and other commitments (Brennan and Osborne, 2005: 4). Focusing on diversity in higher education, the project provides new insights into how institutions, by the ways they are organized, provide opportunities for students to create a collective experience. The differentiated student experience in the UK is revealed through the analysis of student choices and expectations in specific fields of study. It identifies the tensions and issues raised in the interplay between social and academic cultures in fragmented higher education landscapes where university culture is not uniformly accessed or experienced (Houston and Lebeau, 2006: 12).

First-Year Experience

The first-year experience has perhaps attracted as much attention outside the US in recent years as the studies of the student experience in general. Students' initial experiences of higher education are pivotal in establishing attitudes, expectations, motivation, and approaches to learning (McInnis, 2001). It is now widely understood that investing in the quality of first year brings substantial benefits for institutions (Tinto, 1998). Research into the first-year experience provides critical insight into wider issues of student engagement and the development and improvement of learning and teaching. The sheer volume of research from the US has generated academic journals and specialist centers dedicated to understanding and improving the first-year experience. For 40 years, US first-year students from around 700 colleges and universities have been surveyed annually by the Higher Education Research Institute at the University of California. This has produced a rich database of change in the norms and profiles of students (Astin, 1998; HERI, 2007).

A decade of national trend studies in the first-year experience in Australian universities has revealed trends in patterns of student engagement, their use of information and communication technologies, and the ways they manage their everyday lives beyond the classroom and in

paid employment. The study monitored changes in student time devoted to academic endeavors, including class attendance and time spent on campus (McInnis and James, 1995; McInnis *et al.*, 2000; Krause *et al.*, 2005). The impact of the increasing numbers of students working in part-time paid work has only recently been considered of national significance in many countries. In many instances, changes in student financial support systems have put pressure on students to work to sustain themselves and to pay fees. However, there is also clear evidence that students are increasingly working to maintain a level of financial independence from their families for discretionary spending. This represents an international phenomenon of a shift in student expectations about their lifestyles and their commitment to university life.

The first year has also generated interest in the UK recently where the first major UK study of students' first-year experiences in higher education produced many findings in common with the Australian research. The study, commissioned by the HEA aimed particularly to find out what aspects of the student experience may affect students' decision to withdraw from their studies – an area that has been underresearched in the UK (Yorke and Longden, 2006). It surveyed students on their experiences of learning, teaching, and assessment, and on other aspects of their first-year experience such as travel, finance, and social life. At the same time, the HEA commissioned a substantial review of the literature on the first-year experience (Harvey and Drew, 2006).

Student Engagement and the Social Experience of Learning

A growing number of studies have been prompted by a widely perceived decline in the level of engagement in the face of competing pressures on student time and interest (McInnis, 2002; McInnis and Hartley, 2002). The decline is indicated by factors such as the number of days students spend on campus and the amount of contact they have with fellow students. Students are now more likely to study in multiple settings: in large lecture theaters, in groups on collaborative exercises, in computer laboratories with two or three others in an online tutorial, or simply work at home alone. They are less likely to spend significant time in small-group tutorials, or to have one-to-one consultation with their lecturers. On the other hand, they often have access to the personal homepages of their lecturers and easy access to comprehensive learning resources through learning-management systems.

The National Survey of Student Engagement (NSSE) reports on the levels of engagement of large numbers of universities and colleges across the US. The initial findings confirm the pattern of declining engagement on many fronts, for example, "First-year students on average

reported only occasional direct contact (once or twice a month) with their teachers" (Kuh, 2001: 13). The purpose of the NSSE is to provide benchmark and diagnostic information to individual institutions that will assist them to improve practice. It is quite deliberately limited in scope to identifying those aspects of the student experience that can be addressed directly by institutions.

In Australia, the major conclusions with respect to engagement from the first-year studies (Coates, 2005) have recently been supported by a systematic and comprehensive analysis of open-ended comments from graduates in a government funded annual survey of graduates. The study confirmed that it is students' total experience of university – not just what happens in the traditional classroom – that shapes their judgments of quality, promotes retention, and engages them in productive learning (Scott, 2005: vii).

Diversity in the Student Experience

Studies on the whole continue to work from the assumption that undergraduate education is primarily concerned with the transition of individuals from adolescence to adulthood. This does not reflect the reality of declining populations of young people in many developed countries, the expansion of lifelong learning opportunities provided by universities, and the subsequent shift in student profile toward mature age and part-time students. Notwithstanding this widely acknowledged observation, the literature, government policy, and public debate persist in presenting undergraduate education as synonymous with young full-time students. Harvey and Drew (2006) make the point with respect to the first-year experience that there is a multiplicity of experiences contingent on type of institution and student characteristics.

There are at least four major subgroups of students that should be considered in thinking about diversity in the student experience: traditional domestic school leavers (residential halls and commuter); traditional international school leavers; deferred entry under 25 years age; and, mature-age return-to-study over 25 years age. The evidence is clear: the 18-year-old school leaver, the 23-year-old delayed-entry student, and the 35-year-old return-to-study students are different in significant respects in terms of their approaches to study, and their expectations of university (McInnis *et al.*, 2000). Students who take up university places even after just a few years of work experience are markedly different in the ways they experience university life. Their expectations, aspirations, and sense of identity vary significantly from those who go straight from school to university. The experience of each group is qualitatively different and the outcomes vary accordingly. Although the groups have a great deal in common as a consequence of their shared experience, it is a mistake to

assume homogeneity in terms of outcomes and attributes. They have not simply arrived at the same endpoint by different paths: their experience is qualitatively different with distinctive patterns of time and space in their connection to the university. The evidence base for the efficacy of the social dimension is quite strong and generally convincing with respect to young full-time undergraduates, but there remains far less understanding of the impact of the social dimensions of university on mature-age students.

While there is a compelling case for treating young undergraduates as a key focus of research and policy related to the student experience, it should be recognized that being a student no longer has the transitional and marginal status it once had when students were a relatively small minority of the late adolescent population who went to university before they entered the real world. A European Commission project titled 'Students as Journeymen between Communities of Higher Education and Work' illustrates the persistence of the ideal type of undergraduate experience shaping current research (EC, 2004). However, students are now less different from the mainstream society simply because, by virtue of their numbers in mass higher education systems, they are the mainstream of their generation. The values, behaviors, and outlooks of students are now much more in alignment with those of the society in which they live.

Moreover, the traditional divide of full- and part-time enrolment has become blurred for many undergraduates. Likewise, there is pressure on universities from governments and universities to redraw the traditional academic calendar. The trend to concurrent college-vocational education enrolment in the US, and reflected in some respects in the Australian experience, as well as the popularity of combined and double degree programs, means that students in many systems are in effect creating their own collage of university-study programs.

Here lies the central challenge for the organization of undergraduate education. Where once it was assumed that students would naturally form peer-support groups and make regular informal contact with faculty, it is now clear that the mix of part-time work, idiosyncratic timetables, and the accessibility of web-based resources requires lecturers and course designers to create learning experiences that encourage students to develop informal networks. Students are now highly strategic in the choices they make (McInnis, 2004).

Rapid advances in communications technologies have increased options students have for configuring their approaches to learning. Indeed, separating the two is entirely superficial. It is difficult to predict the impact of technology change on the student experience in the long term. Even the most enthusiastic observers of the impact of technological change, consider that a 4–5-year time-to-adoption perspective is about as far as they can reasonably

go in their predictions (Educause, 2006). New challenges emerge with every major innovation. In the current environment, the impact of instant messaging, pod casting, and social-networking websites require universities to manage multiple ways of communicating with students to reconfigure and promote the collective experience of learning. While the new media forms embraced by young students can complement their engagement with universities, they add another layer of social networks independent of the university that have the potential to compete with it.

Patterns of Convergence in the Student Experience

There is no reason why the student experience should be immune from the impact of globalization. The increase in the numbers of students combining full-time study with paid work is recognized internationally. Similarly, most developed systems are placing high priority on students taking part of their undergraduate program in another country. Many are actively encouraging students to include substantial periods of time in the workplace during their studies. Combined and dual-degree programs have proliferated in response to student demand to broaden their employment options. These widely shared patterns of change in the student experience suggest considerable convergence that will be accelerated by the globalization of quality-assurance processes, and a changed emphasis away from institutional inputs and toward what students actually do in the process of learning.

The global shift in high levels of accountability for universities has placed responsibility for the management of the student experience squarely with institutions. The capacity of universities to respond to the changing needs of undergraduate students, and the desirability or efficacy of doing so, is a significant issue both for governments and universities. For many universities, providing a quality experience beyond classroom instruction is a matter of legitimacy and survival; for others, it is not a significant consideration. While much of the current research and scholarly discussion is directed toward measuring, monitoring, and managing the student experience, notable work is also in progress on the impact of these changes on institutional responses, adaptation, and student outcomes.

The theoretical and conceptual frameworks that shape models of the student experience are currently being reassessed and overhauled. The focus of research is shifting away from formal academic and institutional processes to the relatively unknown and sometimes competing influences of the informal or unsystematized student experience. Understanding these experiences and how they might be harnessed to enhance new forms of undergraduate education will continue to be a major focus for higher education research.

What Do University Students Learn?

G D Kuh, Indiana University Bloomington, Bloomington, IN, USA

B K Bridges, American Council on Education, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

This article summarizes some of the more important investigations into the impact of postsecondary education on desired learning and personal development outcomes. We draw on summaries done by Bok (2006), Kuh *et al.* (1994, 2006), and especially Pascarella and Terenzini (2005) – who produced the most recent definitive volume on how university postsecondary education affects student development. The vast majority of the studies reviewed by these scholars were done in the US. Economic and market forces are shaping curricular design and educational goals throughout the world (Yorke and Knight, 2006). With this in mind, we also report findings – when available – on student learning in other countries and research on study abroad.

We focus primarily on studies that take into account the influence of different types of institutional conditions, such as selectivity, and differences in learning and personal development for students with different characteristics such as race and ethnicity, gender, and socioeconomic status. These distinctions are important because many of the effects of postsecondary education are conditional and indirect – meaning that some students gain more than others and their participation in certain activities mediates (or makes possible), but does not contribute directly to, certain outcomes. For example, living on campus does not by itself contribute to desirable outcomes, but it creates opportunities for other experiences that do contribute directly to these outcomes, such as interacting more frequently with faculty members and peers. We use the terms college and university interchangeably to denote postsecondary educational enrolment eligible for baccalaureate degree credit, whether at a 2- or 4-year institution.

Learning and Personal Development Outcomes

To organize the review of learning and personal development outcomes associated with college attendance, we use the five outcome domains in **Figure 1** distilled by Kuh (1993), which encompass the range of skills, competencies, and abilities addressed in most studies on this topic.

Cognitive Complexity

The development of cognitive skills and competencies is one of the most important intended outcomes of university study. Developing intellectual and practical skills – particularly critical and creative thinking – has

never been more important than when the pace of change escalates in almost every dimension of human endeavor (AAC&U, 2007). The cognitive complexity domain consists of two outcome categories – reflective judgment and application of knowledge, abilities needed to think critically and to evaluate logically or assess the quality of one's own thinking and experience by exercising independent judgment.

Students become more critical, analytical, reflective, and intellectually flexible in their thinking in college (Baxter Magolda, 2001). Institutions that emphasize close relationships and feature high levels of student–faculty contact tend to foster greater gains in critical thinking, analytical competencies, and general intellectual development (Pascarella and Terenzini, 2005). Students who spend more time with faculty outside of class also exhibit the greatest gains in cognitive outcomes, such as comprehension, interpretation, evaluation, and application abilities. Those who engage more in such areas as intellectual, vocational, athletic, political, or social activities typically gain more in abstract, analytical, and evaluative thinking than those who are less involved. In general, students reporting greater gains in cognitive development are those who (1) perceive faculty as being concerned with teaching and student development, (2) have developed a close, influential relationship with at least one faculty or staff member, and (3) report that their peers have had an important influence on their development.

Gains in cognitive development linked to out-of-class experiences tend to be related to the amount of effort students expend in educationally purposeful activities, such as service-learning, studying or talking with peers and faculty about substantive matters, or other issues related to their studies such as paper topics or career aspirations. Students who work off campus tend to benefit in similar ways as those who work on campus or who do not work during the first year of college (Pascarella *et al.*, 1994).

Students who live on campus usually gain more in critical thinking than those who commute. Living on campus may not directly affect desired outcomes; rather, it is a mediating factor because it puts students in more regular contact with peers and faculty. Some residential environments are more powerful than others. For example, first-year students in living–learning residences exhibit significantly greater gains in cognitive development compared with their counterparts in other types of campus residences.

African-American students attending historically Black colleges or universities (HBCUs) and predominantly

- *Cognitive complexity*: cognitive skills including reflective thought, critical thinking (e.g., ability to summarize information accurately and perceiving logical coherences and discernable themes and patterns across different sources of information), quantitative reasoning, and intellectual flexibility (i.e., openness to new ideas and different points of view).
- *Knowledge acquisition and application*: understanding knowledge from a range of disciplines and physical, geographic, economic, political, religious, and cultural realities, and the ability to relate knowledge to daily life including using information presented in one class in other classes or other areas of life.
- *Humanitarianism*: an understanding and appreciation of human differences including an increased sensitivity to the needs of others.
- *Interpersonal and intrapersonal competence*: a coherent, integrated constellation of personal attributes (e.g., identity, self-esteem, confidence, integrity, appreciation for the esthetic and spiritual qualities of life and the natural world, sense of civic responsibility) and skills (e.g., how to work with people different from oneself).
- *Practical competence*: skills reflecting an enhanced capacity to manage one's personal affairs (e.g., time management, decision making), to be economically self-sufficient, and to be vocationally competent.

Figure 1 Outcome domains associated with college attendance. From Kuh, G. D. (1993). In their own words: What students learn outside the classroom. *American Educational Research Journal* 30(2), 277–304.

White institutions (PWIs) perform comparably on standardized measures of reading comprehension, mathematics, critical thinking, and composite success measures. Some research shows that African-American students at HBCUs report greater intellectual gains than their counterparts at PWIs (DeSousa and Kuh, 1996; Fleming, 1984) and interact more frequently with their faculty (Pascarella and Terenzini, 2005). These findings corroborate the widespread perception that HBCUs provide more supportive learning environments for their students.

Institutional mission and culture shape campus environments – which, in turn, are associated with intellectual development to varying degrees. For example, although attending an academically selective institution has a negligible impact on general cognitive development, students attending small, private, liberal arts colleges more frequently reported gains in cognitive complexity, ostensibly fueled by their engagement in educationally purposeful academic activities, and with peers and by the institutional ethos (Kuh, 1993, 1995). In contrast, participating in student organizations and other out-of-class activities had a negative effect on cognitive outcomes and the grade point average (GPA). The conflicting findings may be due to campus-specific differences; that is, some institutions are more effective than others in structuring learning opportunities to encourage students to integrate what they learn in class with their lives outside the classroom. Such activities seem to be especially important for African-American students and older, part-time students in terms of cognitive development.

Knowledge Acquisition and Academic Skills

The outcomes in this domain are primarily a function of course-related learning and the amount of effort students devote to their studies and independent research. At the same time, engaging in certain kinds of out-of-class activities also contributes to knowledge acquisition – with men and women benefiting to a comparable degree (Kuh, 1993, 1995).

Students learn more when their instructors use effective educational practices, such as providing feedback and inducing students to engage in active and collaborative learning activities – both inside and outside the classroom. Learning is also fostered when assignments and class activities complement students' preferred learning styles, and when faculty and peers positively reinforce student effort directed toward educationally purposeful activities. In addition, the more time students spend studying, the more they learn; because full-time students have more time to devote to their studies, they typically acquire more knowledge in college. This is generally true for all students – men and women, adult learners, traditional-age students, students from historically underserved minority groups, distance learners, and so forth (Astin, 1993; National Survey of Student Engagement, 2006).

Students gain substantially in subject-matter knowledge, verbal and quantitative skills, and oral and written communication – especially in those subjects connected with their major (Pascarella and Terenzini, 2005). For example, natural science and engineering majors report

greater gains in scientific and quantitative reasoning than humanities and social science majors. As expected, full-time students gain more than part-time students; and black students tend to report greater gains than Asian students (Horn and Ethington, 2002).

As with cognitive complexity, where one attends university has a modest effect on knowledge and academic skill acquisition. Students attending small, private liberal arts colleges more frequently tend to report greater gains in knowledge and academic skills attributable more often to classroom, laboratory, and studio activities than to out-of-class experiences (Kuh, 1993), while attending an academically selective institution seems to have only a negligible effect on knowledge acquisition (Pascarella and Terenzini, 2005).

On balance, first- and second-generation students benefit to comparable degrees as to how much they learn, after controlling for student background characteristics and engagement during college. When differences exist in terms of academic skill development, they tend to be in mathematics, science, and foreign languages (Chen, 2005) with first-generation students gaining less; these differences may be due more to individual student characteristics, such as educational aspirations, and college experiences – such as living off-campus – than their first-generation status (Pike and Kuh, 2005). Intercollegiate athletes – especially men's football and basketball players – appear to gain less in reading comprehension and mathematical problem solving compared with other students (Pascarella and Terenzini, 2005). Working (on campus, off campus, or not at all) does not seem to matter in terms of gains in reading comprehension or mathematics, at least during the first year of college. Students who study abroad learn a substantial amount about the culture, politics, and society of their host country (Carlson *et al.*, 1991; Oppen *et al.*, 1990).

As engagement increases, so do gains in literacy – especially prose and document literacy. The number of analytical courses completed also affects gains in literacy with relationships being stronger for students at 2-year colleges than their counterparts attending 4-year schools. Other activities that show a consistent pattern between engagement and literacy are asking questions in class, frequently receiving prompt feedback, and perceiving the institution emphasizes studying and academic work and provides support to succeed academically (Baer *et al.*, 2006). Taken together, these findings suggest that students at 2-year schools marked by challenging classroom activities and a success-oriented campus climate gain more in literacy.

Humanitarianism

The two outcome categories within this domain – altruism and estheticism – represent interests and actions that advance the welfare of others – especially for people

from diverse backgrounds – and appreciation for the arts. These sensibilities and habits of the mind and heart that prepare students to engage in civic affairs and work effectively with people from diverse backgrounds have never been more important than in the twenty-first-century global economy (AAC&U, 2007).

As they near graduation, students are more likely to support gender equality and are more likely to be tolerant of the political, social, and religious views of others compared to their views when they started college (Pascarella and Terenzini, 2005). Among the factors associated with these changes are living on campus, participating in cultural awareness workshops, undertaking social leadership activities, and perceiving that their institution places an emphasis on diversity and multiculturalism. In addition, faculty attitudes and values along with peer interactions consistently and positively influence changes in a range of sociopolitical and civic attitudes and behaviors. For example, the frequency with which a student volunteers in college predicts similar behavior following college. Student interactions with other students who are different ethnically or culturally have a strong, positive effect on cultural awareness. Interacting with faculty members is also positively correlated with promoting racial understanding, as are voluntarism and socializing with persons from different racial/ethnic groups.

Race and gender are significant, consistent predictors of student involvement in humanitarian efforts, which is linked to promoting racial understanding and an appreciation for diversity. Women tend to engage more frequently in civic pursuits compared with men, who are more likely to be aware of current events.

Students who live or spend time with others from different racial and ethnic backgrounds gain in appreciation for the aesthetic qualities of life and sensitivity to, and appreciation of, human differences. Other university experiences linked to these outcomes are enrolling in ethnic studies courses, attending racial awareness workshops, engaging in cross-racial interactions, and participating in community service. In addition, exposure to people with diverse perspectives and interaction with people who have more advanced stages of moral reasoning, such as discussions between first-year students and senior students or faculty members or staff, and work-related experiences appear to enhance moral reasoning abilities. Finally, students from the US who study abroad tend to become more civic-minded, more committed to international issues, and become more appreciative and aware of cultural differences. International students studying in the US tend to benefit in terms of general education outcomes as well as personal and social development.

Community-college students evidence greater gains than their counterparts at 4-year institutions in becoming more open to intellectual and racial/ethnic diversity (Pascarella and Terenzini, 2005). Students attending small,

private liberal arts colleges more frequently reported changes in altruism and estheticism (Kuh, 1993).

The relatively homogeneous environment of HBCUs does not seem to inhibit the development of humanitarianism in African-American students (Pascarella and Terenzini, 2005), even though they tend not to report as many experiences with diversity (Umbach and Kuh, 2006). Attending an HBCU also appears to have an impact on civic orientation as their graduates are typically much more likely to participate in community service activities (Redd, 2000). Compared with their counterparts at PWIs, HBCU African-American students report more contact with faculty, a greater belief that their institutions contribute to their spiritual growth, and a greater sense that their campus experience has contributed to their community involvement and civic engagement (National Survey of Student Engagement, 2004). Students at HBCUs also report greater increases in self-understanding and the likelihood that they will vote.

Interpersonal and Intrapersonal Competence

This domain consists of five attributes considered indispensable to living a meaningful, self-regulating, fulfilling life. They are self-awareness, autonomy, confidence, social competence, and sense of purpose. These outcomes contribute to one's sense of self-worth and well-being, and affect the quality of interactions with others.

Educationally purposeful out-of-class experiences such as peer interactions, work experiences, and meaningful leadership activities are linked with positive social self-esteem, self-confidence, and other aspects of personal development – with women typically gaining more in self-esteem than men; this may be, in part, because of a ceiling effect with men scoring higher on such measures when they start college. Similarly, experience in a paraprofessional role, such as tutoring or being a residence hall assistant, is related to gains in self-confidence, self-awareness, skills in interpersonal communication, and awareness of group dynamics. Attending an institution with large numbers of students from different racial and ethnic backgrounds is also related to enhanced social self-concept. Service-learning courses help students clarify and define their identities and strengthen their self-esteem, internal locus of control, and interpersonal skills. Living on campus, taking diversity courses, helping teach a course, working with a faculty member on a research project, and being involved in collaborative group projects are all positively linked to varying degrees with academic self-concept, self-esteem, and self-directed behavior (Terenzini *et al.*, 1996).

Student-faculty interaction beyond the classroom is positively correlated with personal growth in the areas of leadership, social activism, and intellectual self-esteem, and academic as well as social self-concept. Such interactions include the hours per week spent talking with faculty

outside of class, assisting faculty in teaching a class, working on a professor's research project, and being a guest in a professor's home.

Students of color tend to report making greater gains in personal and social development compared with white students. African-American students at HBCUs tend to be more confident than their counterparts who attend PWIs (Fleming, 1984; Watson and Kuh, 1996). Because African-American students attending PWIs have to devote more effort to maintaining supportive social relationships due to their minority status, they tend to gain more in areas such as interpersonal skills. African-Americans at HBCUs also appear to benefit more in terms of desired outcomes of college from course-related experiences than out-of-class engagement. Hispanic community-college students reported gaining more in communication skills and personal and social development compared to their Asian counterparts, and greater gains in personal and social development compared to Caucasian students.

Practical Competence

Practical competence represents students' capacity to perform effectively in and after college in a variety of areas. This domain includes the acquisition of time-management skills and other attitudes and competencies, such as interpersonal communication, group process, teamwork, decision making, and understanding and demonstrating sensitivity to workplace culture – needed to manage one's own affairs and perform well in post-college employment settings. Employers and policy-makers are increasingly interested in this arena, stating that while students are well-prepared in their major field, many lack the skills and abilities needed to be successful in the workplace. Although practical competencies can be obtained in classrooms, laboratories, and studios, the nature of many out-of-class activities often requires that students become competent in these areas, demanding that students examine and test their skills and values in a variety of situations not unlike those they will encounter following college. For example, experiencing diversity and voluntarism and community service in particular are linked with student-reported gains in competence or the belief that their college experience provided good preparation for work.

Educationally purposeful out-of-class experiences such as voluntarism, community service, and holding office in student government or other organizations contribute positively to leadership development, decision-making skills, and feelings of personal competence. Although the research is mixed as to whether leadership experiences in student government or other organizations has a direct effect on career choice, some studies suggest that extra-curricular activities may positively affect career aspirations

(especially for African-American students) and career mobility. Although the influence of co-curricular student involvement on career development is inconsistent, college graduates think such activities are important to their success after college; that is, college graduates typically refer to leadership roles as being important to the development of practical competence and later achievements. However, it is likely that other variables (personality, motivation, etc.) may be more important in explaining such effects on practical competence (Pascarella and Terenzini, 2005).

Involvement in intercollegiate athletics also shows mixed effects in relation to occupational status. Some research shows that athletic participation was related to occupational status attainment for African-American men and had a positive indirect effect on occupational status for Caucasian men, after controlling for race, socioeconomic background, occupational aspirations, college grades, and educational attainment. Other studies found negligible and statistically nonsignificant effects when comparing athletes and nonathletes.

Working during college – particularly in a job related to one's major or vocational goal – is related to such practical competencies as decision making and time management as well as subsequent career attainment.

Student–faculty informal contacts outside the classroom appear to significantly influence career choice, career interest, and eventual career selection. Relationships with faculty members had meaningful and positive effects for female students on self-reported growth in career-related skills. Interactions with faculty members positively affected self-reports of career preparation for 2-year college students, particularly those in trade and industry fields. Student–faculty interactions also appear to positively influence the likelihood of students choosing careers in academic and scientific research. However, other aspects of practical competence such as decision-making and time-management do not seem to be influenced by contact with faculty.

Conclusion

On average, a wide range of benefits are associated with postsecondary education for everyone – men and women, students from various racial and ethnic backgrounds, international students, residential and commuter students at 2- and 4-year colleges, and so forth. These effects are cumulative and mutually shaping, with cognitive growth influenced by a variety of experiences and conditions on a campus, particularly when out-of-class climates and experiences complement and encourage students to integrate what they learn in class with their lives outside the classroom. In addition, out-of-class activities that impact the development of cognitive skills may also impact the

development of ethical and moral reasoning abilities. More specifically:

- Institutional type influences development of personal values.
- Peer interactions are the single most powerful influence on students' academic and personal development.
- Interacting with faculty is positively associated with persistence, practical competence, and other measures of success and desired outcomes.
- Community college students have different goals and outcomes than their counterparts at 4-year institutions.
- Student effort and engagement in educationally purposeful activities have a cumulative positive effect on values development, cognitive development, and life-long learning outcomes.
- Students who participate in study abroad benefit in a number of ways, including enhanced cultural awareness and civic involvement.

Associations of Universities

G F Moodie, Griffith University, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

This article considers national associations of universities, national subgroups of universities, university consortia or associations of universities to fulfill a closely defined purpose, and international associations of universities. While these groups are very different in their specific purpose and organization, they are all associations of whole institutions to further their institutional interests and often a broader social purpose. Notwithstanding the breadth of the article, several important types of academic associations remain beyond its scope. The article does not cover various types of disciplinary associations such as the American Society for Engineering Education, Chinese Society for Engineering Education, Conference of European Schools for Advanced Engineering Education and Research, Engineering Professors' Council, Indian Society for Technical Education, International Federation of Engineering Education Societies, and the Société Européenne pour la Formation des Ingénieurs. Neither does the article cover learned academies such as the Royal Swedish Academy of Sciences (which awards the Nobel prizes for chemistry, economics, and physics), the Royal Society (the national academy of science of the UK and the Commonwealth), the US National Academy of Sciences, and the International Council for Science.

National Associations of Universities

National associations of universities have been established in several countries. Many important characteristics such as their age, scope, legal status, size, and role reflect the country in which they are established. For example, one of the earliest national associations of universities, the *Österreichische Universitätenkonferenz* (Universities Austria), was established in 1911 as the rectors' conference of higher education institutions in the Austro-Hungarian Empire. During much of its history, Universities Austria was a statutory corporation, an institution of public law, but at other times it has been a nonprofit association under private law, its current legal status. Higher Education South Africa (no date) describes itself as “the unified body of leadership in a transforming, dynamic and diverse system of higher education in South Africa,” reflecting the government's restructuring of higher education as well as South Africa's general political environment.

Notwithstanding their important differences, national associations of universities have some characteristics in common. Many originated as informal meetings of university leaders. Thus, the Association of Universities and

Colleges of Canada evolved from a meeting of university presidents in 1911 to discuss issues they planned to raise at a meeting of the Congress of Empire Universities which was to be held the following year in London. Most have comprehensive if not complete membership of the institutions within their scope, which are usually either universities, or, more broadly, higher education institutions in their country. Many have roles similar to those of the *Hochschulrektorenkonferenz* (German Rectors' Conference) and the *Finlands Universitetsrektorers Råd* (Finnish Council of University Rectors) of formulating and presenting common positions to government and the public, and advancing cooperation between their members.

Some national associations of universities have distinctive roles in addition to the roles commonly discharged by such associations. Thus, the New Zealand Vice-Chancellors' Committee is responsible for institutional quality assurance and for approval, accreditation, and moderation of university programs. The *Vereniging van Universiteiten* (Association of Universities in the Netherlands) is the universities' employers' organization. The American Council on Education mounts senior managers' development programs, and the Association of Universities and Colleges of Canada administers more than 150 scholarship, fellowship, and internship programs on behalf of governments, foundations, and private companies.

National and Regional Subgroups of Universities

Some national associations of universities circumscribe their scope and membership criteria, leaving other higher education institutions to be represented by other bodies. Thus, France has both the *Conférence des Présidents d'Université* and the *Conférence des Grandes Ecoles* (conference of professional academies), and the Netherlands has both the *Vereniging van Universiteiten* (Association of Universities in the Netherlands) and the HBO-raad (Netherlands Association of Universities of Applied Sciences). Other countries have both a comprehensive universities association and various subgroups of universities to pursue more specific interests than those represented by the comprehensive national association of universities. An illustrative example is the UK.

The UK has a comprehensive national association of universities and colleges of higher education, Universities UK. Universities UK originated in the nineteenth century from informal meetings of several university vice chancellors and principals of university colleges. The first meeting of all vice chancellors was held in 1918 and a standing Committee of Vice-Chancellors and Principals was established in 1930. In 1992, the UK Government dismantled the binary divide between universities and polytechnics, allowing polytechnics to become universities. The Committee of Vice-Chancellors and Principals

admitted the newly designated universities as members, doubling in size and becoming much more diverse in membership.

The attempt by the UK Committee of Vice-Chancellors and Principals to represent the diverse interests of its newly expanded and diverse membership soon led to the establishment of subgroups of universities to advance more specific interests. The 20 big research-intensive universities formed the Russell Group in 1994 and later the same year, 17 of the smaller research-intensive universities formed an association, calling itself the 1994 group. The 29 newer or modern universities established as universities since 1992 formed themselves into a group now known as Million+. This left a diverse mixture of pre- and post-1992 universities without a subgroup affiliation and in 2006, some 24 such universities formed themselves into a group now known as the University Alliance.

While these UK subgroups were formed mainly to represent different interests to the national government, at the same time, another collection of subgroups was formed, mainly to promote higher education and institutional cooperation in their region. Examples of these regional subgroups include Universities for the North East (of England) established in 1983, East Midlands Universities Association (1998), West Midlands Higher Education Association, and London Higher. There is in addition a national subgroup of UK universities based on a special function. The Council of Validating Universities was formed in 1982 to promote good practice and standards of awarding institutions' validation of their programs offered by other institutions, called collaborative provision by the Council but known more generally in the UK as franchising. The Council of Validating Universities has 78 members, ranging across all the other subgroups.

The US has numerous diverse national and regional subgroups of universities. The American Council on Education is the comprehensive representative body of all types of accredited, degree-granting institutions in the US. It was founded in 1918. Several national university subgroups were established before then. The US's oldest higher education association is the National Association of State Universities and Land-Grant Colleges, which originated in 1887 and now promotes public higher education. The Association of American Universities was founded in 1900 to promote the standing and acceptance of their members' doctoral degrees among European universities. The Lutheran Educational Conference of North America was established in 1910 and the Association of American Colleges and Universities was founded in 1915 to promote undergraduate liberal education.

The most prominent subgroup of US universities is the Ivy League, which is an athletic conference or sports competition among eight private higher education institutions in the Northeastern United States. Its members are Brown University, Columbia University, Cornell

University, Dartmouth College, Harvard University, Princeton University, University of Pennsylvania, and Yale University. While these colleges had competed against each other informally since 1900, the first Ivy Group Agreement was not signed until 1945 and covered only football. The Ivy League now sponsors conference championships in 33 men's and women's sports. While the Ivy League is an athletic conference, the term is also used to refer to its members which are some of the most elite and oldest colleges in US, seven of its members having been established before the start of the American War of Independence in 1775.

The US is distinctive in that its most authoritative accreditation of education from kindergarten to doctoral level is conducted by six regional associations. The oldest such body, the New England Association of Schools and Colleges, Inc., was founded in 1885. It accredits more than 2000 public and private schools, colleges, and universities in the six states of the New England region. While regional accrediting associations are now established as independent corporations, they originated as associations of universities and colleges which remain strongly represented on their governing bodies.

Other regional US university associations range greatly in geographic coverage. A number of associations cover several states, such as the Associated Colleges of the South which comprises 16 liberal arts colleges and universities across 12 states in the US south. Some associations cover a region within a state, such as the Colleges of Worcester Consortium which comprises 13 public and private colleges and universities located in central Massachusetts. The Associated Colleges of the Twin Cities is a group of five private liberal arts colleges located in either Minneapolis or Saint Paul, Minnesota. The Atlanta Regional Council for Higher Education comprises 19 public and private colleges and universities in one city, Atlanta, Georgia. There are several associations of universities in parts of cities, such as Rochester Area Colleges which comprises 18 higher education institutions in Rochester, New York. Perhaps the regional association with the smallest geographic coverage is the Claremont Colleges, a group of five undergraduate and two graduate schools of higher education located in Claremont, California. The Claremont College campuses are adjoining and within reasonable walking distance of one another, covering roughly one square mile or 260 hectares.

University Consortia

University consortia are associations of universities to fulfill a closely defined purpose. The expansion of information and communication technologies has stimulated the formation of several university consortia to offer programs online, often in combination with other study modes. The Great Plains Interactive Distance Education

Alliance was established in 1994 by ten western and Mid-western US universities to offer graduate programs in human services by distance education and online. Students enrol in an alliance program through one of the partner institutions. The revenue-sharing formula provides for 12.5% of the student fee to be retained by the admitting or home university to cover student records and services, 75% is passed to the teaching university, and 12.5% of the fee is allocated to the alliance to support joint activities such as promotion and maintaining its website. Students graduate with a degree from their home institution.

Western Governors University is a prominent cooperative online university in the US, having been founded in 1997 and enrolling 10 000 students in 2008. However, it is perhaps not strictly a university consortium since it was founded and is governed by 19 state governors. University Alliance involves nine US universities offering certificate, bachelor, and masters programs online through a system operated by Bisk Education. Bisk Education's system includes instructional designers who support teachers at the participating universities to develop online materials, media production to record and edit teachers' classes in video and audio, a course management system, and marketing and student support.

An example of an international university consortium is the online university U21Global. U21Global was formed in 2001 by Universitas 21 and a private partner. Universitas 21 was in turn founded in 1997 and now has 21 members in 13 countries. U21Global offers masters programs in business management and information-technology management. Programs and their subjects are reviewed and accredited by U21pedagogica, a wholly owned subsidiary of Universitas 21. Degree certificates awarded by U21Global bear the crests of Universitas 21's members.

International Associations of Universities

Kirkland (2004: 49) observes that the development of the Association of Commonwealth Universities, the oldest international association of universities, prefigures the development of many other such associations. The Association of Commonwealth Universities originated in 1903 when universities of the then British Empire met in the then premises of the Royal Society in Burlington House, London. The ensuing interest encouraged the University of London to initiate a congress of universities of the Empire which was held in London in 1912 and attended by representatives of 53 universities. They formed the Universities Bureau of the British Empire in 1913. The Bureau was a federation founded on sentiment according to Ashby (1988: 27 (1963)). Its membership was and remains both voluntary and based on subscriptions. It grew to 100 members by 1953, almost 400 by 1994, and it now has some 500 members.

As Kirkland (2004: 52) notes, many of the interests of the participants in the precursor and earliest meetings of the Association of Commonwealth Universities remain salient now. Participants in the 1903 meeting discussed student and staff mobility among other matters of common interest. What is now the *Commonwealth Universities Yearbook* originated in 1912 and is now published as an online database as well as a book of over 2500 pages. The initial aims of the Universities Bureau of the British Empire set out in its constitution of 1919, included collecting and disseminating information, both about university members and about topics of shared interest, holding conferences, and facilitating the exchange of students and teachers. In time, the Association established a regular information bulletin for members.

The Association of Commonwealth Universities is like numerous other international university associations in having developed from an informal meeting of heads of institutions which share an interest. The common interest of the Association of Commonwealth Universities is based on political geography. This is in common with a third of 50 international associations of universities, such as the *Unión de Universidades de América Latina* (founded 1949), Association of African Universities (1967), Inter-American Organization for Higher Education (1979), *Communauté des universités méditerranéennes* (1983), and the Circumpolar Universities Association (1989). Many other international associations of universities have goals similar to the Association of Commonwealth Universities of sharing information and facilitating staff and student exchange which they likewise advance by holding regular conferences and occasional workshops, publishing newsletters, conducting research, and publishing occasional reports. The Association of Commonwealth Universities is, however, unusual in having been founded at least 50 years before most other international university associations.

One of the most important international bodies, the International Association of Universities, was first proposed in 1948 by the government of the Netherlands and the United Nations Educational, Scientific and Cultural Organization (UNESCO). Since its foundation in 1950, the association has grown to over 580 higher education institutions. The association holds conferences, runs staff-development programs, and publishes a journal *Higher Education Policy*. The association has also published the *International Handbook of Universities* since 1959. It now contains entries for 17 000 higher education institutions published in a print directory of two volumes and now also online as the world higher education database. The International Association of Universities also importantly issues policy statements, on: sustainable development (1993), funding (1994), academic freedom (1998), internationalization (1998), information technologies (2004), quality higher education across borders (2005), and equitable access (2008).

Complementing the International Association of Universities is the International Association of University Presidents which was founded in 1964 and now has some 600 members. The International Association of University Presidents holds triennial conferences of its whole membership and regional conferences; it convenes working groups on various matters and it publishes a quarterly newsletter.

In the mid-1960s two associations were formed on common cultural interests: the Association of Arab Universities and the International Federation of Catholic Universities. The Hispanic Association of Colleges and Universities is similar to the Association of Arab Universities in being based on common sociocultural interests, but was formed 26 years later in 1986. There are at least three other international university associations based on shared religion: the Council for Christian Colleges & Universities (founded in 1976), the International Council of Universities of Saint Thomas Aquinas (1993), and the International Association for the Promotion of Christian Higher Education (1975).

The number of international associations of universities has exploded since the 1970s. In the 35 years from 1972 to 2007 at least 38 international associations of universities were established, more than one each year. Neither is the pace slackening. In 2006 alone, three associations were formed: the Global U8 Consortium, the EuroMed Permanent University Forum, and the International Alliance of Research Universities. The newer associations continue to follow the pattern set by the Association of Commonwealth Universities almost a century ago. Many like the Association of Commonwealth Universities are formed at the initiative of a single university, often of an individual. The Inter-American Organization for Higher Education was initiated in 1979 by Gilles Boulet, president of the *Université du Québec*; the *Communauté des universités méditerranéennes* was formed in 1983 following the lead of the *Président de l'Université de Bari* and a group of lecturers; the *Europaeum* was conceived in the early 1990s by George Weidenfeld and Ronald Grierson, and many other examples can be given.

The newer associations also follow the Association of Commonwealth Universities in seeking to share information and promote student and staff exchange, and most undertake much the same activities: holding conferences and publishing newsletters and occasional papers. We have seen that many are also based on a shared political geography. Common cultural interests have also continued to stimulate the foundation of new international associations of universities, with newer associations being based on a common religion, and others on a common language, such as the *Associação das Universidades de Língua Portuguesa* (1988) and *L'Agence universitaire de la Francophonie* (1989).

Some associations have been founded on a different principle: status, almost always based on claims of research distinction. For example, Consortium Linking Universities of Science and Technology for Education and Research

(CLUSTER) (founded in 1990) describes itself as 12 leading universities of science and technology working together; the Association of East Asian research universities (1996) describes itself as a forum for leading research-oriented universities in East Asia; the League of European Research Universities (2005: slide 5) notes in its promotional presentation that it was founded in 2002 by a group of 12 European universities with the objective of creating a common policy forum of top research universities in Europe (it has since expanded to 20 universities); the Worldwide Universities Network (2003) says that it is a partnership of 16 research-led universities from Europe, North America, South East Asia, and Australia; and the International Alliance of Research Universities (2006) seeks to be the premier alliance of universities in the world.

International university associations differ greatly in size, falling into three groups. There are at least eight associations with 400 or more members. One of the biggest associations is the European Association of Institutions in Higher Education which was founded in 1990 and now has 830 members. This association's central interest is occupational education and its members include all types of higher education institutions. Another very big association with 775 members is the European University Association. This association is the representative body for European universities, most importantly recently in the Bologna process. Other big associations are *L'Agence universitaire de la Francophonie* (692 members), Magna Charta Observatory of Fundamental University Values and Rights (622 members), International Association of Universities (580 members), Association of Commonwealth Universities (500 members), and the Inter-American Organization for Higher Education (400 members).

The second group has 100–200 members. Two of the bigger associations in this group are based on religion: the International Federation of Catholic Universities (200 members) and the Council for Christian Colleges & Universities (181 members). One of the smaller associations in this group is based on language: *Associação das Universidades de Língua Portuguesa* (117 members). Most of the other universities in this group are based on political geography, such as the *Asociación Universitaria Iberoamericana de Postgrado* (Latin American Association of Postgraduate Universities) which was formed in 1998 and has 119 members.

The third-sized group of associations of universities has from 10 to around 60 members. Some of these smaller associations were established before the explosion: the *Unión de Universidades de América Latina* (established in 1949), the Association of Arab Universities (1964), and the Women's College Coalition (1972). As with the other-sized groups, many smaller associations are founded on political geography, such as the *Asociación de Universidades Grupo Montevideo* (founded in 1992) and the Association of Pacific Rim Universities and Øresund University, both of which were founded in 1997.

Analysis

Whetten (1981) offers a useful theoretical analysis of inter-organizational relations. Whetten (1981: 2–4) notes that interorganizational relations have been analyzed from four distinct research traditions. Public administration researchers seek to improve coordination within a service-delivery system, such as health. More specifically, they examine lateral coordination of agencies at the local level. In contrast, marketers examine vertical links between businesses in channels of distribution between suppliers of raw materials, manufacturers, wholesalers, retailers, and customers. Some economists study the relations between businesses in a sector and the relations between sectors, positing industry clusters and innovation systems. The aim of this research is to determine the conditions for forming clusters and fostering innovation. And sociologists study the formation and dynamics of groups and organizations to understand their power relations. Most analyses of associations of universities are in the sociological tradition, but the other perspectives could usefully be applied to universities' associations with other organizations, both within the sector and between sectors.

An early analysis of international associations of universities was offered by Neave (1992). Neave (1992: 52) posits five stages along a continuum of international links between higher education institutions: (1) monodisciplinary bilateral links, (2) exchange partnerships, (3) network partnerships, (4) multidisciplinary networks, and (5) consortia. It will be noted that most university associations considered in this article are of the last three of Neave's types. Other analysts have followed Neave's lead and developed typologies of university associations (Wächter, 2000; de Wit, 2002; Beerkens, 2002). de Wit (2004: 34–36) distinguished between academic associations which are loose associations most commonly established to advance interest in a discipline, academic consortia which are groups formed to fulfill a contract, and institutional networks which are groups established to advance multiple purposes.

Future

Whetten (1981: 15) posits five conditions for organizations' voluntary coordination. A positive attitude to coordination may be established by a cosmopolitan ethos, strong shared background and values, or rewards, such as may be provided by research grants or special government grants. Organizations may see the need to coordinate with others on which they partly depend or with which they share goals, and Whetten (1981: 17) found that organizations are likely to perceive partial interdependence if they have broad goals and provide diverse services to a wide range of clients. Organizations may become aware of prospective partners from informal contact, geographic

proximity, or formal communication. Organizations assess the compatibility and desirability of potential partners by their status congruity, compatible ideology and definition of problems, consensus over domain or the allocation of roles, complementary organizational structures and procedures, and goal compatibility. Whetten's fifth condition of capacity to maintain the coordination process depends on adequate resources and staff, adequate communication channels, and flexible rules and procedures.

These conditions are satisfied for many universities; hence, their associations of universities seem to have a strong future. This is borne out by their dynamism. Well-established associations continue to be active, many are still growing in size and activities, and numerous new associations continue to be formed. There are approximately 9,60 universities in the world; so if, as some argue, international associations are formed in response to globalization which affects most universities (de Wit, 2004: 29), there is considerable scope for the formation of new associations and the considerable expansion of associations that seek comprehensive membership. In 2004, Kansas State University established an institute for academic alliances to study and support inter-institutional academic program development, implementation, and management. Associations may be further encouraged and strengthened by sharing information on their operation in international meetings of associations of universities convened by the International Association of Universities. The first such meeting was held in 2005, the second in 2007, and the third in 2009.

On the other hand, as Teather (2004: 1) observes, "Some international networking alliances and consortia of universities started with a media fanfare, but have not lived up to their founders' expectations. They now limp along with a low level of activity, or have disbanded altogether." Some, perhaps many, associations are formed by universities responding to similar conditions. A change in universities' environment or international conditions may result in the disbandment of some associations, or perhaps their amalgamation or consolidation into overarching associations, as various associations of European universities have done. The associations of disparate universities formed on the initiative of an individual seem most vulnerable to withering once the initial champion leaves his/her current position or his/her enthusiasm wanes.

Glossary

Beamte – A civil servant.

Beihilfe – A subsidy or economic assistance.

Fachhochschule – A university of applied sciences.

Grande Ecole – A higher education establishment outside the mainstream framework of the public universities system.

Kunsthochschule – A university of applied sciences focusing on art.

Musikhochschule – A university of applied sciences focusing on music.

Polytechnique – A technical institute.

Technikon – A university of technology.

Universität – A university.

Higher education teaching and research personnel increasingly work in an international environment, and there are international standards that are generally expected by United Nations Educational, Scientific, and Cultural Organization (UNESCO) under its Recommendation on the Status of Higher Education Teaching Personnel, passed by its general conference in 1997. These standards specifically highlight the importance of academic freedom and institutional autonomy as core standards that are expected of all higher education institutions. In like vein, there are also International Labour Organization (ILO) conventions which, while not specific to higher education, also support the rights of higher education staff to collective bargaining. In general, these standards have been seen to be necessary in order to ensure that all higher education institutions are able to assure freedom of expression, and maintain an independent voice without government suppression. In some countries, these freedoms are defined in national or regional legislation, but for others, it is the right to collectively bargain that provides a solid foundation for the roles and rights held by higher education teaching and research personnel. In New Zealand, the Education Act specifically speaks about the role of universities as ‘critic and conscience’ of society.

Higher education teaching and research personnel also have rights and responsibilities in their teaching, research, and public commentary roles. In order to ensure that academic freedom is not stifled, such staff retain the right to participate in academic associations, including trade

unions. The UNESCO recommendation sees these freedoms as essential in the maintenance of academic freedom.

27. Higher education teaching personnel are entitled to the maintaining of academic freedom, that is to say, the right without constriction by prescribed doctrine, to freedom of teaching and discussion, freedom in carrying out research and disseminating and publishing the results thereof, freedom to express freely their opinion about the institution or system in which they work, freedom from institutional censorship and freedom to participate in professional or representative academic bodies. All higher education teaching personnel should have the right to fulfill their functions without discrimination of any kind and without fear of repression by the state or any other source.

However, over the last decade or so, higher education has become both more internationalized and more connected to the market. Governments have instituted reforms of their higher education systems that have had the effect of propelling higher education institutions to engage in academic capitalism. Throughout the world, academics are now expected to become involved in the market, and to search for increasing private income to sustain the core public work of teaching and research. This tendency, referred to in the Singapore context as ‘jumping into the sea’, pervades many higher education institutions and has been a powerful transformative force. The impact of embracing the market has been profound and has led to an unprecedented expansion of private higher education institutions, including private operations of public universities from the developed world. It is in these contexts that collective bargaining has become more important as a tool for the protection and enforcement of rights articulated in the 1997 UNESCO recommendation.

Introduction to Bargaining Systems

All higher education systems or institutions employ academic/faculty and other staff. Therefore, in each case the following questions must be asked.

- What are the terms and conditions of employment?
- How are they to be determined?

In higher education, as in other spheres of voluntary employment, these questions are determined in one of the following ways:

- By direct state regulation. The state may be the employer and use its legal power to directly prescribe conditions of employment, or it may empower an employer unilaterally to determine employment conditions.
- By individual contract between each employer and employee, usually subject to a regime of minimum legal conditions.
- By a system of binding arbitration by state agencies. These can range from a genuinely independent quasi-judicial tribunal, to *de facto* political determination.
- By collective bargaining.

Collective bargaining refers to negotiations between employees, through representatives which are usually labor unions, and an employer or group of employers, with a view to establishing agreement, usually with legal force, on working conditions and terms of employment, and regulating the relations between the relevant employer(s) and the employees and their representatives.

The right to collective bargaining is enshrined in a number of conventions of the ILO, which is the agency of the United Nations charged with the promotion of internationally recognized human and labor rights. The right to collective bargaining and the right to take strike action in pursuit of bargaining claims are acknowledged as core labor standards.

In the specific context of higher education, the UNESCO recommendation states in part:
