There are now at least 71 models of learning styles. These have been reviewed by Coffield *et al.* (2004a). Despite the proliferation of models, Coffield concluded that the field, as a whole, could not be characterized as healthy: “the field of learning styles research as a whole is characterised by a very large number of small-scale applications of particular models to small samples of students in specific contexts” (ibid. 1). This makes it difficult to assess the impact of learning styles on learning and teaching, including learning and teaching in vocational contexts: “there are very few robust studies which offer reliable and valid evidence and clear implications for practice based on empirical findings.” Nor does the field exhibit the conditions necessary for the development of a robust evidence base: “Leading theorists, and developers of instruments tend to ignore, rather than engage with each other. The result is fragmentation, with little cumulative knowledge and cooperative research” (ibid.: with omissions). Besides this, there are large commercial interests at stake in respect of some of the better-known models, and that is not always conducive to encouraging robust and independent evaluation.

Learning Styles and VET

Much of the research on learning styles in relation to VET has been carried out in Australia. In general terms, research indicates that VET learners are inclined to:

- be more visual than verbal, preferring to watch and see rather than read and listen,
- prefer to learn by doing and by practicing, and
- prefer learning in groups, to have instructor guidance, and to have a clear understanding of what is required of them.

For example, Christie and Choy (1998) showed that VET learners in Queensland were averse to textual presentations, and that they tended not to be independent learners. A study by Smith (2000) in Victoria produced similar findings. Brennan (2003), in an online context, showed up the importance of social contexts for learning among VET students, and the need to develop a lower reliance on texts, and greater self-direction.

However, VET students are by no means a homogeneous group. The quoted studies found that female students were more verbal than males and were likely to be self-directed. Students in areas such as health and community studies and business were found to be more verbal and less hands-on; while apprentices were more hands-on and less verbal.

Smith and Dalton (2005) examined learning styles in the VET context. They showed how practitioners view style differences between students, and how they take account of those differences in designing and delivering teaching. Sites included five technical and further education (TAFE) institutes and one professional network of trainers in private and public-registered training organizations. Participants included teaching staff, students, and management staff, and were largely self-selected. The major findings were as follows:

- VET providers deliver programs in new and flexible ways, using a wide range of media and approaches, in a variety of locations.
- The diversity of students requires that teaching staff are able to adapt to different learner groups and individuals.
- VET teachers generally recognize group and individual learning style differences among their learners.
- Teachers see the identification of style and their responses to it as part of good professional practice.
- Teachers rely on previous experience: they have a range of methods for identifying individual and group learning styles, and for responding to these.
- Teachers rely on practice rather than theory; they observe learner reactions to the learning context and to the media used, and they adapt their teaching practices in the light of those observations.
- Professional development should focus more on practical examples of good practice and practical teaching settings, and less on theories of learning styles.
- Students had a limited knowledge of learning style but thought that teachers did take account of their learning characteristics in their teaching.
- There is need for the development of learning-to-learn training for students.

Buch and Bartley (2002) have explored the hypothesis that learning style influences training preference. A total of 165 employees from a large US financial institution completed the Kolb Learning Style Instrument and

a survey that measured preferences for styles of training delivery. Results found evidence of a relationship between the two, with convergers showing a stronger preference for computer-based delivery and assimilators showing a stronger preference for print-based delivery. However, results also revealed an overall preference for classroom-based delivery for adults in the study, irrespective of their learning style.

Flexible Learning in the Workplace

Sadler-Smith and Smith (2004) reviewed the literature on flexible learning programs and learning styles. There is a growing use of flexible forms of delivery for workplace learning and development (Calder and McCollum, 1998). Distance learning, programmed instruction, technology-based training, telematics, and e-learning enable learners to acquire job-related knowledge and skills in ways that match their learning preferences.

Nikolova and Collis (1998) examined flexible instruction from the point of view of designers' and learners, and argue for a role for telematics. Morgan *et al.* (2000) explored the instructional features of learning environments as a source of understanding the relationship between the learner, the environment, and learning outcomes. The interaction of learners' style and instructional design has already been discussed; in this context, Ford and Chen (2001) provide evidence that matching and mismatching can have significant effects upon learning outcomes.

Learning preferences

Researchers have explored the impact of preferences on work-based learning (Allinson and Hayes, 1996; Riding and Sadler-Smith, 1992; Smith, 2000a, 2000b). Smith (2000a, 2000b) examined the styles and learning preferences of over a thousand VET learners in Australia. His evidence suggests that the majority of VET learners tend to be dependent learners, preferring visual means of presenting and absorbing information, while resource-based flexible delivery tends to assume that VET learners are independent, and prefer text- or oral-based means of presenting and absorbing information.

Through interview-based research with apprentices and trainers, Brooker and Butler (1997) suggested that apprentices rated highly the learning methods that involved structured approaches with assistance from other experts in the workplace, and that learning or practicing alone were not favored approaches. In addition, Smith's (2000a) research with apprentices provided further evidence for more structured, rather than self-directed, approaches to learning.

Billett (1996) used observational approaches in the workplace to explore the use of resource-based learning materials and engagement in everyday practice. He found that everyday practice was consistently viewed as more

effective than instructional materials. In the UK, Sadler-Smith *et al.* (2000) compared managers' perceptions of the effectiveness of a range of learning methods. Work-based methods, such as on-the-job learning, were perceived as being more effective – and were implemented more frequently – than other methods such as taught courses, while the method perceived as least effective (and used least frequently) was distance learning.

Sadler-Smith *et al.* (1999) investigated the learning preferences of personnel practitioners in the UK and found that work-based and traditional learning methods were preferred over self-directed methods. This preference is not confined to individuals in the workplace; Sadler-Smith and Riding (1999) found that business and management students preferred dependent and collaborative learning methods to autonomous methods.

Readiness for flexible learning

Smith (2001) developed workplace strategies for improving the readiness for flexible learning. Success requires that enterprises accept the need to develop learning to learn and task-related skills of workplace learners, through the use of instructional design, learner-centered, and workplace support strategies.

Riding and Sadler-Smith (1997: 203) identified strategies for trainees to make learning easier by playing to strengths and overcoming weaknesses. This requires that learners are trained to be self-reliant (see Gropper, 1983: 124). It has been argued that learners' understanding of their own styles promotes their performance in independent learning programs (Boote, 1998), and Smith (2000a, 2000b) argues for the need for strategies that enable vocational learners to become self-directed learners in a flexible learning context.

In their research, Warner *et al.* (1998) found an un-readiness among vocational learners for the self-directed learning required by flexible delivery. Smith (2000a, 2000b) and Sadler-Smith *et al.* (2000) suggest that workplaces often lack effective learner support for flexible delivery, and that includes an unresponsiveness to differences in individual learning styles. Learner support would (1) identify learners' styles and give appropriate feedback; (2) enable learners to distinguish among styles, strategies, and preferences; and (3) use learning contracts and integrate an awareness of learning styles into these. Workplace trainers will themselves need training in how to identify learning styles, and incorporate that knowledge into their work (Smith, 2001).

Related Theories of Learning

The understanding and use of models of learning styles must go hand in hand with some knowledge of related models of learning in the workplace. We can only briefly

note these here. Eraut has emphasized the nature and importance of nonformal learning, implicit learning, and tacit knowledge in the workplace (Eraut, 2000). The distinguishing feature of learning and knowledge of these kinds is that the learner is either (largely) unaware of much of it, or it remains far from explicit. However, explicitness is a distinguishing feature of learning-style theory and practice – learners being encouraged to become aware of their learning preferences and dispositions. There is, then, a question of which combination of attention to the explicit and implicit works best in vocational learning environments.

Situated learning theory provides resources for analyzing how learners become participants in a community of practice. The concept of “legitimate peripheral participation,” developed by Lave and Wenger (1991), is used in connection with their account of how learners participate in communities of practitioners, and, in so doing, acquire the knowledge and skill to allow for full participation in the practices of the community. A “community of practice” describes how people learn through mutual engagement in common tasks. The work by Fuller and Unwin (2003) on apprenticeship in the UK illustrates the detail and application of these ideas.

Theories of learning styles are sometimes criticized for taking too little account of the social and contextual detail of learning, giving insufficient attention to the nature of the workplace and the distinguishing features of the relationships and communities that develop in them. Profiles of learners in the workforce provide one example: UK evidence shows that these differ from learner profiles found in other sectors in post-16 education. A longitudinal study of literacy and numeracy interventions in the workplace found, from a sample of 564, that almost two-thirds were male, the average age was just over 40, and that English for Speakers of Other Languages (ESOL) learners were heavily represented – 35% of the sample. This compares with 3% ESOL in the UK employee workforce as a whole, while in many other post-16 education contexts (including the largest, Further Education) we find a lower average age and a higher representation of women (Wolf and Evans, *in press*). These distinguishing characteristics of workplace learners will have a bearing on how they learn and on how they prefer to be trained and mentored. The use and development of learning-style practices in the workplace would profit from more extensive use of situated and contextualized learning theory.

Concluding Remarks

Trainers are busy people: there are many elements of pedagogy to think about besides learning styles, and there are numerous learners making demands on their time. Nor can we realistically expect practitioners to

assess each of the many models of learning styles competing for their attention. How are trainers expected to manage? Smith (2006: 265) found that teachers often revealed an understanding of learning styles in the absence of any knowledge of theory: “functional and effective approaches are taken by teachers in the absence of theoretical understandings of style, but nevertheless developed to quite high levels of sophistication” (Smith, 2006: 265). He also found that teachers did not, on the whole, distinguish between different forms of learning style, learning preference, or cognitive style (*ibid.*). It would, in any event, make a large demand on time if teachers were to assess all the different theories of learning styles, since there so many, and of uneven quality, and there is no clear and agreed-upon body of knowledge. In addition, there are numerous other practices to take account of that promise significant benefits to learners – formative assessment, for example (Black and Wiliam, 1998).

The question of which theory of learning styles to adopt will also depend on the context in which it is to be applied – the institution, culture, curriculum, and so on. Unwin *et al.* have explored the implications of this for learning at work. They offer the example of a ‘tutor pack’ in a component-manufacturing plant, which might be thought of as a standard training manual for use with new shop-floor operatives, but that would be quite misleading: “all those who use the pack on a daily basis (operative, shopfloor coaches, trainers and shift supervisors) regard it as a ‘live’ artefact to which they regularly contribute and, by doing so, engage in a collaborative process where learning crosses role boundaries and takes place on several levels. Thus the pack is not limited to being a mechanism for training new recruits but has become a vehicle for the consideration of how work is organised, how knowledge can be shared, and how new knowledge might be created” (Unwin, 2005).

Two points follow for research on learning styles and VET: first, any theory has to acknowledge context in its account of learning styles. (For a fierce expression of this view, see Reynolds, 1997.) Second, the application of theory will itself be subject to the influence of context, and that will require of those using it – trainers, mentors, or learners – a detailed understanding of the workplace, its working culture and practices, and so on.

This article points to a final, as yet unanswered, question. Much of the research suggests a preference among workplace learners for traditional methods of teaching and learning, in a formal learning environment (such as a classroom) that includes a teacher, trainer, or mentor, and that allows for a fair degree of dependency. However, many of our hopes for improving learning in the context of VET lie in the direction of supporting learners to become more autonomous – able to direct their own learning using various media, and often on their own or away from the presence of an expert. In this same spirit,

the priority among many researchers and policymakers is personalized learning and learning to learn, enabling learners to become self-directed, independent, and autonomous. The question remains: do we know enough about the actual preferences and dispositions of VET learners, and the conditions and environments in which they learn, to know how these aspirations are to be achieved in practice?

Modularization in Vocational Education and Training

H Ertl and G Hayward, University of Oxford, Oxford, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Modularization is regarded as one of the main approaches to create increased flexibility in vocational education and training (VET). Flexibility of structures, contents, aims, and outcomes in VET is, in turn, a major objective of current modernization processes in many countries globally. The main reasons for this period of change in VET are the economic and social megatrends that are influencing economies and consequentially training systems in similar ways worldwide. While these megatrends have certainly been influential in terms of the relevant policy discourse, the extent to which they have actually lead to convergence in training provisions remains to be seen. However, most commentators would agree that megatrends include globalization, internationalization, individualization, new information technology, and the advent of the knowledge economy (Flitner *et al.*, 1999).

Particularly in the 1990s, a far-ranging discussion on more flexible training provision as a consequence of the debate on megatrends ensued. Flexibility in the context of this discussion primarily meant the following:

- The responsiveness of training provision to the changing work environment. This responsiveness is necessary in order to meet the latest skill demands which emphasize comprehensive skills and knowledge structures.
- The responsiveness of training provisions to the varying degrees of personal potential of trainees in the form of individualized training pathways. This individualization is also concerned with increasingly individualized pedagogical approaches and assessment procedures (Sloane, 1997: 231; de Bruijn *et al.*, 1993: 1).

The main argument in favor of modularized structures is that they can potentially be more rapidly updated than the conventional training provision. This curriculum flexibility is also linked to short-term assessment goals and enhanced motivation of learners due to manageable short-term goals and regular feedback. Further, proponents of modularity argue that modules can structure a course of learning to allow for appropriate and progressive development of knowledge and skills.

Despite these pedagogical aims, the debate regarding modularization in VET in the 1990s seemed to be largely driven by the arguments of political actors and, often, conflicting assessments by the social partners, rather than by arguments concerning pedagogical aspects or the processes of teaching and learning (for the German

discourse, see, e.g., the comments by Pütz (1997) and Münk (1995); for a discussion of the English context, see Hayward and McNicoll, 2007). It is, therefore, perhaps not surprising that evaluations of modular qualification structures often come to rather negative conclusions regarding the potential benefits of modular approaches. These negative assessments range from modularized programs resulting in fragmented and commodified learning to mechanical and instrumental approaches to teaching (teaching to the test) to overassessment resulting in examination burnout (learners) and excessive administrative burdens (teachers) (see, e.g., Hayward and McNicholl, 2007).

An analysis of the debate on modularization also shows that the unclear and ambiguous use of the terms module and modularization is widely acknowledged, but still has detrimental effects on both the debate on modularization and its impact on structuring learning processes in VET (cf. Wiegand, 1996a; Heidegger and Schreier, 2006).

Definitions of Modules in Education

On Using a Comparative Approach

Defining the nature of modules in education is no straightforward task. A comparison of selected definitions (Ertl, 2001) suggests that there is no generally accepted explanation of what is meant by organizing the teaching/learning process in modules (Postlethwait, 1985; Schmidt, 1997a; Kloas, 1996, 1997a; European Commission, 2006). Nevertheless, it seems to be generally accepted that any definition can only be valid and appropriate in the normative context within which it has been developed. Therefore, this article focuses on the concepts of modularization developed in two specific national contexts: Germany and England.

An important premise for the comparative approach underlying this article is that systems of education and training are embedded in the cultural environments and traditions of their respective societies. As the discourse in the field of comparative education has demonstrated, it is not advisable to take over arbitrarily selected parts of educational practice from foreign systems to inform the debate in other countries (see, e.g., Noah, 1984; Ochs and Phillips, 2002).

The English and the German contexts were chosen for the development of the conceptualizations because they have developed divergent modular structures in the training sector. It has been argued elsewhere that this is due to

the different origins of modular approaches in the two countries. (It would go beyond the scope of this article to attempt to trace the origins of modularity in VET in the two countries. For details, refer to, e.g., Ertl (2002a), Evans and Kersh (2006), and Hayward and McNicholl (2007).) Research in these two contexts has also substantially contributed to the debate in other countries.

The motives for research in this field differ considerably: Whereas the research in the English context has been mainly aimed at the further development of existing modularized qualifications (such as National Vocational Qualifications (NVQs) and General NVQs (GNVQs)), research in Germany has been mainly preoccupied with the potential of modularity for the modernization of the dual system of training. (GNVQs are currently being phased out and replaced by applied General Certificates of Secondary Education (GCSEs) and A levels. As a result, the uptake of other vocational qualifications has increased.) Modular structures exist in comparatively small areas of VET in Germany, for example, in the qualification of specific target groups, in certain programs for further training and retraining, schemes for additional qualifications in initial training (see Ertl, 2002b), and prevocational training (see Seyfried, 2002, 2003; BIBB, 2006). For instance, the German crafts sector has developed a structure of building blocs aimed at integrating prevocational, initial, and further training (Kloas, 2003; ZHD, 2004).

On Different Definitions of Modules in VET

A description of the way a module in VET is to be constructed and embedded in a wider curricular framework, its intended function, and its pedagogical structure cannot be separated from the wider context of VET.

The terminology in English and in German is confusing. It is unclear in many cases whether the words unit and module are used interchangeably (Watkins, 1987) or whether they mark a difference. A widely accepted English definition of these terms explains a unit as “a coherent set of learning outcomes” and a module as “a sub set of a learning programme” (FEU, 1995). In line with this definition, Stanton (1997: 122) specifies unitization as “the analysis of existing qualifications into units of achievement” and – in contrast – modularization as the process of “[...] subdividing courses into modules of delivery.” In Raffé’s definition, however, this distinction is not as clear: “a module is a unit of delivery and a unit of assessment/credit” (Raffé, 1994).

In the discussion in Germany, both of these meanings are normally ascribed to the term *Modul*. In most cases, a word for the above-mentioned meaning of unit is not even needed as German vocational qualifications are not defined in outcomes; however, the qualifications are regulated by defining the relevant input factors, such as the

duration of the training course or the qualification of the trainer. Nevertheless, a German term for unit could be necessary in the future if the connection between modularity and the outcomes approach (Young, 1998) follows the patterns established in the post-16 education and training sector in England and Wales. The development of multilingual training profiles as a result of the need for more transparent vocational certificates in the single European market toward the end of the 1990s may be regarded as an initial step to supplement the German provision with outcome criteria (Benner, 1997; Herz and Jäger, 1998).

Following the technical origins of the term, there seems to be agreement that a module is a part of a larger entity or system. Modules are distinguished from conventional courses by their shorter duration (Watkins, 1987; Young, 1995; Lauterbach and Grollman, 1998; European Commission, 2006). In this context, a modularized system is a whole composed of a number of self-contained elements. The comparison of over 20 definitions drawn from the relevant literature in England and Germany (see Ertl, 2001) shows that the understanding of what constitutes modules varies decisively in one key point: the relationship between the qualification system as a whole and modules as the elements of this whole.

Some definitions emphasize the self-contained character of modules: they cover “a single conceptual unit of subject matter” (Postlethwait, 1985), “are complete in themselves and examinable as such” (Wiegand, 1996b), and independent from other curricular elements (Deissinger, 1996).

The other group of definitions emphasize that educational modules can only fulfill their envisaged purpose within the context of other parts of the system: they are primarily “part of a whole” (Schmidt, 1997a). The whole in the context of VET may be a qualification in the broadest sense which itself is embedded in “the horizontal and vertical structure of a qualification system” (Reuling and Sauter, 1996). For the attainment of a qualification “a designated number of modules is required” (Theodossin, 1986). In this line of argument “modules only have a logic in terms of the broader qualifications and set of awards of which they form a part” (Nasta, 1994). On their own, modules only provide a qualification “below the level of occupational and professional needs” (Lauterbach and Grollman, 1998). In terms of the curriculum design process, the latter definitions of modules entail a process which starts with considering the qualification as a whole before considering its elements. The learner’s choice is essentially between one course of study or another. If the former approach toward modules is taken, the building of a curriculum starts from the design of the individual modules and the learner chooses a certain combination of modules instead of a discrete qualification.

The contradiction of modules as basically free standing and as only valuable in the context of the wider structure

of a qualification may be overcome by the built-up effect as suggested by Ainley (1990): “a module can stand alone or form a part of a route picked through the various units on offer,” or by Schmidt (1997b): “Combining them [modules] like building blocks, they can form an overall qualification.” This notion seems to be in line with the twofold character attributed to educational modules by Sloane (1997), who not only regards modules as wholes in themselves, but also requires them “to be embedded into a ‘bigger whole.’” In Young’s (1995, 1998) definition of modularization, an existing curriculum seems to represent such a bigger whole and, therefore, the starting point for the module design process. For instance, Nasta (1994) identifies starting a curriculum design process from the whole as the predominant practice in England, whereas starting from the module is widespread in the American system.

Characteristics of Modules in VET

The relationship between modules and qualifications seems to be a crucial aspect for the setup of a modular structure in VET. In the following, this relationship is clarified by deriving the characteristics of modules from a technical example.

The method of induction for defining the functions of modules in education has been applied several times before. For instance, Postlethwait (1985) derives the definition of modules in education from the use of the term in biology and Kloas (1997a) illustrates his definition of modules in VET with the relationship of the elements of a building (modules) and the building as a whole. The method seems to be appropriate as the term module itself originates from technical and biological contexts. In the work by Ertl (2001), the analogy of modules or components in the motor manufacturing industry is utilized to clarify the application of modularization in VET. The following list of characteristics of modules in VET generalizes the analogy:

- *Integrative function.* An overall qualification consists of a combination of modules or part-qualifications. This combination of modules generates the qualification’s function (which might be to develop vocational competence of the individual). This overall function is more than the sum of the single functions of the part-qualifications. Some modules may be utilizable independently from the overall function. This characteristic cannot, however, substitute the overall function of a qualification.
- *Standard definition.* The capability of working competently in an occupational environment is defined by social and economic standards. Some modules are indispensable for basic standards in VET and others improve the individual’s capability to work in a highly sophisticated environment. Accepted standards are the precondition for the combination of modules leading to

recognized qualifications. The standard of modules needs to be broad enough to ensure relevance of modules for more than only one or a few companies and providers of qualifications.

- *Multiple relevance.* Modular systems in VET are effective if modules are relevant to several areas of occupation. However, the variability of the temporal sequence of modules is restricted by pedagogic criteria and inherent content structures.
- *Outcome orientation.* Modules are the result of a qualification process and are only of value if they contribute to the overall function of the qualification. Therefore, modules represent categories of outcome or competence. When new competences are necessary, single modules can be modified, replaced, and adapted without changing the overall qualification.
- *Additional competences.* Modules required for a certain vocation can be augmented by additional modules in order to improve the vocational perspectives of the learner. Accepted standards of modules are the precondition for supplementing the overall function of a qualification reasonably (see also Kloas, 1997a, 1997b).

The underlying assumption for a number of these characteristics is that modules in education can fulfill their envisaged purpose only in the context of an overarching system. This assumption follows the second line of argumentation in the previous subsection. Following the German notion of *Berufskonzept*, the ability of the individual to act and work competently in the occupational environment is the superordinate aim of VET (see Ertl, 2000). As we will see in the following section, there are concepts of modularization in which this aim plays a minor or no role. The next section attempts to identify more general principles of modular strategies by analyzing combinations of module characteristics as applied in different modular approaches. The result of this process is a number of different concepts of modularization.

Before a number of conceptualizations are introduced, it needs to be reiterated that the sociocultural context in which modules are developed seems to determine the status of and relationship between modules and full qualifications. For instance, the notion of what constitutes the occupational environment differs between and, often, also within national contexts. In England, for instance, the primary aim of new modules is often to develop a specific, narrow piece of occupational competence. Recent examples for this are new modules amending a variety of existing qualifications to fulfill new health and safety requirements. This has resulted in the creation of comparatively small health and safety modules which were then conceptualized as independent certificates. This exemplifies how the distinction between modules and qualifications can become blurred due to the way an occupational environment is structured.

Concepts of Modularization

Conceptualization of Modularization in the German Context

In many respects, the German debate about modularity seems to be in the early stages. The assessment by Richardson *et al.* (1995a: 22) that “[...] education and training systems which are relatively stable have shown little interest to date in modularity and credit” still applies to the case of Germany. However, there is an increasingly intense debate regarding the modernization of the dual system of initial training. This debate is based on the perceived inadequacies of the dual system for meeting the demands of a rapidly changing economic environment. Modularization is regarded as a promising way of reforming the initial training system by increasing the flexibility and responsiveness of training provisions.

In the debate, it often remains unclear as to what concept of modularization is under scrutiny. The following three concepts are a synopsis of different conceptualizations developed in the German context:

- *Expansion concept.* Modules supplement initial training qualifications to generate additional competences that are typically the subject of further education and training. The overall functions of initial qualifications are expanded. There are two types of organizational implementation: in the consecutive model, the contents of initial and further training remain separated; in the integrative model, the contents of further training are integrated into the initial qualification.
- *Differentiation concept.* Modules are self-contained and can be assessed and credited individually; however, they are only marketable as part of an overall qualification. The framework of the overall qualification regulates the combination of modules. Modules can be the result of restructuring the curricula of existing qualifications. The differentiation concept facilitates the accreditation of prior learning. Modules can be accredited not only toward different vocational qualifications, but also across the academic/vocational divide.
- *Fragmentation concept.* Modules are credited and marketable without the framework of an overall qualification. By combining modules freely, trainees create individualized qualifications that mirror the requirements of a rapidly changing occupational environment. In comparison to the expansion and the differentiation concept, the fragmentation concept offers the greatest opportunities for flexibility and individuality in VET. Unlike the other two concepts, it is not consistent with the German concept of the vocation.

This attempt to conceptualize modularization in VET is based on accounts by Deissinger (1996), Zedler (1996), Sloane (1997), Rützel (1997), and Kloas (1997a, 1997c).

Conceptualization of Modularization in the English Context

In England, the system of NVQs represents a modularized structure of qualifications that has been created to reform an entire existing training and prevocational sector. This task is similar to the role that modularization could play in other countries that have not yet experimented with modularity to a great extent.

In the 1990s, research at the London Institute of Education has distinguished three forms of modularization in England: internal, external, and connective. (The conceptualization presented here draws on the work of the Learning for the Future and Unified Learning projects and, in particular, on the work of Michael Young within these projects. The following accounts provide further details: Richardson *et al.* (1995b), Hodgson and Spours (1997), and Young (1994, 1995, 1998).)

For all three forms, modularization means the breaking up of the curriculum of a qualification into discrete and relatively short phases of learning. Each module can be assessed independently from other modules at the end of the learning experience. In order to facilitate the assessment process, the curriculum is expressed in terms of measurable learning outcomes. This outcome's approach contrasts with conventional curricula which are expressed in terms of inputs (teachers' and trainers' qualifications, class contact hours, training contents, etc.; Koch and Reuling, 1998). Young (1994: 11) identifies three kinds of outcome approaches and provides examples derived from the British education and training system:

1. In the unitized approaches to outcomes, modules (which are mostly termed as units in these approaches) can be assessed on their own and there is no overall curriculum goal. The most important examples of this approach are units of NVQs.
2. In the integrated outcome approaches, outcomes are assessed with regard to an overall curriculum goal, that is, modules are grouped together to form a qualification. These approaches are exemplified in GNVQs (which are currently phased out), and many other (academic and vocational) qualifications in England.
3. In connective outcome approaches, groups of outcomes are related not only to specific qualifications, but also to the individual aspiration of the learner with regard to the curriculum as a whole. Connectivity in this context is regarded by Hodgson and Spours (1997) and Young (1998) as a stepping stone for a “curriculum of the future” that would not only bridge the vocational/academic divide, but also create the basis for the lifelong continuation of the learner's educational pathway.

In theory, all three of these outcome approaches can be combined with the three concepts of modularization in

VET as identified by the research at the London Institute of Education:

- *Internal modularization.* Courses and qualifications are subdivided into modules of delivery. Modularity is only adopted within a particular qualification. Internal modularization is typically combined with integrated outcome approaches to provide a step-by-step approach to qualifications that allows regular assessment of the trainees' progress. There is the opportunity for regular feedback for trainees so that they can build on their strengths over time. Each module is only valid for one specific qualification and not marketable outside this qualification.
- *External modularization.* Modularity is adopted across different qualifications, that is, a particular module can be part of several qualifications. The choice of a particular qualification can be made during the training process as training modules can be taken and accredited toward several qualifications. Credit transfer schemes make this kind of credit accumulation possible, particularly if they are combined with appropriate rules of combination to assemble modules into qualifications. Typically, existing qualifications are restructured, resulting in outcome-oriented provisions. Unitized as well as integrated approaches of outcome-oriented assessment are possible in this concept of modularization. The number and characteristics of overall qualifications are determined by competent bodies. Individual modules are not marketable outside this system of modularized qualifications.
- *Connective modularization.* The disadvantages of restricted forms of modularity are overcome by the adoption of a holistic curriculum approach. Connective modularity combined with connective outcome approaches provides a tool through which trainees can relate specialist vocational knowledge, broad-based general knowledge and skills, and generic skills. This would entail the restructuring of qualifications into a single system based on modules of delivery and on units of assessment. The restructuring would result in a unified curriculum for all young people in the postcompulsory sector. Connective modularization, therefore, would bridge the entrenched division between vocational and academic curricula. Individual modules in such a unified curriculum would be connected not only by an overarching credit framework, but also by value-added models of provisions designed to promote progression and attainment.

Concepts of Modularization: Similarities and Differences

Concepts of modularization are deeply embedded in the relevant national context. Both conceptualizations are

aiming for a more integrated system of training and education. Integration in this context can be regarded in two different ways that determine the debates on and conceptualizations of modularization in England and Wales on the one hand and in Germany on the other.

First, there is the integration of initial and further training. In both contexts, initial training is no longer regarded as a separate phase in young people's lives, but as the first part of a lifelong learning and training process. However, the concept of initial training as a separate educational phase seems to be particularly strong in Germany (Sengenberger, 1987). The traditional, chronological pattern of training comprising vocational orientation and preparation, initial vocational training, and further training and education which has determined the careers of the majority of working people in Germany for decades is rapidly dissolving (Kloas, 2003). The expansion concept in particular recognizes these developments and integrates initial and further training in a systematic way.

Second, there is the integration of vocational training and general education in the postcompulsory sector. The debates in both national contexts reveal the need for the integration of these two sectors; in addition, in both national contexts, certain concepts of modularization are regarded as particularly suitable reform options. Both the differentiation concept in the German context and external modularization in the English context recognize this type of integration as a central aim of modularity. However, in England the academic/vocational divide is certainly more pronounced than in Germany. Whereas in Germany vocational education always includes subjects providing a certain degree of general education, training provisions in England seem to be more focused on occupation-specific knowledge and skills, in some cases only relevant for certain companies. As a consequence, the concept of a unified curriculum determines the discussion on the further development of modular structures in the training provisions (see Hodgson and Spours, 1997; Young, 1998; Tomlinson, 2004). Connective modularization is mainly regarded as a stepping stone on the way to the ultimate goal of a unified curriculum. As the reaction to the Tomlinson report (Tomlinson, 2004) demonstrated, it has proved to be politically impossible in the English context to achieve this goal.

Trends in Modularity in VET

From the investigation of modular approaches in VET in six European countries (in the work by Ertl (2001), the conceptualizations derived from developments in England and Germany (see previous section) are used as an analytical framework for the investigation of modular approaches in France, Scotland, Spain, and The Netherlands) and an

analysis of two international projects on module development (see European Commission (2006) and RRBK (2007)) the following development lines can be identified.

Integration of Educational Sectors

Modular structures are being increasingly adopted in order to integrate formerly separate sectors of education and training. Modular frameworks can cover vocational preparation, initial, and further training. These frameworks connect the training and education of people in work with training provision for full-time students. This means that modularization is being used to bring school-based and work-based training routes closer together. Further, the divide between general and vocational education in the postcompulsory sector can be bridged by establishing modular banks which include both academic and vocational modules. A cohesive system for all post-compulsory education and training may be the outcome of modularization.

Integration Rather Than Fragmentation

In a number of national contexts, a move away from the fragmentation concept can be identified. Increasingly, overall qualifications that regulate combinations of modules have been developed. This represents a change to the modular strategy: free-standing modules are no longer perceived as marketable part-qualifications. Instead, the attainment of more broadly based combinations of modules in the sense of comprehensive overall qualifications becomes the aim of training. Often, trainees' choice of modules has been restricted in order to reduce the number of final overall qualifications.

Introduction of Modularity in Mainstream Training Provisions

In countries in which modularization has not yet been integrated into regular training provision, modularity is increasingly being adopted in sectors outside initial training. In these countries, modular courses are provided for vocational preparation and orientation, for qualifying specific target groups, and in certain further training schemes. It seems that the experience with modularization at the edges of the mainstream VET system has paved the way for a wider application of modularity.

Supranational Development of Modules

Currently, projects funded by the European Union aim at developing modules through international cooperation. The emphasis of these projects is to establish common criteria for the format and structure of modules in VET and thereby developing a framework that assures transparency and quality of modular systems (European Commission, 2006; RRBK, 2007).

These recent developments indicate that modularization remains high on the educational agenda internationally. It needs to be stressed that neither the political nor the academic discourse does necessarily use the term module explicitly to refer to self-contained elements of a learning program. However, the potential of relatively small and units or blocs of learning has had an impact not only in all areas of vocational education, but also in other educational sectors, such as academically oriented secondary education and higher education. The emphasis of the discussion has moved towards internationally recognized modules, often developed by consortia of partners from a number of countries, and the development of a quality assurance framework for modular systems.

Personalized Learning and Vocational Education and Training

Introduction

Personalized learning is a teaching and learning approach which is centered on the needs, aptitudes, and interests of individual learners. While it is not a new concept, it has gathered increased popularity in the last 10 years or so in a number of countries, including United Kingdom, United States of America, Australia, and New Zealand. It has been promoted as a key learning approach to prepare young people for the demands of the twenty-first century and the expectations placed on them by society (Bentley, 2005). Nowhere is this more true than in the area of vocational learning (Duckett and Jones, 2006).

In the United Kingdom, personalized learning has been an offshoot of a broader set of reforms aimed at customizing public services to respond specifically to the diverse needs of individuals. In other places personalized learning has evolved from policies aimed at ensuring equality of opportunity for all students. Here it has focused on helping students from minority groups reach their maximum potential.

In this article, we explore the nature and philosophical underpinnings of personalized learning, its evolution as a mainstream learning approach, and its implementation in a number of different countries, mainly the United Kingdom, Australia, United States of America, and New Zealand.

What Is Personalized Learning?

Personalized learning is a distinct student-centered approach to learning that is increasingly being used to ensure that students are able to meet their goals and their potential. It has been a key element of recent and planned educational reform in the United Kingdom, United States, Australia, and New Zealand. The philosophy underpinning this approach is a belief in the ability of every learner to succeed, communicating this to each individual learner to unlock their potential, and providing them with the resources that will enable them to succeed. Support for its application is based on the findings of research studies which indicate that personalization of learning and assessment results in improved scholastic attainment, thinking skills, personal development, and self-confidence for learners.

Although by definition personalized learning is necessarily student centered, we should not confuse personalized learning with the child-centered learning approaches

of the past which catered mainly to individual interests (OECD, 2006). Personalized learning is also about raising standards by taking account of both personal interests and aptitudes. It is about providing a safe environment for learning and coordinating learning support structures to help students maximize achievement toward a set of negotiated targets. Nevertheless, knowing learners' personal interests continues to be of vital importance in engaging the learner and improving motivation.

Personalized learning is not about abandoning curriculum. "At the core there would still be a common script – the basic curriculum – but that script could branch out in many different ways, to have many styles and endings" (Leadbeater, 2004: 14). A commitment to providing opportunities for students to participate in making decisions about their learning is another key component. This is aimed at equalizing opportunity for learning. However, giving learners (and their parents) a voice in deciding the nature and delivery of education will only equalize opportunity if learners from minority groups have the resources to be able to make such choices. This means that for some groups, the more the "services become personalized" the more the public resources will have to be skewed toward the least well-off (Leadbeater, 2004: 22).

A Culture Shift for the Educational Establishment

"Personalized learning is a highly structured approach that places the needs, interests and learning styles of students at the centre" (Kearney *et al.*, 2007). It requires a change in how educational establishments view and behave toward learners. It requires them to develop a professional ethos that recognizes the importance of listening to learners to ensure that they understand and take account of what learners are saying. They must also accept that learners have unique aspirations, different types and levels of skills, and learn in different ways. Personalized learning requires a commitment to working jointly with learners to identify their personal learning needs. Identifying the way a particular learner learns is crucial to the process. If personalized learning is to be effectively implemented in schools, then educational establishments need also to be committed to supporting teachers through appropriate and effective continuing professional development. Personalizing education also requires education systems to have a commitment to lifelong learning and to provide learners with flexible

learning environments. It is not about allowing learners to do their own thing, or permitting them to coast at their own pace.

Personalized learning should not be confused with individuals sitting alone learning and working through assignments or self-paced programs – a mode that may suit some learners but certainly not all. Personalized learning is about schools promoting a “community of learning” approach which “cultivates strong relationships . . . between home, community, local institutions, businesses and services” (Kearney *et al.*, 2007: 3).

A changed role for teachers

Personalized learning changes the traditional role of teachers. They move their focus from teaching students as an amorphous group of learners toward teaching students according to their individual aptitudes and interests. They become facilitators and learning brokers helping students make the most suitable choices. In doing so, they will also need to respond to the different ways learners achieve their best. An initial step is for teachers to identify individual needs, aptitudes, and preferred learning styles. This will enable them to tailor their teaching and assessment practice so that every learner has the opportunity to achieve the highest possible standard. In personalized learning, teachers set individual learning targets and regularly monitor and review progress toward these. They provide learners with structured feedback and teach them how to use it to improve their work. They also help students learn how to learn by providing them with advice on how to organize their learning and apply study skills which have been found to be effective. They encourage learners to engage in critical self-assessment. In personalized learning, it is crucial for teachers to have high expectations for all learners regardless of background and ability levels and monitor learning needs and progress through on-going dialog and formative assessment. Personalized learning requires students to use information on student progress to modify their learning.

It is sometimes a challenge to keep students interested and motivated (Duckett and Jones, 2006) even when learners have chosen a course of study. This is where personal knowledge of individual learners comes in to play. Knowing which buttons to press for each individual can provide the ignition to motivate and inspire any learner. Once teachers know their learners they are 90% toward raising achievement levels. Which button will differ from learner to learner as the very uniqueness of each individual will form the basis for their personal determination and motivation. Learners crave realism. Making learning real, by linking it to the outside world, can inspire and increase motivation.

A changed role for learners

Personalized learning also changes the role of learners from being passive recipients of predetermined programs

to becoming active agents and problem solvers. Negotiating learning which suits their particular talents or shortcomings not only improves motivation for learners but also helps them to maximize their potential. This gives them a sense of power and fulfillment which in turn helps to increase confidence and self-esteem. However, not all learners will be able to take the same advantage of this increased choice and these learners will have to be supported by knowledgeable and sensitive teachers and counsellors.

Different players in the learning process may share the same or similar goals for learning, but the support individual learners require to achieve these goals may vary. What is fundamentally different in personalized learning is that learning becomes a shared process with learners actively in control. This has clear implications for how students learn how to learn.

A changed meaning for assessment

Assessment in personalized learning is not only about giving learners a test of their achievement at the end of a program of study. It is also about ensuring that learner's goals, aspirations, and aptitudes are analyzed at the beginning. At this time, it is important to diagnose precise learning difficulties that may require additional learning support. Other initial assessments include specific standardized diagnostic tests which in some countries (e.g., the United Kingdom) are used to identify and address any physical disabilities (dyslexia, and vision and hearing impairments) in order to comply with legislation which aims to ensure that these learners have access to required support or modifications. For all learners, the results of such initial assessments are used to help teachers develop appropriate learning approaches, materials, and assignments. Formative assessment processes are used by teachers and students to help students review and understand what they have been learning and how they can improve. Summative assessments are used to determine the extent to which negotiated targets are met.

A key role for information and communications technology

Information and communications technology is a key enabler of personalized learning. It can help systems respond to the needs of learners by providing a personalized space for students to do their learning. This type of learning is not confined to the classroom and allows the learner “to live locally whilst learning globally” (Kearney *et al.*, 2007: 2). The use of technology to undertake learning at home, at work, and at school has also been promoted in the Australian VET system as a key mechanism for ensuring that training remains client-focused and makes use of modern technologies. This generally goes under the banner of flexible delivery.

Personalized Learning in the United Kingdom

Personalization and personalized learning are much in the UK education news. In a conference of educators in January 2004, then Minister of State for School Standards, David Miliband, MP, spoke about the government's aim to put individuals of this country at the center of all public services, including education. This would enable each individual to have a say in the design and improvement of the organization he serves. At the heart of Miliband's speech was his belief in the ability of personalized learning to promote equality and social justice. Since Miliband's key speech, the term personalized learning or the concept of personalization has been repeated in many education reports and in educational discourse.

The Department for Education and Skills (DfES) supports the introduction of the personalized learning approach by appealing to the findings of research on teaching and learning. This includes studies which indicate a link between key principles and improved student performance in scholastic attainment, thinking skills, and self-esteem.

However, implementation is still in its early stages. For instance, in the report 14–19 curriculum and qualifications reform (Tomlinson, 2004) the working group on 14–19 reform highlights observations mirrored in many Office for Standards in Education (Ofsted) and Adult Learning Inspectorate (ALI) inspection reports and puts forward recommendations for personalized learning including:

- stretching and challenging able learners;
- raising learners' personal awareness;
- increasing understanding of learners' strengths; and
- identifying learning and development needs.

A key driver for change toward personalized learning in the United Kingdom is the need to ensure that schooling provides learners with the skills and attributes they will require for the twenty-first century and to meet community expectations (Bentley, 2005). The introduction of student profiles in the United Kingdom schools has gone some way to personalize the data that schools have about individual students. Riel and Bentley (2006) are of the view that this could be extended by treating school facilities as "entry points to much wider networks of flexible, specialist, provision and participation" (p. 122).

Recently, the Learning Skills Council has endorsed the Recognising and Recording Progress and Achievement (RARPA) project. Although RARPA was initially designed for staff working in nonaccredited learning, it has many lessons for practitioners working across the range of accredited and non-accredited programs (Duckett and Brooke, 2006).

The five stages of the RARPA process are:

1. setting the aim of the program of learning, which may define its general purpose, or may be more specific (curriculum design);
2. initial assessment of the learner, to find out the learner's needs and aspirations; this is important as it enables learners to express their desires, interests, motivations and support needs; if undertaken during induction, this stage can promote a greater understanding of the purpose of the program and enable learners and teachers to get to know each other; importantly, in the process of recording progression, it can establish where the starting-point is for the learner and identify what he or she wants to achieve by undertaking learning;
3. identification of learning objectives that meet the stated learning outcomes of the program of learning for the learner group and the individual learner;
4. formative assessment, or the ways in which teachers identify and record progress made by the learners; this may be a very creative process with suggestions of video recordings, learner diaries, exhibitions, as well as more traditional assignments and tests; and
5. end-of-program review of progress and achievement, which may involve learner or peer-group assessment, teacher's record of assessment, and a whole range of artifacts as appropriate to the program of study (summative assessment).

Australia

The term personalized learning is also gradually gaining currency in Australia. However, the concept is often seen as an extension of existing processes for placing students at the center of teaching and learning. Always, the main aim is to enable students to develop the skills, knowledge, and personal attributes required for acquiring qualifications, job skills, and employment.

For example, personalized learning is promoted in the South Australian Government's strategy for reforming senior secondary education, and the South Australian Certificate of Education (SACE). Here, the key aims are to provide students with engaging curriculum and to help them make successful school-to-work transitions. Teachers are asked to work with individual students to take a realistic account of their aptitudes, interests, career goals, and other opportunities and to develop personal learning and transition plans. Schools are asked to develop strong partnerships with the local community, business, industry, and education and training providers to enable students to gain valuable and challenging experience with work, training, or study. A student mentoring program has been established to provide students (generally those

at risk of dropping out) with support and advice from teacher mentors who have been trained to support the learner's well-being, achievement, and pathway planning. In this context, the personalized learning plan which comprises the setting of targets against key learning outcomes is seen as especially important. Currently, about 29 secondary schools are engaged in pilot projects to trial these reforms.

Personalized learning has been especially promoted in the education of indigenous students who have historically not engaged with or benefited from schooling to the same extent as other Australians (Ministerial Council for Education, Employment, Training and Youth Affairs, 2006).

The personalized learning approach is also currently being applied in the Australian Science and Mathematics School, a senior secondary school located within Flinders University in South Australia. Here, it is characterized by the development of personalized learning plans for individual students, and a belief in challenging and rigorous programs using inquiry-based and experiential learning strategies. Personalized learning plans (gradually being developed for all students) involve tutors and students in discussions about what students believe are their strengths and weaknesses and their short and longer-term goals. These are then used to identify strategies to help students achieve these goals. A variety of online tools are also used to help students think about learning preferences and career options. Some students have used electronic portfolios to document their work and their achievements and their plans for the future. These have been found to be successful thus far.

It is also important that we are aware that many of the aspects of personalized learning are exemplified in other approaches to customizing education to the needs of individuals. The concept is also reflected in the flexible delivery initiatives first adopted in Australia to reform the public vocational education and training (VET) system in the early 1990s. The aim of these approaches is to ensure that the training system remains client-focused by enabling students to choose how, when, where, and what they learn. Self-paced learning programs customized the pace of learning and assessments to student interests and aptitudes, to assist them in becoming self-directed and independent learners. This aims to prepare students for workplace of the future. Teachers and trainers adopt a learning facilitator role and work with students individually and in groups to respond to questions, introduce topics, or discuss issues. Computer-assisted learning and other information and communications technologies play key roles in the development of technical skills and in monitoring the progress of students.

A continuing belief in every student's capacity for learning is also exemplified in the 2007 statement on the

future of schools in Australia. Endorsed by the Commonwealth and State and Territory government ministers who have portfolios in the areas of education, employment training, and youth affairs, this statement sets out broad directions for how schools, parents, and communities can assist learners to develop fully their intellectual, physical, moral, and aesthetic talents and capacities in school and throughout life. A commitment to students is a key goal.

Personalized Learning in the United States of America (USA)

The use of the term personalized learning is still in its infancy in the USA. Kearny *et al.*, (2006) are of the view that the term was first used in the 1999 Breaking Ranks report which highlighted the need for personalization through the establishment of smaller schools and the use of a variety of instructional methods. Today a follow-up report Breaking Ranks II developed at the Education Alliance at Brown University stresses the need for personalization. It recommends that schools ensure that personal learning plans and a personal adult advocate for each student, recognize that each student learns differently, and provide support and guidance for each student to set, review, and achieve his or her goals. A personal learning plan for each education is also recommended so that they continue to improve their own skills and knowledge in helping students in the learning process.

Personalized learning as a learning philosophy has also been especially adopted by 35 schools established by the Big Picture Company in conjunction with state educational authorities in a number of different states. The motto one student at a time has been adopted by the 35 schools involved and exemplified by the following mission statement (Big Picture Learning, <http://www.bigpicture.org>).

Each student's learning plan should grow out of his or her unique needs, interests, and passions. We believe that the education system must ensure that students and families are active participants in the design and authentic assessment of each child's learning. Schools must be small enough to encourage the development of a community of learners, and to allow for each child to be known well by at least one adult. School staff and leaders must be visionaries and lifelong learners. Schools must connect students, and the school, to the community—both by sending students out to learn from mentors in the real world, and by allowing the school itself to serve as an asset to the local community and its needs. Finally, schools must allow for admission to, and success in, college to be a reality for every student, and work closely with students, families, and colleges throughout – and beyond—the application process.

Historically, the need to customize learning to the needs and aptitudes of students in mainstream American schools has generally been associated with equalizing educational opportunity for all students and especially those from disadvantaged groups. The No Child Left Behind initiative of the Bush administration which resulted in amendments to the 1965 Elementary and Secondary Education Act aims to “ensure that all children have a fair, equal, and significant opportunity to obtain a high-quality education and reach, at a minimum, proficiency on challenging State academic achievement standards and state academic assessments” (Sec. 101, Title 1, amendment to Elementary and Secondary Education Act 1965 (20 U.S.C 6301 *et seq.*).

Other initiatives to improve the lot of disadvantaged students include early childhood programs like the Head-start program which aims to improve the school readiness of pre-schoolers from disadvantaged backgrounds. A key aim is to develop reading and math skills of these pre-schoolers so that they can experience success in school. The program provides children and their parents with educational, health, nutritional, and other services. In 1995, the program was extended to ensure that children from birth to 3 years of age were also engaged. Parents are involved in the administration of their local program and in their children’s learning. They are also assisted to develop and meet their own educational, literacy, and employment goals.

New Zealand

The Ministry of Education of New Zealand has launched its vision for personalizing learning (Ministry of Education, 2007). It notes the need for the country to transform its education system to meet the challenges of the twenty-first century. In doing so it emphasizes its mission to no longer tolerate failure for any student.

Personalized learning in New Zealand is viewed not only as a strategy to place students at the heart of the learning system, but also about making learning more meaningful. It is felt to succeed best when students know what they know, how they know it, and what they need to learn next. Two key components of the New Zealand approach are effective teaching and appropriate assessments. Teachers will be expected to appreciate the capacity for learning of every student and to monitor progress for future learning. They are also expected to help students develop their skills of working independently and in groups, and support each other in learning. To do this, they will develop a wide range of effective learning strategies including using new technologies to support student learning. Initial needs assessments will be conducted and the results used to determine the strengths and weaknesses of each student and to develop suitable

learning programs. Timely and effective feedback that improves learning outcomes and engages students in learning is also required. The “Assess to Learn” project and assessment tools for teaching and learning (aTTle) have been developed to help teachers, students, and parents with information which accurately records student achievement and progress.

In turn, the Ministry of Education promises to play its part in providing the resources, conditions, and policies to support these changes. Personalized learning will also be supported by the New Zealand Curriculum which will provide direction for what is to be taught and opportunities for teachers to better structure learning so that it meets the needs of individual learners. It will require strong partnerships between schools and parents to provide teachers with the information they require to better structure learning to suit the individual needs and aspirations of students. The “Team Up” program established to facilitate this partnership will also help parents understand how they can help in their children’s learning. The professional leadership skills of principals are also critical in implementing personalized learning. A First Time Principals program has been established to train new principals for their roles. A Kiwi Leadership Framework is also being drawn up to reflect the country’s unique educational culture and environment.

The Te kotahitanga program is an example of a program which implements a key principle of personalized learning, (that is, the need for teachers to understand the backgrounds and strengths of students and build supportive relationships with students), to improve school retention and achievement of indigenous students.

Issues around Personalization

Personalized learning locates students at the heart of the learning process by not only giving them a voice in determining their own learning, but also ensuring that they are provided with suitable guidance and targets to meet their goals. Research conducted by the Quality Improvement Agency (QIA) in the United Kingdom has highlighted some issues of controversy, which largely focus on learner voice and provider guidance (LSN, 2006). It is clear that the issue of learner voice, and the extent to which it plays a role in the delivery of personalization, needs to be resolved.

The major issue is that of learner voice, that is, how much learner control is appropriate (see e.g., QIA, 2006). A better formulation is how we enable the learner to take more control. It is the transition from an inexperienced to a self-directed learner which is key and which coincides with the concept of the expert learner. Clearly, becoming an expert learner, and being able to take control of their learning, are two very similar skills which come with age

and experience. In short, although the issue of learner participation seems to be a significant point of debate and potential conflict amongst the sector, this can be resolved by taking a more flexible, developmental approach. We know that expert learner skills can be developed over time – so it is perfectly feasible that the (very similar) skills required for a learner to make responsible and informed choices about his or her learning can be developed too.

Conclusion: Personalized and Individualized Learning

Individualizing learning is something which learning and skills providers have been carrying out for many years. It is much more than offering a broad range of curriculum choices and flexibilities – it is also about adapting teaching and learning strategies to meet the needs and abilities of different learners. This may include (and often does) individualized learning plans, individual targets, group and one-to-one work, and different forms of pedagogy to suit different learners. We have used the term personalized learning to distinguish it from the student-centered learning approaches of the past; however, we must also be careful to make sure that we do not invent another term to describe activities that are essentially similar in scope, intent, and application.

Recognition of Prior Learning and Vocational Education and Training

J Keating, University of Melbourne, Melbourne, VIC, Australia

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The idea that learning that takes place outside of formal education courses can and should be recognized within formal qualifications or their components is relatively widespread and has been around for some time. The received history of the first example of the recognition of prior learning (RPL) is that of US servicemen returning at the end of World War II who sought formal recognition of their learning gained from their service experiences (Harris, 2006). (RPL is practiced under different names across different countries. The various forms of assessment and recognition of informal and prior learning are all referred to as RPL in this article.)

The second iteration in the form of formal systems and more widespread innovations in the implementation of RPL was concentrated in Anglophone countries, notably the United Kingdom, Australia, New Zealand, Canada, parts of the USA, and South Africa. These countries have had some common features, apart from language. All separate their initial vocational education and training (VET) systems from their secondary school sectors and none have had the strong social partner participation in the steering and management of their VET sectors that is common in Europe. In most of them, liberal market orientation economic reforms were introduced in the 1980s or 1990s, together with the devolution and decentralization of governance in education and training. In several of these countries, forms of competency-based training (CBT) and associated forms of outcomes-based qualifications evolved with the spread of RPL.

It now seems that RPL in its latest iteration of recognition of informal learning is entering a third age as the concept is championed by international organizations including the Organization for Economic Cooperation and Development (OECD) and the International Labor Organization (ILO) and spreads to other countries, especially those within the European Union (EU).

The RPL Claim

From the basic objective of the US servicemen to have their learning formally recognized, the RPL journey has been a mixture of robust, ambitious and at times extravagant claims, multiple innovations, and diverse practice. The RPL journey has been most intense over the past two

decades and recently has traveled beside major institutional changes in the structures and processes for the formal recognition of learning.

The period of the evolution of RPL has been that of the massification of tertiary education, with a number of countries achieving levels of 50% or more of school leavers entering tertiary education and the EU adopting its Lisbon target of 50% participation. The period has also seen the evolution of the human capital agenda across all developed countries and an increase in public and private investment in postschool education and training.

The RPL story is immersed within these developments. Across its phases it is an innovation that has expressed democratic ideals of education, challenged the construct of formal knowledge and teaching practices within education systems, initiated major systemic and cross-national dialog and formed a foundation element of systemic changes in the characteristics of formal education and training systems and especially qualifications systems.

The basic principles, let alone the more extravagant rhetoric of its champions, have not gone unchallenged, nor have its most conducive curriculum forms of CBT and outcomes-based education and training and their epistemological underpinnings. Given its now considerable history in the Anglophone countries, the realization of RPL could be judged as disappointing (Cameron and Millar, 2004; Pokorny, 2006).

Yet, RPL in its latest iteration of the recognition of informal learning has attracted even more ambitious claims. The EU has endorsed the "principle of learning throughout life, the identification and validation of non-formal and informal learning aim to make visible and to value the full range of knowledge and competences held by an individual, irrespective of where or how these have been acquired" (EU, 2004:1). The ILO has several conventions that endorse RPL and the right of workers to have their skills formally recognized. The OECD has launched a new activity on the recognition of nonformal and informal learning.

By the late 1990s, RPL had traveled to the Scandinavian countries, which, perhaps not coincidentally, had adopted more liberal and decentralized governance arrangements for education and training earlier in the decade. It is now being addressed by countries such as Germany where stakeholder organizations have until quite recently taken a cautious view toward the recognition of informal learning. The extraordinary spread of national qualifications frameworks

(NQFs) across Asian, Middle Eastern, Southern African, and Latin American countries, as well as Europe, is likely to signal a further spread of RPL and its underpinning principles.

So what is the extent of the RPL claim, and what has been realized through the concept and the myriad systemic and localized innovations and practices? Is the RPL claim legitimate, and does it have legitimacy within systems of qualifications that have been designed for formal learning systems? Does it enhance or threaten the practices of education, especially within its construct through the subject disciplines?

Drivers and Constituents

These are large questions, and it is perhaps unfair to suggest that the RPL movement and its champions have made such extravagant challenges. However, the RPL claim is significant. For example, a recent EURYDICE (2007) document describes RPL in the following terms:

“RPL ... enables access, transfer and progression. It can be instrumental in motivating non-engaged adults to resume or continue learning as it identifies and makes visible knowledge, skills and competence of which the adult may not have been aware and, if a national framework of qualifications exists, it places the individual at the appropriate level on the framework. It enables existing knowledge, skills and competence to be formally recognised, rewarded and signalled to different stakeholders, including employers, thus increasing economic returns. It reduces opportunity costs through eliminating or reducing the need to spend time and money relearning what has already been learned” (p. 1).

These various perceived benefits of RPL relate to the rights of workers to have their skills recognized, mechanisms that encourage individuals to access and engage with formal learning, the capacity to align the levels of knowledge and skills for the purpose of learning progression, increased productivity and economic returns, and resource efficiencies within education and training systems. RPL therefore brings a range of constituencies.

In countries such as Australia, much of the early impetus came from unions that saw RPL as a means of securing formal recognition of their members' skills within industry-based wage systems. In South Africa this extended to the wider non-white population that had been largely excluded from both the formal waged economy and the postelementary education system (Cooper, 1998). Post-apartheid, the position of the Congress of South African Trade Unions on RPL, was readily adopted by the African National Congress as a means for the non-white population to help overcome and redress exclusion. The strength of this constituency and its expectations of the principle of RPL extended to the

decision to move the entire education and training systems to an outcomes-based approach, where sets of unit standards were developed independently of established qualifications and educational institutions (Lugg *et al.*, 1998).

At the same time, decisions were taken by the New Zealand government to establish an NQF and a qualifications system based upon unit standards. These developments occurred in a different political context to that of South Africa. By the early 1990s, New Zealand, arguably more than any other OECD country, had embraced neoliberal economic reforms with widespread economic deregulation and privatization and the injection of market principles into most areas of the economy. The idea of a demand-led education and training system and more open education and especially training markets connected with the idea that learning can take place in contexts outside of formal education and training institutions. The newly established New Zealand Qualifications Authority (NZQA) began a program of building a system of standards-based qualifications, which in principle were intended to include all education sectors. Thus, in 1990, the government passed legislation that empowered the NZQA to “develop a framework for national qualifications in secondary schools and in post-school education and training in which:

- (i) All qualifications have a purpose and a relationship to each other that students and the public can understand; and
- (ii) There is a flexible system for the gaining of qualifications, with recognition of competency already achieved.” (cited in Blackmur, 2003).

The common experiences of the two countries juxtaposed against radically different political landscapes were mirrored in Australia and the UK, albeit less starkly. A Labor Government in Australia initiated a national training reform based upon competency standards. The reform program was informed by developments in the UK, but much of the push had come from unions, and notably the metals industry union (as was the case in South Africa). The VET qualifications that have evolved are packages of units of competencies, which, in principle, can be gained by individuals from a range of learning experiences and contexts and thus can be assessed and recognized independently from a formal training course. In the UK, a competency-based VET system had been introduced more or less in parallel with the Australian system under the Conservative Government that had introduced deregulation and privatization to wide areas of the economy, including the public sector. The national vocational qualifications (NVQs) that have evolved are based upon the principle that their specified knowledge and skills can be gained and therefore should be able to be recognized outside of formal learning programs.

Thus, constituents for RPL included a spread of unions, employers, and governments of different political hues. However, RPL's philosophical underpinnings also are diverse. On the one hand, it is seen as a democratic principle of the right of people who have been disadvantaged within or excluded from formal education and training systems to have their knowledge and skilled formally recognized for the purposes of re-accessing educational programs and for employment and social recognition. On the other, RPL and its base in learning outcomes that can be independent from formal education programs is a means of breaking down supply-side education and training systems and reducing provider capture of the education market. Furthermore, outcomes-based education and training systems, when linked to funding systems, can reduce the need for central administration but increase the accountability of education and training systems and increase the capacity for policy steerage.

The assembly of these constituents, principles, and reforms in RPL took place mainly in the early 1990s. They were confined largely to the VET sector, and across the Anglophone countries the drawbridges into the higher education and school sectors were drawn. Allais (2007) has shown that the unit standards of the SAQF have had almost no impact on the higher education and schools sectors. The resistance of the universities contributed to the near demise of the NZQA (Strathdee, 2003). The universities in Australia rejected outcomes- or competency-based curriculum and qualifications (Bowden and Masters, 1993). In the UK, there was little attempt to assault the bastions of the universities and the prestigious senior secondary qualifications, the English (and Welsh) A Levels and the Scottish Highers. The RPL movement lacked both the constituents and the cultural and political capital to tackle the universities and the senior secondary certificates that have a symbiotic relationship with university education.

Through what we have described as a second phase of RPL, there have been a series of settlements within the Anglophone education systems that largely confine RPL to the VET sector. The confinement has not been total, as many, if not most, universities have formal policies in support of RPL, allow some access to postgraduate courses on the basis of professional experience, and have given *de facto* RPL through the establishment of professional higher degrees that can be completed over shorter time period through reduced credit points. However, in most countries where RPL has been such a deliberate movement, endorsed by national and regional governments – the UK, South Africa, New Zealand, and Australia – and institutionalized within outcomes-based VET systems, the institutional divides between the VET sector, on the one hand, and the university and senior secondary education sectors, on the other, have been significant.

Philosophical Underpinnings

To an extent the literature on RPL carries the assumption that the benefits and moral underpinnings are self-evident truths. The literature on equity is voluminous, and there is little doubt that access to education and training is not evenly distributed across social groups, and that opportunities for success within educational systems are uneven. The idea, therefore, that learning that is achieved outside of formal instruction should be recognized does have a moral base in democratic rights. Systems that allow for the recognition of informal learning and thus avoid unnecessary time and effort being invested in the duplication of this learning also have clear benefits. Furthermore, if recognition systems can encourage individuals to engage in formal learning, this should increase the level of participation in education, the skills base, and productivity across a nation.

The RPL claim, however, must go beyond the benefits and address the foundations of formal knowledge and the processes of formalization. The claim appears to recognize that formal knowledge has an elevated status. Otherwise, there is a potential for a contradiction in the claim: that is, if informal learning is as legitimate as formal learning, then why should it be formalized through the RPL processes?

Of course, a claim of equal legitimacy is not an inherent part of the recognition of the informal learning argument. In its basic form, the RPL claim is that learning can take place in multiple ways, through multiple settings, and through multiple experiences and that the processes for the recognition of learning should take account of these multiplicities. This claim would thus acknowledge the value in the formalization of learning through accreditation and qualifications, as in Young's (2001) terms, there are communities of trust that bestow this value. However, the claim should also confront the nature of formalized learning, including its knowledge base.

The traditional construct of a qualification has been through disciplines that in most cases constitute a hierarchy of learning that is bounded by codes and with systems and procedures for ordering and relating knowledge. Subject disciplines have been fundamental to university learning. On the other hand, qualifications within the VET sector have had their base in sets of knowledge and skills drawn from occupational modes and conventions. The training and induction procedures, and the recognition procedures, for new entrants into the occupations, replicate these modes and procedures.

RPL has evolved with two broadly associated movements that in some versions challenge both of these traditions. Social constructivist theories of learning underpin much of the rhetoric on informal learning and either directly or by association with RPL as well. Learner-centered

approaches that are based upon the learners' own construction of understanding and knowledge have an obvious link with the idea of informal learning and give it both a claim for legitimacy and a platform for its recognition. On the other hand, the qualifications within the VET sector in the Anglophone countries are now based upon empirically derived sets of outcomes or standards that are packaged into qualifications.

The constructivist view of learning has to adopt a theory of knowledge that deals with the relationship of personally derived knowledge with socially derived forms, especially in the form of subject disciplines. A constructivist concept of learning can take a poststructural position where legitimate knowledge is constructed by the individual and where the codified versions of knowledge in the form of mainstream qualifications represent the constructions of powerful or dominant groups within a society. This interpretation thus leads to the RPL dilemma that if informally derived learning is as valuable and legitimate as formally derived learning, why should people bother to then gain recognition for informal learning?

It should be stressed that a constructivist view of learning does not have to equate with an individualistic view of knowledge – that is, informal and formal learning are not mutually exclusive. Dewey (1966), who is often cited as one of the founders of constructivism, rejected the individualistic view of knowledge and argued that an individual's construction of knowledge needed to take place in social settings. Indeed, this was the very essence of his notion of democracy in education.

On the other hand, the idea that knowledge can be expressed and recognized as outcomes is more central to the RPL case. Young (2001) located outcomes-based qualifications as being a mainly Anglophone countries approach, with process-based qualifications being more common in Europe. His classifications are not perfect. However, RPL has been most robustly associated with qualifications systems and subsystems that are outcomes or competency based. The high form of an outcomes-based qualifications system is that of South Africa where the objective has been to construct all qualifications through unit standards developed by user rather than provider groups. Allias (2007) is severe in her critique of the South African qualifications system. She argues that its construct of qualifications lacks an epistemological base, and for this reason the vast majority of qualifications that are awarded continue to be those that were developed outside of the unit standard system.

Keep (2006) makes the point that the VET sector in the UK has evolved without the active participation of the 'social partners' in the ongoing system. The same point could be made for Australia and New Zealand and this compares with the active roles of employers and unions in the European countries. Thus, the more formalized processes of the European countries, to which the social partners are strongly attached, contrast with the centrality of

validity and reliability of the outcomes in the Anglophone countries. Thus, it is not surprising that there has been (and continues to be) resistance to the idea of RPL within the VET sectors from some of the social partners in a number of European countries, and especially Germany (based on consultations with VET officials in the Netherlands, Flanders, Germany, Norway, Sweden, and Finland (April, 2007)) where governance of VET is very much in their hands (Attwell, 2006).

This does not necessarily challenge the educational or epistemological legitimacy of RPL. However, it does raise the question of the nature of a qualification. The idea of a qualification is deep within the educational psyche. Outcomes-based education has made only sporadic tilts at the higher education windmill and with minimal impact. Correspondingly, RPL has a weak presence within the sector. Pokorny, 2006 noted that APEL has "failed to establish itself as part of the mainstream" (p. 261) within higher education in the UK. Universities have mostly ignored the unit standard system in South Africa (Mathais, 2007) and have resisted a similar system in New Zealand. In Australian universities, RPL appears to be beset with problems of inconsistency (Fox, 2005).

In the UK and Australia, a high proportion of universities have RPL policies in place, but with little evidence that they are being accessed by students. This possibly relates to Wheelahan's (2006) discussion about the nature of a qualification, which she argues is more than the sum of its parts, and the inherent attributes of gradueness mean that a qualification should not be awarded solely upon the basis of RPL. The concept is useful because it approaches the idea of a qualification from both the provision and participation sides. The reluctance of the education sector to issue an award solely upon the basis of assessments without some formal engagement in learning is matched by the reluctance of the potential graduate to gain an award without some engagement. The numerous studies of RPL participation have frequently identified the lack of student applications as a key factor in low rates of realization.

This argument then leads to the question of whether there are and should be differences between RPL for course entry and for credit. It seems likely that there is a widespread acceptance of the principle that informal learning should be a basis for course entry.

Practice and Outcomes

The point of the above discussion is that much of the official rhetoric on RPL from national education and training agencies and international organizations is about the RPL claim and the procedures that need to be taken to achieve recognition. However, behind this rhetoric the very idea of prior and informal learning, there are fundamental

questions about what constitutes informal learning and its association with formal learning Colley *et al.*, 2006) and by implication the sociology of knowledge.

Such questions may not consciously confront most RPL practitioners and participants, but they are inherent in their practice, motivations, and experiences. Much of the case study and other literature on credit-based RPL has typically located student preference for engaging in whole courses of study or training and provider and provider personnel behaviors that do not readily relate the unaccredited learning of individuals to the learning outcomes of formal qualifications and their elements.

Where the outcomes are stated in behavioral terms, as they are in competency based training (CBT), which, in turn, can be gained through experience of apprenticeship types of learning, the capacity for RPL should be greater because the individual and providers can more readily associate experience with the nature of the outcomes and processes for achieving it. So it should be expected that the realization of RPL would be greater within CBT and outcomes-based qualifications than in the more traditional course- or process-based qualifications. In Australia, one of the countries that have led the charge on RPL and which has had a CBT-based VET system for well over a decade, the percentage of VET students with an RPL was 3.6% in 2004 (Hargreaves, 2007). The percentage had grown through the 1990s, but now appears to have stabilized. Although the percentage is not insignificant and is certainly greater than in the higher education sector, it would appear to be relatively modest. Total recurrent VET expenditure in Australia in 2004 was \$4887.1 million. Therefore, the level of financial savings through RPL could be \$176 million, but is discounted by the fact that not all students gained all of their awards through RPL and also by the costs of the RPL procedures. There is some speculation that the savings and costs are nearly the same.

On the other hand, 10% of students at the diploma levels and above had an RPL. RPL for course entry is also likely to be higher at the diploma level. As Hargreaves (2007) points out, this suggests that it does remain an important principle and instrument for adult learners, and its potential role in continuing education and training should not be under-valued.

Lifelong Learning: A Third Age of RPL?

Despite the mainly disappointing levels of realization of RPL, the international rhetorical and policy investments in it have risen in recent years. This appears to be associated with two interrelated sets of developments: the policy goal of lifelong learning and the reform and integration of qualification systems.

In 1996, OECD education ministers adopted the principle of lifelong learning for all as the guiding motif for

education and training policies and activities. In 2001, the European Commission adopted a Communication on *Making a European area of lifelong learning a reality* (EC, 2001). Subsequently, the Council of the EU has passed a series of resolutions endorsing principles and practices of RPL, and under the banner of making learning visible, the EC has initiated a series of activities including the establishment of an inventory on tools and systems for recognition (Otero *et al.*, 2006).

Parallel with these developments has been the spread of NQFs beyond the Anglophone countries to most of the European countries (CEDEFOP, 2006) and to most other parts of the world. The OECD has drawn the link between lifelong learning, qualifications systems, and RPL in both its study on national qualifications systems (OECD, 2006a) and its recently launched activity on the recognition of non-formal and informal learning (OECD, 2006b).

There is an observably new interest in RPL across countries and there are frequent link between RPL initiatives and NQFs. Countries with strong apprenticeship systems with high levels of social partner steerage or management of qualifications systems, such as Germany and the Netherlands, are now developing NQFs. There is a common assumption that these developments will go hand in hand with the development and spread of different recognition practices, and in each of these countries there are reported tensions with some stakeholder groups and organizations over these principles and practices.

Furthermore, these developments appear to have revived interest in extending recognition of prior and informal learning to younger age groups. For example, the Council of the EU has resolved that "The value and visibility of non-formal and informal learning for young people should be enhanced by recognising the work and achievements of young people and those active in youth work and youth organisations" (EUROPA, 2006: 1). In Australia, two states have recently included the recognition of community-based learning within their senior secondary certificates.

Of course, the use of NQFs as a means of spreading, deepening, and validating the practices of RPL has yet to be realized in any measurable forms. In this third stage and iteration of RPL, there are questions about the characteristics of NQFs. If Allias' (2007) and Strathdee's (2003) critiques of the South African and New Zealand NQFs were to be applied across all NQFs, it is likely that their evolution will be troubled and their capacity to advance the RPL case will be limited. However, NQFs are a variable concept and have very different institutional forms. By and large, the South African and New Zealand examples were regulatory frameworks: all qualifications were to be designed within common formats. The alternative is enabling frameworks that establish a common language for qualifications and their learning elements to be compared and articulated. For example, the Scottish

example (the Scottish Credit and Qualifications Framework) is described as a credit framework that is designed to enable and encourage articulation between courses and to support the wider recognition of prior informal learning (Scottish Executive, 2004).

The hopes and expectations of RPL have grown and waned and now grown again over the last two decades. The returns to the investments in rhetoric, system governance, and innovations in qualifications, assessment and RPL procedures to this stage have been weak. The latest surge in investment is considerable and comes with the rhetorical force of lifelong learning and major developments in qualifications systems. Its realization is much anticipated.

The Competency Model

A Gonczi, University of Sydney, Sydney, NSW, Australia

P Hager, University of Technology, Sydney, NSW, Australia

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This article first outlines the recent origins of the competency-based training and learning model. It then outlines briefly the various main understandings of competence. These differences help to account for variation in the ways that the model has been deployed in different countries. Next, the international impact of agencies such as the Organization for Economic Cooperation and Development (OECD) on the spread of the competency model is outlined. Some examples of the implementation of competency-based training and learning are then briefly described. The article concludes with a discussion of various important ongoing issues surrounding the competency model. These include:

- limitations of verbal descriptors of competence;
- role of learning from work in competence development;
- contextuality of generic competencies;
- relation of competencies to curriculum;
- relation of competencies to assessment; and
- competency and lifelong learning.

The Recent Origins of Competency-Based Training and Learning

Over recent years, there has been an increased interest internationally in the relationship between education and the workplace. Countries in almost every part of the world, including Scotland, England, and Wales, Canada, the United States, Mexico, many South American countries, Australia, New Zealand, Sweden, France, Kuwait, Indonesia, Korea, and Thailand, have all undertaken substantial reforms of their vocational education and training systems. A number of them are also making substantial changes to higher education and to their school systems. But it is in the vocational education training (VET) area where the changes have been most significant. These reforms include: attempts to link traditional vocational education more closely to industry requirements; attempts to increase VET student numbers; introduction or expansion of vocational options in schools; attempts to develop partnerships between vocational and other educational sectors, partly to raise the status of vocational education; the development, by industry bodies with government support or participation, of occupational and employment-related competency standards which influence the content of

the curriculum in both general and vocational education; schemes to facilitate student transfer from one level of education to another, and to facilitate the recognition of prior and experiential learning; blurring of the distinction between vocational and university education; attempts to increase the quantity and quality of industry training and to develop alternatives to what is perceived as a government monopoly in the delivery of VET.

In addition to these systemic reforms, virtually all the countries mentioned above are committed to a particular approach to VET – competency-based education/training – though what is meant by this differs substantially between countries. What the reforms have in common is that the content of VET courses is based on occupational-competency standards, that it is expressed in terms of outcomes to be achieved by students, and that the assessment of students is (at least partly) based on the criteria expressed in the competency standards. Another common feature is that influential people from outside of the education profession have been involved in the formulation of the aims and content of education. This includes industrialists, governments, unionists, lobbyists, and bureaucrats. What is different between countries is how these competency standards are conceptualized, how and by whom they are developed, and the degree to which the standards shape the curriculum and assessment of VET.

The international interest in VET and in more relevant professional education and in employment-related competencies in general education in schools, is partly a product of a complex range of factors associated with national and international economies. Technological change, industry restructuring due to changes in global trade arrangements, changes in the capital and labor markets, and so on, have contributed to general unease and uncertainty about the aims of education. The reforms in higher education, the upgrading of VET, and the introduction of employment competencies in the school sector, have all been justified by their capacity to increase the levels of skills and flexibility in the economy, assumed to be a prerequisite to increased international competitiveness in the global economy. The relative cultural stability of the period from 1950 to 1980 has been deposed by the globalization of the last two decades and by the vast technological changes which, among other things, have led to a phenomenal decrease in the half-life of knowledge. This has led to a far more complex world and a widespread cultural anxiety which is at the root of much of the

educational policy of the last decade. It is certainly at the heart of the currently perceived need to develop skills-formation policies and to enlist the education system at all levels in this process. But it also helps explain the desire of a variety of groups to influence and even determine the content of educational provision.

In the schools sector, governments have attempted, among other things, to develop and incorporate employment-related competencies into the general-education curriculum. The aim has been to develop in young people competencies which would make them more effective participants in work, more flexible and adaptable, and more able to move into higher education, since schooling has failed to develop in students skills that are needed for the high-skills workplace of the 1990s. For instance, the Finn report in Australia in the late 1980s argued that Australia had inherited a tradition of education which accepted the divisions between general and vocational education and that the two needed to be brought together both for the sake of individuals and for the economy generally. It argued that schools needed to be concerned with employability and that the vocational sector needed to be concerned with more general, broader vocational education.

The Finn Report recommended that schools needed to be concerned with competency areas that all young people needed for employment: language and communication; mathematical and technological understanding; cultural understanding; interpersonal; and problem solving. In 1991, a new committee which has become known as the Mayer committee was given the task of developing the areas outlined in the Finn report into a number of more specific competencies. In the Mayer report, *Putting General Education to Work* (1993), seven key competencies were developed: collecting, analyzing, and organizing information; communicating ideas and information; planning and organizing activities; working with others and in teams; using mathematical ideas and techniques; solving problems; and using technology. Later, another was added – displaying cultural understanding.

These reforms which were introduced in many countries in the 1990s resulted in some fierce debates among educationalists. One view was that they have been part of a conservative agenda to refashion education in the interests of financial capital. Another, however, has been that introducing employment-related competencies in the curriculum is essential to equity policy – the desire to increase life chances of individuals (most often those from working-class backgrounds) failed by the traditional education system.

Most academic educators have opposed these reforms on the grounds that:

- they give too much weight to industry needs at the expense of the needs of students – that the reforms are too economically driven and are overly instrumental;

- they attempt to control teachers'/trainers' work through national curriculum and assessment; and
- the outcomes of education should be far wider than vocational outcomes and must include values and orientations related to justice, esthetics, democracy life skills, and so on.

They also claim that these reforms are inimical to the interests of students. Any vocational emphasis in education, it is argued, is technocratic, specific, practical, and managerial. It supports a view of the function of education that it is concerned with the transmission of exploitable knowledge and participation in the market through the development of skills which possess an exchange value (Feinberg, 1983). General academic education on the other hand is democratic, egalitarian, critical, and collaborative (Wellington, 1993).

Interestingly, similar arguments are used by at least some conservative politicians. They claim that such developments are merely trendy, that they deemphasize the traditional canon and thus lead to a reduction in educational rigor. In the United Kingdom, this has led to demands from some strands of the conservative hierarchy to strengthen academic education (the so-called gold standard) at the expense of education designed to appeal to a wider cohort of students.

However, it can be argued that these criticisms of the education reforms in schools (which include criticisms of the role of key competencies in general-education settings) are ill-founded. They rest on a view of vocational education which is both elitist and conceptually impoverished. Furthermore, they ignore the potential of key competencies to liberalize vocational education as well as to liberalize, even transform the curriculum and pedagogy of general education. Incorporating the key competencies into VET will ensure that VET becomes more liberal, supporting Dewey's concept of education through, rather than specifically for, occupations.

In addition, incorporating the key competencies into general education may provide the impetus for the reform of traditional subjects and traditional modes of teaching (see Lohrey, 1995). A key competency such as problem solving, for example, can be developed through traditional academic subjects but lends itself better to holistic, interdisciplinary knowledge and its application and the use, for example, of problem-based teaching methods.

Taken as a whole, these developments mark a significant change in educational policy. For the first time, education has been openly debated in instrumental terms and is being judged, at least partly, by the extent to which it is succeeding in advancing national goals related to economic restructuring and competitiveness. It is hardly surprising, given the politically charged atmosphere in which it was first advocated, that there has been little real analysis of the nature of such competency-based education and the concepts on which it is based. It is to this subject that this article now turns.

Nature of Different Approaches to Competency-Based Education

Competence can be thought of in several quite different ways. How we view competence significantly shapes the ways competency standards are used and assessed. As performance of tasks is something that can be readily described, the common sense but naive view of competence equates it with successful performance of a set of discrete tasks. Competency standards are then thought of as objective descriptions of the set of tasks. The basic error here is the confusion of tasks with the capacity to perform the tasks. According to the Concise Oxford Dictionary, competence (or competency) denotes the ability to do something or the ability for a task. Here the emphasis is on competent people having ability or capability that will enable them to complete tasks. But abilities or capabilities involve concepts such as knowledge, skills, and attitudes, that is, relevant personal characteristics that underlie competent performance. But these personal characteristics are not so readily describable as are sets of tasks. Our understanding of human capacities and abilities remains limited, in the sense that attempts to specify them are invariably debatable and contested. The task view of competence skates over these matters by pretending that a relatively objective checklist of tasks describes competence. It does no such thing. One result is that the task view of competence omits vital higher-level competencies, such as planning or reacting to contingencies. Hence training programs based on this approach are flawed.

Another approach views competence as having a series of desirable attributes including appropriate kinds of knowledge, skills, abilities, and attitudes. This is a generic approach that centers on training and assessing learners' performance on each of these separate attributes. At least this approach promises to address the less predictable, nonroutine aspects of work. But its main limitation is that training and assessing attributes in isolation from actual work practice bears little relation to future occupational performance. It turns out that attributes such as problem solving, analysis, pattern recognition, etc. are highly context dependent, thereby vitiating the effectiveness of attempts to train and assess them out of context. Another problem with this approach is that when the generic attributes of various occupations are compared, it can be difficult to tell one occupation from another. This is another way of saying that competency-based theory (CBT) needs to be grounded in context.

The two approaches considered so far have focused exclusively on either tasks or attributes. A third approach, the integrated conception, views competence in terms of knowledge, abilities, skills, and attitudes displayed in the context of a carefully chosen set of realistic professional tasks which are of an appropriate level of generality

(Gonczi *et al.*, 1990; Hager, 1994; Biggs, 1994). This approach centers on key tasks involved in the practice of the occupation. Major attributes, such as cognitive skills (knowledge, critical thinking, and problem-solving strategies), interpersonal skills, affective attributes, and technical/psychomotor skills that are required for competent performance of these key tasks are identified. Competency standards that integrate these attributes and tasks provide a richer representation of practice than was possible with the other two approaches. This approach accords with the dictionary definition of competence that links ability or capability with tasks. The integrated view of competence is holistic in that it situates attributes in the kinds of contexts in which they are employed in the practice of the occupation. This is also suggestive of training and assessment situations suitable for effective learning and assessment.

The integrated approach highlights an important asymmetry surrounding the concept of competence. We have seen that competence links abilities and capabilities with tasks. But though performance of tasks is directly observable, the abilities or capabilities that underlie the performance are not directly observable. We infer their presence or otherwise on the basis of the performance. So assessment of competence is necessarily based on inference from samples of performance. A literature has also developed around the notion of capability as a replacement concept for competence. However, there appears to be little discernible difference between the integrated approach to competence and the notion of capability.

The Role of the OECD in the Debate about a Competency Approach to Education

Over the last decade, there has been an increasing emphasis in OECD publications on the impact of social and economic change on education and a desire to investigate whether the citizens of developed countries are learning what is appropriate for the new age. What are these skills understandings and dispositions (what we define as competencies in our integrated approach to competence)? Are students well prepared to meet the challenges of the future? Are they able to analyze, reason, and communicate their ideas effectively? Do they have the capacity to continue learning throughout life? These are questions that parents, students, the public, educational bureaucrats, and increasingly, politicians, in both developed and developing countries, are asking. One project in particular, Definition and Selection of Competencies: Theoretical and Conceptual Foundations (De Se Co), commenced in 1997 under the OECD's education indicators program International Indicators of Education Systems (INES) has recently attempted to answer this question. The project's

aim was to clarify what competencies apart from reading, writing, and computing are necessary for an individual to lead an overall successful life and for society to face the challenges of the present and the future. The program of work was the most extensive ever undertaken to answer these and other questions. A number of activities were undertaken: an analysis of international studies on educational indicators, a study reviewing scholarly work on the concept of competence, expert papers on key competencies by academics from different disciplines and different countries (economics, psychology, anthropology, sociology, and philosophy from Switzerland, France, Germany, UK, and the USA) and comments on these from practitioners and policymakers. These were all discussed at a symposium in 1999 and the papers and comments later published in a book in 2001 (Rychen and Salganik). Following this, an analysis of country-specific key competencies was undertaken and a second symposium convened in 2002. A strategy paper followed and then a second book appeared by the same authors (Rychen and Salganick, 2003). The project concluded that the notion of competence is an important one and goes well beyond the notion of skill. Competent performance implies the mobilizing of knowledge, cognitive, and practical skills, as well as attitudes, emotions, values, and motivations. Competencies become key when they: contribute to highly valued outcomes at the individual and societal level, are instrumental for meeting important complex demands and challenges in a wide variety of contexts, and are important for all individuals.

They identified three main categories of competencies:

- interacting in socially heterogeneous groups,
- acting autonomously, and
- using tools interactively.

The specific competencies in the first category – the ability to relate well to others, to cooperate, and to manage and resolve conflict were seen to be vital to life in a globalized world and increasingly in individual multicultural societies. In the second category – the ability to act within the big picture, to form and conduct life plans, the ability to defend and assert one's rights, interests, needs, and limits – are all vital in various aspects of life: work, family, and civic society. The third category included the ability to use, interactively, language, symbols and texts, knowledge and information, and technology. This category had in mind reading, mathematical, and scientific literacy among other things.

Underpinning all these is a critical and reflective stance. The conclusion of the project was that if we are to understand the idea of key competencies, it is necessary to go beyond the outcomes of the typical curriculum of formal institutions, which stress on variously recalling knowledge and sometimes thinking abstractly, to the kind of capacity that is developed through the integration

of formal and informal knowledge. These are capacities which can only be developed gradually over a lifespan.

Clearly, this approach to the nature of competency provides a persuasive justification for lifelong learning and in particular the need to provide opportunities for adults to develop and learn throughout their lives. In addition though, this approach also obviously has potential implications for the curriculum and structures of schools and tertiary institutions.

The project also supported the principle that the key competencies were interrelated and that these constellations of key competencies (DESeCo summary p. 4) will vary with the contexts in which they are applied.

The implications of this work for future international assessments are significant. The project also enables those involved in school-based assessment to understand the work on assessing key competencies in adults. This should have the effect of improving the assessments in both contexts. The International program for Student Assessment (PISA) is the most prominent example of these assessments. The PISA program is a collaborative program which measures how well students at age 15, the end of compulsory schooling in most OECD countries, are prepared to meet the challenges of contemporary society. The assessment reflects the curriculum in the OECD but is focused on the use of knowledge in the real world. The assessment reflects the capacity of students to engage in lifelong learning by using their school-developed knowledge in a variety of nonschool settings. Thus while PISA does assess curriculum knowledge, it also examines the capacity to reflect and apply knowledge. The assessment takes place every 3 years, through the use of pen-and-paper tests. The survey was implemented in 43 countries in 2000/2 and 42 countries in 2003 and again in 2006 (results available in December 2007). Between 5000 and 10 000 students from 150 plus schools are typically tested in each country. It is administered over a 3-year cycle covering reading literacy (2000), mathematical literacy (2003), and scientific literacy (2006).

The reasons for adopting this approach are outlined in the PISA 2003 Framework (OECD, 2003). In summary, the OECD believes that certain broad general skills are essential to success in life beyond school. These include communication, adaptability, flexibility, problem solving, and the use of information technologies. These competencies are developed across the curriculum and assessment of them requires a cross-curriculum focus. In addition, in the specific domains measured in PISA, the application of knowledge in adult life depends more on the acquisition of broader concepts than knowledge acquisition in schools. In mathematics, for example, the capacity to reason quantitatively is more important than answering text-book questions.

These OECD initiatives reflect increasing international attention to so-called generic skills, core skills, or

basic skills, or, more recently, employability skills. (Sometimes the term competencies replaces skills.) These terms refer to diverse qualities and capacities that are argued to be important in many life situations, though work and education as a preparation for work are usually the main focus. As noted earlier, examples include thinking (logical and analytical reasoning), problem solving, communication skills, teamwork skills, knowledge and information skills, together with values such as persistence, integrity, and tolerance. These so-called generic skills are seen as different from the knowledge that characterizes traditional disciplines or the physical skills associated technical fields.

As the list makes clear, generic skills covers a very diverse range of things – skill, attitudes, values, and dispositions. Some of these are clearly not skills in the usual sense, such as attitudes and dispositions. Even those that most resemble genuine skills range from the physical (e.g., body language in interpersonal communication) to the mental (e.g., reasoning). There may be significant differences here that are masked by the blanket term skills. The more attitudinal and dispositional qualities can be more accurately viewed as products of cultural, ethical, and social circumstances that may be refined and modified by knowledge and reflection. Rather than being unitary things, they are complex relations that connect persons and particular contexts.

Adoption of the Competency Model in Various Countries

Competency-based approaches to education have been taken up in many countries over the past decade. However diversity is evident in these initiatives, reflecting differing views of purpose, as well as somewhat different understandings of competence. The United Kingdom for instance has set up a system of national vocational qualifications (NVQs) and general national vocational qualifications that cover many occupations and work roles, including many that had no previous formal qualifications. The NVQs in particular have tended toward a task approach and have been criticized for atomizing work into checklists of discrete observable skills. In Australia, a more integrated understanding of competence has been influential. This has tended to distinguish competency standards from course curricula. This separation has reached the stage where so-called training packages which outline competency standards and ways to develop them effectively have effectively replaced formal curricula. It is left to the training providers to develop their own curriculum in order to deliver a given training package. New Zealand, on the other hand, specifically equates units of competency standards with units of curriculum. Scotland also has a system that bears similarities to the one in New Zealand.

Many countries in Latin America have adopted competency-based approaches to VET over the last decade or so. The impact of globalization on countries such as Mexico, Costa Rica, Ecuador, and Chile, for example, has resulted in significant economic and educational reform to both vocational and in some cases higher education. In Mexico, for example, with the support of the World Bank, technical education was reformed, between 1995 and the early years of this century through the development of a national system of labor competencies and a system of colleges *El Colegio Nacional de Educación Profesional Técnica* (CONALEP) which developed competency-based curriculum to enable students to meet these national labor competencies. In the early stages of this modernization process, there was little industry involvement, though this is slowly changing. However, unlike Britain and Australia, the implementation of these reforms has been government rather than industry led. Developments in Mexico have been influential in many Latin countries (Morales, 2000).

Ongoing Issues Regarding Competency-Based Training and Learning

Limitations of Verbal Descriptors of Competence

Competencies are commonly assumed to be easily and unequivocally describable in language. So it is thought to be a straightforward matter to describe occupational competence in written form. But actually, it is tasks to be performed that can be accurately stated in language. As already suggested, specifying the precise attributes that underlie performance is less well founded. Some aspects of performance are tacit or implicit. Consider, for instance, the case of face recognition. Humans can easily pick out a familiar face from thousands of unfamiliar ones. But to state in words exactly how this is done is something that remains elusive. As Lum (1999: 410) succinctly puts it, the assumption that human capabilities can be unequivocally described and accurately communicated by means of language is unfounded. So, at best, written competency standards are rough and ready, though useful, guides. They have inherent limitations and disadvantages. We should be wary of the tendency to assume that reality is exhausted by attempted descriptions of it.

Role of Learning from Work in Competence Development

The competence approach to vocational education can be seen as an attempt to render it fail-safe. It was thought that traditional curricula reflected what teachers regarded as important rather than what industry really needed. CBT remedies this by being based on explicit descriptions of competent performance in the given occupation. So, it was

assumed that if CBT is implemented effectively, it will produce graduates who are ready to function competently in any workplace. However, this optimism proved to be misplaced. It seems that a gap between skill-development outcomes and workplace competence is inescapable. A prime reason for this is that contextual factors, which are often unique to particular workplaces, shape and partly constitute competence in any given situation. This means that

... the learning required for competent workplace performance is normally much greater than the learning that can occur in formal pre-service courses based on standardised training outcomes. It seems that some context-specific learning, that can only occur from the actual practice of an occupation, is a vital part of competence. Nor is this learning necessarily directly transferable to practice of the same occupation in a different context. (Hager and Smith, 2004: 43)

This crucial feature of CBT was widely overlooked leading to inevitable disappointment as the new approach failed to produce graduates able to immediately perform competently in the workplace. This gap can be reduced if suitable varied workplace learning and experience is organized in parallel with standards-based learning and achievement of skill-development outcomes. This is what happens in well-run apprenticeships. However, even here, if the novice worker or apprentice moves to a job in a different organization, he/she will very likely need a further period of workplace learning and experience to become competent in the new situation.

Contextuality of Generic Competencies

Not only is competence significantly contextual as outlined in the previous section, but generic attributes and the ways in which they cluster are strongly shaped by the particular features of the context in which work is carried out (Hager, 1997: 13–15). The influence of the context is such that it is unhelpful to identify the generic attributes of an occupation or profession. The relative importance of these generic attributes and the ways in which they cluster will very much change with the workplace context. The notion of context is itself complex and includes a multiplicity of workplace-related factors such as:

- the specific history of a workplace or company;
- its particular culture and norms;
- its institutions and practices, for example, work organization and career structure;
- its economic and social environment;
- its strategic needs;
- its deployment of technology; and
- the extent and intensity of change to which it is subject.

Research on the workplace role of generic attributes shows that there is significant variation in competence requirements across work sites within one occupation. Such variation means that prespecified skill-development outcomes, including standardized generic attributes, cannot meet all of the requirements of particular work sites. For example, in the United States Stasz *et al.* found differences not only in generic attributes needed across occupations, but also in the same occupation practiced in different organizations and work sites. They concluded (Stasz *et al.*, 1996: 102) that

... whereas generic skills and dispositions are identifiable in all jobs, their specific characteristics and importance vary among jobs. The characteristics of problem solving, teamwork, communication ... are related to job demands, which in turn depend on the purpose of the work, the tasks that constitute the job, the organization of the work, and other aspects of the work context.

Thus, even within the same occupation, job demands can vary so much between different companies or work sites that it makes little sense to try to specify the exact generic-attributes mix for a particular occupation. The high contextual sensitivity of generic-attribute requirements of work is further illustrated by the later research findings of Stasz and Brewer (1999).

Relation of Competencies to Curriculum

We can start this section with some basic logical points (Hager, 1995). Performance descriptors are outcomes. They describe what the end products are like at particular stages of development. Curricula are about what needs to be gone through to attain outcomes, that is, they are essentially processes. So performance descriptors as outcomes are logically distinct from curricula as descriptions of processes. Moreover, learning outcomes are mini-stages in these course processes, and so are not to be confused with the performance outcomes of a workplace. To the extent that they have any connection with courses, performance descriptors describe course outcomes (states), whereas curricula describe a process to be gone through (literally a course to be run). So, a typical curriculum describes what is to be learnt and some processes of how it is to be learnt, as well a statement of what people should be able to do at the end of the course. As performance descriptors are summative rather than formative, they will hinder curriculum development if they are thought of as being a curriculum. In other words, a curriculum describes a developmental process by which certain outcomes will be achieved, whereas, at best, performance descriptors describe some of these outcomes without specifying how they are to be learnt. The temptation to confuse performance descriptors with curricula presumably comes from viewing learning as bite-sized discrete chunks and performance

as a series of discrete skills that might be equated with these chunks. But these ideas spring from viewing learning as a product together with its other accompanying assumptions. As is argued later, a better view of learning is available.

Similar arguments apply to teaching. Teaching is an important part of the process that aims to arrive at, among other things, some of the outcomes specified in the performance descriptors. However, various attributes, such as knowledge and skills are typically prerequisites for performances specified in the performance descriptors. Thus it will be a waste of effort to try to teach the performance descriptors bit by bit unless the groundwork of requisite knowledge and skills has already been laid down. But as we have seen, the constituents of competence are themselves contested, so there is room for various views about the capabilities, abilities, skills, etc. that a given course should be fostering. Besides, in most cases, this requires a significant developmental process. Thus the performance descriptors, as a guide to actual teaching activities, are of very limited value. Certainly, if useful at all, it will be in the later, rather than the earlier, stages of a course. This is when vocational courses are usually more concerned with actual workplace conditions anyway. The futility of teaching the performance descriptors bit by bit should be obvious except to those with the most naive learning-as-product views. Rather than raising the skill levels and capacities of the workforce, the opposite would result from such an approach.

As always, there is more than one way to teach effectively to achieve some specified outcome. Hence, though the performance descriptors at best describe some major expected outcomes of successful completion of the course, they do not prescribe the teaching strategies that will best lead to these outcomes. Thus, for teachers there is as much responsibility as ever to decide what to teach, and when and how to teach it.

Relation of Competencies to Assessment

Atomistic performance descriptors are attractive to some because they offer the possibility of simple piece-by-piece assessment by direct observation of the performance of tasks against a check list. Once again, this springs from viewing learning as a product together with its accompanying assumptions. However, such assessment raises invalidity problems of several kinds. In general, it assesses superficial aspects of an occupation and ignores the holistic character of quality performance. Experience has also shown that, despite its initial attraction for some, this approach leads to unacceptably large amounts of time being spent on assessment of a myriad of discrete tasks.

In the early stages of courses, foundational knowledge and a range of enabling skills, which provide an essential basis for the future development of occupational competence,

need to be acquired. So the occupational performance descriptors will not be immediately relevant to course-assessment practices. When curriculum is construed as a process, attainment of appropriate developmental stages, rather than of full occupational competence, will be most typically the concern of assessment. Only in later stages of the courses will assessment against occupational performance descriptors be likely to be of any relevance.

It has been argued at length that we need to clearly distinguish:

- performance and its outcomes;
- the underpinning constituents of competence (capabilities, abilities, and skills); and
- the education, training, or development of people to be competent performers.

The idea that learning is a product encourages these three categories to be confused one with another. More holistic and process-oriented approaches to teaching avoid this trap.

Competency and Lifelong Learning

The preceding considerations suggest one way of thinking about lifelong learning. From the early years of schooling and before, learners can be expected to be in situations in which they would be acquiring some basic proficiency in deploying at least some common generic attributes, for example, using household microelectronic technology. One outcome of a sound education would be a growing capacity to deploy successfully generic attributes in an increasingly diverse range of situations and contexts. This suggests that the development of generic attributes should become gradually more integrated and holistic as young people move through schooling. The idea is that sound performance in very many of life's situations centers on successful deployment of suitable combinations of generic attributes. Such a staged development of generic attributes would facilitate students' transition to vocational training, higher education, work, and other postschool activities.

In the Australian vocational sector, the recent agenda to embed generic attributes in the training courses is an attempt to achieve a balance between the capacity for lifelong learning in the longer term and employability in the short term. The greater articulation between vocational-education courses and university courses, as well as more clearly delineated curriculum pathways are, of course, an identifiable form of lifelong learning.

The development of graduate attributes by universities is closely linked to their role in fostering graduates with a capacity for lifelong learning. Various graduate attributes have been recognized as important for lifelong learning (see, e.g., Candy *et al.*, 1994). Developments at the University of Otago provide an example of the close links

between these two notions. Viewing lifelong learning as an element of gradueness, a concept elaborated by the English Higher Education Quality Council (HEQC, 1996), the university has instituted an iterative process in which links are strengthened in its courses between the fostering of desirable attributes and the deployment of innovative teaching and instructional-design strategies. Part of this iterative process is the obtaining of ongoing feedback from both employers and recent graduates on the generic attributes required of graduates.

It is also crucial that generic attributes should be thought of more broadly than in terms of just university and work. These attributes represent a basis for lifelong learning in all kinds of life situations. Rather than being viewed as discrete attributes that people learn to transfer, generic attributes should be seen as learnt capacities to handle an increasing variety of diverse situations. Thus transfer becomes more a growth in confidence and adaptability as learners experience ever more success in their deployment of generic skills in a range of situations. To put it another way, perhaps it is not so much generic attributes that transfer, as growing understanding of how to deal with different contexts. In this way, nonwork experiences can benefit workplace performance and vice versa.

Conclusion

The competency model, despite the diversity of interpretations and practices associated with it, continues to flourish. Whether it will evolve further and continue to maintain its current position of preeminence in VET remains to be seen. Certainly, there is little evidence of a different model of VET emerging to replace it in the near future.

Introduction

Globalization has many adherents and detractors (e.g., Friedman, 2005; Bhagwati, 2004; Stiglitz, 2003), including large groups of people opposed to the effects they believe it has on traditional ways of living, especially in developing countries (Klein, 1999).

Defining globalization is a problematic task and usually involves economic, technological, sociocultural, and political contexts. As early as 1994, Friedman came up with a useful literal definition of globalization as the “process of transformation of local or regional phenomena into global ones. It can be described as a process by which the people of the world are unified into a single society and function together” (Friedman, 1994).

Since that time, understanding of globalization has become more sophisticated, such that commentators now characterize globalization as consisting of three phases:

- Phase 1: the mobility of capital.
- Phase 2: the mobility of goods and services.
- Phase 3: the mobility of people.

Each of these phases poses distinct challenges to vocational education and training (VET), in terms of adapting to changes brought about through economic restructuring, the entry and exit of skills through migration flows, and a focus on new types of skills in an increasingly knowledge-based society.

This article seeks to establish the causes for the growing interdependence of nations and the degree to which VET is being impacted by the developments within the global economy. In particular, it addresses issues around patterns of labor mobility and the development of mechanisms to facilitate this phenomenon, including

international education, the growth of higher-level skills, the transparency of qualifications systems, and the transferability of skills.

Economic Restructuring

The free flow of capital and goods and services allows employers the option to relocate investment from one region of the world to another, in anticipation of greater returns. In many Western countries, the most recent examples of this are the closure of factories, with operations typically moving to China or Southeast Asia (low-cost manufacturing), and the establishment of call centers and back-room processing for financial services in India (service-sector work). Workers who are made redundant may be unable to find work in the same industry and may have to acquire new skills to regain employment. This has been the fate of many workers in the textiles, clothing, and footwear industry in some developed nations (Webber and Weller, 2001).

Finegold (2009) suggests there is a process of ‘bifurcation’ of skills and jobs occurring in the global labor market – where there is demand at both the ‘low-end’ and ‘high-end’ of the job market creating a form of ‘barbell’ market. With, presumably, most of the jobs at the low-end concentrated in developing countries, the corollary is that those at the high-end are concentrating in more developed economies that have access to pools of highly educated and skilled people. Many jobs in the middle are simply disappearing.

Further, some estimates suggest that, by 2030, up to 60% of all jobs could be automated, and new industries are beginning to emerge (such as biotechnology, renewable energy, and nanotechnology) which are all requiring

new skills to be developed – and it is these (and other) industries which will provide the high-skill jobs of the future (Elliott, 2007).

At the macro level, governments worldwide have adopted different responses to the economic and social consequences of globalization. Often, assistance is provided to firms and workers in vulnerable industries to enable them to adjust – with the scale and type of assistance provided varying according to the industries affected. The political consequences of allowing adjustment to occur with or without assistance are also an influencing factor.

Another significant strategy adopted by governments is the development/enhancement of workforce skills to maintain or improve the competitiveness of industries – relative to equivalent industries in other countries. Industry bodies – including unions and employer associations – are willing supporters of government policy and initiatives in this area. Examples of these types of initiatives are occupationally linked literacy, language, and numeracy programs.

A further response (which has usually come much later) has been to develop overarching national skills strategies – examples being the Leitch Review in the United Kingdom which resulted in a national skills strategy for Britain through to 2020 and the Lisbon Strategy in the European Union. In Australia, the National Skills Shortages Strategy (NSSS) – and, more recently, the establishment of Skills Australia – are examples of national skills planning in response to global economic factors.

Alongside the restructuring occurring as a result of more open economies has been the development of the new information and communication technologies (ICT), which have been increasingly deployed across all areas of industry and which have had a profound impact in many industries, from computer-aided design and just-in-time management of inventories, to a range of new and enhanced telecommunication services requiring workers to gain entirely new skill-sets.

During the 1990s, the term knowledge economy became a popular way of describing the economies now underpinned by the information and communications technologies. The term had originally been coined by the well-known management expert, Peter Drucker (1968), in his book, *The Age of Discontinuity*. Governments in many countries adopted the notion of a knowledge economy as an overarching goal through which to frame overall policy direction – including in the area of education and training. The European Union, for example, set itself a goal in its 2000 council meeting in Lisbon to become, by 2010, “the most competitive and dynamic knowledge-based economy in the world,” with lifelong learning one of the means of realizing this goal.

An early commentary which anticipates the impact the knowledge economy will exert on people’s working lives

is Reich’s (1991) *The Work of Nations*, in which he categorizes the workforce according to three groups: routine producers, in-person service providers, and symbolic analysts. The last category was defined as those who “solve, identify and broker problems by manipulating symbols. They simplify reality into abstract images that can be rearranged, juggled, experimented with, communicated to other specialists, and then, eventually, transformed back into reality” (p.178). Examples include engineers, lawyers, journalists, academics, and most professionals.

The VET system needs to reflect the general societal changes from an industrial society to a knowledge society as well, and be able to meet the skills needs of a changing labor market. New occupations are arising within sectors such as ICT, the services, and in new technologies such as biotechnology, and these have to be integrated as new training provisions within the VET system.

In addition, the process of economic restructuring has highlighted the disjuncture of VET systems which, in the main, have been set up primarily to deliver skills to entry-level students when, in reality, a component of the existing workforce requires re-skilling. Therefore, it is imperative to explore a range of mechanisms that provide workers, who have already completed their formal training, with the opportunity to acquire new skills (Ball *et al.*, 2001).

Movement of Skills through Migration Flows

Another facet of globalization is the mass movement of people. The United Nations (2003) estimated that some 175 million people lived outside of their country of birth at the beginning of the twenty-first century.

An aspect combined with this phenomenon has been skilled migration. Comparative data (from 2000) suggest that some 20 million highly skilled workers from developing countries (i.e., highly skilled foreign-born workers with tertiary qualifications) now live in Organisation of Economic Co-operation and Development (OECD) member countries alone; a 70% increase in merely 10 years (Beine *et al.*, 2006).

The global trend toward mass movement of skills has increased significantly following World War II. This phenomenon has seen a brain drain to receiving nations – and a perception that more developed nations have been ‘poaching’ the best and brightest (Grecic, 2007).

Recent theoretical literature suggests, however, that emigration prospects can raise the expected return to human capital and foster investment in education at home – although there are clearly winners and losers in this (Beine *et al.*, 2006). In fact, some economists have established that there is an overall increase in the standard

of living for both donor and recipient country through the migration of skilled people.

There are a range of consequences for VET arising from labor mobility, especially in supporting migrants to work to their full capacity. This may include the need for training in language, literacy, and numeracy skills; country-specific health and safety training; and particular vocational skills training. In addition, there could be a need for more practical training on living in a new culture (Learning and Skills Council, 2007).

VET also has a role in ensuring the integration of immigrants and weak learners, and thereby contributing to social cohesion. As informal learning is the dominant form of skills acquisition in some countries and for many learners, these experiences will increasingly need to be incorporated into the more formal system of skills development – especially if these learners are to be fully effective in the modern labor market. In this respect, VET is starting to play an important role in the integration and social policies of many countries.

To ensure good learning outcomes for new migrants, educators and trainers need to be aware of alternative classroom-management strategies. These may include smaller class sizes, different types of institutional support, and placing learners from similar backgrounds together (Burgoyne and Hull, 2007). There are other considerations such as integrating education, training, and employment pathways more effectively. The main barriers to success for many migrants relate to a lack of recognition of the qualifications and experiences they bring from their former countries and restrictions on using overseas-acquired skills through regulation (Phillimore *et al.*, 2007).

International Education Markets

International education markets, according to the World Trade Organization (WTO), are defined as the cross-border trade or ‘consumption abroad’ of education and education-related services. This can be in the form of students attending study in a country other than their own (onshore education), through distance learning, or by undertaking courses offered in a student’s own country by an education provider of a second country (offshore or transnational education). Many countries, such as the United Kingdom, America, and Australia, have been quick to grasp the potential for this – especially in the domain of higher education.

The twentieth century saw a surge in higher education; in the early twenty-first century, the idea of going abroad to study has become thinkable for ordinary students. In 2006, the most recent year for which figures are available, nearly 3 million were enrolled in higher education institutions outside their own countries – a rise of more than 50% since 2000 (Economist, 2008).

(Australia – by comparison with other OECD countries, for example – has by far the highest proportion of overseas students among its higher education intake, at 17.8%, well in excess of the OECD average of 6.9% (OECD 2008, Table C3.1). International education services are Australia’s third largest export industry worth 12.6 billion dollars per annum (ABS, 2007).

Finegold (2009) suggests there are other benefits beyond the influx of dollars that can be generated by global education services, especially through the access to new innovation networks provided through the graduates. In fact, graduates are a major source of potential business incubation and start-up companies, especially in high-technology areas. Benefits also derive to the recipients who take home credentials that are considered world-class and which help local business.

International education has had a direct impact on patterns of mobility as well. For the qualification holder, having Western qualifications often makes migration (especially for skilled-migration purposes) to a new country much easier. Access to Western-country qualifications is also seen to benefit the growth in trade and the rise of the middle class in many countries (e.g., China and India). In countries such as Australia, international education has been a direct route to permanent residency.

The growth of international education has resulted in a range of issues, however, including how to assure quality, the accreditation process where multiple countries’ contexts need to be considered, possible diminished research capacity, and crowding out of native-born populations in the intensified efforts to recruit international students (Lim, 2007; Finegold, 2009).

The move toward internationalizing curriculum which takes into account a wider view of the world – and is aimed at preparing all students for performing professionally and socially in a global context – is becoming increasingly important both in terms of good global citizenship and plain good business! Although difficult to quantify the actual benefits, the value of international education in promoting intercultural development should not be underestimated.

Transparency and Transferability

Another element of globalization and its links to both education and the labor market has been the rush to develop a range of mechanisms to facilitate mobility. In this, the education and training sector has a major role to play.

People increasingly require skills that are portable and transferrable and which, in some circumstances, can be recognized across national borders. In fact, the development of qualifications systems that can accommodate skills and qualifications acquired in other countries are being

seen as a key part of trade diplomacy. In some regions of the world (particularly Europe through the Copenhagen and Bologna processes), efforts are afoot to realign qualifications frameworks to become regional in nature.

The need then for harmonizing country-specific VET systems (such as what is currently occurring through the new European Qualifications Framework (EQF)) has significant consequences for the cultural patterns underlying both the practice, the theory, as well as the policy of VET in these countries, and in addressing incompatibility between systems (Deissinger, 2008). For example, the development of country-specific VET systems happen over a significant time span and are fashioned to meet local and national imperatives. The question of how to then balance these national needs with the wider regional or international agenda often produces conflicting goals.

A strategy for dealing with perceived incompatibility may lie in a nation-specific strategy which encourages and enables change without dumping the benefits and the functionality of the established system (Deissinger, 2008).

Another recent strategy from Europe has been the introduction of the European Credit System for Vocational Education and Training (ECVET – a device which will facilitate the transfer, validation, and recognition of learning outcomes acquired by individuals moving from one learning context to another or from one qualification system to another – in particular, during a mobility period – and who wish to obtain a qualification (European Commission, 2009).

Issues around the recognition of qualifications and transnational quality assurance strategies which require local, national, and regional approaches need to be considered. This will become increasingly pressing as the world continues to divide into major trading blocs with the erosion of traditional borders and trade barriers. These need to be balanced with other issues to do with quality assurance and ensuring training standards are maintained, however.

Innovation and the Growth of Higher-Level Skills

It has been widely argued that global economic competitiveness rests in the main on the knowledge and skills of the workforce (see, in particular, Brown *et al.*, 2001). But the link between global competitiveness and skill formation is complex – especially when other factors are taken into account, such as country context, social justice, and the role of government. In some countries, especially those in Europe, there is a far stronger role for government in driving skill formation – irrespective of global economic factors – than in others (such as the United States).

Bosworth *et al.* (2008) identified globalization as a major factor in placing pressure on less skilled jobs and driving the

policy in Western nations, in particular, toward concentrating on raising education and skills levels in response. This has especially been a feature of many European countries – through the European Lisbon Strategy. This has also been the experience in Australia as well, where successive governments have targeted skill development as a way of maintaining the country's economic performance.

Several recent government reports ('Rising above the storm' from the United States, 'Race to the top' from the United Kingdom, and 'Benchmarking against the global best' from Canada) note the importance of innovation in driving growth in national productivity and competitiveness and that this plays an equally important role in achieving social-inclusion objectives (Finegold, 2009).

Globalization is perceived as a factor in stimulating growth in higher skills as the nature of production becomes more sophisticated (Curtain, 2004). This dictates that as methods of production become more complex, so the need for people with higher level technical and problem-solving skills also increases. Despite there being an accepted view that there is a strong and tangible link between university education and the process of innovation, there is anecdotal evidence that there also needs to be a pool of highly trained technical expertise at the para-professional level – and that this, in itself, can foster the development of entrepreneurial skills in workers; essential for success in an increasingly globalized free economy.

Changes in production, in particular, have resulted in the need for the workforce to acquire higher-level skills; and VET clearly needs to have a focus on the development of higher skills if it is to contribute to this phenomenon. However, the nature and numbers of these higher-level skills required for the economy are difficult to determine, and can only be predicted at a highly aggregated level for a few years ahead. This clearly has implications for training-program development and in a wider national skills-planning sense.

Examples of higher-level qualifications within the rubric of VET include foundation degrees in Britain, professional degrees and Advanced VET in Scandinavia, and vocational graduate certificates and diplomas in Australia.

Conclusion

This article has attempted to demonstrate that the effect of globalization on national VET systems is substantial and complex. A range of international factors such as economic restructuring – coupled with technological development and the growth of ICT and the internationalization of education and skills development – are all playing a part in the move toward the growth of higher-level skills. To date, this has probably impacted higher education more than VET, but this is changing as work practices and occupational skill-sets become more sophisticated.

Second, the trends described in this article all have a significant professional development needs attached to them; and VET practitioners need to be provided with ample opportunity to develop skills for coping with a rapidly changing world.

Finally, it is important to note that it is not correct to attribute all structural change to the process of globalization. There are many factors – including the specific country's economic and social development as well as the prevailing economic, political, and educational institutions – fashioning structural change within the economy. Nevertheless, globalization is a substantial force, and it has direct consequences for the VET sector.

Glossary

Citizenship education – A learning programme designed to promote participation in democratic societies by equipping learners with the knowledge, skills, values, and dispositions for active informed civic life.

Economic literacy – The ability to understand and apply basic economic concepts in situations relevant to one's life.

Economic sustainability – An aspect of sustainable development that seek to maintain and enhance economic capital to promote human prosperity and ecosystem health.

Education for sustainable development – A dynamic and expansive undertaking that envisions a world where every person has the chance to benefit from educational opportunities and to learn the skills, knowledge, and values that are necessary to create a sustainable future.

Environmental sustainability – An aspect of sustainable development that seeks to improve the total quality of life, both now and in the future, in a way that maintains the ecological processes on which all human and nonhuman life depends.

Social sustainability – An aspect of sustainable development that encompasses peace, international understanding, gender equality, human rights, labor rights, and corporate governance. In common with environmental and economic sustainability, social sustainability is underpinned by the idea that future generations should have the same or access to resources as the current generation.

Sustainable development – A process by which the needs of present generations can be satisfied without compromising the ability of future generations to satisfy their needs.

Sustainable production – An approach to the manufacturing and delivery of goods and services in ways that respond to basic human needs, promote a better quality of life, and minimize environmental impacts, so as not to jeopardize the needs of future generations.

A Call to Humanity

This article considers some of the implications for technical and vocational education and training (TVET) that flow from the processes of environmental decline that are characteristic of the modern world. The crises of unsustainable development that have followed economic modernization, and which interacts with local, regional, and global patterns of culture, geography, and population, have not been sufficiently analyzed in TVET or, indeed, in broader educational circles. This is despite the fact that, scientists around the globe, including 102 Nobel laureates, signed the World Scientists' Warning to Humanity, which read in part:

Human beings and the natural environment are on a collision course. Human activities inflict harsh and often irreversible damage on the environment and on critical resources. If not checked, many of our current practices put at serious risk the future that we wish for human society and the plant and animal kingdoms, and may so alter the living world that it will be unable to sustain life in the manner that we know. Fundamental changes are urgent if we are to avoid the collision our present course will bring about.

WARNING – We the undersigned, senior members of the world's scientific community, hereby warn all humanity of what lies ahead. A great change in our stewardship of the earth and the life on it is required, if vast human misery is to be avoided and our global home on this planet is not to be irretrievably mutilated. (see <<http://www.secondnature.org/vision/vision.nsf>>)

Building the skills base required understandings to help meet this challenge is a key task of TVET. Integrating TVET into approaches to development that balance economic and social progress, address cultural differences, and respect ecological values and limits is the key to sustainable development. However, efforts to define exactly what sustainable development is must reflect the varying conditions in different parts of the world and their impact upon national and cultural priorities and values. For example, "to an individual living in rural poverty in the developing world, 'sustainable development', if it is to make any sense, must mean increased consumption and a higher living standard. By contrast, to an individual in a wealthy country, with a closet full of clothes, a pantry full of food and a garage full of cars, 'sustainable development' could mean

* Adapted from the discussion paper prepared by the authors for the UNESCO-UNEVOC International Centre, Bonn (UNESCO-UNEVOC, 2006).

[†] Deceased.

more modest and carefully considered consumption” (UNESCO, 1997: para 25).

Thus, sustainable development is not a fixed concept; rather, it is a culturally directed search for a dynamic balance in the relationships between social, economic, and natural systems, a balance that seeks to promote equity between the present and the future, and equity between countries, races, social classes, and genders. The interdependence of people and the environment requires that no single development or environmental objective be pursued to the detriment of others. The environment cannot be protected in a way that leaves half of humanity in poverty. Likewise, there can be no long-term development on a depleted planet.

This makes sustainable development more a moral precept than a scientific concept, and links it as much with notions of peace, human rights, and fairness as it does with theories of ecology or global warning. Indeed, while sustainable development involves the natural sciences, policy, and economics, it is primarily a matter of culture: it is concerned with the values people cherish and with the ways in which we perceive our relationship with others and with the natural world (UNESCO, 2002).

The Crucial Role of TVET

Business and industry today often speak of the triple bottom line of their operations. This is a recognition of the integration of social, economic, and environmental concerns and a move away from business as usual, when the priority was only on economic growth and profit. In integrating social, economic, and environmental concerns, sustainable development involves new ways of thinking about how we use resources to provide the goods and services we need. Thus, Salim (2002) from Indonesia, who was the chair of the United Nations World Summit on Sustainable Development, argues that:

... there are serious shortcomings in the way development has taken place in the 20th century ... development has followed only the economic track and has left behind social and environmental stability, resulting in rising poverty, inequality in income and development and natural disasters through rising flood levels affected by sea rise due to global warming. Development as implemented in the 20th century was not sustainable. (p. 16)

Yet, these problems were not caused intentionally. Rather, they were the results of well-meaning development initiatives that, unfortunately, were implemented without a full understanding of the interlocking nature of social, economic, and environmental issues. Education and training for sustainable development is a process of learning how to make decisions that consider the long-term future of the economy, ecology, and equity in the

workplace and wider community. Building the competencies and commitments needed for such future-oriented thinking is a key task of TVET for sustainable development. This requires attention to the environmental, economic, and social pillars of sustainability. This article explores the implications for TVET of each of these three.

TVET and Environmental Sustainability

Using resources wisely and minimizing waste and pollution are central to ensuring that the natural environment will be able to continually supply business and industry with the natural resources and energy needed for economic activities. Indeed, there can be no long-term economic growth on a planet depleted on natural resources, too infertile to support the production of the plant and animal products upon which people and industry depend, and too polluted for humans to enjoy a healthy and productive life. Environmental sustainability requires a change from business as usual to the responsible use of raw materials, energy, water, etc., awareness of the impacts of production processes, and careful management to minimize any unintended results of production. A number of approaches have been developed to support sustainable production, including: cleaner production, environmental auditing through ISO14000 quality assurance, life-cycle analysis, ecodesign, industrial ecology, the Natural Step, natural capitalism, Factor 4, and so on (see International Institute for Sustainable Development, 2001; UNEP, 2002). However, all share several common principles as illustrated in **Figure 1**.

However, it must be constantly borne in mind that, despite the growing adoption of such principles and associated tools by business and industry, the resource efficiencies that result may not be enough to ensure long-term environmental sustainability. Drawing upon a United Nations Environment Programme (UNEP) report on the future of the global environment, Yencken (2000) argues that:

Given the assumed growth of the world economy between 1990 and 2050, a 4 to 5 fold increase in overall ‘efficiency’ is needed just to keep environmental pressure at its current level. In many cases this will not be sufficient to prevent environmental degradation of environmental resources. Depending on assumptions made with respect to population growth, economic growth and levels of sustainable use of various natural resources, the actual efficiency improvements required within the next half century are estimated to be in the range of five to twenty fold. This can only be achieved by increase in technological efficiency and the ‘dematerialisation’ of production and consumption. (p. 10)

Principle	Application
Nature is not subject to systematically increasing concentrations of substances extracted from the Earth's crust, for example, fossil fuels, heavy metals, and minerals.	Substituting scarce minerals with ones that are more abundant; using all mined materials efficiently; and systematically reducing dependence on fossil fuels.
Nature is not subject to systematically increasing concentrations of substances produced by society, for example, PCBs, CFCs, HCFCs, and PVC.	Substituting persistent and unnatural compounds with ones that are normally more abundant and/or biodegradable.
Nature is not subject to systematically increasing degradation by physical means, for example, dams to change river flows, clearing rainforests, intensive monoculture agriculture, and overfishing.	Drawing resources only from well-managed ecosystems; systematically pursuing the most productive and efficient use both of those resources; and exercising caution in all modifications of nature.
Human needs are met worldwide, for example, access to food, water, healthcare, shelter, and education.	Using all our resources efficiently, fairly, and responsibly so that the needs of all people on whom we have an impact, and the future needs of people who are not yet born, stand the best chance of being met.

Figure 1 Principles and applications for environmental sustainability. From Smith (2002).

Environmental imperatives such as these call for the integration of environmental sustainability into all aspects of TVET. This will involve designing programs and courses that not only provide technical expertise for a student's chosen industry but also include the following objectives:

- developing an understanding of a relevant range of environmental concepts (see **Figure 2**);
- developing an ethic of care and responsibility, and encouraging reflection on the effects of personal values and lifestyle choice; and
- promoting skills for critical thinking and practical action.

TVET and Economic Sustainability

Unfortunately, TVET in many countries remains locked into the role of being a supplier of skilled labor to industry. Anderson attributes this to the culture of productivism in TVET “which presupposes that economic growth is a permanent and necessary feature of human existence, regardless of its environmental impact and consequences” (Anderson, 2000, 2003). Giving precedence to economic interests, productivism subordinates the needs of individual learners to those of industry and prioritizes work and employability over the noneconomic outcomes of TVET. This has resulted in TVET being seen as training for growth and skills for work, two goals for TVET that are antithetical to the broader general education for personal autonomy, citizenship, and sustainability that TVET also needs to serve.

Nevertheless, the economic aspects of sustainability are very important but, instead of productivism, they look to TVET systems, institutions, and instructors to ensure that students and workers develop a different,

wider, set of economically related knowledge, skills, and attitudes. These include:

- *Economic literacy.* This involves using appropriate economic ways of thinking and problem solving that lead to sound and informed economic choices as consumers, producers, savers, and investors and as effective participants in the local, national, and global economy. It involves understanding how changes in government policies, in taxation, interest and exchange rates, and in demographic and market trends will impact upon decisions to be made by individuals, families, communities, and enterprises. In relation to the world of work, economic literacy involves an understanding of sustainable production and ways in which resources can be conserved, waste managed through recycling and reuse, and toxic waste and pollution minimized and controlled (National Council for Economic Education, 2002).
- *Sustainable production.* This is an approach to the manufacturing and delivery of “goods and services in ways that respond to basic human needs and bring a better quality of life, while minimizing the use of natural resources, toxic materials and emissions of waste and pollutants over the life cycle, so as not to jeopardize the needs of future generations” (Norwegian Ministry of the Environment, 1994).
- *Sustainable consumption.* This is the necessary corollary of sustainable production. The people of the developed countries are among the world's largest consumers of natural resources and their production and consumption patterns have major environmental, social, and economic impacts around the world. As indicated in the 2004 *State of the World Report*, the 20% of the world's population living in Organization for Economic Cooperation and Development (OECD) countries earn 85% of the world's annual income; consume 75% of global energy and over 80% of other resources annually; and generate

- *Sustainable development*: A process by which the needs of present generations can be satisfied without compromising the ability of future generations to satisfy their needs.
- *Carrying capacity*: The capacity of ecosystems to support continued growth in population numbers, resource consumption, and waste production.
- *Ecospace*: The total amount of energy, land, water, and other resources that can be used regionally or globally without environmental damage, disadvantaging the capacities of others to meet their basic needs or impinging on the rights of future generations.
- *Ecological footprint*: The area of land and water needed to support the total flow of energy and materials consumed by a person, household, community, or work place.
- *Natural capitalism*: An approach to managing workplace processes in ways that restore, conserve, and expand natural resources (stocks of natural capital), use, recycle, and reuse resource inputs as efficiently as possible, and assume responsibility for making products last longer and easier to dismantle for reuse or recycling.
- *Eco-efficiency*: A strategy for maximizing the productivity of material and energy inputs to a production process while also reducing resource consumption and waste production and generating cost savings and competitive advantage.
- *Life-cycle analysis*: A management tool for identifying the net flows of resource and energy used in the production, consumption, and disposal of a product or service in order to leverage eco-efficiency gains.
- *Triple Bottom Line reporting*: An approach to corporate accounting that reports not only on financial matters but also the outcomes of a firm's environmental and social activities.
- *Environmental management system*: A coordinated approach to ensuring that all environmental issues are taken into account in the workplace and regularly monitored and improved to ensure compliance.
- *The 5 Rs*: Reduce, reuse, renew, recycle, and rethink!
- *Local-global links*: The recognition that the production and consumption of a product or service in one part of the world is dependent on flows of energy and materials in other parts of the world and that this creates potential opportunities and losses economically, socially, and environmentally at all points in the local-global chain. The brain drain from developing to developed nations also affects sustainability in TVET and education.

Figure 2 Concepts of environmental sustainability relevant to TVET. From UNESCO (2002). *Education for Sustainability: Lessons Learnt from a Decade of Commitment from Rio to Johannesburg*. Report to World Summit on Sustainable Development. Paris: UNESCO.

75% of annual global pollution (Worldwatch Institute, 2004). Too much consumption also affects health with over 50% of people in countries such as the US and the UK reported as being overweight (Barber, 2001). While these problems are disturbing, they pale beside those of the 2.8 billion around the world who do not have adequate access to food, water, and shelter. Consumption provides one of the most potent examples of the inequalities that exist today. Thus, a key aspect of education and training for sustainable consumption is the integration of concepts of sustainable consumption into the planning of workplace production processes and in the daily lives and expectations of what it means to live a good life in the minds of workers and their families.

Social Sustainability and TVET

Social sustainability is the third pillar of sustainable development. On both the global and local scale, social sustainability involves ensuring that the basic needs of all

people are satisfied and that all, regardless of gender, ethnicity, or geography, have an opportunity to develop and utilize their talents in ways that enable them to live happy, healthy, and fulfilling lives.

Sustainable livelihoods are central to social sustainability and meaningful work plays an important role in this. The concept of sustainable livelihoods embraces existing concepts of work and employment but widens them to include the multiple forms of economic and noneconomic activities through which people create opportunities to sustain themselves, their families, and their communities. The United Nations Development Programme (UNDP) defines livelihoods as “the assets, activities and entitlements which people utilize in order to make a living” – with assets including local natural resources (i.e., land, water, common-property resources, flora, and fauna), as well as social (i.e., community, family, and social networks), political (i.e., participation and empowerment), human (i.e., education, labor, health, and nutrition), physical (i.e., roads, clinics, markets, schools, and bridges), and economic resources (i.e., jobs, savings, and credit).

The wide view of resources and abilities in the concept of sustainable livelihoods raises questions about traditional person–job relationship that forms the foundation of many approaches to TVET. While education, particularly TVET, has important roles in developing the social, human, and physical capital needed for a sustainable livelihood, it is perhaps a very different form of TVET that is required (Lawrence, 1997). Nevertheless, it is important to ensure that young people receive the best education possible to prepare them for a life of productive employment and to have the entrepreneurial skills not only to develop work opportunities for themselves and others but also to have the commitment and initiative to contribute to the social, economic, and environmental well-being of their communities.

Thus, basic education is central to effective TVET. Literacy and numeracy are vital here. The health and safety of workers often depends upon their ability to read instructions (e.g., on fertilizer bags) and to make accurate calculations (e.g., of mixing and application levels). The wider skills of scientific and social literacy are also important for, for example, equipment maintenance and repair and understanding technological change (scientific literacy) and for group work, dialog and negotiation with colleagues and supervisors, gender and ethnic tolerance, and other skills needed for harmonious relations in the workplace (social literacy). The application of such literacies to the world of work and active citizenship needs to become core dimensions of TVET if it is to respond to the imperatives of social sustainability (Lawrence and Tate, 1997).

Thus, Quisumbing argues for an “holistic and integrated human resource development program for TVET” that “aims to prepare the individual to become a responsible, free and mature person, equipped not only with the appropriate skills and know how of the latest technologies, but also with deep human and spiritual values and attitudes – a sense of self worth, self esteem and dignity” (Quisumbing, 2001). Central to the development of knowledge, skills, and attitudes for social sustainability, she argues, are the abilities:

- To work by oneself and with others in teams, with integrity and honour, with honesty, punctuality, and responsibility;
- To adapt to varying situations; to know and understand problems and issues; to work out solutions creatively;
- To resolve conflicts peacefully;
- To have a good grasp of the reality of the world, of oneself and of others;
- To possess some general knowledge with specialization in some field or area of work; and
- To continue learning and pursue lifelong education in a learning society (Quisumbing, 2001).

A focus on the knowledge, skills, and attitudes for social sustainability can develop all the powers and faculties of the individual – cognitive, affective, and behavioral – and

from them can flow such “work values and attitudes as creativity and adaptability, productivity, quality and efficiency, patience and perseverance, loyalty and commitment, freedom and responsibility, accountability, the spirit of service, a futures orientation, and a genuine love for work itself be developed” (Quisumbing, 2001). This view places ethics at the heart of developing social sustainability through TVET. Wonacott notes that the literature on ethical issues in TVET is most often concerned with dilemmas in teaching and the use of technology related to questions of power, access, control, intellectual property rights, privacy, equity, speech, etc. Ethical and legal issues for specific occupations are also often addressed (Wonacott, 2001). There are also definite ethical and moral implications associated with social sustainability. Some of these include:

- *Respect for cultural diversity.* This is a core value in social sustainability. All people have the right to employment regardless of their ethnic or racial heritage and their religious beliefs. The rights to employment of indigenous peoples are especially important. This also applies to opportunities for further training and promotion. The internationalization of the workforce through globalization and labor migration also emphasizes the importance of developing respect for cultural diversity in all TVET programs (Pegg, 1997; Brown, 2002).
- *Gender equality.* This is also a core value in social sustainability. The rights of women to equality of outcomes from education and training (as well as access) and to equality of employment opportunities, working conditions, and access to further training and promotion are important human rights that need to be enshrined in TVET programs. The vital importance of freedom from discrimination and sexual harassment, associated monitoring, reporting, and disciplinary processes also needs to be taught. These are matters for both male and female students and workers: women need training in ways of protecting their rights and freedom in the workplace, while men need training in their obligations to respect and honor all their work colleagues (Scott, 2003).
- *Inclusion.* The inclusion of other excluded groups – disabled, ethnic minorities, etc. – is essential for the attainment of sustainability in TVET and workplaces. Without the inclusion of all groups in a society sustainability will not be achieved.
- *Workplace relations.* One positive result of the reduction in levels of management and the increase in workers’ levels of educational attainment has been the empowerment of workers to advise management of better ways to operate or produce finished goods. This reduction from as many as eight to as few as three levels of management has improved communications between labor and management. Historically, communications between employers and employees has been mainly

top-down. Increasingly it has become the practice of enlightened employers to elicit – and utilize – ideas from their employees that improve production and lessen waste. The same holds true for the creation of sustainability, both in TVET and in the workplace. Relations between coworkers also benefit from improved communication, as well as from tolerance of others' differences. It goes without saying that a contentious workplace is not likely to be a sustainable one.

- *Teamwork at the workplace.* A harmonious workplace is one at which teamwork is both valued and practiced. The restructuring of assembly lines during the industrial age, and the maintenance of many assembly-line principles and practices in the emerging information age – in particular, the assembly of electronic equipment of all types – necessitate the enhancement of teamwork principles to ensure sustainability. Productivity measures, for example, the failure rate of assembled equipment, highlight the importance of teamwork. Therefore, it is incumbent upon TVET institutions to foster the necessary climate and/or culture of teamwork right from the initial entry of students and trainees into TVET institutions. It is also imperative that TVET teachers and instructors set a correct example by functioning as a team.
- *Relations between employers and employees.* Conflict between labor and management has been a long-standing impediment to harmonious relationships between employers and employees. However, in some countries, enlightened employers recognize that harmony is directly related to improved productivity, reduced spoilage, and even innovations suggested by employees.
- *Safety.* Considerations of safety are of prime importance in TVET and at the workplace. Employers bear responsibility for the working conditions and well-being of their employees. Employees are responsible for actions that might place their peers in peril, produce dangerous or substandard goods, or damage property. This suggests that another aspect of safety is the protection of TVET students/trainees and employees at the workplace.
- *Citizenship.* Social sustainability depends upon the willingness of people to cooperate in building and safeguarding a fair and democratic society. Reciprocal rights and responsibilities are important in a democracy, where the collective voice of citizens is the source of all legitimate authority. These rights include: equality before the law and the freedom to vote, to speak freely on public issues, and to participate in public interest groups. The duties of responsible citizenship include: paying taxes, obeying laws, demonstrating commitment and loyalty to democratic ideals, constructively criticizing the conditions of political and civic life, and participating to improve the quality of national and community life (Klusmeyer, 1996).

The rights and responsibilities of citizens extend to the workplace as well. This is why respect for gender and

cultural differences and skills for developing harmonious workplace relations, teamwork, and negotiating improvements in work practices are so important to social sustainability. TVET has key responsibilities to ensure that these civic disposition and participation skills are developed with experience, suggesting that this can perhaps best be done through the following kinds of learning experiences:

- student participation in democratically conducted student organizations;
- college-facilitated community service that is connected directly to the curriculum and classroom instruction; and
- cooperative learning activities in which groups of students cooperate to pursue a common goal, such as inquiring about a public issue or responding to a community problem (Patrick, 1999; Battersby, 1998).

Conclusion

This article has examined the role of TVET in addressing three pillars of sustainability. Although all aspects of sustainability have been analyzed separately, there are very close links and interrelationships between them. It is proposed here that an integration of environmental, economic, and social sustainability in TVET can only be undertaken – and achieved – through the inclusion of a relevant range of environmental, economic, and social concepts into the content of teaching (by identifying eco-footprints, life-cycle analysis, toxic materials, etc.). There is also a pressing need to orient students toward sustainable production; through the appropriate development of students' responsibility, their personal values, consumption patterns, and appreciation of cultural diversity; and through development of generic skills of critical thinking, team work, workplace relationships, and safety, and their ability to adapt to varying, often very demanding situations.

It is also highlighted in this article that sustainable development is not a fixed concept, but culturally and contextually directed activities for achieving an appropriate balance in the relationships between social, economic, and ecological systems.

Therefore, TVET's role is considered not only as building the skills base relevant to the sustainable practices of particular occupations, but also in developing understanding and appreciation of all aspects of sustainability.

The Relationship between Technical and Vocational Education and Training and Innovation

K Ruth and L Deitmer, University of Bremen, Bremen, Germany

Understanding of Innovation

The notion of innovation is rather complex and multifaceted, because it is not only describing purely economic change in companies' policy and business strategies but also referring to organizational and technical change. Thus, in a very broad sense, innovations could also be thought of quite simply as changes – such as the practical implementation of alternative concepts for work organization (e.g., group work). The example of group work quite clearly illustrates that innovation can be assessed from different perspectives: from the perspective of workers, for example, group work may signify an improvement when compared to their previous working conditions; for some companies, however, the expected benefits fail to materialize – that is, no increase in productivity is generated (Manske *et al.*, 2002).

It is for these reasons that we would like to use innovation in a broader understanding to find out whether or not there are relationships between innovation and the vocational education of workers. The notion of innovation as a social process, which includes many different actors, is widely accepted in innovation research (e.g., Lundvall, 1992; Morgan, 1997). In the classical understanding of innovation as companies' process to develop and commercialize new products or to launch new processes in order to improve product quality or lower the production cost, the view was very strictly limited to the boundaries of companies where engineers were the experts for innovation (or more precisely, for new product development or the design of processes). Among others, Morgan (1997) expresses the concerns with this limited understanding of innovation by pointing out that "... the weakness, which is still prevalent in the western countries today, stems from an elitist conception of knowledge in which scientific knowledge is extolled, while lower forms of knowledge are undervalued" (Morgan, 1997: 493).

It was the work of von Hippel (1988) on the sources of innovation that drew the attention to the hitherto unrecognized innovation actors – users and suppliers. He opened the view to network-based innovation processes by considering other companies (suppliers or customers) as important actors in the innovation arena. By his work, innovation experts who were not recognized up to then were brought into the game. These new experts also introduced new knowledge domains into the innovation processes: in von

Hippel's case studies, key users of the machinery or aircraft industry had the opportunity to mainly bring in their practice- and experience-based expertise into the development process, and similarly supplier companies were given the chance to include manufacturing and material know-how into the overall innovation process (von Hippel, 1988). These tendencies have nowadays developed toward innovation networks (Duschek, 2004), which today are a widespread form of organizing innovation processes. Innovation networks can have different forms: either intra-organizational or inter-organizational; they can either be local and regional or global; and their communication and cooperation can range between direct contacts (meetings) and virtual/electronic communication and collaboration or a mix of these forms. Finally, the innovation networks do gather a wide range of people with different educational and professional backgrounds. These different actors contribute different types of knowledge, skills, and expertise, which add new dimensions to innovation processes.

An important step in opening the innovation arena was targeting design to manufacturability: this meant to leave the sequential track, which saw the manufacturability of a new product as the final problem to be solved (if at all targeted). It was the Japanese who taught the world that manufacturability is a primary goal of product innovation and that in order to ensure a high level of manufacturability, the production planning and shop-floor people need to be included in very early stages of the innovation cycle (Imai, 1991). These changes widened up the formerly closed monastery of design monks – that is, the engineers as key innovation actors – to a lively bazaar of many actors with diverse backgrounds and a diversity of design and innovation goals. Since knowledge creation is widely accepted and studied as a core activity of innovation (Nonaka and Takeuchi, 1995; Nonaka and Nishiguchi, 2001), the focus of the following paragraphs is on knowledge capacity development, particularly on knowledge sharing.

Shared knowledge is one of the important resources for successful innovation. Therefore, those organizations or those networks or teams, which have established the best structures and methods to develop a common understanding among individuals representing different functions (organizations or disciplines) are the ones with the best innovation performance and thus with competitive

advantages (Hong *et al.*, 2004). The synergy of shared knowledge cannot easily be achieved, because knowledge does not have a unique nature. There can be different cognitive universes between organizations or departments; there can be incompatible knowledge domains between departments or teams; knowledge can be tacit in its nature and thus difficult to codify or to make explicit (Senker, 1993); and, eventually, a lot of knowledge is sticky, that is, held by individuals and cannot be separated or objectified. Thus, we observe plenty of obstacles to knowledge sharing, which impede knowledge sharing as a planned process. But nevertheless, good practice with regard to knowledge sharing is reported (e.g., Nonaka and Teece, 2001; Harryson, 1998).

Morgan (1997) pointed out the interactiveness and the multiactor-based character of innovation processes: “There is now growing support for the view that innovation is an interactive process between firms and the basic science infrastructure, between the different functions within the firms, between users and producers on inter-firm level and between the firm and the wider institutional milieu and that this process should be conceived as a process of interactive learning in which a wide array of institutional mechanisms can play a role” (Morgan, 1997: 493).

Taking into account the above-sketched circumstances, we need to consider two influential aspects of contemporary innovation:

1. The idea of sequential innovation steps – concept design, system design, detail design, prototype testing and refinement, and manufacturing – has made room for the conception of concurrent innovation which is including many actors.
2. Particularly, the hitherto well-accepted distinction between radical and incremental innovation is difficult to maintain in the future, if trying to figure out the role of practical knowledge and experience in innovation processes.

The latter refers mainly to the insight that many radical or breakthrough innovations in history have not been made by scientists or engineers, but rather through technicians or highly skilled craftsmen. As an example we might think of the technological progress before 1850, particularly in the case of the steam engine that was developed and produced by craftsmen, skilled workers, or technicians who deployed a knowledge that originated from practice rather than from science (Mokyr, 2002; Rolt, 1986). Similarly, practitioners developed the transistor by advancing through trial-and-error methods, which eventually rendered a result (Braun and MacDonald, 1978; Rosenberg, 1982; Senker, 1993). Thus, the assumption that radical innovation is based on (theoretical and scientific) knowledge and incremental innovation thrives on skills/experiential knowledge is nowadays increasingly

obsolete – not to mention the difficulty to distinguish radical from incremental innovation.

The aforementioned evolution from sequential to concurrent (or at least overlapping) innovation phases has an important impact on the necessity to share knowledge: knowledge and experiences that are available in functional areas at the end of the formerly sequential innovation process (e.g., not only manufacturing expertise, but also suppliers’ capacities) are now required at the early stages (concept design) and during the ongoing innovation process. The particular case of knowledge sharing between manufacturing and early design stages is alike with the need to bring workers’ knowledge into the design process.

The following section picks up the findings of this special case and feeds them into a more general concept of experience as an innovation factor.

Workers’ Experience as an Important Source of Innovation

The contact point of technical and vocational education and training (TVET) and innovation is the quality of production and products. Industries that are still in the field of large-scale production with little variants and a rather fixed mode of production will need workers who exactly just operate the handlings on the product they are obliged to do. There is little maneuver for any change and the impulses from the production line onto changes or incremental improvements are very limited. Eventually, quality control departments are needed to assure the quality of the products and the work done by the production workers. However, in a post-Fordist era of production, there are more complex and saturated markets to be dealt with. Industrial and private costumers get a bigger say in the final function of the product and wish to receive tailor-made solutions. This requires new production concepts, which assign workers an important role as reflective practitioners and which take their experiences and knowledge as an important source for improving production. Industries that follow this one-of-a-kind product philosophy will increasingly need highly skilled workers who are competent to act on comprehensive work principles. These principles imply that the workers are able to do the planning and control of their own work – beside the factual production itself. Therefore, these workers must hold planning and control competencies. Besides, they must also be able to undertake production process improvements, which require innovative skills that enable them to shape the production processes. These skills are needed to avoid pitfalls and dysfunction in the production process which will occur when new products are to be introduced – a situation that comes up in a one-of-a-kind production model quite often. Equipped with shaping skills (Rauner, 2007) they must be

able to react on challenges for improving the product and its efficient production. Technical and social communication skills with planners or engineers are needed, concerning improvements of the manufacturability or the design-to-assembly quality of the different products (Ruth, 2006).

Looking closer at the relationship of workers' abilities and innovation, there is a gap between the designated engineers' models of machine systems design and that of the actual operation mode of these systems at the side of production and at the side of the workers. The engineering and the production knowledge represent different knowledge domains, one representing the planning knowledge and the second representing the practical knowledge in producing the products. This accumulation of experience and knowledge is very often used to improve the machines or to make the operation more efficient. The direct machine workers as well as the maintenance workers are in that respect some very important innovation actors who might contribute to both, process and product innovation.

In the case of process innovation, there are production systems, which are more tolerant toward different operation modes and that are in every stage under the immediate control of workers (e.g., short assembly lines for simple products). Such easygoing systems are an ideal playground for influencing (or in other words: improving the processes) by production line workers. Here, workers can apply their expertise which is to a large extent experience based – experience gained through daily operation in the production line. This is somewhat different in the case of large technological systems (such as nuclear power plants, or chemical processes), where controlling and maintaining the systems is a complex task, which additionally is characterized by a separation of the real processes and the actual operators. In other words, the processes are of reach of the immediate senses, but nevertheless, their basic source of building expertise (which contributes to the construction of innovation capability) is experience. But, experience itself – though a potential wellspring of expertise – always covers the risk of blinding people and narrowing their minds by lulling them into a false sense of security about their hypotheses (on the operation, their tasks), their skills, and their expertise and mastery (e.g., the case of a nuclear power plant accident in Japan is analyzed in Ruth, 2001: 177). In order to avoid wrong or at least misleading hypotheses on the operation mode of complex production systems, it is essential that the operators do also hold a certain level of theoretical knowledge, which ideally is complementary to the experiences – or rather, theory is the backing into which experience is embedded. At this stage of the argument, it can be stated that education and training systems and respective qualification frameworks at best need to cover and address both, theoretical and practical knowledge. A closer look at different types of vocational education and training

(VET) systems will provide insights into the relationships between favorable (or disadvantageous) combinations of theoretical and experience-based knowledge, and the level of innovativeness. Before approaching this issue, the field of product innovation is touched upon briefly.

Similar to the sketched field of process innovation, the production workers can play an important role in product innovation. If we consider the manufacturing of machinery as the arena, the actual production experts are workers of manufacturing and assembly – in so far as it concerns improvements in the manufacturability or the design-to-assembly quality of products. In the very particular case of machine tool manufacturing, the products manufactured (and assembled) are at the same time the (technical) means of production. In particular this typical bivalent situation enables the workers to use their experience, knowledge, and imagination for product improvements (Ruth, 1995, 2003). Even if these improvements are somehow incremental steps in the continuous innovation process, their impact can be enormous, for example, regarding the increase of a company's competitiveness (Imai, 1991).

The outlined relationships between work process experience (knowledge) and innovation obviously depend on various factors, which are supporting the innovativeness of companies' product and process improvements. Considering not the wafer development in the semiconductor industries as an example of a strongly science-driven high-tech innovation field, but rather the product innovation in the more traditional mechanical and electrical machinery as the source and subject of the following reasoning, we can assume the qualification structure and qualification level on the shop floor as a crucial component of innovation capabilities. The composition of qualification and skill is covered by the concept of competences, which can be defined as:

... an ability that extends beyond the possession of knowledge and skills. It includes: i) cognitive competence involving the use of theory and concepts, as well as informal tacit knowledge gained experientially; ii) functional competence (skills or know-how), those things that a person should be able to do when they work in a given area; iii) personal competence involving knowing how to conduct oneself in a specific situation; and iv) ethical competence involving the possession of certain personal and professional value. (Leney, 2004: 94)

The important point, besides the aspects of recognizing different forms of learning (theoretical and practical learning) originating in different learning spheres (shop floor, research and development (R&D) laboratories, and also outside organizations in everyday life), is the factor of providing learning opportunities at work while working. We can assume that the more learning opportunities workplaces (especially on shop floor) do provide, the better are the opportunities to actively involve the

people in innovation processes. However, evidently this involvement is highly dependent on the individual's competence level, which we can assume as being made up of the general education level, the knowledge level of the subject field, and of experiences during work at the workplace. A systematic and international comparative view on the relationship between qualification and innovation, thus requires one to consider the interaction between the systems of VET, and the innovation systems – the latter not on highly aggregated levels (such as national or regional innovation systems) but rather on the company or network level.

Institutionalizing Innovation Capacities in VET Systems by Implementing a Shaping Orientation

If the assumption of an existing relationship between skills, experience, and knowledge on the shop-floor personnel side, and the level of companies' innovativeness is acceptable, then we can assume that the underlying vocational learning and training system can also exert an important impact on innovation.

In an international comparative perspective, the differences between national VET systems need to be investigated if the possible relationships with innovation and innovativeness is to be stressed. It is particularly necessary to consider possible differences in the structure, the processes and the outcomes of the VET systems. **Table 1** gives a general overview of the structure of VET systems (focusing on the initial VET). A structural analysis shows one cluster of countries with a predominantly apprenticeship system, which is labeled dual system, because it combines theoretical and practical learning at different learning sites (school and workplaces). Among others, not only Germany, Austria, Denmark, and Switzerland can be mentioned as examples but also internationally some other Asian countries follow this dual model, such as Malaysia, Thailand, and Taiwan.

The second logical cluster of VET schemes comprises school-based systems, which – according to the international classification system (ISCED) – can be differentiated into one subcluster that follows a vocational path leading to a qualification that is recognized by the labor market (e.g., Finland, Sweden, France, and China), and another subsector that follows a prevocational track directing toward a general educational level with no recognition at the labor market (e.g., Ireland and Greece). The fourth cluster is characterized by a mix of school-based and apprenticeship/dual systems (e.g., the UK, Netherlands, and Italy).

This classification, on the first hand, gives us a description of the routes or pathways followed to achieve a certain goal – employability. It also allows for some

Table 1 Structures of IVET in Europe

<i>Predominantly dual system/ apprenticeship routes</i> Examples: Austria, Germany, Swiss, and Denmark	<i>Mix of school-based and apprenticeship routes</i> Examples: UK, the Netherlands, and Italy
<i>School-based (mainly vocational)</i> Examples: Finland, France, Sweden, and China	<i>School-based (mainly prevocational)</i> Examples: Ireland and Greece

considerations regarding the outcomes of the different pathways: as a rough estimate we can assume that those individuals running through a dual system/apprenticeship program will most likely hold a competence that comprises theoretical and practical experiential knowledge and can support innovation processes. The former is acquired during schooling, the latter earned at the workplace during real production processes. Compared with this type of outcome the school-based pathways lead to somewhat deficient competence structures. The prevocational school-based track supplies individuals with almost no practical job-relevant experiences to the workplaces. Evidently, these workers at their early entrance stages into the workplaces cannot be expected to hold significant practical, experiential knowledge that might contribute to innovation processes. Similarly, the school-based vocational path does not provide the learners with sufficient practical knowledge. This classification is challenged by the perpetual trend of thinking on the further improvement of their VET systems, which is observable in almost all countries. Even countries with little history in dual VET think of following a work-oriented change in the didactics of the VET curricula which try to identify significant vocational work situations and the associated work process knowledge as the key factor to redesign their vocational curricula as well as their teaching and learning processes. What is interesting in this respect is the change of perspective from merely academic discipline-based teaching methods toward a reformulation of action-oriented vocational teaching methods for VET practice that are building on development theories (Rauner and Spöttl, 2002; Bremer and Haasler, 2004; Dittrich and Deitmer, 2003; Deitmer and Heinemann, 2007; Rauner, 2007). Development theories reflect the idea of a VET student being confronted with developmental tasks (Havighurst, 1972). These are paradigmatic work and learning tasks derived from the occupational field the student intends to work in; the tasks' complexity is increasing to allow competence development that enables the learner's aptitude to shape work and technology.

Relevance of Practical and Theoretical Learning for Developing Competent Workers

The highest level of useful practical experience is acquired through dual systems with a systematic theory–practice relationship, but since apprenticeship programs have a limited duration (usually around 3 years), the practical experiences are limited anyway. But it is a much better starting point for augmenting the experience basis – as compared with school-based systems. Even if the latter include some temporary work placements, these practical experiences often do not offer sufficient learning opportunities, nor do they necessarily have a close relationship to the subjects taught in school. However, we have to consider that even the graduates from school-based systems have the chance to gain experiences during their work. This evidently depends upon the opportunities for learning offered in work, once they made the transition from school to work. Thus, we can say that the type of VET can offer an initial advantage (or disadvantage) regarding the acquisition and composition of theoretical and experiential knowledge. Depending on learning opportunities offered in and during work, this deficiency can be compensated after the school-to-work transition.

If the relationship between the VET systems and their outcomes, and the innovation capabilities of individuals are to be strengthened, we have to go beyond simply offering learning opportunities in work and rather demand the shaping orientation of working and learning (Rauner *et al.*, 1988). The shaping orientation can be understood as a goal that targets at enabling the workers to proactively shape their immediate working environment, form their processes, and be able to understand the work processes and the products they are dealing with, in order to develop improvements and put them into innovative action. This can be learned by developmental tasks. These developmental tasks have two learning functions. First, they are used as an evaluation instrument to demonstrate the formation of occupational competence and identity at the (as-yet-unidentified) critical thresholds of occupational competence development (Bremer and Haasler, 2004). Second, developmental tasks are at the same time a didactic tool for establishing and designing vocational curricula as well as learning and working tasks for structurally oriented VET (cf. Howe *et al.*, 2001).

Prospects: Can TVET Systems Be Transformed into a Pillar of Innovation?

Even though the arguments developed and the examples given in the preceding section focused on the

manufacturing sector and its particular constitution of TVET, it can nevertheless be concluded that the findings also apply to the service sector – at least those fields of the service sector that have similar structures of VET as the manufacturing sector. Besides the service fields that are closely linked to production (such as repair and maintenance of machinery and equipment) we might consider the field of healthcare as such a field, where skilled persons (e.g., at the level of nurses) can become a valuable source for improvements of machinery used for diagnosis and treatment. Furthermore, their experience can be valuable for innovating processes within hospitals, etc. Although more systematic research in the service sector is needed, we assume that basically the role of TVET, the contribution of practical experience held by the directly involved workers in service sectors to product and particularly process innovation is similar to what was developed for the manufacturing sector.

In conclusion, in trying to estimate the future role of experiential knowledge, there are two dimensions to be considered: first, the potential role of work-based practical knowledge is a huge and widely ignored store of knowledge; therefore, second, it is a matter of utilizing this source by creating favorable circumstances. As favorable conditions we might count (1) production processes that are simultaneously learning environments, to which the provision of learning opportunities at work is inherent; furthermore, (2) a corporate culture that facilitates cooperation, communication (and thus knowledge sharing) among all relevant innovation actors – particularly including those players who hold practical experience, that is, shop-floor people; and another beneficial condition is (3) a pronounced shaping orientation being expressed at all levels of vocational training and learning (in initial VET, continuous VET, and all informal and nonformal learning).

As far as VET systems are concerned, the most favorable to contribute to a high level of innovativeness are those that target beyond such simple goals as employability in the meaning of creating functional skills and qualification. Even if these functional qualifications are acquired at a high level of proficiency, their graduates lack those core capacities that make up for shaping orientation: expertise in the subject field, virtuosity of performance, (social) responsibility, transcendence, and reflexivity. Evidently these goals are idealistic to some degree, but they are highly useful as role models, and the better existing VET systems are approaching these goals, the more likely they can achieve shaping-oriented working and learning, which eventually would sustain innovation and innovativeness.

There is only *la petitesse* remaining: how to implement the shaping orientation in VET? Beyond the above-given orientations, at this point, only one general remark can be

made: theoretical and practical learning need to mutually sustain each other. In every phase of vocational training and learning, there must be a balancing of theory and practice. For the school-based VET systems, this means providing access to work practice and relate practice systematically with theory learning. For dual systems, the abundance of practice has to become seamlessly interlocked with theoretical knowledge.

If this balance of theoretical and experiential/practical knowledge can be achieved, a leapfrog has been done; however, it requires other important organizational and sociocultural factors to be met, one aforementioned is the culture of knowledge sharing, which is the transmission belt under which innovation competence is thriving.

Glossary

Candidate countries – They refer to Croatia (HR), Macedonia (FYROM), and Turkey (TR) in the European Union (EU).

EEA – This is the European Economic Area including Iceland (IS), Liechtenstein (LI), and Norway (NO).

EU – It refers to the European Union. EU-27 countries are the 27 member states of the European Union. The EU countries (abbreviations and the year of joining to EU) are as follows: Belgium (BE) (1952), Bulgaria (BG) (2007), Czech Republic (CZ) (2004), Denmark (DK) (1973), Germany (DE) (1952), Estonia (EE) (2004), Greece (EL) (1981), Spain (ES) (1986), France (FR) (1952), Ireland (IE) (1973), Italy (IT) (1952), Cyprus (CY) (2004), Latvia (LV) (2004), Lithuania (LT) (2004), Luxembourg (LU) (1952), Hungary (HU) (2004), Malta (MT) (2004), Netherlands (NL) (1952), Austria (AT) (1995), Poland (PL) (2004), Portugal (PT) (1986), Slovenia (SI) (2004), Slovakia (SK) (2004), Finland (FI) (1995), Romania (RO) (2007), Sweden (SE) (1995), and United Kingdom (UK) (1973).

Formal learning – It includes learning taking place in an organized and structured environment (formal education, staff training at workplace) that is designed for learning. It may lead to official recognition (certificate). From the learner's point of view, formal learning is intentional.

Informal learning – It takes place in everyday contexts at work, at home, and in one's free time. It is often referred to as experiential learning, and to a certain degree it can also be considered as unintentional learning. It is not structured in terms of goals, time, or guidance, and is normally not attested by any certificates. It may be purposeful but is typically unintentional and takes place more or less accidentally.

Nonformal learning – It covers planned action that is not actually designed for the purpose of learning, but still includes important elements of learning. From the learner's point of view, however, learning is intentional.

Occupational status – It corresponds to prestige, the socioeconomic status of an occupation, and to class measures in the past.

Social status – It is understood as ranking or hierarchy of prestige as perceived by the respective

groups and as seen in economic structure and division of labor.

Status of VET – It is related to the social and occupational status that is yielded by vocational qualifications such as recognition, prestige, and autonomy attached to one's position in society. In terms of a type of education and training, measured as progression chances and income returns later in young people's lives, the meaning of status (or standing or prestige) of VET is associated with parity of esteem between VET and other education tracks while comparing their standing of equality.

Validation – It refers to identification, evaluation, and recognition of the broad range of skills and competencies people have acquired in various contexts throughout their lives.

Introduction

For some 20 years, improving the attractiveness and status of vocational education and training (VET) has been one of the education and training policy priorities and objectives set by the European Commission, recently by the Lisbon–Copenhagen processes, and related follow-ups such as the Maastricht and Helsinki Communiqués. Attractiveness is strongly associated to the observed status of VET in terms of employability, salary, and chances for education and occupational mobility, as well as to young people's and their families' attitudes and preferences.

Status of VET is associated to social and occupational status that is yielded by vocational qualifications as recognition, prestige, and autonomy attached to one's position in society. In terms of a type of education and training measured as progression chances and income returns later in young people's life, the meaning of standing and prestige are close to status referring to the social status. Social status is understood as ranking or hierarchy of prestige as perceived by the respective groups and as seen in economic structure and division of labor. Occupational status corresponds to prestige, the socioeconomic status of an occupation, and to class measures in the past.

The status of and esteem for VET has been discussed in comparison with general/academic education, which has traditionally been assumed to be a more attractive pathway than VET to students and their parents. However,

the status of VET varies between countries and social groups measured as students' choices of educational pathways. Measures of esteem for VET refer to (1) improving access and entry to employment, career development, and progression; (2) the diversity of quality learning environments (meeting the needs and aspirations of different learners); (c) self-development choices as a citizen and individual; and (d) willingness to invest in VET. Attractiveness is observed as preferences, attitudes, and related behavior of individuals, groups, and their families.

Improving the attractiveness of VET is an educational policy goal in the European Union (EU). Attractiveness is a policy term rather than a theoretical concept. Some variables, such as equal access to progression through different education and training pathways that determine esteem for VET, are also assumed to improve the attractiveness of VET. The disparity of esteem between vocational and academic education may have its roots in the occupational status based on a traditional conception of social class structure that does not function in modern societies.

Parity of esteem is a theoretical concept that has fairly recently come out in academic literature. The first references are dated in the early 1990s. Charles Taylor did some pioneer work followed by Fraser, Habermas, Honneth, and Tully. They all share the premise that a just and stable political order guarantees all citizens a possibility to enjoy due recognition, which can be significantly promoted by education policy, as well. Thompson (2002) attaches the concepts of parity of esteem and the politics of recognition. The dual concept of parity of esteem and, especially, the theoretical and philosophical concept of recognition were introduced in the context of analyzing the diversity of communities and distribution of resources. The diversity of communities and nations and its lacking recognition have even led to conflicts and wars.

Parity of esteem describes the vertical relationship between a state and a citizen, whereas due recognition refers to horizontal relationships between citizens. Parity of esteem and recognition are based on the identities of different people and groups; for example, minorities and indigenous peoples. The notion of parity of esteem is parallel to the principles of equal opportunities and rights as well as nondiscrimination. However, it is not synonymous with equal rights or equal treatment. Parity of esteem refers to measures of equal recognition enjoyed by two or more communities.

Socioeconomic status is often measured in parity of income, education, and employment, while the lack or unequal distribution of these is often perceived as seeds of community conflicts. Du Toit (2004) points out, however, that the real causes are connected with regional autonomy and national independence, which at the individual level have to do with self-respect, dignity, recognition, and sense of worthiness. In analyzing parity of esteem, he highlights the concept of self-esteem, stressing

its importance for personal identity: "... a positive sense of self-esteem, along with a sense of self-efficiency (a sense of personal competence) and self-consistency (a sense of personal coherence), allow the individual to maintain an identity ... " (Du Toit, 2004: 197). Self-esteem develops on interaction with other people within communities attached to certain cultural backgrounds, values, and norms. A person's social identity consists of the social categories in which he or she builds his/her self-image and identifies with. Du Toit (2004) argues that groups with different identities compete with each other. Parity of esteem is the ultimate goal of such competition and its results. "Perceiving one's self as being an object of primary value within a meaningful universe, within a competitive context where culture and ethnicity affect both identities and competitive abilities, is the key to maintaining parity of esteem" (Du Toit, 2004: 200).

In the context of education and training systems, parity of esteem concerns

- the flexible and transparent education and training systems and job markets that provide access for all individuals in learning, career chances, and in life histories and
- relevant lifelong learning visions and options for all.

Parity of esteem has been analyzed between different pathways and/or different groups of people (e.g., gender, ethnicity, and social class) to examine the results of possible streaming and allocation of resources. The focus can thus be on the future and looking for learning opportunities for all with relevance to individual's quality of life.

The status of VET is looked at in the European education and training context where the concern has been one of the policy targets for several decades. A history of the status of VET can be traced to research on social stratification. Instead, the idea of parity of esteem has emerged in the early 1990s to the political theory, philosophy, and education research though some roots derive from Hegel's thoughts. This article, first, casts an overview to the main terms that are associated with the status of VET after which an origin and background of social status is sought. Third, the recent VET policy context in Europe is surveyed. Finally, parity of esteem between academic and general education is elaborated as reform strategies.

Parity of Esteem between Academic and Vocational Education and Training

Parity of esteem refers to a founding principle of recognition and a just and stable political order that allow all citizens to enjoy dignity by having equal access to resources available in their communities with cultural, social, and ethnic diversity. Parity of esteem between vocational

and general education has been an education and training policy goal followed by some reforms in the member states of the EU.

Improving the status of VET has been a European education policy goal since the 1990s. The first cycle of the Leonardo da Vinci program attracted several research and development projects that evaluated European education and training systems and upper secondary education reforms about the extent to which education and training policies promote parity of esteem between academic and vocational education. The following section elaborates the updates of the original strategies.

Reform Strategies

Parity of esteem between vocational and general/academic education is related to the societal rewards resulting from education and training whereby the concept is linked to the status of VET. Such rewards may be social status, the level of salary, prestige, and chances for further education and career development. In addition to societal and economic rewards of gaining occupational qualifications, having access to personal and intrinsic values such as self-fulfillment and meaningfulness provides esteem for vocations among individuals.

The synthesis of the results of four European collaborative projects with some 20 European partner institutions, which focused on the upper secondary education reform strategies and schemes, showed potential to reduce the disparity of VET. The conclusion drawn from the strategies of improving the attractiveness of VET and of promoting parity of esteem between vocational and general education is based on research results provided by four major partnership projects (Lasonen and Manning, 2000).

Upper secondary education systems can be characterized in several ways on the basis of how they have managed to offer opportunities to move either to higher education or to work for young people with diversified talents and needs. A study of European upper secondary education system identified four hypothetical strategies (unification, linkages, enrichment, and enhancement) to indicate the esteem for vocational education.

Unification

Unification is about merging vocational and general education into a single system of post-16 education. The educational systems in Sweden and Scotland were based on this strategy, where the goal has been to offer all students a core program of common general subjects and abolish the distinction between vocational and general learning. Their unification strategies were not identical. Sweden emphasized uniformity of treatment and outcomes for all students and joint administration for vocational and academic courses; in Scotland, the emphasis

was, instead, on providing choices among a flexible range of opportunities through modularized study programs. The distinction between vocational and academic students and vocational and academic teachers, however, remains even after the administrative unification and modularization of study programs. The Higher Still Reform of post-16 education in Scotland, consisting of seven levels of studies, replaces all upper secondary education and partly further education and follows the principles of flexibility in progress and inclusiveness in access. Looking back to a decade, this strategy has not worked out in its ideal way. There have been signs of academic drift, referring to favor academic tracks rather than vocational tracks, especially in Scotland. In Sweden, under the same institutional administration some 15 different vocational and academic education pathways, that have quite distinct cultures, exist. Raffe *et al.* (2001) found that there is no clear association between unification and parity of esteem.

Linkages

Linkage seeks to make vocational and general education formally more equal by connecting them through measures such as a common certification framework, arrangements for credit recognition and transfer, and common curricular elements. The English, French, and Spanish educational systems, seeking to make their vocational education more attractive to parents and students, have adopted the linkage approach. In France, the emphasis of the *Baccalaureat professionnelle* was created to improve employment prospects. In England, again, the main focus has been on enabling students on the new vocational programs through General National Vocational Qualifications (GNVQ) to have access to university on similar terms that have been available to A-levels students. Traditionally, in the English and French systems, academic education has tended to prepare upper- and middle-class children and young people for high-status jobs. Academic education has been popular to aspire after as it carried a prospect of social status and prestige (**Case study 1**).

Especially as the enhancement and linkages strategies are not exclusive but their features can be found across the countries, in the British context they have been combined as a linked strategy. The three countries of Great Britain illustrate tracked, linked, and unified strategies in academic and vocational education (Howieson and Raffe, 1999). England has developed distinct vocational diploma. The Welsh Baccalaureate represents an overarching qualification linking academic and vocational qualifications. Scotland has the Scottish National Qualifications standing for a partially unified system. However, in many other European countries' context, the enrichment strategy, including the features of the linkage strategy, is more relevant from the aspects of joint programs and organizing students' choices.

Case study 1

Is there a parity of esteem between vocational and academic qualifications?

However, Robinson (1997) indicated that there is no parity of esteem between academic and vocational qualifications in the labor market. The conclusion was drawn from an empirical study based the British labor force survey showing that on average male and females working full-time with academic qualifications at one level in the British qualifications framework earn about the same as men and women with vocational qualifications set notionally one level higher. For example, those with A levels have earnings similar to those with higher or level 4 vocational qualifications. However, the length of work experience and learning is much higher for persons who have attained vocational qualifications. Academic qualifications are more successful in providing access to more highly paid occupations. Further, academic qualifications are associated with higher earnings leading to the highly paid managerial, professional and technical occupations.

Enrichment

Mutual enrichment bring various types of schools, such as vocational and academic institutions, closer by encouraging cooperation between vocational education establishments and general upper secondary schools and between vocational schools and enterprises with the aim of providing students with a wider range of options and offering them stimulating learning methods and environments. The educational systems of Finland and Norway were examples of the enrichment strategy. It has enriched both vocational and general education through measures that allow them to draw on each other's best features in students' choices. The administrators and career counselors from both the types of education providers have to cooperate to design a set of integrated courses based on students' choices. In Finland, new types of qualifications and certificates have been established. The strategy has lowered the traditional barriers between these two types of education, vocational and academic upper secondary education, while maintaining a distinct identity for each. On the one hand, general subjects have been added to the curriculum in order to ensure preparedness for continuing education and training. On the other hand, curriculum reform has led to a restructuring of study programs by improved opportunities during on-the-job training, with the result that work-based learning has renewed teaching approaches. Cooperation between vocational education and enterprises has enriched both of them in terms of work-based learning and lifelong learning. In Norway, general and vocational education teachers are educated in the same teachers training colleges. Both countries of the enrichment strategy have a strong full-time vocational education system and have proved to improve esteem for VET and parity and to avoid academic drift (unrealistic desire for academic education). On the contrary, by diversification and differentiation of higher education to vocational dimensions, a phenomenon of vocational drift can be observed.

In addition to the macro- and system-level approaches, curriculum-level reform schemes may show new kind of qualifications produced. The schemes of dual qualifications in Europe revealed a holistic model of teaching qualifications that provide choices and chances for students. The schemes of dual qualification prepare for both

employment and higher education (Manning, 1997). The starting point of dual qualifications is a varying degree of integration between general/academic and vocational education and work- and school-based learning in students' learning. The most successful examples of such qualifications represent school-based full-time education (e.g., Finland). Most dual qualification systems have emerged within vocational education as a part of the qualification process (e.g., Austria and Germany). A strong tradition of vocational programs offering a dual qualification has existed in Czech Republic.

The implementation of dual qualifications is assessed in terms of enrolment, the integration of academic and vocational education, and the students' success in their studies and in finding employment and/or gaining admission to further or higher education. Depending on the country, the proportion of the age cohort taking dual qualifications ranges from 1% to 45%. Those completing a dual qualification either enter working life or continue their studies, in most cases, in higher vocational education. However, in most countries the stress is on employment. The employment rate of holders of dual qualifications is high (**Case study 2**).

Enhancement

Vocational enhancement stresses the distinctive nature of vocational education on the basis of its characteristic content and links between employers and the providers of education of this kind. The German, Austrian, Czech, Spanish, Dutch, Danish, and Swiss educational systems have been founded mostly on this strategy. They have enhanced vocational education and made it more attractive to potential students through measures that have maintained and strengthened its distinctive ethos and its separate character alongside general education. Esteem for vocational education is linked with the high standard of the content and pedagogy offered in VET that provides a path to employment and to higher education. In addition to reforming the vocational upper secondary education, the countries have invested in higher vocational education. Parity of esteem between general subject teachers and vocational teachers has been enhanced with equalizing measures. As a strong work-based system,

Case study 2

An evaluation of co-operation between general and vocational upper secondary education and training

In Finland, although general and vocational upper secondary education (ISCED 3) provide parallel opportunities to progress to higher education, academic upper secondary schools and vocational institutions function separately. The reform in the 1990s focused on enrichment strategy by establishing cooperation between these two sectors in order to increase student choice of courses/modules, for students' benefit. This offered secondary students new options and flexible study paths. A recent large-scale evaluation of the Finnish upper secondary education revealed that 63% of VET providers cooperated with the providers of general upper secondary education during the academic year of 2005–6 (Mäensivu *et al.*, 2007). Correspondingly, 83% of the providers of general upper secondary education cooperated with those of vocational education and training. The providers in the study formed 102 cooperation networks that include, in minimum, one provider from each type of secondary education.

Based on cooperation, students have three options to utilize the course work across general education and vocational programs for their certification and qualification: completing one or more separate courses or a whole module either in vocational institutions or upper secondary schools, or completing a double or triple qualification. About 5% of all upper-secondary graduates in the whole country and 6.9% of the cooperation networks' graduates of the evaluation study have completed double or triple qualification studies.

Vocational students are more eager than general education students to take courses across the education institutions. On average, 2.2% of general upper secondary students have completed at least one course offered by vocational schools in the cooperation networks. Accordingly, 4.1% of the vocational students have completed at least one course offered by upper secondary schools in the network in 2004–5. Similarly, vocational students are more goal oriented in their course choices from the academic side than the general education students. On average, 5% of the students who completed a vocational degree were pursuing a double or triple degree, and 10% of the students completing their vocational degree also took and passed the matriculation examinations.

The cooperation between general and vocational education providers may be restricted by various factors, such as distance between the schools, incompatible schedules, differences in working environments and administration, as well as mutual relations and attitudes. The systems of funding and administration by results do not support cooperation, although it is binding according to the upper secondary education legislation.

countries with vocational enhancement have high rate of participation in education and training and inclusiveness.

A further study on the strategies focused on the vocational-enhancement strategy as European countries are faced with the challenge of improving the quality of VET. Additionally, most of European upper secondary students enrol in vocational programs. The sub-strategies of the enhancement strategy for improving upper secondary education and the quality of VET were identified: (1) promoting access to higher education; (2) increasing cooperation with employers and enhancing quality of curriculum; and (3) raising the status and qualifications of VET teachers.

Access to Higher Education

The expected length of time spent in education has increased since 1995 along with greater participation in preschool, secondary, and higher education. In the majority of European countries, the expected duration of studies for the current five-year-olds is more than 16 years. The highest expectancy figures are found in Belgium, Finland, Iceland, Sweden, and the UK – ranging from 18.5 to 20 years. The mean of the years of educational attainment in formal education was 11.9 years in the OECD countries in 2004 (OECD, 2006).

On average, 53% of the youth of industrialized countries participate in some sort of higher education in universities or polytechnics. In 2003, some 16% of higher education students were enrolled in educational institutions other than universities (OECD, 2005). The increasing demand

for higher education also calls for a broader and better educational choice, diverse learning environments of good quality, and opportunities for further studies.

Direct access from initial vocational education to higher education has improved in many European countries, helping to promote parity of esteem between vocational and academic education. On the one hand, there are countries which are trying to improve access for those in vocational courses through a unified system of higher education (such as in the UK and Sweden). On the other hand, some countries are seeking to diversify their system of higher education (or to expand an already diversified system) by developing vocational higher education for graduates of initial vocational education (e.g., Finland, Germany, and Austria). In Finland, the upgraded polytechnics are also designed to attract those graduating from general upper secondary schools. (Although the Finnish polytechnic system does not have a particular international model, it resembles the German Fachhochschule and the Dutch HBO [*middlebar beroepsonderwijs*], now BOL4 [*beropleidende leerweg*] system.) This can be seen as another way of promoting the parity of esteem of vocational and general upper secondary education. In Europe, four different systemic patterns of organizing higher vocational education can be identified:

- gradual integration has led to a unification pattern and to a single higher education system (e.g., UK);
- the co-existence of university and non-university sectors with different status refers to a diversifying pattern (e.g., Germany);

- upgrading existing tertiary VET for separate but equal non-university sector indicates two parallel higher education systems, vocational and academic higher education (e.g., Finland); and
- establishing a new vocational non-university sector again represents a diversifying pattern (e.g., Austria).

About 17% of all higher education students enrolled in vocational higher education programs in EU-25 countries in 2004 (Eurostat, 2006). The proportion varies among European countries. For instance, in Finland more students ($n = 20\,821$) graduated from vocational higher education colleges than from universities ($n = 18\,293$) in 2004.

Co-Operation between Workplaces and Education Institutions

When compared to school-based vocational education with apprenticeship training system, cooperation with enterprises has a different nature. For instance, in Germany workplace learning is company-led whereas in Finland it is led by educational institutions. In Finland, the upper-secondary-level workplace learning scheme has the unanimous support not only of educational decision makers but also of the organizations of working life. The social partners have taken active part in planning and implementing workplace learning periods as well as in preparing subsequent legislation for integrating on-the-job learning periods to initial vocational education on regular bases. Behind the employers' willingness to contribute toward a smoother transition from education to working life lies their worries about the aging of the population and about recruiting newly qualified people. The government and the pivotal labor market organizations have issued a recommendation in favor of work-based learning, and the social partners and education providers signed joint agreements committing all the parties to the implementation of the scheme. The wording of the Vocational Education Act (1998) emphasizes the workplace experience component of learning. The trainees are called workplace learners (previously trainee), and workplace-based practice is called work-based learning (previously work practice). This undertaking also affects the way in which curricula are reformed to promote work-based learning. The guidance involved in, foci defined for, and assessment of work-based learning are based on educational objectives set down in a curriculum planned and designed mainly by the teachers.

In school-driven education systems, learning through work has been traditionally considered an informal activity, that is, an activity without links with formal study requirements and gaining a certified qualification. In the 1990s, a central objective of Finnish educational policy was to bridge the gap between educational and employment policies. The place of learning at work in upper

secondary education (ages 16–19) has been underpinned by schemes for developing competence-based qualifications and other examinations for adults as well as by a reform of apprenticeship training.

Raising the Status and Qualifications of VET Teachers

The position of VET teachers varies widely across different European countries. Some countries have detailed selection criteria including both university-based qualifications and specific periods of relevant employment. In others, colleges are free to recruit as they wish. However, in terms of qualifications, work experience and pedagogic skills as well as closer equivalence with general education teachers, there is greater emphasis on developing and broadening the skills of vocational teachers so as to also raise their status. The prestige of VET is reflected in the status of vocational teachers and their education, and vice versa. Prestigious VET is essentially based on broadly competent vocational teachers who respect their own work. The demands set for their expertise have evolved from vocational pedagogics into broad professional mastery of relevant sections of the education system and economic sector. The curricular development of vocational teacher education with respect to education strategic competence and international educational knowledge are some of the challenges of quality assurance. New demands set for education, such as transparency, cooperation, and internationalism are not field specific, although they will take on different forms and emphases in different VET programs. Teachers need to have a broad international perspective in order to achieve the present and future educational goals. To be successful, vocational counseling calls for an overview of the options of further studies abroad, as well.

Vocational teacher education curricula can be criticized for the way they build up systemic thinking in teachers: Do the student teachers obtain a holistic overview of the role, goals, and criteria for the successful functioning of the whole education system, or do these matters end up scattered at the margins of separate sections?

Beyond the Strategies

The results of this project on European reform strategies were exploited in the UK as Home International comparisons of post-16 education and training (Croxford, 2001). The education and training systems of the four UK home countries were compared in data on a single cohort. As a result of the policy learning from abroad was found higher levels of social segregation and wider social inequalities in attainment in England than in Scotland and Wales. The English education policy has emphasized diversity whereas Scotland and Wales have more uniform

comprehensive education systems. The British practice of exploitation of the reform strategies showed a possibility to view the four strategies as representing a continuum between strategies based on the distinctiveness of academic and vocational education and those based on their full integration, with linkages and mutual enrichment as intermediate strategies between the two poles. This continuum can be described for several different dimensions of change, such as curriculum, certification, and institutions, and a country's strategy can vary across these dimensions.

Each country's reform programs have included elements of different strategies, and the emphasis of a country's policy might have changed over time. No one strategy was found to be superior or more effective than the others; the effects of each strategy must be judged in relation to the educational system and the context in which it was introduced. The analyses of the strategies have pinpointed many practical lessons which the European countries have learnt from experience elsewhere through which they have reviewed their home systems from a different perspective as a result of policy learning.

The current challenges of vocational education systems in many countries emphasize recognition of prior learning, especially among immigrants, and flexible training modes in order to get employed and have a chance to contribute to a nation's economy as citizens. The most recent developments of education and training policies in Europe show that the most important objectives for which the strategies strove have been achieved. A new kind of thinking has taken over in the development of a European vocational education area.

Different types of educational systems provide different starting points for promoting social equality through education and training. When looking back to European history and the development of their educational systems, some countries have been more advanced than the others in terms of a rate of inclusiveness. Upper secondary education systems can be characterized in several ways on the basis of how they have managed to offer opportunities to move either to higher education or to work for young people with diversified talents and needs. In dual-systems (examples from Austria, Denmark, Germany, the Czech Republic, the Netherlands), VET has had high status and equal hold in educational systems representing professional technical and VET cultures. Also, strong relationship between education system and labor market exists, including a tracked system of education and a qualification structure which has direct relevance for occupational entry. Advantages of the systems have been that they allow many kinds of opportunities for learning and inclusiveness by meeting diverse learners' various needs.

In school-based systems, such as in the Nordic countries (Finland, Norway, and Sweden), vocational

education has been integrated within educational systems representing educationalist culture. The aim is to promote parity of esteem between academic training and VET. Upper secondary education offers alternative progression routes and prepares citizens to higher educated society, especially in Finland and Norway. Relationship between education system and labor market has been quite loose, allowing for predominant school-based, broad vocational, and subsequent firm-based training. Advantages of the systems have been that relatively low drop-put and exclusion rates exist.

In so-called mixed systems (for example England and France), educational systems have been highly selective and divisive in the past. The function of education has been to prepare students for academic studies and ensure education for the elites. The education system has been used as a mean of social class tracking. Vocational education has had a low status and exclusiveness has been relatively high. However, the countries have had many development projects to raise the quality and status of technical and VET.

VET Policy Context in Europe

The Bologna, Lisbon, and Copenhagen agreements and the associated processes that are underway have given a new drive for education and training policy formation and implementation in Europe. The development of high-quality VET has been a crucial and integral part of the Lisbon strategy (2000) in terms of promoting social inclusion, cohesion, mobility, employability, and competitiveness. The Copenhagen Declaration (November 2002) and the Council Resolution on Enhanced European Cooperation in Vocational Education and Training (December 2002) identified concrete outputs in the fields of quality assurance, transparency, and recognition in order to improve the overall performance and attractiveness of VET. The first joint review of the process took place at a ministerial meeting in Maastricht. Based on the Education Council Conclusions adopted on 15 November 2004, the Maastricht Communiqué set out priorities for the next phase of the process.

The Maastricht Communiqué (2004), linked with the Copenhagen Process and Education and Training 2010 Work Programme, introduced national priorities. The necessary reforms and investment should focus on:

- the image and attractiveness of the vocational route for employers and individuals in order to increase participation in VET;
- achieving high levels of quality and innovation in VET systems in order to benefit all learners and make European VET globally competitive;

- linking VET with the labor market requirements of the knowledge economy for a highly skilled workforce, and especially, due to the strong impact of demographic change, the upgrading and competence development of older workers; and
- the needs of low-skilled (about 80 million persons aged between 25 and 64 years in the EU) and disadvantaged groups for the purpose of achieving social cohesion and increasing labor market participation.

European countries are challenged to make further efforts to cope with demographic trends and rapid structural and technological changes. Aging of the European workforce in numbers means that by 2009, there will be more people aged between 55 and 64 than young people aged between 15 and 24. By 2030, the number of young people will decrease by 9 million and the number of those aged between 55 and 64 will increase by 14 million (European Commission, 2005b). There is also a trend toward polarization of jobs. Compared to several non-European countries, the EU-27 countries score relatively low in high skills and high in low skills. Some 80 million European citizens, that is, some 30% of the European working-age population are formally low skilled. Meanwhile, two-thirds of the jobs in the EU-27 countries are found in skilled and higher skilled occupations. Increasing demand is expected for higher-skilled people across all occupations due to technological changes and innovations.

VET is increasingly taking place at all educational levels and, therefore, the parity of esteem and links between VET and general education, particularly higher education, need to be fostered by innovative strategies and instruments at the national and European levels. This should include designing VET systems that attract more students to higher qualifications, which is assumed to contribute to innovation and competitiveness.

The Helsinki Communiqué set four priorities as of 2007: (1) policy focused on improving the attractiveness and quality of VET, again; (2) development of common instruments and tools to enhance a European area of VET and a European labor market; (3) strengthening learning from others; and (4) taking all stakeholders on board.

Particularly, priority 1 refers to the objective that focuses on improving the attractiveness and quality of VET. This calls for:

- strong links between VET and working life, both in formal initial VET and continuing workplace learning for employees;
- better counseling and information in preparation for working life and improved guidance throughout life;
- permeable VET systems offering access to flexible, individualized pathways and progression to further education and training, for example, higher education; and

- highlighting excellence in skills – for example, by greater use of skills competitions.

European Commission (2006) in its Education and Training Programme 2010 has identified five priority benchmarks that are monitored in European countries. The agreed priorities and benchmarks to be attained by 2010 are:

- All member states should halve the rate of early school leavers by 2010 in order to achieve an EU average of 9% or less. The progress report in 2006 showed that EU-25 average was as high as 14.9%. Instead, Poland (5.5%), Slovakia (5.8%), and Czech Republic (6.4%) have already reached the European benchmark in taking care of the youngsters who are under the threat of dropping out.
- Members should ensure that the average percentage of 25–29-year-olds with at least an upper secondary education reaches 80% or more. The EU-25 average was 77.3% in 2006. Slovakia (91.5%), Slovenia (90.6%), and Czech Republic (90.3%) had the highest upper-secondary competition rates.
- The EU average level of participation in lifelong learning should be at least 15% of the adult population aged between 25 and 65, and no country should have it lower than 10%. The EU countries' average is 10.8% challenging to reach the benchmark of 12.5%. Sweden (34.7%), UK (29.1%), and Denmark (27.6%) were the best performers in adult participation in lifelong learning according to the 2006 progress report.
- The percentage of low-achieving 15-year-olds in reading, mathematics, and science, as measured by PISA tests, should be halved in each member state between the years 2000 and 2010.
- Member states are expected at least to halve the level of gender imbalance among graduates in mathematics, science, and technology while securing a significant overall increase in the total number of graduates from 2000 to 2010.

A comprehensive European VET agenda has been launched since 2002 within the framework of the Copenhagen process. The common objectives to be gained were agreed upon by the participating countries (33 countries include EU-27, EEA, and candidate countries), the social partners, and the European Commission. The common objectives were, to prepare a European area of VET, to support competitiveness of European labor market, and to facilitate mobility of workers and students. The following instruments and tools have been established to strive for the objectives:

- European Qualification Framework (EQF);
- European credit transfer system for VET (ECVET);
- Europass;

- Common quality assurance framework (CQAF) and the European network of quality assurance in VET (ENQA-VET);
- common principles on validation of non-formal and informal learning; and
- lifelong guidance.

At the national levels, the member states of the European Union are expected to continue to modernize their VET systems and to improve the image, attractiveness, quality, relevance, and efficiency of VET.

Are European citizens satisfied with VET? The Eurobarometer survey was conducted in 25 EU countries at the end of 2004 to find out how well the current VET system meets the expectations of EU citizens and what reforms should be made. Instead of general/academic education, most EU citizens recommended VET or apprenticeship training to young people leaving school. In the VET Eurobarometer 39% of the respondents recommended VET as the first option, whereas 32% were in favor of academic studies. VET is most popular in France and Great Britain, where 57% of the respondents would recommend it as the first option. In addition, Finland is ranked above average with 48% in favor of VET and 29% recommending academic studies.

As many as 83% of the respondents were very or fairly happy with their education. The highest rates of satisfaction in this respect were found in Luxembourg (92%) and Malta (91%), followed by Finland (90%).

Education alongside work is particularly popular in Europe. A large majority of the respondents (73%) were willing to study in their free time. Also employers support continuing vocational education alongside work; 52% of the respondents stated that their employer supports and encourages continuing education.

More negative responses concerned study counseling and guidance. Only 25% of the respondents had got help or guidance in educational matters during the past 12 months. In Finland, the situation was much better, as 55% had received such help and guidance, while Sweden ranked second with 41%.

European Qualifications Framework

As part of the Lisbon Programme and subsequent Education and Training Programme, the Commission issued a proposal on 5 September 2006, for a Parliament and Council recommendation in order to establish an EQF (KOM (2006) 479 Final). The EQF has been constructed from the viewpoint of lifelong learning and it covers general education, VET, higher education, and adult education. The proposed recommendation aims at improving EU citizens' international mobility and promoting lifelong learning, for example, by making it easier to compare and determine the equivalence of qualifications against a

common frame of reference in the cooperation between member states. The member states should relate their national qualification levels to the EQF levels and create a national qualifications framework where applicable by national legislation and practice. According to the proposal, by the year 2011, all new qualification certificates granted should state their EQF level.

The EQF is based on eight levels that would describe the learning achievements of the person having the qualification. The learning achievements are defined in terms of skills, knowledge, and competence. Levels 5–8 correspond to the cycle descriptions of the framework for the European Higher Education Area (EHEA) in line with the Bologna Process. Placing a qualification on an EQF level would not affect the rights migrants have by the directive on professional qualification.

Vocational Qualifications and Status

For individuals, studying for vocational qualifications means a long-term, goal-oriented learning process so as to develop necessary competence and assets for the labor market. A qualification certificate tells outsiders something about the person's competence with regard to certain standard requirements. From the employment point of view, a qualification may largely determine placement in certain jobs as well as the income level, although ultimate success in working life does call for competence rather than diplomas and certificates. A recognized certificate is nevertheless an easy way to show and attest one's competence to a potential employer. Qualifications are also important for professional esteem. For society, qualification systems and related quest for competence contribute to more highly skilled workforce and greater productivity. International classification frameworks enable evaluation and comparison of educational attainment levels in relation to other countries.

The status of VET is linked to the qualities and properties of the vocational qualification system, such as follows:

- Flexibility and efficiency – referring to how effectively the vocational qualification system functions as such and as part of the larger education and qualification system. The continuum of initial, specialist, and further vocational qualifications promotes lifelong learning. Study programs of different fields should be designed to cater for a wide range of options and cross-disciplinary contents accounting for eligibility for further studies and possibilities for career changes later in life.
- Education that takes into account possible changes of occupations during one's work career, developing and sustaining working-life skills so that the person is able to flexibly respond to changing skills demands.

- Employment indicators that give education providers feedback about young people's placement in the labor market.
- Initial, specialist, and further vocational qualifications that provide eligibility for polytechnic and university studies, which needs to be accounted for in curricular planning (Case study 3).

Recognition of Informal Learning

In 2002, European ministers of education issued a recommendation in Copenhagen, according to which common policies need to be formulated for the validation and recognition of prior learning, so that lifelong learning can be accounted for in practice and give citizens due credit for it. Validation refers to identification, evaluation, and recognition of the broad range of skills and competencies people have acquired in various formal, informal, and non-formal learning contexts throughout their lives. According to Colardyn and Bjørnavold (2004) most EU countries already have such national policies defined at some level, but permanent arrangements to this effect have been endorsed only in Finland and the UK.

Anyway, the development of systems to recognize informal learning has commenced in Europe.

Recognition of informal learning calls for nationally defined standards that serve as reference scales. When validating informal learning, vocational qualification requirements and related evaluation criteria must be defined (Case study 4).

Different parties (states, regions, local communities, social partners, professional associations, voluntary organizations) are developing their own validation systems. This approach of various parallel methods is accepted in many countries (e.g., Denmark, the Netherlands, Norway, and Sweden). A current debate concerns the issue of whether or not validation should be bound to official systems, and what kind of a European approach should be developed based on different national solutions.

Summary

Three criteria – personal competence, educational mobility, and occupational mobility – underpin the assumption that status and esteem correlate to the quality of

Case study 3

A Finnish case: Changing occupations during one's work career

Increasing changes in the occupational structure makes people change their occupations. People also want to secure their professional future by anticipating the change and seeking new posts. According to the statistics on occupational transfers in 1995–2000, more than half a million people, ~27% of the target population, had changed their occupational group during the 5-year period (Statistics Finland, 2002). Here, occupational transfers refer to career changes from one occupational group to another, and concerning people being employed in 1995 and still in 2000. The greatest in-flow rates were seen in the groups of artistic and cultural managers and producers (55.8%), office workers (44.7%), business managers and experts (42.6%), and experts of mathematics and science (42.3%). Correspondingly, the lowest in-flow rates were found among doctors and nurses (about 9%), police, firemen and prison guards (11.9%), military personnel (12.7%), and teachers (13.4%). In general, occupations that typically call for a secondary-level qualification receive people from other groups at an average rate, although there is considerable variation between specific occupations. For example, among mechanics the in-flow from other occupations was 34.9%, machinists 33.3%, and storage workers 30.9%, whereas the corresponding figures were much lower in beauty services (15%), cleaning work, and basic health services (18.3%). Shop-floor level occupations also attract frequently people from other occupations. Hence, labor market dynamics does not concern solely higher-level occupations but affects all occupational groups. Occupations with highly regulated qualification requirements are less likely to attract large numbers of job switchers.

Case study 4

How do the Nordic Countries set the standards for validation?

Sweden seems to have a different view on the need for standards, however. There everybody has a statutory right to get an assessment, validering, of their skills and knowledge attained in different ways, but the Swedish assessment just describes the person's competencies without comparison to any qualifications. In Norway, school curricula serve as standards, even if there is also criticism against such practice. For example, tacit knowledge and related competence gained through experience may be overlooked when using school-based standards. Denmark, then again, has introduced a new adult education system, which offers adults shorter routes to qualifications and further vocational education through recognition of prior learning. To get admission to an adult education program, an applicant must have relevant professional background and work experience of at least two years. In Finland, for example, validation methods have been developed in a national context without European models. Candidates demonstrate their competence in authentic work situations. Such authenticity seems to be missing from the assessment methods used in other European countries, albeit assessment of working is sometimes mentioned. Hence, labor market dynamics, when no other evidence is available about a person's professional competence.

vocational education and to access to further studies, through which VET is seen to be as attractive and prestigious as the other educational pathways. Improving the status of VET has been one of the key education policy objectives in the EU. Rising educational attainment level is supposed to give the best preconditions for active citizenship and employment. By the same token, European countries have adopted educational reform strategies for improving the progression from vocational secondary education to higher education and for enhancing the status and quality of vocational education.

Traditional research on occupational status seems to be based on an assumption that classification of occupations follows a pattern of social stratification. However, modern citizens value their career and occupation choices against their aspirations, identity formation, and cultural communities. Family background is related to young people's education and career choices to varying degrees in different European countries. In addition to equity policy and its implementation, relevant career guidance, enhancing progression and quality of VET can improve the status of VET.

Progression opportunities including choices for double qualifications and access to higher education, prestigious occupations, and interesting learning environments are assumed to attract young people to VET. From the perspective of lifelong learning, it does not matter which type of education was chosen by young and older people, but it matters if education and training produce transparent and flexible competences for continuous education and training at any point in individual lifespan. This is the future focus of the European education policy implementation.

Nearly all the European countries have achieved the goal of universal upper secondary education (ISCED 3). The mass of students in formal education challenges the education and training systems in terms of diversification of secondary and tertiary education. The learning environments of VET are different from those of traditional academic/liberal education. Teaching and learning approaches of VET draw on strategies of constructivist, and situated, work-based, and expanding learning theories. Thus, VET can contribute to modernizing teaching and learning methods and curricula in education systems.

VET seems to hold quite a high status among young people in most of the European countries, especially among male students. In 2004, enrolment in VET programs varied, depending on the country, from 9.2% to 79.2% of all upper secondary education students. In 20 countries out of 35 countries, more than 50% of the upper secondary education students enrolled in VET in 2004. In all EU-27 countries, VET is more popular among male students compared to female students. Exceptions are the UK and Sweden. Ireland has only academically oriented programs at the ISCED 3 level. Instead, she has

pre-vocational programs and vocational programs at the ISCED 4 level (post-secondary non-tertiary programs).

Statistics show that the average salary level rises and the risk of unemployment declines along with the level of education and training, both in Europe and abroad. VET is appreciated if this route is also seen to enable progress in educational and professional careers. With respect to professional socialization and structural reproduction in society, family plays a central role in passing on values and attitudes. Some exceptions exist only in the Nordic countries (Finland and Sweden) where the result of social reproduction between social groups is not strong. Parents' educational and occupational background as well as their attitudes toward different options have significant influence when students are choosing between pathways after primary or lower secondary education.

Vocational and general education and training programs and courses offer different learning environments and experiences. Learning environments which include options meet the needs of a diverse student population and of their different learning styles better than one kind of program, whether general or vocational. Due to the cooperation between different educational institutions at the local level, some countries have made it possible for students to study both general and vocational courses, either for interest and variety or in order to obtain two diplomas. Most countries offer either general or vocational programs to their students, without more options.

Four alternative reform strategies were identified on parity of esteem between vocational and general/academic education as tools for analyzing the differences and similarities of the reform approaches in European upper secondary education systems. The strategies of vocational enhancement, mutual enrichment, linkages, and unification have been largely used for developing national and European education policies. Progression indicates the chances to continue from VET to higher education at any point in the lifespan. The organization of higher education programs varies in Europe. In certain countries, such as Austria, Finland, and Germany there are parallel vocational and academic higher education tracks. In these countries, progression chances are better for vocational students graduating from vocational upper secondary education than in the countries that have only one academic higher education degree.

Vocational Education and Training in Post-Conflict Countries

Conflict forms part of the human condition. Since time immemorial, people have been fighting over power, resources, and ideas. Thomas Hobbes, in his monumental and controversial 1651 work, *The Leviathan* considered that

“...during the time men live without a common Power to keep them all in awe, they are in that condition which is called Warre; and such is Warre, as is of every man, against every man.” (Hobbes, 1651:)

However, to counteract the atrocious consequences of eternal Warre, Hobbes arrived at what he called the “fundamental law of nature,” which is “to seek peace, and follow it.” This can be done through a commonwealth – a government or other central power to which people have delegated the right to conduct violence on their behalf through a social contract. Hobbes’ books were burnt in public when they came out, but his ideas inspired later thinkers such as John Locke, and were reflected in the drafting of the American Constitution.

This article addresses conditions for vocational education and training (VET) in post-conflict countries. In the early twenty-first century, this refers by and large to countries in the developing world, roughly Africa, Asia/Pacific and Latin America, as all recent conflicts have taken place there – the industrialized or developed countries of the West have been involved in many of these conflicts but not on their own territory, hence the focus on developing countries.

The use of the term developing countries for nations in Africa, Asia, and Latin America tends to imply that these are in the process of developing their economies and institutions on the road toward modernity as known in the Western world. In many countries, protracted armed conflict has severely disrupted this development. A new paradigm is therefore underway, by which the way to development is no longer seen as following (more or less) the same path. New structures emerge in the globalized age that tend to weaken state power and disrupt traditional economies. In addition, rising levels of violence and misery are becoming accepted as normal, and new forms of humanitarian aid intervention, far from solving the problem, accommodate and coexist with this instability and inequality.

The Nature of Conflict

Conflict takes place both within and between social actors – the family, village, clan, tribe, nation; or the economic,

cultural, or religious group. Its nature, extent, and level of intensity vary in time and place. The first half of the twentieth century saw two world wars, in which the major powers of the time confronted each other head-on, concluding with the development and use of the nuclear bomb. Many conflicts were conducted by proxy in the developing countries during the Cold War, with the major powers supporting their junior allies directly and indirectly. In addition, an increasing number of conflicts became internal, civil wars, rather than conflicts between nations.

A total of 228 armed conflicts have been recorded after World War II and 118 after the end of the Cold War. In 2004, there were 30 active armed conflicts; this number includes seven conflicts that had become inactive since the previous year, a new one that had started, and seven that had restarted of which three had action taken by new rebel groups and four by previously recorded actors.

When is a conflict over? When is it really post-conflict time, when some 50% of conflicts resume within a year after the peace treaty has been signed? The term post-conflict itself therefore becomes ambiguous: is the conflict really over, or are we in-between two phases of it? Key to this issue is the level of security that can be maintained, and security and development are increasingly seen as interdependent – post-conflict reconstruction and development are impossible without a reasonable degree of security – and security cannot be sustained in the longer term without reconstruction and development taking place. The very different cultures of the military forces and the development-aid community grapple with finding a suitable mode of coexistence in the post-conflict situation with focus on reconstruction.

Armed conflict inevitably adds to the already existing problems of developing countries, causing great social and economic destruction and often leading to the displacement of millions of people. As peace is gradually restored, large numbers of refugees, internally displaced persons (IDPs), and ex-combatants wish to return to their communities, thereby placing an additional burden on overstretched resources. Gainful employment is in short supply (see **Case Study 1**).

New Opportunities?

Post-conflict reconstruction can offer new opportunities to reinvent VET systems from a clean slate, but such development is most often hampered by political competition

Case Study 1 Vocational education and training (VET) in developing countries

Some developing countries draw benefits from the increasing globalization of markets, using the comparatively cheap costs of human labor in mass production for exports to achieve high economic growth rates. The need to produce goods of high quality for the world market gradually calls for the upgrading of skills of the workforce, and human resource development in such situations becomes a key factor for companies that want to be competitive – something they must invest in.

However, many developing countries still only participate in the global markets to a very limited degree, and often only in export of one or two primary products such as oil, minerals, or agricultural produce. Even without having been exposed to violent conflict, the VET systems in such countries is often one of neglect. The following characteristics apply in many countries:

- Modern-sector economy is small and often based on one or two products. The labor market is dominated by an informal (microenterprise) sector, in which informal apprenticeship is the dominant mode of skills transfer. The informal sector is facing harsh competition from cheap imported products, hence has limited potential for growth on its own. The skills development of the informal apprentice remains at the level of what the master craftsman already knows.
- Government-owned and -run VET systems are inflexible and try to cater to a formal sector industry of yesterday. VET standards set 40–50 years ago were perhaps suited to conditions during colonial times but fall short of the requirements of the globalized era.
- Formal VET institutions are starved of resources and driven by supply rather than demand. Their management and instructors are neither interested in, nor capable of orienting themselves to the informal sector on the one hand, or to keep up with technological development on the other. They produce poorly qualified graduates that are rejected by employers in the formal, as well as informal sectors.
- Motivation to join VET programmes is often low among youths and their parents, who prefer secondary and tertiary education rather than vocational training. If a training course is chosen as a last resort, the motivation is likely to be low, the learning may be ineffective, and the proportion of VET candidates actually putting their acquired skills to use is often low.

for resources and power bases, shortage of skilled trainers, no reliable labor-market information, as well as very weak administrative support systems. Add to this security concerns including private armies, landmines, and return of refugees in large numbers with high expectations for a better future.

The potential to seize such opportunities obviously vary greatly between post-conflict countries due to factors such as the level and intensity of the conflict; whether it has actually stopped; geographical, political, and cultural characteristics; and the level of external military and economic support available to win and secure a sustainable peace. The differences between the post-conflict situations are more conspicuous than the similarities, making generalizations hard to arrive at. The examples

described in the sections below serve as illustrations of the diversity more than as indicators of general trends.

The two countries to be described are South Africa after the long but relatively low-intensity struggle against apartheid, and Afghanistan after 23 years of occupation and civil war, most of it with high-intensity violence. In addition to the different types of conflict, the two countries also represent dissimilar sociogeographic features, with South Africa as a unique combination of the two worlds – the industrialized and the developing world – within its own borders at the southern tip of Africa, and Afghanistan, a tradition-bound Asian country first caught in the crossfire of the Cold War and then in self-destructive internal fighting.

South Africa

Industrial development in South Africa took off with the discovery of diamonds in Kimberley in 1869 and gold on the Witwatersrand in 1886. Control over these resources was at the heart of the Anglo-Boer War 1899–1902, ending with the establishment in 1910 of the Union of South Africa, a *de facto* self-governing entity within the British Commonwealth. Economic and political power was in the hands of the white minority, consisting of Afrikaans-speaking descendants of Dutch settlers and more recent immigrants who were mostly English-speaking. A constitution based on political parties was put in place, however for whites only.

The mining industry and, increasingly, a manufacturing industry, provided job opportunities for many workers. Mining especially attracted young Afrikaans-speaking men from the farming areas, most of them with little education. The nature of the work in deep-pit gold mining called for large numbers of unskilled or low-skilled workers, beyond what the white community could supply. This gave rise to the migrant labor system, by which Africans were given time-bound contracts to fill the lower ranks of the workforce under the supervision of white workers. In theory, Africans were regarded as agricultural tribesmen outside the modern world, who did stints of work for a while in order to earn money for a specific purpose such as marriage or acquisition of land. In reality, the government applied a head tax on Africans that compelled them to work for money and hence become part of the industrial world.

The jobs of white workers came gradually under threat from pressure from the Africans who were paid much less for the same work. This led to a general strike by white workers in 1920 and the setting up of a Job Reservation Act by which a specified number of occupations were reserved for whites. From the point of view of South African (white) industrialists this was an inefficient use of the available workforce, and from the point of view of the Africans an unacceptable discrimination against them and their livelihoods.

The migrant labor system continued and became the foundation of the apartheid (separateness) policy that was implemented after the victory of the Afrikaans-speaking National Party in 1948, which aimed at total separation of the ethnic groups in space and time, each group living in its designated area and only visiting other areas for specific reasons such as temporary employment.

The country was divided into areas for whites, coloreds (people of mixed race), Indians (descendants of indentured workers from India who were imported to work in the sugarcane fields in Natal in the 1860s), and Africans, with the latter required to carry and show a passbook to the police upon request when visiting areas of other groups. The result was a country that combined First- and Third-World institutions in parallel systems, one for whites – well resourced and run – and one for blacks – of poor quality and starved of resources. This dichotomy applied in full force to the educational and training systems.

Resistance against racial discrimination took shape with the formation of the African National Congress (ANC) in 1910, initially based on nonviolent principles of the South African Indian Congress formed earlier by Mahatma Gandhi. With the introduction of apartheid in 1948, peaceful resistance increased until the 1960 Sharpeville massacre in which police forces killed 69 unarmed black participants in a lawful demonstration against the detested passbooks. Sharpeville led to the ANC under Nelson Mandela to declare the armed struggle, initially against government installations and not against human targets.

ANC was banned as an organization and Mandela and most of ANC's top leadership were jailed on Robben Island in 1963, after which ANC for many years primarily operated from exile elsewhere in Africa and in Europe. The pressure on the South African governments grew with international isolation through boycott of goods and participation in sports events, as well as with the ANC's increasing capability to upset the functioning of the system through mass action. The pressure from below was met with police brutality, torture, and inexplicable deaths in detention. However, it became gradually more and more obvious that the system was unsustainable in the long run, and apartheid finally died in April 1994 with the first elections based on universal suffrage, which gave power to the ANC with Mandela as the first black president.

From Apartheid to National Qualifications Framework

Recent development in the South African VET sector can arguably be divided into three phases.

1989–94: From resistance to policy thinking

This period was driven by the process toward abolition of apartheid, a political objective that claimed all the

attention of the involved actors. Important was the role of the ANC-affiliated Congress of South African trade Unions (COSATU), which had strong links to unions abroad and was able to benefit from their experience. As primarily freedom fighters with limited experience in the workings of a normal labor market, this support was useful to the South African unionists in the process when ideas of competency-based modular training and recognition of prior learning became prominent. It was in this period that COSATU initiated the National Training Strategy Initiative in which many items were negotiated with other stakeholders in the National Training Board. It was also in this period that employers and unions agreed in principle on some form of a National Qualifications Framework (NQF) that would integrate education and training. An important point for the unions in this debate was to arrive at a system that would include even those with little or no education at all.

1994–99: Turning policy ideas into legislation

Mandela's presidency saw the birth of major development programs, notably the Reconstruction and Development Program (RDP) and the subsequent Growth, Employment and Redistribution (GEAR) program, both with ambitious growth targets in employment, housing, and other areas. In reality however, South Africa experienced a significant decline in formal sector employment in this period – 600 000 formal jobs were lost between 1996 and 2000 – partly due to hesitance by foreign investors, and against an annual growth of the labor force of more than 400 000.

The NQF was elaborated in 1995–96 in order to reconstruct and develop the education and training system into an integrated approach which could enhance access to, and mobility and quality within education and training. To oversee the quality of the NQF, the South African Qualifications Authority (SAQA) was established in 1995. This process was supported in 1997 by the adoption of a Green Paper that proposed a transformed skills development system based on three mechanisms: (1) a levy–grant system, aimed at increasing the involvement of, and contributions by, employers in training of their workforce; (2) establishment of a series of Sector Education and Training Authorities (SETAs); and (3) introduction of a new notion of learnerships.

The NQF consists of eight levels divided into three bands: General, Further, and Higher Education and Training, with basic adult education (literacy training) at the bottom but still as part of General Education, to postdoctoral research degrees at the top of the third band. While this level of integration is clearly a very ambitious agenda for any country, its implementation was actually divided between two agencies, the Department of Education and the Department of Labour, an arrangement that has led to many difficulties.

1999 and later: Implementing the vision

Nelson Mandela was succeeded as president by Thabo Mbeki in 1999. Mbeki's presidency has been tasked with transforming the ideas into practice. The skills levy has been introduced but the lack of administrative capacity to make it a major financing source of skills development and VET has reduced its efficiency, at least in the early years. The GEAR program has helped establish macro-economic stability but has not produced the number of formal sector jobs that were intended.

The VET is placed in the Further Education and Training (FET) band of the NQF. Legislation in 2000 on the FET Certificate stipulates that public FET colleges will be merged into larger entities with 2000 full-time FET learners as the minimum institutional size. Similar mergers take place within higher educational institutions. In the case of VET, this means merging former white VET colleges with former black ones into much larger units. The extent of this challenge on the (white and black) instructors and students, as well as the amount of redistribution of resources between them is daunting.

In conclusion, it can be said that South Africa has succeeded to a considerable degree in overcoming the legacy of decades of conflict. Access to education and training has become much more equal, NQF is undergoing continuous development, and results are beginning to show. On the reverse side, job growth is grossly insufficient and much talent has been lost through emigration of whites. Human Immunodeficiency Virus (HIV)/Acquired Immune Deficiency Syndrome (AIDS) takes a hard toll on qualified people who fall victim to the disease, and the need for replacements puts extra stress on the education and training systems. Add to this continued complaints that the distribution of resources and opportunities remains as skewed as ever. While South Africa had managed to emerge from conflict and become a stable country without major fallbacks to violence, the country is still faced with huge challenges.

Afghanistan

The *coup d'état* of Daoud Khan against his cousin the king, Zahir Shah, in 1973 concluded 40 years of royal governance, and Afghanistan was declared a republic. Daoud claimed to promote modernization of the country and turned toward the West, something that did not please his neighbors to the North, the Soviet Union; he was already at odds with the southern neighbor, Pakistan. In April 1978, he was himself killed in a communist coup.

This was followed by the invasion of Afghanistan by the Union of Soviet Socialist Republics (USSR) in December 1979 and 10 years of Soviet occupation, a period known as the *jihād* (holy war) where private armies under *mujahedeen* (holy warrior) commanders, were supported by the

Central Intelligence Agency (CIA) and Saudi Arabia through the Pakistani secret service Inter-Services Intelligence (ISI). This support was intensified in the second half of the 1980s and became a key factor in the dissolution of the USSR. Militarily, the development and supply of the shoulder-fired heat-seeking Stinger missile to the *mujahedeen* became a turning point with its capacity to destroy the Soviet Hind gunships of which almost 200 were lost in 1988.

The exit of the Red Army in 1988 did not bring peace. Instead, the many armed groups fought each other in a series of constellations where alliances changed constantly. This period was even bloodier than the occupation; in 1994 alone, half of Kabul was destroyed and 25 000 people killed, and the fighting continued in most of the country. The Taliban (*talib*: scholar in Islam) fundamentalist movement entered the fighting in 1994 and gradually advanced throughout the country, taking Kabul in 1996 and most other major towns thereafter. The Taliban introduced a particular strict version of *sharia* (Islam: the road) legislation; banning women from work; girls from schooling; making music, TV, films and photos, sports, games, etc., illegal and subject to severe punishment.

Following the September 2001 attacks on the World Trade Center in New York and the Pentagon in Washington DC, the US army linked up with the Northern Alliance consisting of anti-Taliban *mujahedeen* commanders in the pursuit of Osama Bin Laden and the overthrow of the Taliban. The operation succeeded, and an Interim government under Hamid Karzai was established in Kabul.

The Karzai government had its mandate extended through general elections, but the security situation remained fragile, as Taliban regrouped and prepared new attacks. The International Security Assistance Force (ISAF) under American command was supplemented with North Atlantic Treaty Organization (NATO) troops from several countries, as a national Afghan army was built.

The Aftermath

Throughout the twentieth century, Afghanistan has been among the poorest countries in the world. Twenty-three years of bloody conflict did not improve things – 1.5 million Afghans had died, more were injured, many had been subjected to physical or psychological torture. Afghanistan had become the country in the world with the highest infestation of landmines, and many had lost one or both legs as a consequence of these. Four million had become refugees mostly in Pakistan and Iran, and more than a million became internally displaced. A special problem related to the ex-combatants in the private armies who had to be disarmed and reintegrated into society. In 2002, the big return started. Millions came back to look for their land, their property, or a job.

Most returnees had spent many years abroad and some of them had acquired new citizenship in the country of asylum, as well as knowledge, skills, and even some capital that could be invested. However, the majority returned with low levels of human capital. In 2004, Afghanistan's overall adult literacy rate was estimated at 36%, about the worst in the world; of this, the literacy rate for women was only 21% while the rate for men was 51% – however, these figures hide huge urban–rural discrepancies with over 90% illiteracy for women in some rural areas. Other alarming social indicators include a fertility rate of 6.3 children per woman; an under-5 mortality rate of 257, equivalent to one in every four children dying before their 5-year birthday; and a maternal mortality rate of 1600 per 100 000 live births.

Located on the Silk Route at the crossroads of Asia, Afghans for many centuries had trading links with countries far away. While trade had been disturbed throughout the years of conflict, some of the returnees brought with them new contacts to other, often remote, parts of the world, hence opening new opportunities for trade and production. However, this took place in a setting in which the infrastructure was destroyed and poverty and lawlessness were widespread. The first major economic activity to recover was the cultivation of opium poppy. In spite of government-led and internationally sponsored campaigns to reduce or eliminate poppy, Afghanistan became the world's largest exporter of raw opium, accounting for three-quarters of Western Europe's heroin market with a street value of USD 30 billion in 2004. Opium became Afghanistan's largest industry and is estimated to have grown from 76% to 87% of the world's production between 2002 and 2004.

A New Beginning?

Robust data on the economy and labor market in Afghanistan are few and unreliable. The population was estimated at 24 million in 2004, of which only 20% lives in urban areas, but it was a widespread assumption that the real size was close to 30 million. 80%–90% of enterprises are considered to be informal (unregistered and largely untaxed) family businesses. The labor force was estimated at 8 million with 20%–30 % open unemployment, and high underemployment in the labor-intensive informal sector due to low productivity. Investment in the reconstruction effort by international donors has led to a boom in the construction industry, reinforced by wealthier Afghan returnees who build houses and shops for themselves, especially in Kabul. Most of the construction work is carried out by foreign companies.

Given the challenges ahead, the demand for skills development is extensive and covers a wide range of different types of skills. The country needs masons, road builders, farmers, legal scholars, teachers, carpenters, electricians, hair dressers, accountants, governance experts, office

managers, painters, engineers, and persons in many other professions. However, asking Afghan formal-sector companies about the constraints they are faced with, human capital and skills development is low on the list, which is otherwise dominated by infrastructure issues (electricity, accessibility), administration (corruption), and lack of finance capital.

Responsibility for and delivery of the post-conflict VET sector in Afghanistan can be divided into five categories:

1. Public provision by three ministries:
 - a. Technical and Vocational Education and Training (TVET) by the Ministry of Higher Education (MoHE). Part of tertiary education tier.
 - b. Forty-two VET institutions under the Ministry of Education (MoE). Infrastructure in poor state. Courses 2–5 years with Grade 9 as entry criterion for most courses.
 - c. Seventeen training centers under the Ministry of Labour and Social Affairs (MoLSA) offer nonformal training courses – a variety of mostly practical courses with no common entry criteria.
2. Vocational training by nongovernmental organizations (NGOs). Important especially during the war, but later squeezed out by the government ministers who favor public provision. NGO training is mostly urban based. Most trainers are recruited among craftsmen from the locality. Trainees receive a stipend. NGOs carry out training for donors as well as for MoLSA.
3. On-the-job-training (OJT) by employers takes place in some enterprises and larger reconstruction projects.
4. Private training institutions. Urban based and new, many of these cater to a great demand in the post-conflict situation for computer training and English-language courses for adults.
5. Informal apprenticeships. Impossible to measure but undoubtedly a major mode of skills transfer taking place in the informal micro- and small enterprises (MSEs).

Skills development is seen by the government as important and some VET programs are included in the so-called Afghan Compact which sets the framework for the government's main development programs. However, the emphasis is clearly on public provision where the responsibilities of three ministries often overlap. Streamlining of public VET provision is needed and the setting up of a National VET Authority planned for the medium-to long term, in recognition of the difficulties involved in reorganizing the mandates of the involved ministries.

The central program to restart the VET sector is the National Skills Development and Market Linkages Programme (NSDP), which aims to tackle the following problems:

- Many school dropouts and future high-school graduates are seeking work.

- There is a lack of consistency, quality, and coordination within and among various training providers.
- There is a lack of standardized curricula and qualifications, as well as an overall national VET policy.
- There is no systematic collection of labor-market information.
- There are wide divisions in approaches of MoLSA and MoE training departments.
- There is a lack of qualified staff at MoLSA and MoE with little experience of modern technological development.

The overall goal of the NSDP is to contribute to the socioeconomic recovery of Afghanistan through the provision of a national vocational and training system that is responsive to labor-market needs and provides Afghan women and men with the knowledge and skills for decent work. To achieve this goal the NSDP pursues three objectives, thereby combining short- and long-term tracks in one strategy:

1. Direct provision of training through government and private training providers and NGOs: in the short term, to provide skills for wage or self-employment to 150 000 unemployed Afghans, of whom at least 35% are women.
2. Capacity building of training providers and trainers in pedagogical methods and curricula development.
3. Establishment of an enabling environment:
 - a. In the short term through conducting labor-market surveys, mapping, and registering training providers.
 - b. In the long term by setting up a NQF, developing a VET policy, and establishing a National Vocational Education and Training Authority.

Afghanistan is facing a steep agenda in the VET sector and elsewhere. Security remains a problem with the re-emergence of the Taliban. Poverty is endemic. The infrastructure is dilapidated. The external funding for reconstruction has not come forward in the amounts and with the speed that was hoped for; corruption in the civil service together with the high cost of the military efforts take up a large share of the investments that should go into reconstruction and development.

The VET and skills development programs in Afghanistan are overwhelmingly targeting the small formal sector. This is surprising in a country where the vast majority of enterprises – 80%–90% – are thought to be informal MSEs, and where the majority of skills transfer takes place in the form of informal apprenticeship. The limitations here often lie in the skills of the master craftsman himself – he can only teach what he himself knows already. Some programs have been successful when focusing on the upgrading of skills of master craftsmen, or in the form of sponsored apprenticeships, as shown in (Case Study 2). Such programs have managed to combine the

Case Study 2 Employment of ex-trainees

A study of the employment of Afghan youth who had attended conventional vocational training centers in Baluchistan, Pakistan, in the 1980s, showed that a very small percentage were able to gain employment or become self-employed using their skills. Studies of a sponsored apprenticeship program for Afghan refugees in North-West Frontier Province, Pakistan, in the early 1990s showed that a majority of the ex-trainees were in employment that used their skills.

From: Sinclair, M. (2002). *Planning Education in and after Emergencies*. Paris: UNESCO IIEP.

practical experience of being an apprentice in a real (small) enterprise rather than in a training institution with a low training budget.

Conclusion

Countries emerging from armed conflict need accelerated economic growth and development to bring about internal stability and a sustainable peace. Destroyed or dilapidated infrastructure is a major obstacle to investment and growth, as in Afghanistan. Human capital is typically low due to disturbance of the schooling and VET systems, with many youths having become freedom fighters or combatants in private armies with no marketable skills in the post-conflict era. The apartheid system in South Africa intentionally kept the black majority from developing their talents and skills. The continued presence of firearms and animosity between former enemies calls for special programs for disarmament and integration of the ex-combatants into the national army, or into civilian life.

The two cases presented here illustrate the diversity of challenges that post-conflict countries can be faced with. Does the destruction of old systems through conflict offer new opportunities for reinventing VET from a clean slate? There is obviously no one answer to that question – the most common feature seems to be the great obstacles that lie ahead for such an enterprise. Another one is the recognition of the informal sector, which seems to be very difficult to deal with for governments, in spite of their dominance in terms of employment in many developing countries. When considering the high need for jobs in post-conflict countries, it would be advisable for governments to focus at least part of the VET effort on development of skills and productivity in the informal sector through assisted apprenticeships, upgrading of master craftsmen's skills, and access to credit and business development services, rather than exclusively on the formal sector which typically is small and capital intensive with few job opportunities.

Dual System

Introduction

Dual systems are specific structural and didactical patterns of vocational learning. Normally, they are referred to as systems of initial training, which can basically happen in three ways: (1) by attending a full-time vocational education and training (VET) course in a (vocational) school, college, or higher education institution with neither a training or an employment contract involved; (2) by gaining specific skills or competences in a company based on contractual employment (trainee or employee) – and therefore in a job-specific environment (learning on the job); or (3) by entering a VET program, for example, an apprenticeship, which uses (part-time) school-based and company-based modes of learning and therefore works as a dual system in a wider understanding of the term. In most cases, learners in the latter case are in some kind of contractual employment which can be, but does not need to be, an apprenticeship contract. However, it is the apprenticeship system which offers opportunities of vocational learning within a predominantly occupational context. This means that apprenticeships are not necessarily part of the formal secondary school system.

Looking at the modeling of VET pathways, it has to be observed that VET systems and their typical features are more than mere constructions, mainly triggered by political motivations or economic interests. Instead, in order to understand how they function and how they are capable

of reacting to external demands, they have to be looked at as historical entities. This is especially true for the dual system which at the same time, in some countries at least, functions as a more or less traditional apprenticeship training system. Examples for this subtype are Germany, Switzerland, Austria, Denmark, or the Netherlands. Even in Anglo-Saxon countries, such as Australia or the United Kingdom, apprenticeships, mostly with the additional label modern or new, have been reinvented in the last two decades, following reform purposes to establish alternative routes into employment besides nonformal on-the-job training, traditional school-based VET programs, and higher education courses meant to produce labor-market-relevant qualifications. However, structural and conceptual differences with countries using apprenticeship as a traditional model on a wider scale still remain.

In the following, the major focus will lie on the dual system of Germany. VET in the German-speaking countries of Europe mostly can be described as using alternating learning arrangements, above all as partnerships between schools and companies. Both in Switzerland, Austria, and in Germany, dual systems are specific historical derivatives of apprenticeships. However, despite industrialization being one of the major common features in modern history, differences between the German-speaking systems and most other countries in Europe in terms of a specific apprenticeship culture or learning culture, respectively, are obvious. Their relevance for the current debate

on VET and its modernization may be associated with globalization and various developments at the European policy level which address national VET systems in a specific way. These challenges get a national dimension insofar as solutions appear only possible against the background of what may be called the system reference of a given VET system. This includes different notions of what countries perceive as educational or pedagogical with respect to their VET systems and therefore as realization modes applied to link the idea of training for an occupation or a job to the notion of personality development of individuals.

The idea to bridge the historically and mentally separated worlds of education and training by establishing a specific alternating learning environment for school leavers and at the same time to define it as an apprenticeship system building up on a specific cultural heritage, is very typical for Germany, and also for its two German-speaking neighboring countries. The share of school leavers entering an apprenticeship in the dual system in these countries lies between 40% and 60%, although alternative routes, such as full-time VET or special integration programs, partly using the same setting, partly offering other kinds of training measures, have increased in importance. In Germany, this has been due to what has been called training-market crisis while in Austria full-time vocational schools have traditionally served specific sectors of the labor market quite successfully. Both in Switzerland and in Austria, initial VET can be combined with qualifications leading into the tertiary sector. Denmark, on the other hand, whose dual system is also discussed in this article, has a specific understanding of complementing apprenticeship with school-based VET. This is not possible in the case of Germany which refers to the German VET system as probably the most traditional type of a dual-apprenticeship system.

Structural Features and Working Principles of the Dual System of Initial Vocational Training in Germany

Key Features and Working Principles

In a comparative perspective, German firms employ a high proportion of the workforce with intermediate-level qualifications. The reason for this is that vocational training mostly occurs in the dual system (*Duales System*) which functions as the major nonacademic route for German school leavers by giving them formal access to the labor market as skilled workers, craftsmen, or clerks. The system has traditionally recruited between 50 and 60% of 16–19-year-olds and contributes to limiting the number of unskilled employees to a constantly low proportion in the

German labor market. Unlike in the UK or France, where they form a marginal sector within the vocational training systems, dual apprenticeships exist in nearly all branches of the German economy including the professions and parts of the civil service.

Hereby, the function of the dual system unequivocally is to impart initial training to school leavers in a given range of declared trades or recognized training occupations (*Ausbildungsberufe*) by using two sites of learning: the training company (*Ausbildungsbetrieb*) and the part-time vocational school (*Berufsschule*), with compulsory school attendance for all young people under the age of 18 not attending a higher or a full-time vocational school, hence covering virtually all who have entered an apprenticeship. Instruction can be part time during the week or on a block-release basis. Compulsory instruction in the part-time vocational school is both laid down in the various federal state school acts and indirectly regulated in the Vocational Training Act (*Berufsbildungsgesetz*), which defines the duties of both parties out of the training contract. When it comes to working time and working conditions, the Youth Employment Protection Act (*Jugendarbeitsschutzgesetz*) obliges employers to release young people to attend the vocational school during normal working hours.

The two learning sites correspond with two legal responsibilities due to the German federal political system. The various levels or dimensions of this dualism can be seen in **Table 1**.

Although the dual institutional principle certainly is the striking feature, the working principles of Germany's dual system also comprise at least three more dimensions which render it the character of a special kind of dual system:

Table 1 Levels of dualism in the dual system

	<i>Berufsschule</i>	<i>Ausbildungsbetrieb</i>
Legal status	• Public	• Private
Supervision	• School administration	• Competent authorities (chamber system)
Legal basis	• Education law (federal state)	• Vocational training law (central state)
Young person's status	• Student	• Apprentice
Training personnel	• vocational teachers	• Masters, trainers
Didactical instrument	• Vocational syllabus	• Training ordinance
Form of learning	• Classroom instruction	• Workplace or workshop instruction
Contents of learning	• Theoretical	• Practical
Kind of award	• School certificate	• Chamber-skilled award

- The dual system is a well understood and socially accepted pathway into employment as it follows a traditional pattern of skill formation recurring to the medieval mode of apprenticeship training. This means that training is workplace-led and predominantly practical and that work experience during the training period is seen as an essential asset of this kind of VET. It also implies the notion that the system works in accordance with skill requirements defined around the workplace since it is not task based but occupation based.
- Although traditional at its core, the modern German dual system is also subject to the involvement of the state with regard to the nature and quality of occupational standards as well as to legal conditions underlying apprenticeship training. The German training culture is based on the notion that an apprenticeship should be based on an underpinning pedagogical understanding which sets it apart from normal work.
- As the government sets quality standards with respect to in-company training only in a formal manner, other social groups have a major influence on the dual system. This means that public, private, and semi-private institutions use long-established modes of cooperation within the system and that employers and unions normally take the initiative with respect to training regulations and their revision or modernization.

The specific occupational character of training (*Beruf/Berufsprinzip*) is interlinked with the structural composition of the dual system. This orientation in fact can be traced back to the legal restitution of the master apprenticeship and the development of the vocational character of the continuation schools some 100 years ago. The historical reinvention of the principle of self-administration turned out as the starting point of a consolidation and universalization process which at the beginning of the twentieth century also incorporated industrial and commercial training, thereby creating a general institutional principle for the division of labor and the assignment of competences.

Besides its didactical principles, and its legal and institutional characteristics, the German system relies on a functioning training market which has the character of a suppliers' market. Once a training contract has been signed, the principal financial responsibility for the training process that includes, besides training allowances, all direct and indirect costs such as training personnel, machinery, training administration, and social insurance contributions, lies with the companies. The fact that the system is supposed to be financed mainly by employers reflects the principle of self-government reaffirmed by law in the late nineteenth century. Therefore, companies provide training opportunities on a voluntary basis. Training in the craft sector has a particularly strong tradition (although with a decreasing tendency), and the chambers (*Kammern*) execute public

functions such as the organization of examinations and the supervision of training companies.

Against this background, the German dual-apprenticeship system may be viewed as a system of training rather than a system of employment in which the wages of apprentices reflect this emphasis, with German apprentices typically receiving wages that are far lower than adult rates and apprentice rates in Australia or in the UK. Training allowances are the result of collective bargaining but keep attached to the purpose of giving young people a basic start into their working lives without putting too much burden on employers. As the apprenticeship system is neither part of the school or education system nor a normal sphere of work the system reference is clearly training and recruitment for skilled work. Such a clear separation of pathways or subsystems implies that expectations which rest on the dual system and frictions on the training market can hardly be compensated without additional activities on the side of the state. Among these, the promotion of external training options and the introduction of incentives for employers have been the most important ones in recent years.

Historical Background and Cultural Underpinnings

The German dual system in its present form goes back to the corporatist framework established by legal sanction in the late nineteenth century. It has remained virtually unchanged in its crucial features up to the establishment of the Vocational Training Act (*Berufsbildungsgesetz*) passed in 1969 and recently (April 2005) revised. Around the turn of the century, compulsory attendance at the part-time vocational school emerged as the second pillar, along with workplace training, underlying formalized vocational training. Georg Kerschensteiner (1854–1932), widely known as the father of the German vocational school, was successful in bridging the gap between elementary school and the beginning of military service by establishing vocational schools for school leavers. Although the continuation schools hereby followed the ideal of *Menschenbildung* (education of the individual) Kerschensteiner saw the individual also as a social being, both with respect to his occupation and to his citizenship within the community. This meant a complete break with traditional educational thinking. Kerschensteiner's prize essay delivered to the Erfurt Academy of Sciences in 1901 must be seen to comprise thoughts that were to be of revolutionary significance for the German education system and eventually emerged in the dual system which we have today.

On the company side of the dual system, the historical development appears ambivalent. In 1845, a Prussian Trade Act, though not repealing freedom of entrepreneurship as a whole, reimposed restrictions on free craftsmanship by making a distinction between small workshops and

industrial premises confining the right to take and train apprentices in handicraft occupations to examined journeymen. The definition of apprentice, however, was extended to everybody who entered an employment with a master to learn a trade notwithstanding whether he paid a premium or became a wage earner. Freedom of enterprise was finally incorporated in the Trade Act of the North German Federation in 1869. Three decades later, this was counterbalanced again with the restitution of the old apprenticeship model. In the 1880s, the *Mittelstandsbewegung* (small-business movement) constituted an influential pressure group. The 1897 Trade Act (*Handwerkerschutzgesetz*) was one of the outcomes of this policy. It is now seen as an oblique predecessor of the Vocational Training Act. Although it did not prescribe the *Meisterbrief* (master's certificate) as a training prerequisite, the Act of 1897 revived some of the old apprenticeship regulations. The newly established chambers and guilds became systematically involved with training matters and were given the right to hold examinations for journeymen and master craftsmen. This Act also made provision for the technical qualification required for the training of apprentices by confining it to skilled journeymen of at least 24 years of age who had either served a 3-year apprenticeship or pursued their trades for at least 5 years as independent artisans. Contracts became general practice in the craft sector as well as during the 3-year training period, at the end of which the apprentice should have the opportunity to take his examination. The *Handwerkerschutzgesetz* laid the foundations of the corporatist framework typical of the dual system. Ironically, the new system of industrial training emerged in a climate of anti-industrial agitation holding up the idea of *Beruf* (vocation/occupation) in a world of accelerated change. The pivotal amendment which modern apprenticeship legislation later added to the foundations laid in the late nineteenth century is the involvement of both the state and the trade unions within a system which has remained corporatist in its basic features.

The Critical Relationship Between the Dual System and Alternative Forms of VET in Germany

Recently, in Germany, initiatives that have been taken to assist school-leavers' access to VET qualifications have included several strategies. These strategies comprise, among others, stronger support of sectoral, regional, and in-company training-place initiatives and collaborative vocational-training ventures as well as training schemes organized by external providers in close cooperation with local enterprises with a view to developing sustainable VET structures. New stipulations in the revised Vocational Training Act (2005) are meant to link up vocational preparation programs and full-time VET with the formal apprenticeship system more reliably. Hereby, coping with

the rising number of participants in school-based vocational preparation courses as well as full-time students in VET, of whom only some 50% attend courses leading to vocational qualifications that are nationally portable on the labor market, is a major challenge. To improve the status of these courses, it is necessary to strengthen the work-related features of VET carried out in full-time vocational schools in order to open up genuine alternative pathways and opportunities for young people outside the dual system.

Traditionally, in the German debate on VET, there has always been an understanding that company-based and school-based training represent different pedagogical logics based on diverging paradigms of learning. This may be seen as the other side of the coin when it comes to the dual system. Whereas VET in schools has been associated with a more or less unambiguous pedagogical ethos and therefore not purely with socialization and utilitarian principles, training in an enterprise is bound to occur within an economic environment where normally a strong bias on non-educational purposes prevails. This difference in character is underlined in the dual system of Germany by the fact that even the part-time vocational schools use syllabuses which make provision for the core of the occupational curriculum as well as for additional general education.

Apart from the parking function or buffer function of (full-time) vocational schools due to training-market restraints, the relationship between the dual system and the various subtypes within the system of school-based VET under the auspices of the federal states has to be described as ambivalent. This means that vocational schools basically serve three functions which coexist depending on the specific course and the institution offering it:

- vocational preparation (mostly 1–2 years) which helps young people to apply for an apprenticeship by improving their stakes on the training market;
- further education (mostly 2–3 years) which means leading young people to achieve a higher school-qualification level (including the university entrance qualification); and
- vocational training (mostly 2–3 years) which means leading young people to achieve a portable labor-market-relevant occupational qualification outside the dual system.

With respect to the vocational-training function, school-based VET is considerably complex since full-time vocational schools offer courses leading to qualifications either within or without the scope of the Vocational Training Act. Besides, some of the schools deliver entry-level training based on specialized federal regulations, such as in the area of health occupations. Especially, the ordinary full-time vocational schools accommodate a range of different students and aspirations. Among the major subtypes are both schools leading to a full occupational qualification and institutions which only partly

focus on occupation-relevant competences, as they deliver either school qualifications (such as the intermediate secondary school leaving certificate) or concentrate on vocational preparation. One of the biggest problems certainly is the lack of acceptance in the labor market of most vocational qualifications obtained in school-based full-time courses against the background of a dominant dual system.

In the federal state of Baden-Württemberg the implementation of practice firms (*Übungsfirmen*) in full-time VET, above all in vocational colleges (*Berufskollegs*) is one strategy to tackle the apprenticeship problem. The vocational college is a postcompulsory institution, and as such is an alternative to the later years of the grammar school that academic students attend. It is open to students, normally aged between 16 and 18, with a medium-level school-leaving qualification. Recent research shows that the recognition problem of qualifications gained in a vocational college still persists. Companies have strong reservations concerning learning in a completely theoretical environment and normally rate a dual system (apprenticeship) qualification higher than anything else offered in the VET system. Even practice firms, from their viewpoint, fail to come up with a reliable quality of skill provision as they indeed offer practical and realistic learning opportunities, but lack the benefits of real workplaces and company-specific socialization effects. It is not surprising against this background that both the government and the social partners continue to stick to the apprenticeship system as the still best-practice approach in the area of initial VET.

Features and Working Principles of the Dual System in Denmark

Denmark comes quite close to the German model of the dual system, which can be described as a neocorporatist form of regulation, where the social partners play a central role in the VET sector. However, in Denmark, just one-third of all young people undertake training in the dual system, which uses a block-release structure in the area of cooperation of learning sites. In 1956, the foundations of the modern Danish VET system were laid when theoretical instruction was taken away from evening schools and transferred to technical schools. Modern VET in Denmark now starts with a full-time VET foundation course (*grundforløb*), which can last between 20 and 60 weeks, depending on prior learning achievements or occupational fields. For the following main part of training, young people have to enter a training contract with a company. In contrast to Germany, the vocational college has a distinct supporting function and can even act as a contractor in the apprenticeship itself. In the real dual or cooperative system, apprentices spend two-thirds of their training time in the company. Training ends with a final

examination before a regional branch committee representing the chosen occupation.

The system in Denmark is much less self-focused than the German dual system as it offers additional qualification modules and transition routes into the tertiary sector. Starting with the early 1990s, VET reform in Denmark has been directed toward more parity of esteem between general and vocational education and toward establishing a uniform model out of an amalgamation of the traditional school-based forms of VET and the apprenticeship system. On the other hand, this does not mean inflexibility since programs are individually tailored within a given range of opportunities.

Cooperation between learning sites is an important issue in Danish VET policy. The purpose of this does not only aim at optimizing learning processes and learning quality but also at coping with individualization of learning pathways and institutional flexibility. Although this is also a feature of the VET systems in England and Australia, the Danish system probably comes much closer to the German dual-apprenticeship model where alternating periods of training in two different contexts represent the basic philosophy of the VET system.

Features and Working Principles of Apprenticeships in England and Australia

In England and Australia, recent political endeavors have been directed toward a systematic revival of the apprenticeship system. The schemes created have become known as modern apprenticeships (England) and new apprenticeships (Australia). In both cases, training follows the overarching principles of CBT (competence-based education and training).

The history of apprenticeship in Australia has predominantly been one of industrial relations issues and has been associated with a form of learning for the lower strata of society. This status given to apprenticeships was reinforced when some of its occupational areas were transferred to higher education, such as pharmacy. Today, it is part of the open training market where more or less structured subtypes of vocational learning exist, making use both of full-time and part-time dual models. The new apprenticeship arrangements have also introduced further elements such as training packages and user choice, and they cover school-based and part-time apprenticeships and traineeships as well as formal training that can be wholly on the job or off the job at a training provider. Moreover, they now have been made available to employees, which is a typical characteristic of the English modern apprenticeship scheme, too. In Australia, VET qualifications have now even been made available for study during secondary schooling. Hereby, students can go for a full or a part of a national qualification. A more clearly dual mode has

been created by establishing school-based new apprenticeships and traineeships which involve a part-time apprenticeship or traineeship-employment contract and studying at a college.

However, in contrast with the German type of dual training, apprenticeships in the Anglo-Saxon world are organized in a much more open, volatile way: In England, for example, the apprentice is expected to keep to normal working hours with an employer while undergoing on-the-job training. This allows the apprentice to achieve national vocational qualifications (NVQs). At the same time, the learner is supposed to spend time with a learning provider to gain key skills, and to study for a technical certificate. Hereby, the weekly balance of work and study depends on the type of apprenticeship and on the individual employer. There are models where apprentices are given time off work on certain days to go to a learning provider, often a local further education college. The dual system therefore is much more employment based and not regulated in a uniform way, let alone based on vocational-training law. Many researchers of apprenticeship training in the UK have consistently pointed to the structural weaknesses of modern apprenticeships lacking minimum training periods, compulsory part-time technical education, and other quality standards.

The absence of process regulation in the UK or Australia obviously corresponds with the competence-based approach in the area of skill certification. What matters here is demonstrated competence in the performance of work tasks and no substantial educational attainments. The Anglo-Saxon model of apprenticeship therefore is an interesting mixture of old and new without the political or institutional buttressing of the system typical of Germany, and without locating apprenticeships in senior secondary education, which is the case in Denmark. As a matter of fact, apprenticeship numbers have stagnated on a level which is seen by policy as too low for stabilizing the company-based entry-level training system. Under these circumstances, learning on the job in a more or less formalized manner, is still the dominant way of acquiring skills outside the system of further education. Skills remain job specific as they are not based on a broadly designed initial training program.

Conclusion

As already mentioned above, one of the crucial traits of the German apprenticeship system is its dual character. Whereas in other European countries, including the UK, on-the-job training – even under modern apprenticeship programs – is complemented by off-the-job training on a more or less voluntary basis, in Germany, it is mandatory. While there has been an ongoing discussion about the process character of vocational training in the

UK – including the scope for expansive participation of companies in workplace-related training, in Germany, the law provides the framework for dual apprenticeships by making sure that school leavers are kept within the educational system – although there is now a growing number of school leavers in school-based VET and various vocational preparation and transition programs. For each training occupation, the state education ministries, in line with training regulations under the federal law, work out syllabuses for the vocational and general subjects within a given occupation taught at the part-time vocational schools.

In other countries, dual systems in this narrow sense of the word, do not exist, with the exception of Switzerland and Austria which resemble the German model. In Denmark, the dual system has undergone a number of flexibility changes, including single-venue training in a vocational college and modularization. Against this background, the most traditional model of a dual system exists in Germany and may be described as comparatively resilient to change, which certainly poses problems in the context of European VET policy which tries to integrate obviously different cultural concepts of organizing labor, labor markets, and modes of skill formation.

Glossary

Brokers – Government-appointed agents who direct employers to appropriate further education and training providers, and provide continuing support for company development.

Employer engagement – A term introduced in the UK White Paper: Learning to Succeed (1999) to describe the active involvement of employers in the VET process.

Levy – A charge on employers, usually statutory, to finance training for themselves and other companies in their sector.

LSC – The learning and skills council, a government agency responsible for funding and regulation of the learning and skills sector within England.

OECD – Organization for Economic Cooperation and Development.

Preservice or initial VET – The education or training provision which prepares individuals for work in a general rather than occupational specific sense.

Responsiveness to employers – A term used to describe an open and flexible attitude to working with employers in order to meet their training and development needs.

Select committee – A cross-party committee of UK members of parliament responsible for the scrutiny of government departments' plans, policy, and spending.

TAFE – Technical and further education (in Australia).

Workforce development – The training and development of current employees.

and Northern Ireland and, to a lesser degree, in Scotland. The discussion will also refer to VET systems in other countries facing similar issues in relation to skills development and examine how supporting structures facilitate or impede industry's influence.

Industry is a major user of VET systems, both in terms of vocational qualifications and skills development. There are clearly benefits to employers from their involvement in VET. Securing industry's influence and interest in post-16 learning and workforce development may secure greater relevance in VET provision and qualifications. This in turn should support competitiveness and productivity and develop capacity to cope with changing demands. From a demand-side perspective, industry's engagement in learning could increase employers' commitment to learning and demand for skills. The workplace also provides a focal point from which to reach individual employees and to encourage their participation in learning.

Engaging Industry in VET

The Policy Context

Post-16 learning and skills policy worldwide is increasingly concerned with developing the skills and learning of the workforce to increase economic productivity. Common economic issues, such as globalization, technological advancement, and the increasing pace of change in products and working practice, together with the emergence of new and strongly competing economies, feature strongly in national and international discussions about the role of VET. Restructuring of industry to meet these demands – typified in descriptions of a flexible and adaptable workforce – must be matched with VET systems that are sufficiently nimble to provide the learning required by employers and their workforce – being both responsive to emerging needs and proactive in anticipating future needs.

The ongoing policy debate within the United Kingdom culminated recently in the Leitch Review of Skills, which described the skills profile that should be achieved by 2020 to maximize growth, productivity, and social justice. The development of the skills of the current workforce is seen as a priority because of the demographic profile of the UK workforce – 70% of the workforce of 2020 has already left compulsory education and the flow of young recruits into the workplace will reduce. While school standards have

Introduction

This article considers the influence of business and industry on the vocational education and training (VET) system and the different forms this may take. Its primary focus is on the United Kingdom, as this system has been subject to substantial changes which have then often been mirrored in the systems of other countries. While many of the initiatives described relate to England, most will have been adopted in the devolved administrations of Wales

risen, more than one in six young people leave school with basic skills needs, and the proportion of people remaining in education and training post-16 is below the average in the Organization for Economic Cooperation and Development (OECD) countries. The United Kingdom will need double attainment at most skills levels if it is to be within the upper quartile of the OECD countries.

The review places a significant responsibility on employers to develop skills and proposes a commission for employment and skills as a medium for increasing employer engagement and investment in skills. It also suggests that legislation should be introduced if employers do not voluntarily rise to the challenge of developing skills. These proposals have largely been accepted by the government, but the extent to which the subsequent action is strong enough to bring about change remains to be seen.

Incentivizing the Demand for Skills Training

Many VET systems are looking at the role of industry and attempting to clarify the contribution that it can make in helping people to become more employable and developing the relevance of skills supply. France, for example, has in place a train-or-pay requirement with entitlement to employees' continuing development funded by an employer levy and worker entitlement to learning. In the Netherlands, there is a powerful use of fiscal incentives, such as tax relief on trainee wages. In South Africa, there is a 1% wage-bill levy in the private sector to pay for worker training. Within the United Kingdom, free training for basic skills and for a vocational qualification at level 2 is available for employees in England through the Train to Gain program. Train to Gain also provides a brokerage system, to enable employers to identify their training needs and source training provision.

The Train to Gain program was preceded by the employer training pilots (ETPs), which were established in September 2002, in certain parts of England. The pilots aimed to test the effectiveness of an offer of free or subsidized training to employees without a level-2 qualification, wage compensation (of various levels) to their employers for giving time off to train, plus access to information, advice, and guidance. An evaluation of these pilots estimated that only around 10–15% of the training provided by the ETP would not have occurred without the initiative, suggesting that it had a small effect on the incidence of training among eligible employers. Most of the employers taking part also said they would have provided similar training in any event, although only a minority said that this would have been for the same people trained in the pilots.

However, a strong message emerging from the ETPs was that employers were more prepared to take part in training if this was provided in or near the workplace with minimum disruption to work patterns. This message needs to be heeded by providers of skills, who need to

develop more flexible learning opportunities, tailored both to the needs of individuals and employers as well.

The wage compensation within the ETP was not generally seen by employers as a major incentive to train, although this may have been due to the high proportion of large organizations taking part in the pilots. The Train to Gain program has dropped the wage compensation element of the pilots and initially restricted the offer of free training to full qualifications at level 2, with some exceptions where it may be available for level 3.

Some countries have introduced forms of compulsion to increase training of employees, often in the form of the right to time off for training. Takeup has varied considerably. In the United Kingdom, the scheme for 16–17-year-olds has a takeup rate of only 3%. In Denmark, time off for employees has an estimated annual takeup of 9% of the eligible population. In contrast, levies which require firms to spend more on training, can significantly increase the volume of training, as has happened in France in recent years. International statistics suggest that compulsion only works if the training is delivered flexibly and produces clear business benefits.

Relationship to the Supply of Skills Training

Incentives to raise demand for training need to be underpinned by strong links to the providers and qualifications within the VET system. To understand the rationale for industry's involvement in VET in the United Kingdom and the structural arrangements for its delivery requires an appreciation of the changing economic climate, public perceptions of the VET service, and the political debate surrounding this service.

As in most advanced countries, the United Kingdom experienced a significant economic recession during the 1970s and early 1980s. The recession forced industries to downsize and restructure. Similarly, the institutional, organizational, and funding arrangements for VET provision have undergone substantial change and reform, including the measures by which business and industry can exert influence.

Rising unemployment, particularly youth unemployment and the severe long-term and generational unemployment in the United Kingdom during the 1970s and 1980s led to the creation of the manpower services commission (MSC). The focus of the MSC was on job creation, rather than skills development. The trades unions were still in a position of strength, and the agreement to develop work experience and work preparation provision under the youth opportunities program was dependent on these not replacing the traditional apprenticeships or foundation training that employers already provided.

In effect, the diminution of the United Kingdom's key strategic industries, such as shipbuilding and mining, reduced the need for a mass of skilled workers trained collaboratively with large employers. The recession also

weakened the collective bargaining power of the unions and the MSC were later to develop traineeships, which eventually became modern apprenticeships (now apprenticeships). However, the takeup of apprenticeships is only now reaching expectations and perceptions of their quality remain low, reinforced by completion rates that have only recently averaged 56%. The legacy of the reduction in VET during this period is manifest in the low level of skills within the current workforce.

Sectoral Approaches

One of the most commonly found approaches to promoting industry's involvement in VET is through occupational-sector bodies. These bodies are intended to facilitate employers' engagement in skills development and to create a culture of learning across a sector. In Canada, for example, a national system of 30 sector councils has been in place since the 1980s. The councils have mandatory equal representation from employers, trade unions, and government. They were originally intended to be self-financing (by employers), but this was later abandoned and they remain government funded. As a consequence, they are seen as quasi-governmental organizations.

The sector councils have a strong industrial-relations role and are seen to be effective in bringing the government, employers, and unions together. Their focus has shifted from labor-market issues, such as the impact of declining markets, to training. They are increasingly concerned with training standards and promoting a training culture. Standard setting is said to have enhanced employer involvement. Provincial sector councils and provincial colleges form affinity groups to translate sector skills needs into training provision. This is seen to be very successful, but there are tensions between employers' priorities and those of federal government.

Within the Netherlands, sector bodies are at the heart of the VET framework in relation to securing occupational competence. They accredit work-based trainers, provide quality control of examinations, and accredit company training schemes.

In France, there is a highly consensual view on the benefits of a levy system for all companies and all sectors. This system covers initial vocational training for young people and continuing vocational training for those in work or retiring. From 2004, employees have a right to up to 20 h of training per year of service. Employers meet all costs including an allowance for out-of-hours training. There is no national sector network and collection of the levy can be sectoral, multisectoral, or for specific employers.

A sectoral approach is well established in Australia though there is continuing federal-government impatience with the effectiveness of the system. The most recent manifestation of this has been the creation of 24 employer-led Australian technical colleges, operating outside the states'

technical and further education (TAFE) system. Prior to this, in 2004, the industry training advisory boards, which were established in 1992, were restructured into ten industry skills councils (ISCs). These new bodies were formed on a tripartite basis with employers and unions, and were intended to be more strategic and facilitate employer demand for skills as the main driver for the supply side. However, their most significant contribution continues to be the system of training packages, which set the frameworks for the recognition and assessment of sector skills.

Interestingly, the German VET system, often seen as the gold standard of work-related education and training, is nonsectoral, although employers are part of the institutional and regulatory arrangements that develop VET frameworks. This highly centralized, corporatist approach has been under great strain since the reunification of Germany in 1990. The economy can no longer sustain the required number of apprenticeships, and many firms are now poaching skilled workers rather than developing them through training.

The United Kingdom previously had a network of industrial training boards (ITBs), which collected a training levy and secured a ready supply of suitably trained people for their industries. However, many companies, especially smaller firms, perceived the levy to be more beneficial to large firms and the ITB's influence on the relevance and quality of the supply of training to be weak. Most ITBs declined after legislation in 1964, removed their legal entitlement to collect the levy. Only two ITBs remain, the construction industry training board recently re-named construction skills, and the engineering construction industry training board (ECITB). Some became industrial training organizations (ITOs), which had responsibility for setting national occupational standards in the national vocational qualifications.

The UK's sector skills councils (SSCs) now have responsibility for promoting employer engagement, and for describing the learning content of vocational qualifications, but they have little power to impose compliance on learning providers or to secure employers' commitment to take part in the training and development required for the sector. The reluctance to impose a levy system on industry has resulted in a voluntarist approach to employer engagement, although the Leitch review strongly suggested that if industry does not respond to their role in developing skills by 2010, legislation will be introduced to secure a legal compulsion for employers to train.

More recently, the UK's SSCs have led to the development of sector skills agreements (SSAs), which will articulate the skills needed by the workforce and how these skills should be supplied. The SSAs are being created in partnership with the SSCs, trade associations, employer bodies, and organizations that supply and fund education and training. SSAs will describe the training needed by their sector.

This has already resulted in the development of new qualifications or apprenticeship frameworks.

A general message from sectoral approaches is the need to secure industry's commitment to the remit of the sector bodies and to establish the added value of their activities. It appears that sectoral approaches need to focus on a limited number of strategic cross-sector issues. Sector bodies also need clarity about their leadership role and their relationship to other representative bodies.

In practice, VET systems operate in an environment of interrelated funding regimes and regulations, regulatory and assessment bodies, sector-specific and regional development bodies, and so on. The complexity of the interrelationship of these bodies, and their potentially overlapping responsibilities can be confusing to employers, trainees, and providers. There is a need for a multi-stakeholder approach, which is aware of and appreciates the role of other players, and the direct involvement between employers and providers needs to be strongly promoted to secure their active engagement.

Reforming Vocational Qualifications

The changes to the industrial landscape after the World War II have had a major impact on VET systems. The United Kingdom was at the forefront of the development of competence-based qualifications, following the DeVille review, which led to the development of national vocational qualifications. In part, the review was undertaken because of industry's dissatisfaction with the time-served apprenticeships framework and qualifications, and their perceived lack of quality and relevance. The national qualifications framework now includes national vocational qualifications from entry level to level 5, and includes all qualifications accredited by the qualifications and curriculum authority (QCA), including general and academic as well as vocational qualifications. In theory, this enables learners, training providers, and employers to assess the broad equivalence of qualifications in terms of their type and level. However, the level of a qualification does not indicate:

- which jobs that qualification is suitable for;
- equivalence to other qualifications in terms of content or duration;
- equivalence to other qualifications in terms of size; and
- equivalence to any qualifications QCA has not accredited, some of which are highly regarded professional qualifications.

England has been slow to adopt credit accumulation and transfer (CAT) frameworks, although systems are in place in Wales, and higher education CAT systems operate across the United Kingdom. The lack of such a framework has hampered the development of more flexible VET qualifications. QCA is currently testing a unit-based qualification framework that will recognize a wider range of learner

achievements than the national qualifications framework. This will be more responsive to employer and learner needs, but is unlikely to be in place before 2010. Meanwhile, it is very difficult to accredit the bespoke training that employers need.

The UK's National Skills Strategy

The national skills task force further refined UK policy on skills and the resulting skills strategy (2003) asserted that skills and business innovation drive productivity, and that employers should see engagement in training as benefiting their businesses. The confederation of British industry (CBI) and individual employers influenced and endorsed the skills strategy, but difficulties remain in getting beyond a general awareness of the need to engage in VET to genuine participation, especially in the expanding small and medium enterprise (SME) sector. The lack of active involvement bedevils attempts to clarify expectations and needs other than at a very superficial level.

The impact of the decline of the trades unions, and the removal of the levy, is still evident in the UK's response to the engagement of industry in skills development and VET. Government action has focused on making the business case for learning to employers, rather than on imposing industry's involvement in VET through legislation. In contrast to arrangements to develop occupational-sector ownership of skills development in other countries, the UK SSCs have few links to the Trades Unions.

Paying for Training

An underlying theme within this debate is the importance of employers' buy-in to learning in its literal sense in paying for VET. A fully publicly funded VET system addressing the needs of both entrants to the workforce and current employees would require significant shifts in emphasis in the distribution of public funds at a time when demands on other services, notably health, are also increasing.

The United Kingdom has a large further-education system, comprising over 500 further-education and sixth-form colleges and over 1000 work-based training providers. The colleges and providers in England draw most of their funding from a national learning and skills council (LSC) and similar arrangements are in place in the devolved administrations of Wales and Scotland, and in Northern Ireland. The LSC commissions a specified volume of education and training programs for which there is a national funding formula. Most of this funding is now for general education programs for young people and apprenticeships.

Public funding for adult learning is now almost entirely devoted to the Train to Gain program, which initially restricted public funding for workforce development to the achievement of a first full level-2 qualification for employees and any associated basic skills needs.

The rationale for the public subsidy up to level 2 derives from the view of the CBI that employers are less willing to train their employees in basic skills and competences that they expect the public-education system to have already developed. By providing publicly funded education and training for adults in the workforce up to level 2, the government expects to increase employers' contribution to the development of higher-level skills. As qualification strategies are developed for individual sectors, funding for Train to Gain is now extended to encompass further level 2 and level 3 program.

While the Train to Gain program aims to attract greater participation by employers in fee-for-service training, previous national funding formulae and numerous European Social Fund (ESF) and European Union (EU) initiatives enabled colleges and providers to offer training at no cost to employers. This created a dependency culture, which has reduced employers' propensity to pay for training and limits the market for fee-for-service work. Bespoke provision of this nature may well be more immediately relevant to employers' business needs than full qualifications, especially for SMEs, but many employers are reluctant to pay for this.

The Train to Gain program also provides skills brokers, who act as intermediaries to help employers to identify their skills needs and source the supply of skills training. However, their success in attracting employers who would not otherwise have taken part in training has been limited. There are also concerns that too much emphasis on brokerage may hinder the development of direct and long-term relationships between VET providers and employers. Brokers may be particularly useful in securing the involvement of hard-to-reach small firms, but this is a difficult market and does not lend itself to the achievement of short-term targets set for the brokerage service.

A demonstration of the onus placed on employers to drive up demand for skills is the skills pledge initiative, launched in 2007 as part of the Train to Gain program. Employers are exhorted to make a voluntary, public commitment by the leadership of a company or organization to support all its employees to develop their basic skills, including literacy and numeracy, and work toward relevant, valuable qualifications to at least level 2.

Despite the offer of free training, the brokerage service and incentives such as the pledge, take-up of the Train to Gain offer has been lower than anticipated. The emphasis on full qualifications, often at an inappropriate level, is thought to be a major reason for this. Flexibilities introduced in 2008, plus the economic downturn, have strengthened employer take-up of Train to Gain.

Reforming the Supply of Skills

The UK government's voluntarist approach to industry involvement in VET is in stark contrast to the numerous quality initiatives and funding measures used to urge

providers to be more responsive to the demands of industry. One of these introduced the requirement for 3-year development plans for colleges and providers, which set targets to improve in a number of key activities, including employer engagement.

A review of the employer-engagement targets revealed a diverse and uncoordinated activity. A broad range of views on what constitutes employer engagement was evident, suggesting the lack of a shared definition. The review proposed a typology for employer engagement, based on a number of key purposes for engaging employers in post-16 learning, which may help to clarify the part played by employers and ensure that their roles are appropriate in different circumstances. The typology and how it relates to targets set by providers and more general applications is shown in **Table 1**.

Since then, efforts to reform the supply of education and training post-16 have continued. LSC is to introduce measures of success that describe key dimensions of colleges' or providers' performance, which will include responsiveness to employers. A standard for employer engagement and vocational excellence the Training Quality Standard (TQS) is also now available, which will provide accreditation for providers' responsiveness to employers.

Alongside these activities, a major program of staff and management training to develop more responsive approaches to employer engagement is now in place, led by the learning and skills improvement service (LSIS). While this has been well received, it is evident that there is a substantial culture shift required to move VET providers' focus from the needs of individual learners to the needs of employers.

The combination of funding measures, quality requirements, and quality improvement may bring about the changes required to secure a VET system that is in tune with industry's requirements, but this is a long-term proposition. There are also tensions in reconciling colleges' and training providers' mission to develop individuals and communities, for which government and funding bodies have also set targets, while serving the needs of industry.

Relevance of the VET Curriculum

The education and training sector is often seen by employers to be remote from the realities of the world of work and unable to keep abreast of changing needs. Another tactic to increase industry's involvement in VET has been to develop more specialist provision, geared up to meet industry's specific needs. In Australia, this is demonstrated in the new technical colleges. In England, the centers of vocational excellence (CoVEs) program set out to improve radically the capacity of the further education (FE) sector to deliver high-quality learning in specific vocational contexts by developing specialist resources and staff with strong links to employers. There are now over 400 CoVEs,

Table 1 A typology for employer engagement

<i>Type of engagement</i>	<i>Examples of targets set</i>	<i>More general examples</i>
<i>Employers as stakeholders</i>	<ul style="list-style-type: none"> ● Increase by 10% students taking part in industrial/business visits 	<ul style="list-style-type: none"> ● Providing work experience places
Providing leadership through involvement in the design, development, management, delivery, and assessment of learning	<ul style="list-style-type: none"> ● Benefiting from speakers from the world of industry taking part in work experience ● Increase numbers of employers involved in advisory boards from 50 to 80 ● Increase employer involvement in assignments from 10 to 20 ● All vocational sectors to have employer advisory panels ● Increase the number of employers involved in the design of learning programs within the college's Center of Vocational Excellence (CoVE) 	<ul style="list-style-type: none"> ● Acting as a visiting speaker ● Advising on curriculum and its assessment ● Participating in college governance
<i>Employers as consumers</i>	<ul style="list-style-type: none"> ● Increase the number of sponsoring employers by 12% 	<ul style="list-style-type: none"> ● Using training needs analysis (TNA) services to identify workforce-development needs
Purchasing diagnostic services and skills development from LSC-funded providers	<ul style="list-style-type: none"> ● Increased income targets, increasing the range of employer contacts and networking ● Customized provision through an enterprise unit full cost increased by 5% ● Over the 3 years of the plan (name of college) will work with at least 200 SMEs, and the college will increase its revenue framework with employers by 10% 	<ul style="list-style-type: none"> ● Taking advantage of information, advice, and guidance (IAG) services to source training provision ● Using customized day release or regular provision as part of company training ● Buying bespoke training for updating ● Using WBL provision (e.g., national vocational qualification (NVQ) training and assessment) ● Using national qualifications to select new staff and upskill current staff
<i>Employers as strategic partners</i>	<ul style="list-style-type: none"> ● Expand links with providers and develop an employers' forum through links with trade associations to provide the college with LMI on the needs of employers 	<ul style="list-style-type: none"> ● Using providers as sources of support for business development
Sustained interaction between employers and the planners and providers of learning	<ul style="list-style-type: none"> ● To establish a structured workforce-development agreement with at least 25 employers in the priority sectors of manufacturing, care, retail, and construction ● Set up in partnership with an employer a dedicated training facility for industrial updating/training courses 	<ul style="list-style-type: none"> ● Collaborating with planners in developing new provision for the benefit of own company and wider sector ● Contributing in cash and kind to new or updated resources for learning-joint ventures and sharing training facilities ● Sharing or subsidizing specialist staff

Adapted from Hughes, M. (2004). *Reviewing the Impact of Employer Engagement Targets*. London: LSDA.

but the extent to which they have developed stronger links with industry varied enormously. An evaluation of the CoVE program concluded that:

Good progress has been made in the identification of skills priorities and improvements in arrangements to consult with employers in the planning of provision, particularly in engineering, construction and care. There is clear evidence of a positive change in employers' attitudes towards training and their willingness to become more closely involved in its delivery, most notably in CoVEs in engineering, care, and hospitality and catering. However, many employers remain reluctant to meet the costs of training. Most CoVEs in care, construction, and engineering have developed flexible modes of delivery to meet employers'

needs. This is less evident in CoVEs in ICT and in hospitality and catering.

Also that:

Most CoVEs have invested well in developing industry-standard learning environments. Construction and engineering CoVEs in particular have benefited from employers' donations of specialist equipment. Employer sponsorship in hospitality and catering CoVEs has been more limited.

CoVEs received premium funding for the first 3 years of operation, which enabled them to invest in equipment and staff development. However, few CoVEs have put in place plans to replace this funding from other sources and the

reluctance of employers to pay for training will severely restrain their ability to maintain their excellent provision.

More recently, the government proposed the development of a new network of national skills academies (NSAs). These are intended to be employer led, forming a strong network in each sector linking CoVEs with universities, training providers, and specialist schools. The aim is to establish 12 NSAs by 2007/2008 and over time to support one in every major sector.

The first of the NSAs to be established – the Fashion Retail Academy – is supported by major retailers including The Arcadia Group Ltd, which includes the popular high-street brands such as Next, and Marks & Spencer. The academy combines training in retail business and fashion education to introduce the practical and vocational skills needed for the world of fashion retail. Students have access to state-of-the-art technology at the resources of the retail partners' organizations. Teaching is provided by both college and industry staff. Students are given work placements and industry master classes, delivered by key people from the fashion retail industry.

The curriculum has been specifically developed for the Fashion Retail Academy and is fully accredited by nationally recognized qualifications. Students are encouraged to retain or take up paid part-time employment in fashion-retail companies, to expand their skills and put the theory taught at the academy into practice.

The establishment of more academies is proving to be difficult, mainly in relation to securing the required level of funding from employers, and in sustaining the long-term commitment to skills development that the academies require.

Conclusions and Issues

VET systems are facing a huge challenge in re-orientating their mission, purpose, and ways of working to meet the requirements of employer responsiveness. Greater clarity in articulating the role and purpose of employer engagement would support a more coherent approach to target setting and make better use of employers as a strategic resource for learning.

A major policy goal for many governments in reforming their VET systems is to make these systems more employer facing. In the United Kingdom, the current preoccupation is to ensure VET providers are demanded, that is, responsive to employers' requirements rather than continuing to provide their established inventory of courses. The quest to reposition employers as the principal players in skills systems rests on three elements.

The first of these is the creation of employer-led sector bodies responsible for shaping training strategies for their occupational areas. The strongest of such systems can be found in the Netherlands where sector bodies

(knowledge centers) are at the heart of the VET framework, with responsibility for occupational-competency standards, accreditation of work-based trainers, quality control of examinations, and approval of company training schemes.

Very few countries have achieved such a powerful sector-based framework as the Netherlands, though many have sector-skills bodies, which exercise considerable influence, for example, the Australian industry skills councils and their training packages, which create the framework for the recognition and assessment of job skills. In Canada, the tripartite sector councils have led the development of a culture of learning across their sectors. But often, and certainly in the United Kingdom, sector bodies have faced real challenges in representing the views and needs of very diverse sectors, and of SMEs in particular. As such, they are unlikely to serve as alternatives to direct engagement between providers and businesses at local level. If they are to achieve credibility, sector-skills bodies need appropriate levels of resource. Canadian sector councils are fully funded by government, which is unusual, but these were originally intended to become self-financing. In South Africa, the 27 sector education and training authorities are financed by a 1% of wage-bill levy across the private sector.

When such clear revenue streams do not exist, there is a danger that the sector-skills organizations will lack authority and dissipate their efforts in chasing money, projects, and short-term initiatives. This undermines their ability to achieve clarity of role and take a strong leadership position on strategic cross-sector-skills issues. Seeking further funding from employers may cloud the issue and be perceived as paying twice for the same service.

The second mechanism for employers to gain real purchase on the skills system is their relationship with providers and the qualifications system. In the United Kingdom, the Leitch review has proposed that the SSCs be given the power to approve vocational qualifications for eligibility for public funding. This approach has been challenged by the education and skills select committee of the House of Commons as being potentially bureaucratic and less responsive to employer needs. There is also evidence from Finland and Sweden that highly valued VET systems require well-articulated, flexible, progressive qualification routes, which almost certainly means a multiple-stakeholder route. Too much emphasis on employers securing a consensus from employers on their needs and how they should be met beyond a superficial level is difficult for a number of reasons:

- Employers are not a homogeneous group—even within the same occupational sector. The size, success, and maturity of the company and its market position may be a stronger influence on skills needs than the specific demands of the sector. Establishing long-term groupings based on these characteristics would be very difficult, given their dynamic nature.

- There are difficulties in distinguishing between employers' wants and needs, and in establishing long-term priorities for development that will benefit the economy and society in general as well as individual organizations.

Reliance on employers strategically to drive the supply of skills may then be dangerous, producing short-term, instrumental solutions that do not add up to an effective vocational-qualifications framework.

Finally, employers can be central to the VET system through their role in raising demand for skills, usually via financial-incentive schemes. In France, there is a clear train-or-pay (the levy) culture resulting in a strong continuous professional-development program funded by levy and backed up by a statutory worker entitlement to learning. Interestingly, despite this legislative imposition on industry, there is a high level of consensus in France about this investment in skills updating. The Netherlands has a powerful fiscal incentive scheme that provides firms with tax relief on trainees' wages. The key to the effectiveness of these measures is strong linkage through the entire VET system to achieve supply equilibrium with the incentivized demand. There is also a danger that highly centralized schemes cannot cope with internally complex sectors producing homogeneous solutions to a heterogeneity of demand.

Non-Completion in Vocational Education and Training: Issues, Patterns and Possibilities

S Lamb and A Walstab, University of Melbourne, Melbourne, VIC, Australia

© 2010 Elsevier Ltd. All rights reserved.

Research into noncompletion in some sectors of education, such as in schools and higher education, is well developed. However, comparable research into noncompletion in vocational education and training (VET) is more difficult to find and certainly less systematic. Despite this, in many countries, there has been a growing interest in the monitoring of levels of noncompletion and investigation of the causes and consequences. Reducing noncompletion rates is an important goal for both educators and policymakers. Yet, there is a good deal of controversy about how best to measure completion and noncompletion rates. This is partly due to the fact that completion and noncompletion have become less easy to define. One reason for this is that patterns of education and work have become more varied. Some people are taking more time to study and spending varied periods of time in and out of education and training courses. These patterns make it more difficult to establish cut-off points for estimating noncompletion. Another issue is related to intentions. Some participants enrol in courses but only intend to complete part of the course, such as a unit or module. While such participants are course or qualification non-completers, they are completers in terms of their original intentions.

In addition to these matters, noncompletion in VET does not always equate with failure. Noncompletion may signify the achievement of desired goals, either in the sense that skills have been gained, employment outcomes realized, or articulation to further or higher studies successfully negotiated. Given that many students return to study fairly soon after withdrawing from a course and that a substantial number return some time later, the notion of noncompletion from a lifelong learning perspective is less meaningful than it once was. However, for the most part, noncompletion remains a serious problem, especially for students from disadvantaged circumstances and for students in particular fields of study and types of courses.

The main aim of this article is to examine the issue of noncompletion in VET, to look at how it is defined, at some of the different ways it is measured, and to provide some estimates of noncompletion using recent data. In addition, it also examines some of the reasons for non-completion and, following this, presents a brief outline of the sorts of strategies employed to reduce noncompletion. A brief list of further readings of key publications on the topic is also provided.

Defining and Measuring Noncompletion

Internationally, the drive for accountability now makes for stronger emphasis on completion data as a key performance measure in VET. Completion and noncompletion, though, are not straightforward to define or measure. In an environment where lifelong learning is promoted and encouraged, with increasing emphasis on course transfers, recognition of prior learning, and articulation between courses and sectors, traditional measurements and conventional indicators may be inadequate. Added to these factors is the issue that VET provision itself is becoming increasingly complex. There is a broader range of users, increasingly diverse across different age groups and educational backgrounds, a broader range of courses and programs and more varied arrangements for delivery.

International comparisons of VET noncompletion are made more complex because of some of these issues. Some of the difficulties are related to institutional and organizational differences: there are variations between countries in how qualification structures are organized, the range of VET offerings, and the modes of delivery. There are also differences in levels of access to vocational programs, as well as in local labor-market contexts and in the demand for skills.

Other difficulties relate to how noncompletion is measured. The Organization for Economic Cooperation and Development (OECD), for example, publishes survival rates for tertiary type-B programs. Tertiary type-B programs are classified at the International Standard of Classification of Education (ISCED) level 5, the first stage of tertiary education, and focus on vocational and occupation skills for direct entry to the workforce. While the programs have a minimum duration of 2 years full-time enrolment, in some countries they can extend to 5 years of full-time study. They are, however, typically shorter programs than those of tertiary-type A, which are largely theoretical and generally lead to a traditional university-degree qualification (OECD, 2007).

The survival rates in tertiary-type B education for 2004, published for 17 OECD countries, are given in **Table 1**. The completion rates represent the number of graduates in 2004 divided by the number of new entrants n years before, where n is the number of years required to complete the course. While on average two-thirds of students successfully complete tertiary-type B qualifications,

Table 1 Survival rates in tertiary type-B education, 2004

OECD countries	Percent
Belgium (Fl.)	85
Czech Republic	61
Germany	79
Greece	35
Hungary	48
Iceland	76
Ireland	69
Japan	87
Mexico	63
New Zealand	42
Poland	74
Portugal	58
Slovak Republic	77
Spain	79
Sweden	68
Turkey	79
United Kingdom	53
OECD average	67

From OECD (2007). *Education at a Glance 2006*. Paris: OECD, Table A3.6

this figure conceals considerable variation between countries. Rates range from 35% in Greece and 42% in New Zealand to 87% in Japan and 85% in Belgium.

This method for calculating course-completion rates – taking the ratio of the number of students at the point of entry to exit over the length of the course – commonly used in the higher education and schools sectors, has a number of limitations in the VET context. By assuming constant student flows, these survival rates do not account for those who do not complete within the normal time but are still eligible to complete, and fully intend to do so, which includes students enrolled part-time and those taking a sanctioned break from study. Nor do they account for students who have transferred to another course at or above the same qualification level. The growing flexibility in the delivery of VET, whether this be online or in the workplace, along with the modularization of the curriculum, mean that this methodology increasingly excludes a larger proportion of learners in VET. Variations in any of these factors will impact on the reported rate of completion.

Countries with centrally collated administrative data collections are well placed to measure and report on non-completion in vocational programs. England, for example, uses such a collection for the annual reporting of benchmarking data. These data, based on individual student record files and published by the learning skills council, include measures of success, retention, and achievement. Success rates are calculated as the number of learning aims achieved, divided by the number of commencing students, excluding those who have transferred to another course within the same institution (LSC, 2007). The overall success rate in further education in the 2005–06 academic year was 76%. Retention rates on the other hand are calculated by

dividing the number of completed qualifications by the number commencing, excluding those who transferred. The figure for 2005–06 was 87%. The achievement rate represents the ratio of the number of students who achieved qualifications to the number that completed qualifications (88% in 2005–06). The success rate is the product of achievement and retention rates.

Where there is no centralized collection of VET administrative data, national reporting of noncompletion must rely on other sources. In the United States, the National Centre for Educational Statistics draws on its cohort-based longitudinal studies, based on national samples of students who are tracked over time to map pathways and outcomes, including measures of course completion. The 2004–06 beginning postsecondary students longitudinal study (BPS) tracks a nationally representative sample of students who began postsecondary education for the first time in 2003–04, surveying in 2004, and again in 2006 (NCES, 2007).

Longitudinal studies can allow for more flexibility in the measuring and reporting of completion rates, with the ability to take into account student movement across institutions and courses. Continuing students taking longer than usual to complete can also be identified. Findings from the BPS follow-up survey in 2006 report these figures as degree attainment and persistence for students enrolled or with degree plans in vocational certificate programs (which usually take less than 2 years to complete) and associate's degree programs (2–3 years duration) in public 2-year institutions (usually community colleges). For those with certificate degree plans in 2003–04, 31.8% had completed certificate or associate's degree, 21.2% were still continuing, and 47% had discontinued without completing their qualification. Those with initial associate-degree plans had a completion rate of 16.1% (attainment of a certificate or associate degree), a continuation rate of 39%, and a noncompletion rate of 44.9% (NCES, 2007:11).

Levels of Noncompletion Among Different Groups

Aggregate completion rates mask wide variations in completion and noncompletion for different groups. VET has a diverse clientele; reporting completion rates for different groups helps providers to target programs to where there is the most need. Examples of noncompletion and completion rates for different groups by selected course and student characteristics are given in **Table 2**.

Partial Completion

Traditional measures of VET course completion, like the ones discussed above, are based on the assumption that all students enrolling in the course intend to complete the full qualification. Notions of lifelong learning, on the

Table 2 Completion rates by course and student characteristics

<i>Course characteristics</i>	
Length of course	England (LSC 2007): success rates for short courses (up to 24 weeks, usually 12 weeks) in 2005–06 were 84.6% and 69.9% for long courses, thus rates decreasing with increased length of course.
Level of course	Australia (Shah & Burke 2003): withdrawal rates tend to increase with Australian Qualification Framework (AQF) level of the course. The withdrawal rate for Certificate I (lowest level) courses was 25.9% and 27.4% for Certificate II courses. This increases to 36.7% for diploma level and 35.1% for advanced diploma. These figures exclude partial completers.
Field of study	Ireland (Kinsella and Roe, 2005): percentage completion rates by ISCED area of study show large variations across course types, ranging from 60.3% for engineering, manufacturing, and construction to 87.4% for agricultural and veterinary (certificate and diploma courses reported together).
<i>Student characteristics</i>	
Age	United States (NCES 2007): tables reporting persistence show that the proportion of students who discontinued from all education and training in 2006 without obtaining a certificate or associate's degree increased with age of enrolment. For example, 33.9% of those aged 18 years or younger on enrolment had withdrawn compared to 39.3% of those aged 19 years. This increased to 53.7% of those aged 20–23 years and 55.3% aged 24–29 years, and 57.5% of students aged 30 or older.
Gender	New Zealand (Scott 2005): 35% of females who enrolled in certificate courses in 1998, and 34% of females in diplomas had successfully completed by 2002 compared to 26% of males enrolled in certificate courses and 28% of males in diplomas.
Ethnicity	England (LSC 2007): success rates reported for further education institutions by ethnicity showed a range from 69% for students from a Black Caribbean and other background to 76% for Indian students and 77% for White students.

other hand, emphasize the acquisition of skills and qualifications over the longer term, often in smaller, modular components. Indeed, the flexibility of VET systems encourages self-paced learning. In Australia, for example, researchers have estimated that nearly half (49%) of all technical and further education (TAFE) student enrolments result in partial completion of a course (Foyster *et al.*, 2000). This study of student flows through TAFE institutes in the mid-1990s defines partial completion as completing one or more modules within a course, not failing any other modules and having exited the system (Foyster *et al.*, xii). The completion rate (completion of a full course) was estimated to be 24%, which was lower than the noncompletion rate (representing academic failure) of 27%. Partial completion in this context is viewed by the researchers as a positive outcome. However, as Davies (2001) argues, without data on student intention, it is not possible to isolate partial completers who intended to complete the full course from those wanting to complete modules only.

While administrative data collections in the United Kingdom and Canada record student intentions and plans on enrolment (in the form of, e.g., qualification aims), this is not common practice (Lamb, 2005). In a discussion regarding the value of this measure, Lamb (2005) points to methodological implications, including the need to collect this data on enrolment rather than on exit, although it needs to be acknowledged that motivations and intentions are subjective and can change over time.

Information regarding intent may not routinely be collected in many countries; however, it is often possible to compare the characteristics of those who complete a full qualification (graduates) against those who complete only part of a course before exiting the VET system (partial completers). In Australia, such comparisons reveal that the age profile of graduates is younger than for partial completers, with 40.4% of graduates aged between 15 and 24 years, compared to 22.9% of partial completers. Conversely, 22.9% of graduates are aged 45 years or over, compared to 36.7% of partial completers. Partial completers are more likely to come to VET with higher levels of educational attainment, with 26.5% having completed a Certificate IV or higher prior to enrolment, compared to 22.9% of graduates. This could suggest that partial completers are building on qualifications they have already achieved with specific skills and competencies, and therefore pursuing a full course qualification is less important than for the younger graduates who are more likely to be building on school-level study.

Reasons for Noncompletion

Understanding why some learners tend not to complete their study is the key to developing policies or interventions

to help improve chances of completion. Yet, identifying the causes of noncompletion is a difficult task because the process is influenced by an assortment of factors related to individual students, their circumstances, backgrounds and motives for study, and to the college and community settings in which they are located.

Some of the complexity is illustrated by the variety of reasons that learners report for not completing. In a study of 2180 learners in the United Kingdom who withdrew from further education and work-based learning courses without completing, course-related reasons for withdrawal were mentioned by 32%, changes in circumstances were mentioned by 28%, and work-related reasons were mentioned by 20% (Simm *et al.*, 2007). The most specific reasons were that the course was not what they wanted to do or they changed their mind about the course (14%), poor quality of teaching (11%), the course not being at the right level (11%), and work commitments (8%).

But these reasons do not necessarily get at the underlying causes behind why learners withdraw from study, particularly the causes that have shaped from earlier-in-life attitudes, behaviors, and experiences of study and learning. Moreover, as many factors may contribute, it is difficult to identify the various factors and the interconnected nature of their impact on the decision to withdraw from study. The approach of some researchers to this issue has been to develop theories and conceptual models of noncompletion using a variety of qualitative and quantitative research methods, most often elaborated by researchers in the United States. Spady (1971), for example, proposed a model mapping the influence of five predictors (achievement, academic integration, course choice, socioeconomic status (SES), and gender) relayed through a fifth variable (social integration) on decisions by individuals about remaining in study. Tinto (1975), building on this work, developed a more elaborate model, but maintained a focus on the importance of student integration into the social and academic life of college and the sets of factors that shaped these aspects of student engagement. Other models have also been developed, varying in their emphasis, in the different sets of factors, and the importance placed on different precursors (see, e.g., Chen and Thomas, 2001; Sandler, 2000; Bean and Metzner, 1985). Basically, the models treat noncompletion as a result of the student's interaction and engagement with the institution (as a learner and a social participant), with engagement mediated by a wide range of background or input factors such as social, educational, and economic background.

Drawing on this work, it is possible to identify a couple of broad perspectives for understanding the reasons for noncompletion. The first is what could be described as sets of barriers associated with institutions themselves and the way they operate and are organized as places of learning, including quality of teaching, support for

learners, flexibility, and monitoring. The second is the range of factors associated with what individuals bring with them to the place of learning, including their family context, their intentions, previous educational experiences and attainment, work situation, perceptions, dispositions, interests, and motivations. Both perspectives reflect on the way contexts of learning are constructed and operate.

Research on institutional barriers focuses on the way individual's experiences are shaped by institutional settings. Empirical research on noncompletion has identified a number of factors associated with VET providers that influence the likelihood of completion. For brevity, only a few are mentioned here. One is the quality of teaching. Research in several countries has demonstrated a relationship between quality of teaching and attrition rates. In Australia, for example, a study of VET noncompleters who had attended TAFE colleges found that students rated poor quality of the teaching staff and teachers not having relevant industry experience as key reasons for not continuing their programs (Callan, 2005). Similarly, Polesel *et al.* (2004) reported that students dissatisfied with the quality of teaching were far more likely to leave without completion than students who were satisfied. In the United Kingdom, several studies have found that satisfaction with teachers and teacher support correlates with perseverance and completion in ways which suggest that for many, the quality of teaching and support are very important (Davies, 1999). Studies in Canada and the United States have also identified quality of teaching as a predictor of noncompletion (see, e.g., Mueller, 2007).

Factors associated with quality of academic and social interaction are also important influences on student experiences and decisions. These include features such as student-staff contact, student interaction, active learning, prompt feedback, time on task, high expectations, respect for diverse talents and ways of learning, and inclusive, and affirming environments where expectations for performance are clearly communicated (Wetzel *et al.*, 1999; Simm *et al.*, 2007).

Research focusing more on the backgrounds and attributes of students – such as their values, attitudes, behaviors, family circumstances, work, educational history – has identified a range of factors which influence decisions to complete study or not. Important among these are negative attitudes toward formal study often associated with low educational attainment. Leaving school without a qualification, now more prevalent in many countries among older age groups, can often follow low school achievement or academic failure and promotes a lack of confidence and low self-esteem in relation to study and training. These experiences can predispose learners to noncompletion, particularly if courses are not quite as learners expect, or they are difficult, or formal study renews feelings of uncertainty and undermines confidence.

Financial considerations are often reported among factors that lead to noncompletion. The impact of costs may be felt unevenly across different age and social groups. Although lack of income support is often cited as a deterrent to continued participation in study, it tends to be associated with other barriers associated with the structure of provision and student dispositions toward education and training. Dispositional factors are a powerful deterrent to participating in education and training among people with low levels of attainment, and together with other obstacles, such as cost and place, compound the barriers to participation.

Linked with costs are issues with work and family responsibilities, and childcare. This can be a major issue for females and for particular age groups (such as 25–39-year olds). Accompanying these issues is the problem of time constraints as well as other factors including location and distance from place of study.

It is very important to recognize that not all noncompletion is negative or needs to be addressed. Students can leave courses of study for a variety of positive reasons such as changes in their personal circumstances and the attraction of alternative employment and training opportunities. Some learners may never have intended to complete all of the components leading to a certificate, or they obtain from the parts of the course they undertake all that they want without fulfilling the requirements for formal completion. Intentions, plans, and circumstances may change during a course of study. Noncompletion, therefore, is not necessarily associated with failure or negative outcomes, since many learners can achieve what they want from their study even though they may not complete it in the formal sense.

Strategies to Address Noncompletion

The broad perspectives underpinning research on reasons for noncompletion in VET suggest that there are different sorts of strategies needed to improve outcomes. Learners who tend not to complete their courses of study have diverse characteristics and contexts which call for initiatives that can respond to their varied circumstances and needs. As there are interrelated and multiple causes associated with noncompletion, successful interventions need to involve comprehensive, multiservice approaches to providing support.

In the body of research on the effects of the backgrounds and attributes of students, initiatives focus on the physical, material, and dispositional barriers to learning among students, particularly those with low educational attainment and for those from low SES backgrounds.

In terms of financial constraints, various schemes have been developed. Individual learning accounts, student loan schemes, vouchers, reductions in fees for the poor,

paid education leave, and systems of deferred fee payment have been implemented in different countries as mechanisms to support student learning in vocational education (Haukka *et al.*, 2004). Income support schemes are another strategy. In Australia, for example, youth allowance (YA) was introduced to encourage young people from poor families to participate in education or training if they lack the skills to find full-time employment. It is a means-tested income support scheme providing participants with funds while they learn. Evaluations suggest that it has been influential in encouraging greater participation and persistence (Lamb and Robinson, 2001; DFaCS, 2002). Similar schemes exist for different target groups, such as single parents. An example is the jobs, education, and training scheme in Australia which is designed to assist single parents meet the costs of education and training.

Structural or systemic changes are also important in supporting learners more likely not to complete. The curriculum content and institutional delivery mechanisms of education and training can be significant barriers. Negative attitudes to education and training are often the product of an individual's early experience of failure in formal education or training. One way of overcoming such dispositional barriers is to ensure that the content and structure of education and training provision targeted to reluctant participants is different from what they have experienced in the past.

Summaries of initiatives proposed to address noncompletion in VET, based on the broad individual and institutional perspectives on influential factors, suggest the following types of strategies:

- improving and extending advice and guidance services;
- paying particular attention to the early stages of programs of learning (student induction, initial assessment);
- closer monitoring and follow-up of poor attendance;
- early identification of underperforming students or students who are at risk;
- the early diagnosis of student requirements for basic skills and additional learning support and the provision of such support as far as possible within student learning programs;
- the development of a curriculum framework which is appropriate for intended students;
- target setting combined with formative assessment and feedback; and
- improvements to teaching (Davies, 2006; Martinez, 2001; McGivney, 2003).

The focus of strategies and policy effort should be on creating the conditions for effective learning and personal growth that underpin quality education and training programs. This calls for a combination of measures responsive to differences in individual learning needs, on the one

hand, and to the creation of quality programs and learning environments, on the other.

Planning and Policy Development for Technical Vocational Education and Training Systems

R Maclean, Hong Kong Institute of Education, Hong Kong, People's Republic of China

M Pavlova, Griffith University, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Planning and policy development in any organization can be analyzed and understood through a number of approaches. Traditionally, policy has been conceptualized as a program of action. Any policy has usually been presented as a “rational plan, consciously articulated by an authoritative body, usually a government or government agency, codified in text such as law or regulation which articulates clear expectations for behaviour” (Bascia, *et al.*, 2005: xii). This tidy linear process in which policy progresses from one stage to another and where policy is defined as whatever governments choose to do, or not to do (Dye, 1992) has been criticized by policy researchers from different theoretical standpoints (e.g., liberal, neoliberal, positivist, or post-structural approaches). There is now a considerable body of theoretical and empirical work that views the nature of planning and policy development as “far more complex, dynamic, and interactive than any of the traditional linear or staged models suggest” (Walford, 2003: 2). The complexity of the process has become an important feature of a number of well-known frameworks for policy analysis, for example Ball’s (1993, 1994) and the Taylor *et al.* (1997) models. Taylor *et al.* (1997) focus on three aspects of policy: context (economic, social, and political factors that give rise to an issue emerging on the policy agenda), text (broadly refer to the content of the policy), and consequences (differences in implementation). Ball’s (1993, 1994) model of policy as text and policy as a discourse provides another way to understand the complexity of policymaking. Both frameworks are widely used in the literature (e.g., Bell and Stevenson, 2006; Olssen *et al.*, 2004). For example, Olssen, *et al.* (2004) in developing Ball’s approach argue that: “Education policy must be contextualised both nationally and globally as a transformative discourse that can have real social effects in response to contemporary crises of survival and sustainability” (p. 3).

The purpose of this article is not to analyze the differences between the various approaches to policy development and policy analysis but to explore a number of important considerations in terms of technical and vocational education and training (TVET) policy development, such as scope, scale, principles, and theoretical justifications. The point that we are making is that

TVET policy is multidimensional, is value-laden, exists in particular contexts, interacts with policies in other fields, its implementation is never straightforward, and it results in unintended and intended consequences. Policy-making for TVET is mainly a state activity and the state is regarded as a complex and nonunitary entity of competing parts that adds an additional aspect to any analysis.

Complexity of TVET

Scope

The great diversity of TVET systems worldwide illustrate a range of policy options that have been used and are available to shape and reform them. In trying to classify existing TVET systems, researchers have considered a number of factors, including place of learning (typically, vocational schools and the workplace/enterprise workshops); type of regulation (government, market, and tradition, see e.g., Greinert, 1995); or nonformal/informal learning as a leading criterion for classifications.

In reality, combinations of these patterns across the above dimensions can be found in particular countries and all these dimensions should be accounted for when undertaking planning and policy development in particular countries.

Scale

Another component of complexity in policy formulation for TVET can be related to the scale of the policy within (any) TVET system. Improvements within a TVET system can be carried out in terms of a particular element of the system, such as qualification standards and specialization; articulation with general education; assessment and certification for achievements; methods of curriculum development; governance; labor-market analysis; financing; legislation; access and admission; provision of training places; special target groups; institutional arrangements for delivery; and, information and guidance. Alternatively, improvements can be made to the system as a whole which is known as a systematic reform. Systematic reform is built upon the assumption that changing most or all elements of the system is more likely to lead to TVET improvement.

Coherence

In planning TVET systems and in developing policies, coherence across sectors such as the interests of different institutions involved and different policies should be taken into consideration. TVET is situated at the border between education and work. To contribute successfully to economic development TVET policy must outline: “coherent and integrated changes in a range of related institutions, including the economic, human resources and [TV]ET agencies of the state, the labour market, the social organisation of work and in the forms of employer and trade union organisation” (Kraak, 2006: 3).

A coherent approach to TVET policy development needs to relate it to a range of other policies and issues, including general education policy (both school and university); youth policy; adult education policy; vocational rehabilitation; public service employment and remuneration conditions; economic policy; private-sector and enterprise-promotion policies; industrial development policies; and labor-market and employment policies (Krönner, 2006). Thus, TVET policy should be closely linked with other policy areas and institutions, in particular to those dealing with education, work, employment, and economic development.

Globalization

The strategic direction of much of education policy is frequently justified as a means to enhanced economic development leading to a more competitive economy, greater productivity, and increased wealth. Investment in education and training is believed to provide the key to national competitiveness. Globalization processes and the pressures for global uniformity have the tendency to strengthen the Anglo-American influence on policy development and raise concerns as to the appropriateness of such an occurrence:

Anglo-American scholars continue to exert a disproportionate influence on theory, policy and practice. Thus a relatively small number of scholars and policy makers representing less than 8% of the world's population purport to speak for the rest. (Walker and Dimmock, 2002: 15)

However, many recent studies have shown that globalization-driven policy developments are sometimes so sharply modified by national contexts that the output they promise would vary greatly (Rhoten, 2000; Welmond, 2002; Astiz *et al.*, 2002) if implemented in another context. Therefore, for the policy formulation, the specific context of a particular country should be taken into account to identify an adequate response to immediate and future labor-market needs. It is important to “identify that way in which global pressures have driven state restructuring. . . and the particular way in which restructuring at the

micro-level shapes policy development at an institutional level” (Bell and Stevenson, 2006: 33). What is required are the analyses of the state, economy, and models of policy development that recognize different cultural contexts. “Generally, the more ‘loosely-coupled’ state structures are, the more opportunity there is for policy variation at the local level” (Bell and Stevenson, 2006: 30).

Principles of Policy Planning

At the level of global policy, principles for policy planning and administration have been established in the joint document by the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the International Labour Organization (ILO): *Technical and Vocational Education and Training for the Twenty-First Century* (UNESCO and ILO, 2002). The document states that policy should be directed to both the structural and the qualitative improvement of TVET. The partnership between the government and the other interested partners must “create a coherent legislative framework to enable the launching of a national strategy for change” (para 9 a, p. 13). The UNESCO and ILO document presents five principles:

- “Planning should respond to national and, if possible, regional, economic and social trends, to project changes in demand for different classes of goods and services, and for different types of skills and knowledge in such a way that technical and vocational education may easily adapt to the evolving scientific, technological and socio-economic changes. This planning should also be coordinated with current and projected training action and the evolution of the world of work in both urban and rural areas.” (para 11, p. 14)
- “Policies for the structural improvement of technical and vocational education should be established within the framework of broad policies designed to implement the principle of lifelong education through creation of open, flexible and complementary structures of education, training and education and vocational guidance, considering the provisions of modern information technology in education regardless of whether these activities take place within the system of formal education or outside it” (para 13, p. 15)
- “Policy should be directed to ensuring high quality so as to exclude discrimination between the different educational streams. In this respect, special efforts should be made to ensure that national technical and vocational education seeks to meet international standards” (para 14, p. 16)
- “In order to ensure quality, responsible national authorities should establish criteria and standards, subject to periodic review and evaluation, applying to all aspects of technical and vocational education, including to the

greatest extent possible, non-formal education” (para 15, p. 16)

- “National policy should foster research related to technical and vocational education, with particular emphasis on its potential within lifelong learning, and directed to its improvement and relevance to the prevailing socio-economic context. This research should be carried out at national and institutional levels, as well as through individual initiative” (para16, p. 16).

These principles highlight the importance of national policies aimed at the quality of training, which can be achieved through structural change. These principles and approaches represent a traditional way of interpreting policy as a rational plan of action; therefore, the level of effectiveness of their application will be different for different countries. For example, with a state-guided labor market, Singapore might find these principles to be more useful than other countries where the labor market is less regulated. These principles provide a useful list of general rules that should be used creatively by governments.

Theoretical Frameworks

This section discusses a possible basis for theoretical frameworks that could provide a foundation for TVET policy formulation in both developed and developing countries. The first set of theories relates to the structural reform/policy formulation and the second set to the theories that shape our understanding of how humans learn.

The idea of an alignment between education, training, labor market, and economic policies can be underpinned by the theoretical arguments of the high-skills thesis, combined with what is described as the joined-up approach (Brown, *et al.*, 2001). The high-skills thesis has caught the imagination of policymakers around the world (p. 31). It was developed through the work of a UK team in the late 1980s and 1990s (see Finegold and Soskice, 1988; Finegold, 1991; Ashton and Green, 1996; Brown *et al.*, 2001). They argued that diversity and variability in economic performance are underpinned by social, cultural, and historical factors. Finegold (1991) explores the concept of equilibrium in terms of the self-reinforcing nature of the institutional networks that support the continuation of a given skills-formation system and economic development path. Any change of one variable without corresponding shifts in the other institutional variables is unlikely to lead to long-term changes in the social and economic system as a whole. Using this concept, Finegold identified two ideal types of economic and education/training (ET) systems: an institutional framework based on low-skills equilibrium (LSE) and one based on high-skills equilibrium (HSE). Finegold *et al.* viewed Britain as being typical of an LSE

society where “the majority of enterprises are staffed by poorly trained managers and workers produce low quality goods and services” (Finegold and Soskice, 1988: 22). LSE institutional factors identified by Finegold discourage and constrain any movement toward a high-skill alternative. They included uncoordinated state policies, incoherent TVET policies, low educational level of the majority of workers, minimal state intervention in TVET, and labor markets. Another analysis (see Brown, *et al.*, 2001) demonstrates that there is some presence of high skills in Britain. Thus, joined-up or cross-sectoral policy coordination and complementarity are associated with a high-skills thesis. Joining up is essentially an argument about the necessity for educational reforms to interlock with macroeconomic, industrial, and labor-market reforms so that the combined impact would influence the outcome in a significant and positive way.

A high-skills policy has been the center of economic, social, and educational policies in many Western countries. However, due to differences in context “there is no one recipe or blueprint for developing a high-skills economy” (Lauder and Brown, 2006: 37). Lauder and Brown (2006) identified four different types of labor market structures. An occupational labor market where education and training are closely related to the labor market; an internal labor market, where high general skills are provided by TVET and specific skilling is undertaken by corporations; and the state-guided labor market which is a demand-led (e.g., specific to Singapore where the state encourages high-end production and innovation and matches skills to the demand of the multinational corporations) market structure. All three types of labor markets have in common a close integration of TVET and the labor market. The fourth type of market, a flexible labor market, is characterized by a high degree of individualism, “in which the fit between education, training and the labour market is often problematic; there is considerable time spent in job search and work is insecure; and the flexibility is numerical, so that employers can hire and fire as economic conditions change” (Lauder and Brown, 2006: 39). Some authors are less critical of flexible labor market; however, there is agreement that more emphasis on the development of generic skills and good credentialing systems are important for this type of labor market to be successful. Each type of labor market influences policy development in TVET and the type of skills that are emphasized in the policy. If one accepts that the long-term aim of the economy is to achieve an HSE and capacity building, then contributing to achieving such a goal should be seen as an important function of TVET policy development.

Each country can be conceptualized within this framework, for example, high-skills society (Germany), developmental high-skills society (Singapore), bipolar high-skills/low-skills society (UK), and hybrid and

differentiated low-, intermediate-, and high-skills society (South Africa) (Brown, *et al.*, 2001; Kraak, 2006). TVET policy developers could use this analysis as a starting point for policy formulation.

Theories about human learning have shaped our views of the conditions necessary to support curriculum development and instruction. However, it should be noted that learning in TVET as well as learning at work, as such, are seldom the central focus of policy. “Rather, the typical situation is that policies that are targeted at something else include learning at work within their scope. In the process, learning at work is usually assumed to be, in an uncritical and ‘common sense’ way, simply the acquisition of discrete items of knowledge and skills” (Hager, 2005: 830).

Recent research on TVET (see, e.g., Staron *et al.*, 2006) argued that life-based learning (not work-based learning) was required for vocational education focusing on capability development and consideration of the learner as a whole person. According to Staron *et al.*, life-based learning is a win-win situation with benefits to both employee and employer, based on employees taking personal responsibility for their learning, based on the provision of “rich learning environments” (p. 49), which provides, according to Staron *et al.*: “performance, growth and opportunity. It is adaptive, self-facilitated, based on reflexive practice and uses any strategy appropriate to the task” (p. 49). This broad interpretation of learning views TVET as “a knowledge-based industry, where knowledge is its core business” (Staron *et al.*, 2006: 24). As argued in the *Life Based Learning* report (Staron *et al.*, 2006): the current period is one of rapid change where new ways of working and living are required. Staron *et al.* argue that a learning ecologies metaphor can be used to understand how we might work and live successfully. Staron *et al.* focus on the tendency of ecological environments to move to equilibrium as the key to the metaphor. Thus, when there is change (to work or life) this is regarded as a disturbance and we need to work to achieve equilibrium, and we do that by adapting. Rather than a model or a set of procedures, the focus of an ecological approach is orientation and thus “it offers a complex, diverse, dynamic and adaptive framework that gives us a fresh perspective on working and learning in contemporary environment” (Staron *et al.*, 2006: 27).

These two types of theories, one that relates to the economic aim of achieving an HSE and the other that focuses on the learner in coherent ways could provide a useful framework for policy development.

Cases Around the World

Policy development as a complex and multifaceted process can be identified through the product, the policy document, and the process in which implementation is as

important as formulation. According to Bell and Stevenson (2006), “It is important to understand the context in which policy development takes place – how policies emerge, how they form and take shape, and how they become lived through the actions of those engaged in the policy-development process” (p. 25). Smyth (1993) has emphasized the need to recognize the pivotal role of central governments in shaping policy.

This section examines four policies across developed and developing countries to illustrate the points discussed above. Two examples from England and Australia relate to policy as text or the content of the policy itself. They illustrate a capacity-building thesis within the lifelong learning paradigm. Two examples from developing countries relate to policy as discourse that gradually builds over time and sets boundaries to what actors are allowed to think and do. Discourses, then, as Ball (1990) summarizes them, “embody meaning and social relationships, they constitute both subjectivity and power relations” (p. 2).

The first example is the English participation policy (2007). The English document: *Raising Expectations: Staying in Education and Training Post-16* presented to Parliament in March 2007 (Department for Education and Skills, 2007) argues for the new policy on the basis that “the structure of the economy has changed dramatically, with an ever-growing dependence on more highly skilled workers” (1.5, p. 9). The goal of the policy is: “to stop young people dropping out of education or training before 18, because of the benefits that higher attainment and longer participation bring, to the individual young person, to the economy and to society” (p. 11). Continuing in education or training is seen as important to the economy, “which will increasingly demand more highly skilled employees” (2.2, p. 11) and the aim is to reach 90% participation in education or training among 17-year-olds by 2015. Measures across different areas already being implemented in England include: reforms to the 14–19 curriculum; changes to Key Stage 3; a major expansion of capacity in work-based learning; the Education Maintenance Allowance; the Youth Matters reforms, and others. Employers are playing an important part in providing training or releasing young people from work to undertake training. This policy is closely related to a high-skills thesis. It is also an example of a policy that addresses one issue across a number of sectors and positions it within some existing policies. The pressure of globalization is presented through the request to increase competitiveness of the economy.

Since the 1990s there has been a similar concern across Australia that young people are not gaining the right skills to compete in the global economy. Although the different state governments (who have responsibility for education) have responded in different ways, *Australia’s National Strategy for Vocational Education and Training 2004–2010*

(ANTA, 2003) developed at the national level, highlighted an attempt at a systematic approach toward TVET development in the country. Key objectives for vocational education and training (VET) that are formulated in the National Strategy 2004–10 highlighted:

1. the global economic competition as the reason for skills development (industry will have a highly skilled workforce to support strong performance in the global economy);
2. the end-user as a focus of the policy (employers and individuals will be at the center of VET); and
3. benefits for communities (communities and regions will be strengthened economically and socially through learning and employment and Indigenous Australians will have skills for viable jobs and their learning and culture will be shared).

In November 2003, state ministers endorsed the key performance measures for the VET system as part of the 2004–10 National Strategy. The key performance measures cover the following critical areas:

- Student participation and achievement in VET.
- Student employment outcomes and satisfaction from VET.
- Employer engagement and satisfaction with VET.
- VET outcomes for Indigenous Australians.
- Community engagement and satisfaction with VET.
- VET system efficiency (ANTA and NTSC, 2005).

Some of the strategies identified include: increase participation and achievement in TVET, particularly by existing workers; help clients navigate and interact with VET; improve the value, brand, language, and image of VET and public recognition of its employment outcomes; strengthen industry's role in anticipating skill requirements and develop products and services to meet them; make learning pathways seamless; improve quality and consistency; and facilitate access to international markets. This policy is an example of systematic reform, where participation (as in the English case) is just one component of the policy.

Both examples from developed countries represent competitiveness-driven TVET policies as governments sought to defend their global competitiveness by enhancing the productivity of the domestic labor force.

Two examples from developing countries come from Africa and Cambodia. Although education policies in developing countries can be closely related to donor priorities and perspectives, these cases provide illustrations of how policy can be used in different ways. On the one hand, international funds can be used to implement measures that are episodic and lack essential coherence. On the other hand, they can be used to provide partial financial support for a large-scale systematic educational reform.

Between the 1980s and 1990s, international donor funding in Africa was directed away from TVET and toward support for basic education. TVET provision was marginalized as the attention of policymakers was directed elsewhere (McLean and Kamau, 1999). However, during the late 1990s, two factors emerged: a growing crisis of youth unemployment and low levels of economic competitiveness. These factors became the main policy drivers in bringing skills back into the policy spotlight, particularly for the Southern African countries (Roberts, 2005: 50). One of the challenges facing educational planners is the need to develop a coherent policy on skills development that articulates well with the economic development plans.

This example can be analyzed within Estevez-Abe *et al.* (2001) approach where they distinguish three types of skills: firm-specific (Japan and Korea), industry-specific (Germany), and general skills. In any economy all three types of skills will be utilized; however, in some structured economies, the development of one of these skills types will predominate over the others. Firm-specific skills are the least portable, industry-specific skills are portable across an industry, while general skills can be applied across a range of firms and industries. Each type requires different type of training and assumes particular kinds of economic development strategies. As argued by Lauder *et al.* (2006), “for firm-specific skills a high level of general education is desirable. This is then used as the foundation for the in-house development of skills that firms demand. Industry-specific skills require some interaction between the education and training system and industry for the training to be appropriate and up to date in supplying the skills required. . . . For general skills, education at only a minimum level is required for the lower end of the flexible labour market.” (p. 48). Thus, the assumption that an improvement in general education in Africa would provide the opportunity for firm-specific training proved to be wrong. This was due to the limited number of firms able to provide such training. The conclusion to be drawn from this is that more emphasis on the development of industry-specific skills is required so that the economic development plans can be achieved. “This requires government commitment in the form of policy development, sound skills and human resource development planning, inter-ministerial co-operation – primarily between education and labour ministries – and financial commitment to developing a skilled population” (Roberts, 2005: 52).

Cambodia is an example to demonstrate the effectiveness of a sector-wide education approach presented through a developed national program for education in a developing country. In Cambodia's case the approach comprised: The Education Sector Support Program (ESSP) 2001–06. The overall goal of the ESSP was to contribute to the “achievement of the Government's poverty reduction strategy through pro-poor systematic and

targeted interventions” (Forsberg and Ratcliffe, 2002). TVET is included in this policy. Government flexibility in negotiating a mix of donor-financing modalities helped maintain inclusive partnerships. High-level national leadership and authority of the ESSP reform process has been critical and it was provided directly through the minister. This is an example to illustrate when policy development is not a simple case of setting up the priorities. Policy had been seen as a dialectic process in which the government and the donors were involved in shaping its development. “Policy development is therefore both a continuous and contested process in which those with competing values and different access to power seek to form and shape policy in their own interests” (Bell and Stevenson, 2006: 2).

These four cases demonstrate the different ways the governments approach policy development: through the high-skills thesis in Australia and England; and through the combination approach (high skills/low skills) in Africa and Cambodia. Systematic approach at different levels has been seen important for the three cases examined.

Conclusions

This article analyzes issues, such as the scope, scale, and coherence within TVET and across different sectors within particular countries to demonstrate the complexity of TVET policy formulation. It is argued in the article that tensions between the pressures for global uniformity and regional specificity should be considered by policy-makers. It is also argued that any attempt to develop a universal set of principles for policy development should be adopted with caution, particularly due to differences in the labor-market structures across the countries. Two types of theories are proposed to provide the basis for understanding how educational policy could be planned. They are high-skills thesis and life-based learning. They provide the basis for macro- and micro-level planning.

The issues and theories discussed in the opening section of the article provide the basis for the analysis of policy examples from developed and developing worlds presented in the next section. The conclusion is advanced that TVET systems policies and planning should exist as part of a system of lifelong learning adapted to the needs of each particular country and to worldwide economic development. It is important to be aware of the complexity of TVET and its interdependence with other policy areas. In a modern market economy, governments carry primary responsibility for TVET policy design. However, a partnership between government, employers, professional associations, industry, employees and their representatives, the local communities, and nongovernment organizations should play a crucial role in policy design (UNESCO/ILO, 2002: 9a). The overall conclusion to be advanced in this article is that policy planning and

development should be based on research that is directed toward TVET improvement and its relevance to particular socioeconomic contexts.

Qualifications Frameworks and their Role in the Reform of Education and Training

M Young, University of London, London, UK; University of Bath, London, UK

© 2010 M Young. Published by Elsevier Ltd. All rights reserved.

Introduction

This article focuses on the recent trend for governments (in the UK and elsewhere) to use qualifications as a main driver of educational reform, especially, but not only, in the field of vocational education and training. (Qualifications are increasingly linked closely to funding arrangements. These links are important but beyond the scope of this article.) Qualifications are an element of the education systems of all societies; they do, to an extent, motivate learners, they are used by employers to screen applicants for jobs, and increasingly, as discussed in this article, they are used by governments in controlling educational institutions. However, what is questioned is whether, as is increasingly assumed, qualifications expressed as outcomes or standards can be the basis for improving education and, more specifically, can provide an adequate basis for teachers to develop the curriculum. This can only lead, it is suggested, to a collapse of educational standards and a loss of credibility of qualifications.

Outcomes-based qualifications, if seen as a basis for replacing syllabi, in effect, do away the idea of a curriculum at all. The consequences, in the case of South Africa, of introducing such an approach to educational reform are made very clear by Allais (2003) and by a number of contributors to the book by Young and Gamble (2006).

Emerging Trends and Issues in Qualification Reform

The issues discussed in this article arise from the growing interest of governments in the idea of a national qualification framework, based on outcomes defined according to a common set of criteria, and including all levels and types of qualification, whether they are school or work based, general, vocational, or professional in purpose.

The origin of the idea of a qualification framework based on outcomes can be traced back to the National Vocational Qualifications (NVQs) framework introduced in the UK in 1987. (NVQs drew on the method of functional analysis developed within occupational psychology (Wolf, 1995).) To the best of our knowledge, this was the first attempt to establish a framework that was based on outcomes that were defined independently of any specific learning program, although the NVQ's framework was

restricted to vocational qualifications. However, Jessup (1991), a leading figure in its design, envisaged that learning outcomes could be the basis for all education.

What was not fully recognized at the time of the launch of NVQs in 1987 was that the concept of qualifications based on learning outcomes implies very specific ideas about learning. If there is to be formal comparability between different qualifications within a framework, the criteria for learning must be precisely specifiable in advance of the learning itself. It follows that such qualifications disregard any learning that is not specifiable in advance or may not be specifiable at all (e.g., apprentices acquire integrity and a sense of responsibility which could be assessed by professional judgment but not on the basis of criteria alone).

Some kind of broad prespecification of outcomes is, of course, a feature of all qualifications. However, in the case of NVQs, not only did the prespecification of outcomes become more detailed, but also the other features of traditional qualifications, such as a recognized syllabus and an assumed and the requirement to attend a course of study, were excluded. The precise specification of outcomes was designed to replace the kind of tacit assumptions which, in more traditional qualifications, were used to compare and rank learners. There was also an assumption in the NVQ approach that precisely defined outcomes would not only free qualifications from any reference to where they were achieved, but also minimize the human judgment required for assessing learning. It was this claim to independence from both professional judgment and required attendance at an institution that gave outcomes-based qualifications their claim to be radical and egalitarian.

The advantages of an approach to qualifications based on outcomes apply most readily to vocational qualifications, where competences can be specified. However, the implications are far more problematic in relation to the goals of general education which can never be adequately expressed in terms of precisely specified outcomes. The detailed prespecification of outcomes of the kind attempted for NVQs downgrades both the knowledge that may be required for competent performance and the role of the professional judgment of teachers. (The requirement, insisted by the National Council for Vocational Qualifications (NCVQ) in the UK, was that teachers and trainers had to learn to interpret criteria in the correct way. It was

not surprising that this resulted in box ticking and was experienced as de-skilling.) It also underemphasizes the forms of tacit learning that cannot be assessed or expressed in terms of outcomes but which all learners rely on.

The second significant development that this article takes into account is the growing body of research and experience that suggests that outcomes-based frameworks have a number of unfortunate consequences (Young, 2004). It will be argued that these consequences are not just teething problems associated with any radical innovation, but that they reflect fundamental flaws in qualifications-driven approaches to educational reform.

The third issue that is important to bear in mind is that a number of countries, most notably those associated with the Germanic and Nordic traditions of education and training, have remained largely immune from the pressures to develop outcome-based qualification frameworks (Young, 2004). In this article, we contrast the Anglophone approach that sees a qualification framework as the best way of responding to global economic change with one that sees qualifications as part of the institutional structure of a country's education and training system.

The Rest of the Article

The remaining sections of this article explore in more detail the three trends already referred to. It makes a distinction between countries adopting an outcomes-based approach to reform and those relying on an institutional approach. Finally, it draws on a distinction between the intrinsic and institutional logics (Raffe, 1992) of any educational policy. Is Raffe's analysis a step further by distinguishing between the macro and micro aspects of the two types of logic?

Intrinsic logics refer to the claims made for a reform that are independent of the actual contexts in which it might be implemented. They express the political rationale of a reform and are invariably the basis of any borrowing of ideas and strategies between countries. Institutional logics, on the other hand, refer to the social, political, and institutional contexts, and the role that they are likely to play in how (and whether) any reform is implemented.

Whereas macro aspects of institutional logics refer to forms of stratification, power relations, and institutional hierarchies, micro aspects refer to the specific practices of teachers, learners, and assessors. It is the macro aspects of institutional logics that are the most visible constraints on educational reform but it is the less-visible micro aspects that provide the conditions for processes such as acquiring a qualification to take place and gain public credibility.

Those countries that have developed outcomes-based approaches share common notions of their intrinsic logic.

However, they appear to have given very little attention to either aspects of the institutional logic of such reforms. Contrasting the two approaches can shed light on: (1) the limitations of outcomes-based approaches; (2) the strengths and weaknesses of institutional models; and (3) the dangers of assuming that qualification reforms on their own can play more than a modest role in improving education and training.

Qualification Reforms: The Context

The main goals of recent qualification reforms have been to improve flexibility, widen participation, and enhance mobility. In furthering these goals, most reforms emphasize portability – allowing people to move between different types of qualifications and transparency – making explicit what learners have to do to become qualified.

A number of questions about the link between these aims and the proposed qualification reforms need to be asked. First, why have governments focused on qualifications as their main instrument of reform? Second, why has the idea of outcomes-based frameworks proved so attractive to governments? Third, is it realistic to envisage common criteria that could be the basis of a framework for all qualifications? Fourth, given that some of the most effective education and training systems up to now (e.g., those in East Asia and parts of continental Europe) rely on a quite different approach, why are outcomes-based frameworks so popular in Anglophone countries?

Why Qualifications?

It seems likely that one reason why governments have become so enthusiastic about emphasizing qualifications is that not only are they assumed to motivate learners, but they can also serve quite other roles that are just as important but frequently less-explicit aspects of government policy. For example, a greater emphasis on qualifications enables central governments to:

- increase their control of educational provision;
- provide measurable criteria for allocating funds;
- make local and regional bodies more accountable; and
- provide evidence of the success of government policies.

Two continuing parallels are worth noting. The first is that congruence between the growing interest in qualifications and neoliberal, market-oriented approaches both to the economy and the public sector. The second is that qualification reform from the 1980s has been given most support in those countries which had weaker public systems of education and training and most readily endorsed the original Reagan–Thatcher neo-Liberal policies (e.g., the UK, Australia, and New Zealand).

There are parallels between new qualifications, authorities, and the bodies that have been created to regulate the new privatized monopolies such as water, gas, and electricity. Qualifications offer an ideal regulatory instrument for a reforming government. They provide incentives for individual learners and can be used to make educational institutions accountable. The educational problem, however, is that these purposes can be in conflict with each other. More emphasis on accountability leads to tighter specification of outcomes. Promoting learning, however, especially among slow learners, requires teachers the space to take risks. Tackling the problems faced by slow learners will require qualifications that rely more on professional judgment and are less specified in advance.

Why an Outcomes-Based Qualification Framework?

Qualification arrangements in England and Wales have in the past had a number of features in common with those found in other European countries. For example:

- General and vocational qualifications have developed separately with limited possibilities of progression between them. The latter are organized by sectors with few opportunities for transfer.
- Most qualifications are linked to programs in educational institutions.
- Qualifications have traditionally been underpinned by specialist communities – trades, crafts, and professional organizations and disciplinary associations. Historically, these specialist communities have been socially exclusive, both generally and in relation to specific disadvantaged groups distinguished by race, class, and gender.
- Traditional qualifications have offered only limited forms of access to adult learners except by retracing the steps of young learners.
- Many occupations and sectors have been characterized by very few of those employed having any qualifications at all. In the UK, a license to practice has only been applied in the case of a small number of occupations.

Since the late 1980s, all these features have been seen by as barriers to learning, and at odds with the fast-changing skill and knowledge demands of the global economy. A single framework with a single set of levels in which all qualifications are located appeared in principle to be a logical way of overcoming these barriers.

The shift that has been argued for, since 1987 in the UK, is from a qualification system based on shared practices and judgments to one based on formally explicit criteria defined independently of any specific experience or practice.

Support for a change from a qualification system based on shared practices to one based on criteria was political as much as educational. The old provider culture of further education (FE) colleges, local employers, and the examining bodies was widely discredited among civil servants and within national employer organizations. This view fitted in with the marketizing zeal of both Conservative and Labour governments. Initial support for reform was tied to the government's determination to break the power of trade unions and their out-of-date and restrictive practices (Raggatt and Williams, 1999). Attempts to break with the past have been a familiar feature of qualification reforms, and not only associated with the political Right. Examples are Wales and Scotland, both with left-of-center coalitions and the first post-apartheid government in South Africa (Jansen and Christie, 1997).

Lastly, it has been claimed (Jessup, 1991) that a qualification framework, freed from any links with educational institutions, can provide access to groups who have in the past been excluded. The idea of a qualification framework has been closely linked to the accreditation of informal learning (DfEE, 1998). However, it is hard to find evidence that substantial numbers of workers have had their informally acquired skills recognized as qualifications.

The Typology: Outcomes-Based and Institution-Based Approaches to Qualifications

The typology distinguishes between outcomes-based and institution-based approaches. Qualification reforms, however, should not be seen in isolation from other elements of the their wider social context which will shape the way in which qualifications operate. Examples are:

- funding systems,
- devolution of government,
- the role of the private sector as provider and funder, and
- the location of assessment (in public or private bodies)

We shall use the two models to highlight changes as well as some of the problems they give rise to, not as descriptions of particular countries.

Outcomes-Based Approaches

Outcomes-based approaches to qualifications assume:

- a single definition of qualifications,
- a single set of level descriptors, and
- the precise specification of outcomes

As a result of relying on precise specification, outcomes-based approaches invariably lead to over-specification and the trivializing of learning (Wolf, 1995). There is evidence from both New Zealand and South Africa that

outcomes-based frameworks have a series of other serious but unintended consequences. For example:

1. they encourage resistance rather than support from high-status institutions, such as universities (Ensor, 2004) and professional bodies;
2. their emphasis on flexibility neglects the positive role of boundaries between qualifications in promoting particular types of learning (especially at higher levels);
3. in emphasizing generic criteria for all qualifications, single frameworks tend to neglect the importance of specific content in both vocational and general subject areas;
4. the leadership role of qualifications is overemphasized; and
5. there is as yet very little evidence that the quality and amount of learning have been enhanced in countries that have introduced national frameworks.

In the case of NVQs in the UK, the gross numbers achieving vocational qualifications have not changed significantly since they were introduced.

Institutional Approaches

Institutional approaches to qualifications are less easy to characterize, partly because in many countries they are taken very much for granted and have a long history. Qualifications are not treated as separate instruments of reform but as embedded in the wider education and training system; outcomes are closely linked to institutional inputs or programs of study. Qualifications are not used by governments as an independent lever for change.

However, in the context of global economic changes, institutional approaches are not without their weaknesses. For example:

- they exhibit inertia and resistance to change;
- change is difficult because it involves the whole system;
- they are slow to adapt to new learning demands; and
- progression between different sectors is difficult.

Discussion

Most industrial countries still largely have institution-based systems of qualifications, although a growing number are exploring the scope of outcomes-based approaches. The exceptions appear to be the Anglophone countries. However, England, like New Zealand before it and more recently South Africa, is stepping back from an extreme version of the outcomes position initially adopted by the NCVQ (Raggatt and Williams, 1999). The proposed European Qualifications Framework has a different approach as a voluntary register. This evidence of doubts about outcomes-based approaches points to a middle way. The next section draws

on the distinction between intrinsic and institutional logics to suggest future possibilities.

The Intrinsic and Institutional Logics of Outcomes-Based Frameworks

The rationale for introducing an outcomes-based qualifications framework is as follows. First, it is consistent with the increased flexibility of successful modern economies. Second, it offers scope for transferring qualifications between sectors as learners accumulate credit toward further qualifications throughout their careers. Third, the clear specification of outcomes means that higher-level qualifications are open to all, even those without access to a university – nurses can become doctors. This is the intrinsic logic of an outcomes-based qualification framework. However, it comes up against what was earlier referred to as the macro and the micro aspects of the institutional logic of modern societies.

Macro Aspects

First, the global economic changes have not turned out to be as progressive as predicted by political economists such as Piore and Sabel (1984) and Reich (1991). Majority of people in work still stay in the same field or sector for most of their working lives. The new industries of the e-economy create remarkably few jobs. Furthermore, some of the most characteristic jobs of the new economy are in call centers and the fast food and security industries, none of which requires many higher-qualified knowledge workers. In other words, the increasingly mobile and qualified society on which the claims for qualification frameworks are based bears little relationship to the realities of modern economies.

Second, a seamless framework of qualification levels does not by itself guarantee progression or provide a basis for overcoming deep-seated divisions between different types of qualifications. In England, there is a five-level vocational qualifications framework. However (1) the majority of vocational qualifications is awarded at levels one and two, (2) there are extremely few vocational qualifications at level five, and (3) of the few who obtain vocational qualifications at levels four and five, most have entered the framework as graduates from university (levels 4 and 5). These are examples that reflect the influence of what we referred to as the institutional logic of modern societies – in particular, the continued significance of academic/vocational and professional/vocational divisions.

The solution to overcoming these divisions is not primarily to be found through a qualification framework. It will depend on expanding the range of higher-level professional occupations and improving the institutional opportunities for people to progress from low-level

qualifications. It seems likely that such developments will be inhibited by extending the role of outcomes-based approaches.

The older progression routes from vocational to professional qualifications were largely restricted to engineering. A more recent example of progression to professional occupations is through the links between vocational qualifications for accountancy technicians and professional accountancy qualifications. The key factor in this case is the role of the professional body and its involvement in supporting and guaranteeing the quality of both professional and vocational qualifications.

The future policy tasks are not just to create new qualification levels within a single framework. They are: (1) to create genuine occupational progression pathways in sectors that have had few qualified people in the past, such as care, retailing, and hospitality; and (2) to create new access routes for people without initial qualifications. An outcome-based framework could support such developments was in place; it cannot lead them.

Micro Aspects

The micro aspects of the institutional logic of qualifications are less visible but no less fundamental in the problems they pose for reformers. They are expressed in the extent to the credibility and currency of a qualification is only partly based on what it records that the person who is qualified can do or knows (the outcomes). Of far greater significance is the trust that society in general and specific users in particular have in the qualification. This trust, as mentioned earlier, has in the past been embedded in various forms of specialized and usually elite community. These communities of trust have taken time to establish and have developed their own forms of exclusiveness and resistance to change. If these traditional communities of trust are weakened or destroyed (or in the case of many new sectors, do not exist), their function cannot be fulfilled by the specification of outcomes alone. If new communities of trust or some equivalents are not created to give substance and add practical experience to criteria, new outcomes-based qualifications will not gain credibility among users. This analysis may go some way to explaining (1) the persistence of old non-outcome-based qualifications and (2) the phenomenon of academic drift. Academic qualifications still rely on traditional communities of trust such as those linking specialist subject teachers with colleagues in universities and syllabi and have therefore retained their trust and currency value beyond their particular specialist communities.

Relying on qualifications based on old communities of trust is not an adequate solution in the fast-changing and increasingly competitive economic environment that we face today. As has already been noted, they have been exclusive and elitist and are rarely the basis for responding

to new skill and knowledge demands. It was partly these features that led to the development of alternatives based on transparent criteria. However, if interpreted in terms of criteria alone, transparency is a chimera. Learners always, at least to some extent, have to take on trust what they will learn in a program of study. Similarly, those who recruit and select draw on their experience as well as on someone's qualifications in making their judgments about someone's suitability; qualifications are never more than part of the data that they draw on. The traditional communities of trust were not planned – they emerged. New communities of trust in, for example, care, retail, and customer service occupations will have to be created, but not by employer-led organizations with the responsibility for National Occupational Standards. In sectors with a long tradition of apprenticeships linked to college-based programs, employer-led sectoral organizations can continue to take the lead because the old communities of trust can be built on. However, in sectors that recruit largely unskilled labor and where profits can be made by selling low-quality services or low-quality products (Keep, 1997), a quite new and more complex approach is needed that does not rely on employers generating demands for more qualified people. It is likely to involve a new type of leadership role for colleges and universities.

The implication of this analysis is to recognize the relatively modest role of outcomes-based frameworks in educational reform. The major tasks will be creating new forms of production and service that require new qualifications and establishing the new communities of trust that will be needed to underpin them. It is far from clear what the basis of new communities of trust will be or the roles of the various partners involved.

Conclusions

The two approaches to qualification reform that we have discussed in this article have origins in different historical times, and the very different roles of the state, employer organizations, and trade unions in the countries where they have been adopted or replaced. The new circumstances that most countries face today are, however, increasingly common. A qualifications strategy for the future cannot be based on the shared practices of occupational communities and their links with institutions because in many cases neither any longer exists. Conversely, outcomes-based approaches, which break with the traditional occupational communities and their links with educational institutions, take no account of how the trust on which qualifications rely is actually created and sustained.

The specification of criteria or outcomes is designed to make qualifications portable across different contexts. Many of the critiques of this process have shown how such specification is endless and trivializing. There is no

alternative to embedding criteria in shared practices as the condition for the trust on which qualifications rely for their credibility. The question becomes, what form might this embedding take when the identifiable occupational communities within which it took place in traditional qualifications no longer exist, or at least in only a very few sectors? We conclude this article with some suggestions from Gamble's research on cabinet makers (Gamble, 2006) in South Africa, as a way of linking the discussion of qualification reform in this article to the wider debates about the role of knowledge in education (Young, 2007).

Gamble (2006) makes two kinds of distinction between types of knowledge. One is between context-independent and context-dependent knowledge and the other is between types of context independence, principled and procedural. Traditional vocational qualifications relied on context-dependent knowledge located within occupational communities of trust. Gamble points out that in the specific case of cabinet makers, the context-dependent knowledge associated with the different tasks involved in making a cabinet are held together by a vision of the whole – the making of a complete cabinet. The vision of the whole is however context independent – it does not refer to a specific cabinet. At the same time, this vision is tacit, and neither codified nor codifiable; it is in the head of the master cabinet maker. Being un-codifiable, its theory implicit, it cannot be a model for future qualifications. It is, however, important, in pointing to the conditions for the development of future qualifications. Because the outcomes-based model rejects the idea of theory (codifiable context-independent knowledge embedded in specialist communities), the relationship between the qualification and its parts (the outcomes) is arbitrary. The learner acquires the procedural knowledge to make certain types of routine links between tasks. However, he or she has no basis for understanding the relationship between the whole and the parts or for progressing by taking his or her procedural knowledge to new levels of generality. Outcomes-based qualifications claim to be portable – a qualification can be used beyond the context in which it is acquired. However, if such claims are to be realized, learners need access to principled knowledge – concepts that are systematically related to each other (as in a theory) and embedded in contexts which give meaning to the theory. Separate criteria on their own are not adequate to define a qualification. In policy terms, the implications of these suggestions would of course involve a complete reorganization of existing relationships between professions, universities, colleges, employers, and qualification bodies.

Quality Assurance in Vocational Education and Training

D Gunning, Welsh Assembly Government, Cardiff, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The article discusses the main risks associated with vocational education and training (VET) and the associated quality-assurance strategies that can be applied to each, pointing to examples of national and international developments. Generally, since the terms used in quality assurance vary considerably from one country to another and may also be used differently in technical and lay contexts (e.g., the word accreditation) this article has avoided technical terms wherever possible.

The scopes of VET and of quality assurance are worthy of a long and detailed consideration, particularly in an international context, since each is strongly linked to national cultural issues, but there is insufficient space in this article for such detail. For the purposes of this article, the scope of VET is considered to be that which prepares the learner for the world of work, but excludes general education of the kind associated with the school sector and excludes preparation for entry to work that requires a professional qualification obtained from an institute of higher education.

Although several chapters could be filled in the discussion of distinctions between quality management, quality control, and quality assurance, this article takes the scope of quality assurance to cover systems and procedures that are designed to ensure that the VET is fit for its defined purpose and that risks associated with VET are managed and minimized.

The scope of VET adopted here includes learning taking place at colleges such as the post-school institutes of technical and further education, at for-profit training organizations, at in-company training facilities, and in the workplace itself, using methods that range from traditional 'learn by doing' through to more recent e-learning. In this article, the term VET provider has been used generically to describe those organizations.

Key Risks

The risks associated with VET could be said to be located at three main levels. Each is discussed further in the succeeding sections.

The first level of risk is associated with the specification of the knowledge and skills that the learner is required to acquire. Whatever methodology is used to define the knowledge and skills – that is, the outcomes

of the learning – the outcomes must be appropriate to the purpose and must be defined in such a way that they can be reliably assessed.

The second level of risk is associated with the person or organization – referred to as the provider – whose responsibility it is to assist the learner to achieve the outcomes of the learning and to assess that the learner has achieved the outcomes. Although there is considerable literature on the issue of learner retention and success rates as a quality issue for providers, such as Hall (2001) and Martinez (2001), there is relatively little literature on other quality issues for providers, particularly compared to the corresponding volume for higher education and for schools.

The third level of risk operates beyond the boundaries of the learners and the providers and relates to the extent to which the VET system meets its purpose of providing a locality, region, state, or country with the knowledge and skills required to sustain a successful economy and vibrant communities and cultures. There is an associated transnational element where, as for example in the European Union, there are agreed transnational policies relating to mutual recognition of skills or free mobility of labor; in such circumstances, there is a risk that lack of compatibility of national VET systems prevent these transnational policies from being successfully implemented.

Key Risk 1 – Specification of Knowledge and Skills

The risk associated with the specification of the knowledge and skills can be managed through the development of systems that provide for expert input into the development of the specification, for example, through the use of employers to specify required job knowledge and skills; through the development of standardized approaches to the specification of knowledge and skills, for example, using a standard template, terminology; and through the use of level descriptors in national qualifications frameworks. Employer, and in some cases employee, involvement in the development of specifications of knowledge and skills is usually exercised through standard-setting bodies with similar functions – for example, industry skills councils in Australia, sector skills councils in the UK, and standards generating bodies in South Africa.

The way in which the knowledge and skills required to complete a course of VET is specified and assessed has

changed over the years. Specifications in the form of a syllabus – and assessments based on traditional written and practical examinations have given way in many countries to a modular structure, where each module (also called units and units of competence in some national systems) represents a discrete occupational element. In each module, the successful completion by the learner is assessed against specified outcomes, each with its associated assessment criteria. In many countries, which use this type of specification, the specifications are publicly available; the requirements for successful completion are therefore clear to both learners and assessors.

An early example of such a modular, outcomes-based system was developed in Scotland in 1983; the modular approach in Scotland is described in Gunning (2000). The approach was taken further in England in response to the Manpower Services Commission report (1986), which recommended changes to the English system to reduce the plethora of vocational courses available at the time and to increase the role of employers. The latter imperative was because of the view that the system had become dominated by what providers wanted to provide, and not by the skills that employers wanted. The English reforms proposed to adopt a single, employer-led specification of knowledge and skills for each occupation described as national occupational standards and controlled by a new regulatory body that would be responsible for the quality of these standards; the approach is described in Jessup (1991).

Many countries have since redeveloped their VET systems along similar lines to those initiated in England. National occupational standards are defined by bodies that represent employers, as the customers of the VET system, and are developed using a variety of approaches such as Developing a Curriculum (DACUM), which was developed in the US, and functional analysis, developed in the UK. In some countries, employers and trade unions are both involved in the specification of standards as social partners.

One consequence of the processes for developing nationally recognized, portable certificates based on standards set by employers was that the time taken to develop and quality assure the standards could be protracted. Such protracted development times have been seen, in recent reviews of systems of national occupational standards, to be a problem because they impair the systems' capacity to respond quickly to changing industry requirements, particularly in areas where technological change is rapid. See, for example, the reviews of the UK system by Beaumont (1996) and, more recently, by Leitch (2006) and of the Australian system by McDonald and Schofield (2004). Despite the identification of the problem, a solution has been difficult to find to date.

The quality assurance of national occupational standards – and other specifications of vocational knowledge and skills – should take account of two issues. First, do the standards encapsulate all the knowledge and skills

relevant to the occupation in question? Second, are the standards specified in the appropriate technical format and are they written with sufficient clarity for assessors to be able to make reliable assessment judgments on learners? Examples of guidance on standard setting can be found on the websites of national qualifications bodies or regulatory systems such as, for example, that for the Australian Quality Training Framework (AQTF 2007).

Where countries have developed a national qualifications framework that covers VET courses, these are usually defined by parameters of level (a measure of the complexity of the knowledge and skills acquired through a module or course) and the volume of learning (a measure of the notional time involved in acquiring the knowledge and skills in the module or course). In such frameworks, the level descriptors form a useful benchmark for the quality assurance of the specification of knowledge and skills; the quality assurance can check whether the knowledge and skills are at the right level and whether they are comparable to those in other modules or courses in other disciplines. Examples of such level descriptors can be found in the Victorian Registration and Qualification Authority's Credit Matrix and in the proposed European Qualifications Framework.

Where the system is managed by a national regulatory body, a further quality-assurance issue relates to the totality of vocational qualifications and national occupational standards in the national system. Is there coverage of all required occupations across the system of qualifications and standards and has unnecessary duplication been avoided so that the system is as simple as possible for employers, learners, and providers to navigate? Recent reviews of the system of vocational qualifications and standards, such as that led by Leitch for the UK Treasury (2006), continue to highlight problems of proliferation and of slow development times – these are issues which, despite the use of national occupational standards as the basis for VET for nearly two decades, remain to be resolved.

The specification of the outcomes of VET in the form of national occupational standards has also been adopted as a near-universal norm, especially in Anglophone countries that were redeveloping their VET systems. Besides the development of forms of national occupational standards as the basis for reform of VET and vocational qualifications in the UK, Australia, and New Zealand, for example, similar developments have taken place in southern Africa, as described by McGrath (2005).

Key Risk 2 – Providers

The prime risk associated with providers of VET relates to the assessment process. Has the assessment of the learner been carried out accurately against the requirements for success, however these are specified? If so, the

learner will have the knowledge and skills listed on his or her record of achievement or certificate; if not, the learner will either have had the knowledge and skills but been inaccurately assessed as not having them, or, perhaps more dangerously, will have been inaccurately assessed as having the knowledge and skills when the learner does not have them. That final scenario is particularly problematic when the certification of the body of knowledge and skills is seen as a license to practice in an occupation that has health and safety implications.

There are further risks associated with providers, one of which relates to resources. Particularly where the provider operates in a competitive environment, the provider may claim to be able to provide learning that leads to the knowledge and skills for an occupation but where the provider does not have the appropriate premises, equipment, or staff to deliver the learning and/or conduct assessment against the standards.

A further risk associated with providers relates to situations where governments allocate public funding to learning – for example, where the learners are unemployed youth. Has the provider managed the learning and assessment of learners in accordance with the terms under which public funding was provided?

These three risks – assessment risk, resources risk, and funding risk – are discussed in the sections that follow. For reasons of logical sequencing, the resources risk is discussed first because the first stage of quality assurance applied to providers is usually an approval process.

Some providers had pursued internal means to testify to the quality of the education and training they offered, drawing on practice in other industries. For example, in the 1990s, there was interest in the UK among some providers in seeking accreditation against the International Standards for Organization (ISO) 9000 standard, particularly since some businesses required that their supply-chain companies become certified against the standard. This was partly because providers thought that employers might see them as part of their supply chain and partly because providers saw ISO 9000 accreditation as giving them a competitive edge at a time when providers were being encouraged to operate in a competitive environment. The application of such quality standards in a UK context is discussed in Hammond (2005).

Resources Risk

One way to ensure that a provider has the required resources to enable learners to achieve the required knowledge and skill standards is for a regulatory body responsible for VET to operate a process of approval. An approval process will specify criteria that the provider has to be able to meet before any learners can be enrolled. Such criteria may be a combination of generic criteria related, for example, to management practice, and specific

criteria related to the particular occupations to which the learning is intended to lead. Examples of such criteria can be found on the websites of national qualifications or regulatory bodies such as the Scottish Qualifications Authority or the website of the AQTF 2007.

Such approval processes will measure the potential of the provider to comply with the approval criteria. In the case of a new provider, there may be little or no evidence of operation and the evidence available will therefore tend to be of documented management systems and records of staff qualifications and experience. In the case of an already-approved provider which is seeking approval to extend the range of learning it offers, there will be evidence of track record in other areas of learning and the approval process should therefore be able to concentrate on capacity to offer in the new area of learning.

To ensure that the provider's potential capacity is turned into practice, approval systems may be accompanied by a system of follow-up audits. These audits may be based on an assessment of the provider's experience and track record; thus, for example, priority for audit would be assigned to recently approved providers, those who have been found in previous audits to have ongoing compliance difficulties, or providers which had been the subject of learner complaints. Noncompliance discovered during such audits would lead to an action plan to recover compliance or, in the event of repeated noncompliance, to removal of the provider's approved status, either for specific areas of learning or in total.

The body responsible for approval of providers may be a national agency or an arm of government. Where it is not part of the national government, issues of mutual recognition can arise. In the UK, for example, a system had to be put in place to ensure that a provider approved by one awarding body had its approval status recognized by other awarding bodies; this system is described in QCA (2006). In the Australian federal system, where approval is the responsibility of the eight states and territories, a mutual recognition system is in place so that providers that operate in more than one state or territory do not have to undergo multiple approvals.

The approaches to providers adopted by regulators in the UK and Australia were, perhaps inevitably, over-detailed and based on a one-size-fits-all approach. More recently, following system reviews and the influence of regulatory trends promoted by writers such as Sparrow (2000) and by bodies such as the UK's Better Regulation Task Force (2005), which lists five principles of good regulation under a general title of 'less is more', there has been a move away from overburdensome, compliance-driven, process-orientated approval and audit systems by regulatory bodies toward a more constructive approach focusing on key outcomes. The basis of such a move is that previous systems had become orientated toward 'what can be measured is important', rather than 'measure what is important'.

In Australia, the new national quality system for providers includes an optional measure of excellence on the basis that it will influence learner and employer choice. The new Australian system is radically different from its predecessor; providers have welcomed moves to focus audit processes on key outcome measures such as student success rates and student and employer satisfaction rates as well as to reduce audit load on consistently compliant providers.

Funding Risk

Providers that are in receipt of public funding for the delivery of VET may have to satisfy quality criteria that focus on accountability for the use of that funding. Approval and audit processes will therefore concentrate on aspects such as financial and record-keeping systems and on issues related to public policy such as equity and inclusion. In Australia, public funding that supports the New Apprenticeship system is distributed by state and territory governments and these governments have quality-assurance processes that protect the use of such funds. This might involve audits of the accounts of providers and inspection of the delivery of specific elements of the New Apprenticeship system such as the setting up of individual training plans for each apprentice. A summary of the Australian regulatory and financing system can be found in Burke (2005).

In the UK, in the 1990s, the responsibility for distribution of such public funding was initially devolved to local arms of government; national providers and employers were again frustrated by the differences between systems adopted at local level. In addition, there was no mutual recognition system between the approval systems of the awarding bodies and the bodies dealing with accountability for public funding, even though the criteria often overlapped. Providers were therefore dealing with multiple audit systems, each with their own documentation.

In Scotland, an attempt was made to bring together the approval requirements of the awarding body; the quality systems operated by the two national enterprise bodies and their 22 local agencies responsible for public funds for training; and the requirements of the British Standard (BS)5750 and Investors in People. The resulting Scottish Quality Management System (SQMS) standards were applied to training providers seeking to offer courses which attracted public funding. An evaluation of SQMS by Marshall (2002) suggested that it had not met all of its ambitious aims and that providers' main justification for using it was because they had to do so, rather than because SQMS was a particularly effective quality scheme.

Assessment Risk

The provider is responsible for the assessment of whether or not a learner has provided sufficient evidence of

knowledge and skills against the outcomes specified. This requires that an appropriate method of assessment has been chosen and appropriate instruments of assessment have been designed; it also requires that the assessment instruments have been applied fairly and reliably to the learner's evidence of achievement. The competence of the provider's employees in the vocational area being assessed and in the practice of assessment is therefore a criterion applied in approval processes for providers. In the UK, these competences are defined by the national body responsible for standards in education and training.

In many systems, providers have assistance available to them in the form of guidance on assessment. For example, Australian national training packages, which provide the specifications for national occupational standards, also supply guidance for providers on assessment. Quality assurance of the design and appropriateness of assessment instruments might take the form of a peer-review process, for example, where the provider sets up a panel to conduct the review, perhaps made up of the provider's staff and local employers.

Further quality-assurance processes are required to ensure that the assessment judgments made by assessors are consistent, fair, and accurate. This can be through (1) the use of independent assessors (i.e., assessors who have no prior knowledge of the learner), or (2) the use of multiple assessors, or (3) a system of peer verification of the accuracy of the assessor's judgments of the learner's evidence of achievement. A further extension of independence would be introduced by having the verification of assessment decisions done by a verifier external to the provider; that externality would also raise the possibility that consistency of assessment judgments between providers can be carried out if the external verifier verifies a range of providers' assessments.

The assessment risk may be increased by a trend toward providers, even those which are public institutions, operating in a way that sees other providers as competitors. The risk is still higher if the provision of public funding to providers is linked to outputs rather than on throughputs – that is, where the provider receives all or most of the funding only if the learner is assessed as having successfully acquired the specified knowledge and skills.

In the UK systems of VET, providers are required to have a verification system in place through which to review the design of assessments and to review the assessment judgments of assessors. A review of such internal verification systems by Warmington and Wilmot (2004) examined the benefits to organizations whose employees undertook this role. There is also a further layer of external verification, carried out on a risk-based sampling approach by external verifiers employed by the awarding bodies which ultimately issue the record of achievement to a successful learner. Forms of internal and external verification require that the verifiers have specialist

knowledge of the vocational subject being assessed – the verifiers need that knowledge to be able to review learner evidence of achievement against the standards set.

By contrast, the Australian national quality system for VET is largely front loaded and does not involve a system of external verification. The absence of this quality-assurance process places greater importance on the process for approving and auditing providers. In the Australian system, it is assumed that all the specialist knowledge required of those who quality assure assessment rests in the provider – the approval and audit processes are conducted by external auditors appointed by the state or territory regulator for their audit expertise, not because they are specialists in the vocational subject being offered by the provider. Clayton *et al.* (2004) provide an analysis of the implications of the Australian approach to quality assurance for assessment decision making.

Key Risk 3 – The VET System

The third level of risk relates to the extent to which a VET system meets its purpose of providing a locality, region, state, or country with the knowledge and skills required to sustain a successful economy and vibrant communities and cultures. There is an associated risk, where there are transnational policies relating to mutual recognition of skills or free mobility of labor, that lack of compatibility of national VET systems prevents these policies from being successfully implemented.

The management of the fitness for purpose risk may involve formal links between the VET system and the wider skills or economic development strategies adopted by a locality, region, state, or country. The risk associated with transnational policies, especially in a context such as that of the European Union, is usually managed in an environment where individual governments have autonomy; hence approaches to risk management will tend to emphasize voluntary or peer-pressure-driven compliance with transnational frameworks rather than the use of regulatory instruments.

VET serves many different purposes. It can provide generic education and training that allows people to develop their employability skills for entry to the workforce – for example, school leavers and people who are unemployed for a long term. It can provide job-specific education and training that prepares an individual for a specific trade or profession – for example, through apprenticeships or technicianships. In addition, it can provide education and training to those already employed – for example to up-skill to keep pace with changes in technology.

It is beyond the scope of this article to discuss this issue further or to discuss the quality-assurance consequences other than to note that national and regional skills strategies and the setting of conditions on the funding of VET are

forms of quality assurance to ensure that the supply of VET is well matched to customer demand. For examples of such strategies, see Victorian Government (2006) and Welsh Assembly Government (2007).

The aim of such strategies is typically to provide a structure and direction to the VET system, especially in relation to the use of public money to buy training. Such strategies may provide an overall approach, such as moving toward a demand-led rather than provider-led VET system, and may determine ways in which the use of public money is directed, for example, toward defined local and national skills priorities or toward particular training schemes such as apprenticeships. The extent to which VET systems can be demand driven is largely dependent on the extent to which labor market intelligence can accurately predict current and future skills needs and on the extent to which learner choice can be directed toward courses that meet those needs. Keep (2007) argues that there may be inherent tensions between demand-driven systems and the tendency of governments to set national targets and between short-term fluctuations in the labor market and the lead time required by providers to change the courses they offer.

A further large-scale quality-assurance issue arises when individual nations work together to create transnational economic communities and to encourage mobility of labor across national borders. Another form of transnational collaboration occurs when one nation assists another less-well-developed country to build up its national infrastructure, perhaps including its system of VET.

In the case of infrastructure building, there have been international collaborations on VET at various levels. International organizations, such as the United Nations Educational, Scientific and Cultural Organization (UNESCO)/UNIVOC, have identified the importance of quality assurance in VET; UNESCO (2006) provides guidance on the setting up of quality-assurance systems within a VET system.

The development of an economic community of nations and labor mobility is furthestmost advanced in Europe, where the free movement of labor has been seen as a key driver of the development of a genuinely borderless European community. An important prerequisite to such mobility is the recognition of qualifications so that, for example, an electrician trained and qualified in Italy can practice in Ireland without the need to retrain.

Recent work in Europe has been concentrated at a systems level with the aim of making those systems more compatible, within the overall European policy of national subsidiarity. At the meeting of the European Council in Lisbon, the European Union recognized the importance of a radical transformation of its education systems, with 2010 as the target date. This led to a declaration by its ministers of education and training (the Copenhagen Declaration) that a set of priorities would be pursued which

included the promotion of cooperation in quality assurance with particular focus on exchange of models and methods, as well as common criteria and principles for quality in VET.

More recently, the European Union has established the European Forum on Quality in Vocational Education and Training as part of the actions arising from the Copenhagen Declaration; the Forum has drawn up detailed work programs. One of the early aims is to work toward a common quality-assurance framework for VET, including a core set of quality criteria, a set of quality indicators, and a guide to self-assessment for providers. However, initial progress toward the Lisbon 2010 objectives was slow; a further declaration in 2006 by ministers of education and training in Helsinki included renewed emphasis on VET, including the development of common tools for qualifications, credit transfer, and quality assurance.

These developments will have maximum impact on regulatory and qualifications bodies in the individual countries rather than directly on providers. Those bodies may be expected through time to ensure that their quality processes and procedures are compatible with the European framework rather than being expected to adopt the common framework. Over time, this will lead to harmonized quality-assurance systems and, therefore, to greater mutual trust and recognition between countries.

Conclusion

Quality-assurance systems play an important part in the lives of most people who work in, or are in contact with, the VET system – employers as customers or as standard setters, provider employees as teachers and assessors and, last but not least, learners whose pathway to employment depends on the VET system working fairly and effectively. The scale of the VET system and the complexity of the interactions within it are a far cry from the largely local interactions of the traditional apprenticeship systems whose origins date back hundreds of years.

Given the importance of the VET system to those people and the very large sums of public money invested in the system by many governments, it is perhaps surprising that the body of research literature on quality assurance in VET is relatively sparse, especially when compared to that for school and higher education.

Another striking feature of the VET system is the way in which a single model, based on national occupational standards and national qualifications frameworks, has been adopted across a wide variety of countries. If there is a trend in quality assurance within such VET systems, it is perhaps toward more differentiated, outcomes-focused models because these allow high quality to be rewarded and resources targeted on poorer performance.

Training Finance

A Ziderman, Bar-Ilan University, Ramat Gan, Israel

© 2010 Elsevier Ltd. All rights reserved.

Introduction

A central theme of this article is that the system of training finance (and, in particular, its constituent financing mechanisms) has a twofold purpose: not only does it supply funding for the national training system, but it also has a central role to play in achieving many of the broader goals of national training policy. The article opens with a schematic account of training-finance flows as a whole in conventional training markets. This is followed by a discussion of innovative financing mechanisms that have been adopted in many national training systems aimed both at correcting shortcomings of conventional training finance systems in terms of meeting labor-market needs and containing training costs and also to better meet the challenges of competition, technological change, and globalization. Directions of change include a greater diversification of funding sources for skills development (including enhanced cost recovery, cost sharing, and training taxes), encouragement of more and higher-quality enterprise training, the development of private training markets, and increased competition between public and private training providers. The final section presents a schematic account of finance flows that integrates these innovative financing mechanisms, within a unified system, to facilitate the desired development of integrated, competitive, demand-driven training markets.

There is relatively little discussion in this article of the financing of vocational education provided within the secondary schooling system. While vocational education is a major component of Vocational Education and Training (VET) in many countries, with some exceptions (notably, some Latin American countries), the central financing issues relating to vocational education are common to the schooling system generally and, therefore, no special discussion is merited here.

This article draws extensively on earlier writings of the author, particularly Ziderman (2003) to which the reader is referred for a more extensive discussion of the major issues treated in this article.

Finance Flows

Conventional, Fragmented Training Markets

We turn first to conventional, fragmented training markets. A schematic overview is presented in **Figure 1**; institutions that provide training are indicated by the shaded boxes.

Training may be provided through private training markets either by firms or in proprietary training institutions; it may also be provided within the public sector at public training institutions. However, the training market is fragmented into two distinctly differing sectors – private and public.

The major training providers in the private sector are enterprises and proprietary training institutions. The private training sector is market driven, nonsubsidized, and (usually) competitive. Firms (in both the informal and formal employment sectors) provide training to trainees/workers in their employment; payment is made by the employee/trainee through initial lump-sum fee or implicitly in the form of low, below-productivity wage levels. Individuals enrol in pre-employment courses, at full fees, at private training institutions; training fees for continuing training may be borne partially by formal sector employers.

Usually, public training systems have been established, in parallel; they constitute the leading supplier of structured, pre-employment training, frequently dominating the market as a provider of formal sector training. Public sector training institutions are, predominantly, financed from government budgetary allocations. Where fees are current, they are set at purely nominal levels and often accrue to the government rather than remaining with institutions; thus, there is little incentive for training institutions to develop market-demanded courses that could generate fee income. Firms may enrol their workers for continuing training courses, provided at full cost but more usually at subsidized fee levels. Because budget allocations to public training providers are usually unrelated to objective, outcome measures – such as success in placing trainees in productive employment – there is little incentive for institutional training providers to align training courses offered with the needs of the labor market. Linkages between public training centers and formal sector employers remain poor; training provision is dominantly supply driven. Moreover, training centers do not develop training programs focusing on the particular needs of informal sector employment nor do they cater well to the special needs of minority and disadvantaged groups.

A number of emerging trends have rendered this conventional financing framework increasingly outmoded. Ongoing technological change, structural adjustment policies, new and changing patterns of trade and competition, and globalization have combined in many countries to create the need for a much more flexible and responsive

Figure 1 Finance flows: fragmented training markets. Adapted from Ziderman, A. (2003). *Financing Vocational Training in Sub-Saharan Africa*. Washington, DC: The World Bank.

training system than has been manifest in more protected regimes in the past. An increasing problem in many training systems is a tendency to market failure, with firms undertraining in transferable skills, both in terms of the amount of training provided and its quality. The consequent shortages of well-trained, skilled workers in the formal sector, may stunt productivity growth, competitiveness, and industrial development.

This conventional financing framework has become inadequate to meet society's skill development needs. Public training provision remains essentially supply driven. It is not subject to the discipline of competition with other training providers, nor are guidance mechanisms in place to match the skills supplied by public training institutions with the skill needs of the market. In addition, the system is fragmented; in particular, private training institutions do not operate within the same financing framework as public sector training providers.

Innovative Financing Mechanisms

Thus, in many national training systems a strong trend away from these traditional forms of training finance and provision is in evidence. The driving force behind these moves has been the increased intervention of the state in training markets; paradoxically, this process has involved a retreat by the state in the financing of training. Increasing pressures on government budgets in general, and on public training budgets in particular, have led to a search for additional or alternative sources of funding for training. In addition to the need to tap nongovernment sources of funding, governments have intervened more strongly in training markets in order to counter shortcomings of conventional private training markets and, notably, a tendency for enterprises to undertrain.

Augmenting funding for training

A central feature, common to virtually all training systems, is the pressing need to augment the total amount of funding for public sector training, in the light of a paucity of government funding – in part the result of the adoption of structural adjustment policies and increasing calls on government funding from competing sectors. The response is greater funding diversification: seeking alternative or additional funding for public training from other sources.

Funding diversification can take many various forms; in particular, four different avenues may be pursued, separately or in combination.

Fund augmentation

Public sector funds available for the support of training institutions through subventions may be augmented from other sources. Earmarked training taxes, usually levied on the payrolls of enterprises, have emerged as the most widely adopted alternative to central government budgetary allocations for training. Payroll levies of this type were first introduced in Brazil in the 1940s, spread widely to other countries in Latin America (a recent discussion is provided in Galhardi, 2002) and has been adopted by training systems in many other countries. Levies are usually set at between 1% and 2% of the total wages bill of the enterprise; proceeds are used mainly to support public sector training provision, with the emphasis on initial training at formal public training institutions. Training levies can constitute a stable and protected source of funding for national training provision. However, the expectation that levy income would complement existing government financing, thus providing an additional source of funding, has not always realized in practice, and levy income has displaced government subventions for training. There are also notable cases of the opposite tendency,

where earmarked training taxes are absorbed into general government revenues rather than being used for the financing of public training. A fuller treatment of payroll levies is provided in Ziderman (2008).

Governments in developing countries may turn to donor institutions to provide funding, either to the government or directly to individual training institutions; in some country settings, donor funding constitutes a very important finance source for public sector training institutions.

Cost sharing

The weight of training finance falling on public funds may be lightened through the introduction of cost sharing with the beneficiaries of training. Unlike fund augmentation, which results in a larger funding pool, cost sharing aims at reducing the size of allocations to individual training institutions. The best-known and most widely used method is the imposition, or raising the level, of user fees to trainees or students enrolled in training courses. These measures allow a reduction in public subsidies for training or the provision of more or better training services with given levels of public support.

A central issue in fee policy is whether a regime of standard, nationwide compulsory fees should be instituted or freedom should be accorded to individual training institutions to fix the level of fees, overall and differing by type of training course. Institutional autonomy in the setting of fees represents the more desirable approach; it will encourage training providers to develop a more dynamic, even aggressive, approach to exploiting the potential of the local market environment. It is in this manner that institutional fee policy becomes more than a device for cost recovery and cost sharing: in providing a mechanism for varying fee levels across courses and client groups it serves as a tool for moving the training system toward an environment characterized by open, demand-oriented training. However, the voluntary setting of user fees may not be feasible in the otherwise centralized training systems; standard, compulsory fee setting is generally acceptable as the second-best measure for reducing pressures on public budgets.

The positive financial benefits from greater cost recovery need to be examined alongside the potentially adverse effects on equity. There is a clear trade-off here. Higher, realistic fees will exclude from training those who are unable to pay; fees set at comfortably low levels will fail to make a sizable contribution to cost recovery. In particular, negative impacts on the access to training opportunities of the poor, minorities, rural populations, and other disadvantaged groups are likely to ensue. This risk points to the widely recognized need to introduce targeted subsidies directed to these at-risk groups, in the form of scholarships and reduced fees.

Institutional income generation

Income generated from the sale of production and service activities of trainees can constitute a useful form of additional institutional income. Income may be derived as a byproduct of the training process itself. But it is possible, more purposefully, to utilize available skills and facilities to produce output for sale in the local market; indeed, exposure to local markets may lead to more relevant, market-oriented training. Here, the issue is one of maintaining a healthy balance between these two activities. As more weight is given to instruction, the income potential from production declines; alternatively, quality of training will suffer as emphasis is placed on production rather than on instruction. Training institutions may also generate income from the sale of services, including the renting out of underused facilities and providing consulting services to local enterprises.

Private training provision

The growth of private training institutions, with trainees paying full costs, represents a pathway for expanding the national training system without heavy commitments of public funds. Indeed, the encouragement by government of private training institutions' development, through subsidies and nonmonetary means, may represent an effective way of both generating additional funding for training and, in parallel, reducing the call on public funds. Thus, reduced public training provision could be possible (and concomitant budgetary reductions) with the reduction in public training supply made up by compensating expansion of private training institutions. In many countries, the lack of private training provision is the result of various constraints that hold back the development of private training institutions. These are: financial constraints, issues of rigid fees policy, excessive regulation of private institutions, and information gaps, and these are detailed below:

- To offset a lack of capital resources, especially for high-cost industrial and technical courses, governments may offer development loans or subsidies, particularly in strategic skill areas, to assist these firms in their start-up phases.
- Imposed tuition fee ceilings, while aimed at protecting trainees from exploitive activities by private training institutions, may too rigidly limit the ability of these institutions to enter new training markets, especially those with high investment and recurrent costs.
- Private training institutions are unlikely to flourish in an overly strict regulatory environment. Regulation and enforcement should be sparing; while sufficiently robust to counter dishonest practices and low-quality training, they should be designed to encourage private training institutions to operate fairly and efficiently within a facilitating, regulatory environment.

- Without reliable information, consumers are unable to make wise and informed choices. Information on both the quality and stability of private training institutions is often lacking; this may be provided by government in the form of updated information on the relevance of courses to labor-market demands and job opportunities.

These various approaches are set out in **Figure 2**. The first three approaches act directly in bringing in additional revenues to the training sector, while the fourth one affects training budgets only indirectly. Of the methods of direct funding augmentation, the first one increases the size of the funding pool available for distribution to training institutions but there is no immediate effect on the income of individual training institutions. Diversification options are not alternatives and all four avenues are often explored simultaneously.

Encouraging enterprise training

A second major reason for government intervention in conventional training markets is a corrective one: to encourage formal sector enterprises to provide more and better training. Governments subsidize enterprise training, either directly from central government budget appropriations or, less usually, from specially designated training funds, also financed (fully or in part) by government (see below). However, tight public budgets may limit the government's ability to subsidize enterprise training from public funds.

Levy-Grant Schemes

Levy-grant schemes, based on payroll taxes, have provided governments in many countries with an alternative mechanism for promoting company training. Unlike the

revenue-generating rationale for payroll levies discussed above – where the revenues from training levies are earmarked to finance public sector training institutions – levy-grant schemes are directed toward training provided by enterprises. While many variants are found in terms of actual practice, the common feature of levy-grant schemes is the provision of incentives for firms to invest in more and better in-service training. Thus, payroll levies are often linked to reimbursement mechanisms, whereby firms receive payments related to the amount of designated forms of training they provide. Firms are encouraged to invest more in the skills development of its workforce, be it in the sphere of on-the-job training (setting up or extending and improving existing company training) or by sending workers to train externally. The need for government intervention, by the introduction of levy-grant arrangements, arises because of shortcomings in the amount and/or quality of enterprise training.

While there are numerous variants, a threefold classification of levy-grant schemes (Gasskov, 1994) has been widely adopted – cost reimbursement, cost redistribution, and levy exemption, which are explained below:

- Under cost reimbursement, firms receive grants on a cost-incurred basis, for certain designated forms of training (both on and off the job). The purpose of these schemes is often misunderstood, particularly among employers; the scheme aims not at reimbursement of the levy as such but rather reimbursement of training expenditures incurred (to encourage firms to train more or better). Thus, a training expenditure reimbursement ceiling (for firms that train to acceptable standards) is usually set, up to a given percentage of the levy paid.
- Designed in particular to deal with the ill-effects on training supply of the poaching of skilled workers by nontraining firms, a cost redistribution scheme redistributes the burden of training expenditures among enterprises away from companies who do not train, toward those who do. Training companies may receive grants far in excess of the amount of levy paid, providing strong incentives for firms to train.
- Levy exemption is usually employed as part of broader cost-reimbursement scheme. This exemption allows firms, adequately meeting their training needs, to withdraw from the levy-grant system or at least to benefit from reduced levy assessments. A major advantage is freeing firms from the bureaucratic fatigues of levy payment and subsequent grant claim – potential cash-flow problems are avoided. This mechanism is found more typically in industrialized economies.

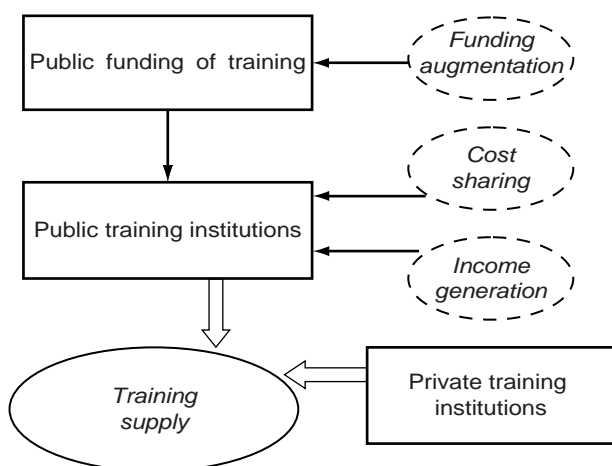

Figure 2 Funding diversification. Adapted from Zideman, A. (2003). *Financing Vocational Training in Sub-Saharan Africa*. Washington, DC: The World Bank.

While national payroll levies are the best-known, and most widespread, form of training taxation, a number of countries have preferred to employ forms of training

taxes. These training taxes tend either to be sector specific or are introduced to finance a fairly narrow training outcome. Sectoral training levies may be based on value of turnover, output, and value of contracts or employment, rather than on company payrolls. The main advantage of sectoral levies is that they offer a means of tailoring the levy format to the specific characteristics and needs of the sector in question. The disadvantage of sectoral levies is their narrow focus obviating an integrated, national approach to the finance and planning of skills development. Thus, most countries have preferred to employ standard, national-level levy schemes, based on enterprise payrolls

There are some limitations of levy-grant schemes. Given particular training needs, many firms, particularly small ones, do not benefit from the levy-grant scheme; this breeds resentment, opposition, and compromises the status of training levies as a form of benefit taxation. Firms may come to regard the scheme as just another tax. For these reasons, stakeholder ownership in the operation of levy-grant schemes – particularly with regard to disbursement policy – should be assured by employer representation levy-grant scheme management boards.

Earmarked taxes in general may be seen not to conform well with the principles of sound public finance and weaken attempts to unify the national tax system. Payroll levies raise the cost of labor to the employer, possibly discouraging employment. Alternatively, employers may shift the incidence of the levy on to workers in the form of lowered wages; in this case, workers, not the employers, bear the burden of the tax.

We have noted the usual classification of national payroll tax schemes into two distinct groups, reflecting very different underlying objectives: revenue generation schemes (where levy proceeds are used to finance training provided by public sector institutions) and levy-grant schemes (aimed at encouraging training investment by firms themselves). However, this traditional dichotomy is becoming somewhat outdated as evolving levy schemes begin to take on a broader range of tasks, particularly in the context of the development of national training funds and training authorities.

Alternative Forms of Subsidy

Where firms undertrain, training incentives may be justified to encourage firms to train. Apart from training-cost reimbursement that is part of a levy-grant system (as discussed above), direct subsidies may be provided out of public funds to encourage enterprise training; or indirect subsidies may be offered through concessions on company tax obligations, for firms that train.

Levy-grant systems have some clear advantages over the two alternative incentive systems: direct government

subsidy payments and concessions on enterprise tax obligations. A major advantage of levy-grant systems is that they do not draw on public funds, a point of some importance in times of parsimonious government budgets; in addition, they can lead to a more systematic, structured approach to training, rather than a more *ad hoc* one. The central lacunae in training under-provision is not only that amount of training provided is too low, but rather that it is often piecemeal and not sufficiently well integrated.

The response to direct and indirect subsidy schemes may be low, if they are insufficiently focused to catch the attention of senior management. However, in the case of levy-grant schemes, involvement is assured automatically by the compulsory payment of the levy. The disadvantages of tax concession schemes have militated against their adoption barring a very few countries: they require a well-developed and broadly based system of corporate taxation, often lacking in developing countries and responsiveness of firms may be low where few firms earn sufficient profits to benefit from tax exemptions.

Training funds

One outcome of the introduction and spread of earmarked training levies has been the development of a relatively new type of financing mechanism: the national training fund. These training funds usually constitute not only the depository of collected training levies but also the mechanism for their distribution. Government budgetary allocations may supplement levy income to the Fund, or represent its major income source; donor support is important in some cases. The intention is to provide a sheltered funding source for national training development, including the financing of public sector training, the provision of incentives for enterprise training, and meeting the skill needs of special groups. Training funds usually operate outside normal government budgetary channels; thus, they are more readily accessed and may be utilized more flexibly than would be the case normally with direct government-financed training programs. However, operating as they do under varying degrees of autonomy from government control, a fund's freedom of maneuver may be constrained. Thus, in cases where the degree of independence from Ministry of Labor and Treasury control is limited, the funds may often emerge as conservative, reactive bodies, rather than adopting a proactive, independent stance in fund policy and management.

National training authorities

In many countries national training agencies or authorities (NTAs) form the linchpin of the financing system. NTAs may be attached, with varying degrees of autonomy, to a government department (usually the labor ministry); however, they are likely to operate more effectively

as largely autonomous bodies forming a buffer between government and the training system. They are usually run by boards representing the training system's major stakeholders. While most NTAs receive general government funding, a large number are financed solely or in addition, by payroll levies. NTAs are much broader in scope than training funds; they are usually empowered with a wide range of national training responsibilities. In addition to managing the system of enterprise training subsidies and, where levy-grant systems are in place, levy reimbursements, they may be charged with responsibilities for developing national training policies and standards, planning the national training system, accreditation of institutions, and generating and disseminating relevant labor-market information.

NTAs may be better placed than environmentally constrained government departments to operate payment mechanisms for training institutions in ways which promote efficiency and competitiveness in training markets. This is discussed below.

Funding allocation to training institutions

Formula funding of public training institutions (such as output-related funding) provides one example of such measures. The allocation among institutional training providers of the total government budget for training (or of the national training fund) is a major component of the training financing system in most countries. However, and particularly in developing countries, a clearly formulated, objective disbursement policy is lacking. A much needed reform is the adoption of moves toward the gradual dismantling of the arbitrary, *ad hoc* institutional core funding

arrangements in place, and their gradual replacement by objective funding formula, such as those related to inputs, outputs, and outcomes. Based on competitive tender that is open to public and private training institutions, contracted training (particularly the needs of disadvantaged groups) can, through the bidding process, both integrate training markets and pressure public training institutions to be more efficient and to operate at lower cost. In line with this approach, donor agencies would fund the NTA only, not individual training institutions.

These reforms are important because the mechanism through which government transfers funds to training institutions has an important effect on the way in which this funding is used and on institutional behavior more generally. An inherent shortcoming in the transfer mechanisms currently used is that they promote low internal efficiency of training institutions and a strengthening of supply-driven training provision. An important task of funding disbursement policies is to provide an appropriate mix of regulation and incentives to ensure that public training can hold its own in an environment of competitive training markets

Integrated, Competitive, Demand-Driven Training Markets

Most industrialized economies have adopted some or all of the financing mechanisms surveyed in the previous section; strong moves to reform the training financing system in this direction are evident in many developing and transition economies. However, the value of these

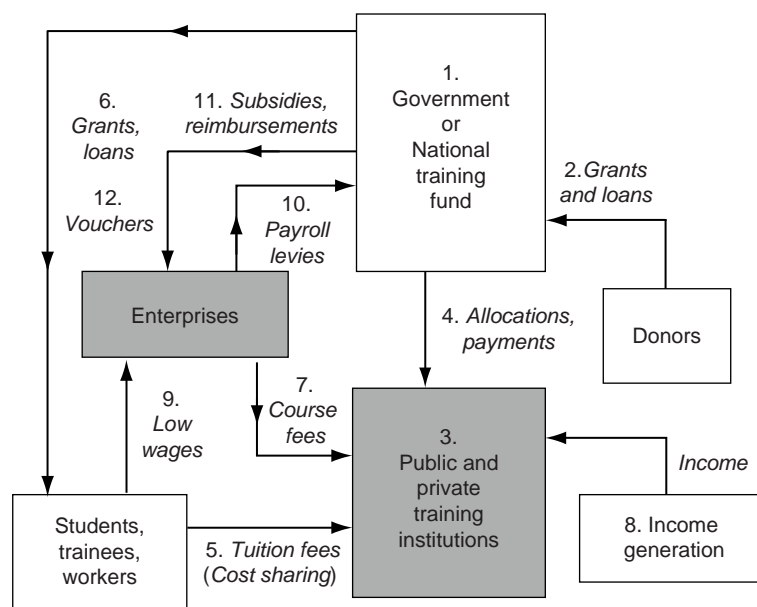

Figure 3 Finance flows: integrated, demand-driven training markets. Adapted from Zideman, A. (2003). *Financing Vocational Training in Sub-Saharan Africa*. Washington, DC: The World Bank.

reforms lies in their adoption in combination as an integrated system, rather than piecemeal. Innovative training finance mechanisms should be fashioned as an integrated system whose central role is to encourage and facilitate the transformation of fragmented, inefficient training systems (with underfunded, supply-driven public provision) into an integrated competitive, demand-oriented training system. The financing flows, in such an integrated framework, is set out in schematic form in **Figure 3**.

Government funding of training institutions is made either direct or through a national training fund (or NTA), as shown in (1). Where available, donor funding is supplied centrally to the government or training fund and not to individual institutions (2). Core financing of public training institutions is based on objective formula funding (3); contract financing of designated government programs (such as for the unemployed) are made available to both public and private and training institutions on a competitive basis (4). Greater cost sharing is introduced in public training institutions, through augmented course fees closer toward competitive levels (5); this is facilitated by the availability of selective scholarships for the poor or student/trainee loans (6). Additional income for public training institutions derives from fee payments for tailor-made courses for firms (7) and from income-generation activities (8). On-the-job training within firms is partially financed by workers (Becker, 1964) through low wages (9). Payroll levies on firms (10) may be used to either augment national funding for training or may constitute part of a levy-grant scheme to encourage enterprises to train more (11). Vouchers schemes, although still largely experimental, may enable potential trainees to purchase training in the open market, with public and private training providers competing for trainee enrolments (12). Vouchers, like grants, typically do not lighten the financing

burden falling on the funding body; training remains subsidized and cost recovery is not an integral part of a voucher scheme.

Glossary

Asymmetric information – A situation in which the buyer of the service has less information about its quality than does the seller.

Commercialization – The introduction of contractual relationships and for-profit private provision into the organization of a public service.

Contract – A legally enforceable agreement to buy and sell specified goods or services.

Cost disease – The tendency for the unit cost of a service to rise relative to its counterpart in other sectors, as a result of its low relative growth rate of labor productivity.

Efficiency – The extent to which the allocation of resources to the production of different goods and services maximizes the total value of output, including the extent to which the cost of producing any particular mix of goods and services is minimized.

Motivation – The considerations that elicit effort from the providers of training services, including economic (profit, pay, and effort) and noneconomic (professionalism and altruism) components.

Quasi-market – An allocative mechanism in which a public agency sets the demand for and the price of a service and a range of providers, public as well as private, for profit as well as nonprofit, compete for contracts to provide it.

Reputation effect – When buyers in a market obtain sufficient information about low-quality training programs to avoid purchasing from their sellers.

Training provider – A producer of training services, including public colleges, training companies, training charities, employers training their own staff, and employer groups.

The training market is a mechanism through which many governments nowadays organize the training services that they choose to subsidize. A public agency contracts with training providers on behalf of potential trainees for the delivery of specified training services. The contractors may be public or private organizations, for-profit or nonprofit; the trainees may be employed by them, by another employer, or out of work. The transactions typically comprise skills enhancement, job search, and other services for disadvantaged and unemployed workers. In some

countries, training markets also play a role in the vocational preparation of young people.

This definition of the training market is narrower than the literal one, which would include training that is financed entirely privately, by individuals or employers – including training in foreign languages and software applications, as advertised in cities around the world. This article focuses on the subset of training for which a public agency is the dominant purchaser.

A prominent contemporary example of the training market is provided by youth training in the UK (i.e., strictly speaking, England). Under the Apprenticeships program, a public agency, the Learning and Skills Council (LSC), contracts with a range of training providers, including further education colleges, specialist training organizations, including companies and nonprofit private associations, and employers themselves, whether singly or jointly. These training providers, in turn, subcontract extensively among themselves for specific services, including off-the-job training and the assessment of trainee attainments (Ryan and Unwin, 2001; Lewis and Ryan, 2009).

The training market is part of the wider commercialization of the public services (Pollitt and Bouckaert, 2004). Commercial relationships and market-like allocations replace, in whole or in part, the combination of political representation and public administration that previously governed and administered services, such as compulsory education and vocational training. Commercialization nowadays dominates such public services as rubbish collection and information technology. In the US and the UK in particular, it has made substantial inroads into the prison, security, defense (frontline military), welfare to work, television, education, and health services.

In both countries, the training market has operated more extensively and for longer than have its better-known counterparts in education and health services. The training market plays a greater role in the vocational development of young people in the liberal market economies, including the US and the UK, than in the coordinated ones, including much of continental Europe (Hall and Soskice, 2001).

The training market may be termed a quasi-market, as it both resembles and differs from a regular market in the private sector (LeGrand and Bartlett, 1993). It is similar to a regular market in that contractual exchange governs the allocation of resources, potential training suppliers compete for contracts, and a market price exists for specified services. It differs from a regular market on the demand

side, where a public body dominates purchasing decisions. This means that political priorities rather than trainees' preferences determine the content of training. It also means market power: the market price is set by the buyer rather than by market clearing, governed by fluctuations of supply and demand across time and place, as in commodity markets.

On the supply side, even when providers compete for public business, economic incentives and competition are potentially weakened when the providers are public bodies, as are vocational colleges in apprenticeship training in Germany. Market forces may then be replaced by administrative decisions. However, the relationship between buyers and sellers within the public sector can still be contractual, and public sellers be required to compete for business with private providers, as are further education colleges in the UK.

Quasi-markets have been used to organize training programs for disadvantaged young people in the US since the advent of the Job Corps program in the 1960s. Their role expanded rapidly in the 1980s, under the Job Training and Partnership Act in the US and the Youth Training Scheme in the UK. A striking attribute of training markets in both the US and the UK has been employer leadership. Employers' representatives – in principle at least – supervise the allocation of public funds to training programs or determine training standards for their sectors (Heinrich, 2000; Burghardt *et al.*, 2001; MAAC, 2001).

Adult training programs are organized through quasi-markets or regular markets in most developed countries, including the ones as institutionally different from the US and the UK as Sweden and Germany. However, market-based organization has had only limited effect on youth (apprentice) training in Germany and its smaller neighbors, where the governance and administration of vocational preparation are shared between representatives of employers, employees, and vocational educators (Ryan, 2000).

A salient concern in the UK training market has been low service quality. A low point was reached in 2002, when the public inspectorate failed a majority of the commercial training providers that held public contracts and a majority of young trainees did not complete their training programs (ALI, 2002).

Two aspects of the training market are discussed here: its economic functioning and merits, with particular reference to service quality; and the political constraints on its performance. The examples used are taken primarily from youth training in the UK.

The Economics of the Training Market

The economic potential of the training market starts with private ownership and competition. Just as a

private-ownership market economy is shown by welfare economics – under particular conditions – to maximize efficiency, so commercialization, that is, the introduction of contracting and the profit motive, might be expected to increase efficiency in training activities. Certainly, public administration, which has often provided the alternative, is characterized by weak incentives to cost reduction and innovation (Shleifer, 1998; Dixit, 2002).

A key ingredient is private ownership and profit seeking. The presence of for-profit providers, that is, not just public colleges and training centers, increases incentives to eliminate waste and improve products and processes. Under public provision, the performance of the service tends to be reduced by ineffective management, by high pay for and low effort by employees, and by weak pedagogy. Training companies have the incentive to increase profit by making improvements in all three areas: to improve management structure, to obtain from staff as much effort for as little pay as the external labor market permits, and to develop new modes of service delivery, such as replacing classroom-based instruction with information technology (IT)-based self-instruction.

In principle, the incentive to providers to cut costs can be intensified by including performance-based bonuses in both the provider's overall contractual payments and its employees' pay. Thus, under output-related funding, one-fifth of the LSC's payment for providing a place in the UK's apprenticeship program has, in recent years, depended on the trainee's completion of training.

The training market also offers the prospect of economies of scale. Training providers are encouraged to specialize in their own areas of expertise. Subcontracting between themselves according to expertise is expected to reduce costs further.

Potential market-related benefits also include increased choice for trainees and increased responsiveness of the content of training to the preferences of its beneficiaries, both trainees and employers. However, the quasi-market has less to offer here than would a full market. The dominance of the demand side by a public authority means that the preferences of trainees and employers play only an indirect role in purchasing decisions.

The benefits of commercialization also depend on the extent of competition for public contracts. If many providers compete for contracts, none enjoys market power, and the price that the public purchaser pays is pushed down to the minimum cost of the most efficient competitors. Public providers, such as post-compulsory colleges, that wish to win contracts must then reorganize their operations in order to compete with commercial providers.

The competitive potential of the training market appears to be broadly realized in practice. In the UK, the ten largest noncollege providers account for only one-fourth of apprenticeship training places (Lewis and Ryan, forthcoming). Seller concentration is undoubtedly

higher in particular submarkets, such as that for a particular occupation in a particular town. Nonetheless, given low barriers to entry by new suppliers, a dominant purchaser, and fixed-price contracting, even large sellers, should have limited scope to profit directly from market power. Indeed, commercial providers face particular risks as part of short-term contracting with a buyer whose priorities and requirements are subject to sharp change at short notice. An extreme instance was the UK's Individual Learning Accounts program, set up in 2000 and canceled abruptly a year later, in response to evidence of lax administration and contractual abuse by some providers.

Economic Difficulties

Nevertheless, the effects of the training market on efficiency are problematic. The principal problem is asymmetric information. Training services may be taken to have both quantity and quality dimensions: for example, the number of people trained, and the amount learned by each, respectively. Information on quantity is typically better than that on quality. One problem in measuring quality is disagreement on the meaning of learning and skill: for example, the types of each that matter in a particular program (Kirkpatrick and Martinez Lucio, 1995). Thus, the UK's training programs have seen disputes as to whether technical (underpinning) knowledge should be valued separately from practical skills within vocational competence.

A further problem is that, even were a particular definition of quality to be widely accepted, the degree to which it is attained in practice would still be difficult to measure. Were the learning in question to be certifiable, the qualifications attained by trainees would in principle capture both quantity and quality. However, some learning is invariably not certified, and both the validity and the reliability of assessments of the learning that is certified are often questionable. Therefore, training quality tends to be proxied in practice by various attributes of provision, including the qualifications of trainers, the use of appropriate materials and equipment, and the completion rates of trainees.

Assuming for simplicity that quality is an agreed, unidimensional but not directly measurable attribute of a training program, contracts for training are then intrinsically incomplete: that is, any quality-related clauses cannot be enforced at law. Assume further that: suppliers are motivated entirely by profit; producing higher quality means higher cost; up to some nontrivial level of quality, the economic benefit of higher quality exceeds its cost; and training providers are better informed about the quality of their services than is the public purchaser. An efficient contract must then motivate providers to offer the optimal level of quality.

Then, the quality that they supply depends on the type of contract on offer. Three possibilities stand out. The first bases their payment on some proxy for training quality – such as output-related funding in the UK's apprenticeship program, under which the LSC's payment to a provider is partly contingent on the qualifications attained by its trainees. The problem here is that, as quality is not fully measurable, any proxy measure is prone to distortion, to an extent that increases with the intensity of the incentive. Thus, when the UK government, in the early 1990s, increased the performance component from one-fifth to one-half, it soon reversed its decision. The new payment system was seen to further undermine what was already a fragile assessment system for work-based competence under the National Vocational Qualifications system, under which training providers enjoyed considerable scope to certify inadequate learning as competence (Felstead and Unwin, 2001).

A similar problem potentially affects the labor contracts used by the training provider. A strong incentive component potentially increases employee motivation. However, if the quality dimension of performance is not readily measurable, dysfunctional results are to be anticipated. These include overproduction of the quantitative aspects, which can be measured and rewarded (e.g., numbers trained and formal qualifications), and underproduction of the qualitative ones (e.g., trainee learning).

The second contractual option avoids these snags: a fixed-price contract, in which payments to the supplier depend only on quantity, with no reward for raising quality. Producers now maximize profit by offering minimum quality – a clearly inefficient outcome.

The third option is a cost-plus contract, which compensates the provider in full for the additional cost of providing higher quality. The provider is now induced to offer high quality – indeed, to gold plate, raising quality beyond its optimal level. Such contracts have been widely used in defense procurement and health services, when quality is seen as more important than cost reduction (Chalkey and Malcomson, 2000).

The best contractual choice for the public buyer is then a second-best one, combining all three approaches. Partial cost sharing compensates providers partly but not wholly for providing more expensive services, with higher cost assumed to result from higher quality. Small performance bonuses encourage higher effort without providing strong incentives to reduce quality.

The contracts used by the LSC for its apprenticeships program involve all three principles, but the fixed-price component dominates. The price paid to training providers varies by occupation, skill level, and trainee disadvantage – all potentially associated with differences in the quality and cost of training. One-fifth of the total payment depends on the attainment of qualifications by trainees. Otherwise, the price is fixed: within a particular

occupation and skill level, providers who provide higher-quality programs at a higher cost are not compensated for doing so, and have therefore little incentive to do so – in contrast to, for example, an automobile producer considering the introduction of a high-quality model (LSC, 2003).

The exception is training provided by an employer for its own staff. Here, the benefit of an increased future supply of skilled labor provides an incentive to high quality that is absent for a specialist training provider, whose training budget is limited to revenues received from the public purchaser of training (MAAC, 2001; Ryan *et al.*, 2007).

Commercial contracting threatens to result in not only low service quality but also positive selection into training. If the cost of training varies across individuals and if the training provider knows more about individual circumstances than does the public purchaser, then fixed-price and incentive contracts encourage the selection of individuals with low training costs – that is, cream skimming. When the goals of the training program include equity as well as efficiency, for example, seeking to serve disadvantaged low educational achievers, their attainment may therefore be impeded by commercialization.

The prospects for high quality in the training market are therefore limited, in terms of contractual enforcement at least. They are improved by a further economic mechanism: reputation effects. It may more plausibly be assumed that training quality, while not strictly measurable and contractually enforceable, is observable: that is, buyers have some, albeit only partial, information about the quality of a particular provider's training. The provider then has an incentive to raise quality, insofar as low quality fosters a reputation that reduces demand for its services. The feedback from quality to demand may involve both search and experience: buyers may obtain information before purchasing, and buyers may learn from their earlier purchases, which affects the demand for repeated purchases (MacLeod, 2007).

The attributes of both providers and trainees might suggest only weak reputation effects in the training market. The business is one in which the priorities of the public buyer can change rapidly, economies of scale are limited, and new providers can enter easily, as capital requirements are low, and proprietary knowledge is not important. The benefits to a training provider of investing in a reputation for quality would therefore be low, even were the price received for the service to respond favorably.

On the demand side of the market, most trainees are young, and unlikely to be either well-informed first buyers; and, as only a minority participate more than once in a public program, repeat purchases are rare. Nevertheless, as the purchasers are not trainees themselves but the public body that buys services on their behalf, reputation effects could still prove strong. Thus, the LSC has bought apprenticeship training for vast

numbers of trainees, at both local and national levels. It is intrinsically a repeat purchaser, buying training repeatedly from many providers over the years. It should possess enough information about particular providers' service quality to steer its purchases to those that provide acceptable quality. The LSC claims to have withdrawn contracts from particular providers, but the extent to which it uses information on quality to reallocate contracts more generally remains unclear.

The information on which reputation effects depend is potentially enhanced by the external inspection of training provision and the publication of inspection findings. In the UK, the Adult Learning Inspectorate (ALI, now part of the schools inspectorate – the Office for Standards in Education, Children's Services and Skills (OfSTED)) has reported on a 4-year cycle on the quality of the services of all contractors for public training programs, and published the reports individually on its website. The quality of the provider's operations is assessed in detail and as a whole. Providers whose services were rated inadequate overall were in principle debarred from public contracts if they failed to make the changes deemed necessary by the inspectors.

Nevertheless, the informational contribution of external inspection proves disappointing, in the UK at least. Inspection practice focuses more on the provider's organization and procedures than on the substantive attributes of its services: for example, the creation of individual training plans for trainees receives more attention than their content and implementation. The primary role of inspection proves to be sociopolitical rather than economic. Inspection concentrates on the attributes of providers that are easily inspected and readily improved, thereby providing reassurance that public money is being well spent even when all is far from well on the ground. Thus, the ALI's inspections have emphasized procedural attributes, notably leadership and management, rather substantive ones, such as the content of training and the amount learned. In particular, the extent to which trainees complete training has had little influence on inspection verdicts: providers with very low completion rates have been rated adequate as long as their management procedures are deemed satisfactory. Providers who have been deemed inadequate at first inspection have typically managed within a year to implement the procedural changes needed to pass on reinspection, without being required to show evidence of substantive improvement. The informational value of inspection reports to purchasers is correspondingly weak (Power, 1999; Lewis and Ryan, 2009).

A further potential buttress for training quality under market-based contracting is the presence of noneconomic motivation, including both altruistic and professional dimensions. The owners and employees of a service provider may be less concerned with maximizing their

incomes and more concerned with the needs of trainees or the standard of service provided. As such, they may opt to provide higher service quality than is strictly in their own economic interests.

Such outcomes are particularly likely under nonprofit provision, including both private bodies, such as youth charities, and public colleges. It potentially mobilizes gifts, whether of labor, from employees and volunteers, or capital, from philanthropists. For-profit providers have negligible access to such gifts, because they can be expected to expropriate them – that is, use them to increase profit rather than to improve the service. Similarly, professional commitment on the part of training staff is intrinsically more compatible with nonprofit than with for-profit ownership. Commercial contracting weakens noneconomic motivation, by undermining professionalism and weakening the willingness of employees to work hard for substandard pay (Rose-Ackerman, 1996).

The supply of altruistic and professional motivation to training services may, however, be limited. The traditional view of the public services, in which employees were seen as ‘knights’ and entrepreneurs as ‘knaves’, ignored evidence of self-interest and inefficient practices, in terms of weak management and slack employee effort, in the public provision of many public services. To the extent that the supply of altruism and professionalism is limited, the problem of service quality remains to be solved, but nothing much is lost by commercialization (LeGrand, 2003).

More generally, the effects of commercializing a public service depend on its specific attributes. The principal ones are: the socioeconomic importance of service quality itself; the scope for cost reduction, both through reorganization and innovation, under for-profit contracting; how much collateral damage is done to service quality by cost reduction; and the strength of reputation effects, external inspection, and noneconomic motivation as antidotes to low quality. Service-specific combinations of these attributes favor commercialization more strongly, for example, in rubbish collection than in education or defense services (Hart *et al.*, 1997).

What about training services? First, in principle, high service quality is accepted as important by all contributors, including governments. That should apply to the vocational preparation of young people, for which educational and personal development, and not just economic performance, is at stake.

Second, the scope for cost reduction under traditional public provision was undoubtedly considerable. Undemanding employment conditions for vocational teachers in UK further education restricted labor inputs and protected traditional pedagogical methods. The scope for innovation in training is, however, disputed between those favoring classroom-based group teaching and those who look instead to self-guided, IT-based learning. This difference of opinion

reflects a difference in objectives: the extent to which youth training should comprise educational development, not just occupational learning. The assessment of the third attribute follows directly. If youth training is viewed in terms of personal development as well as of job skills, serious damage to quality can be anticipated from the cost cutting that is encouraged by commercialization. Finally, as already discussed, the scope for reputation effects and inspection to curb quality losses under commercial contracting appears to be modest, while the contribution of professional and altruistic motivation is weakened by for-profit provision in particular.

The balance of these considerations is not readily determined. The evidence on them is limited, as is to be expected from the low visibility of training quality. Comparing the performance of for-profit and nonprofit specialist training organizations in the US and the UK, no systematic differences are found between their completion rates and their trainees’ outcomes after leaving, (Heinrich, 2000; Lewis and Ryan, 2009). Therefore, commercialization does not appear to reduce quality.

However, such evidence is of limited value, as it covers only specialist training providers and narrowly defined program objectives. In the UK, employers who train their own employees have substantially higher completion rates than do specialist training organizations – a difference consistent with other evidence, such as additional investment and greater staff expertise, of higher quality in many employers’ programs (*ibid.*).

Second, the learning aspirations of public training programs are themselves limited. This is most clear in comparison to the national apprenticeship systems that pursue clear educational objectives. Commercial methods are less suited to the diverse objectives of vocational education than to the narrower objectives of public training programs. By the same token, the commercialization of public training programs in Britain has reoriented youth learning from vocational education toward job training.

The Cost Disease, Public Spending and Politics

The quality problems of the training market may have additional causes. The leading candidate is the cost disease of the services, combined with fiscal politics.

Education and training services are labor intensive. They are produced with little physical capital, with little scope for technical change and productivity growth. Their technological stagnancy means that they exhibit the cost disease of the services: cost per unit of output – and, in a market allocation, the price – of their output increases over time, relative to that in other sectors. The lower the sector’s relative productivity growth, the faster is the rise in its relative unit cost (Inman, 1985). The trend increase

in real tuition fees for private education in the UK and the US can be understood in such terms.

If the demand for a technologically stagnant service is income elastic and price inelastic, then in a mainstream market system its share of national income at current prices will rise over time: increasing real income stimulates demand, while increasing relative price does little to reduce it. The private education market shows such attributes, in terms of trend increases in both relative price and the demand for places. The same is taken here to apply to skills and training generally.

In a quasi-market, the response of demand to rising relative unit cost depends on the government's budgetary policy. If the government chooses to reduce the real growth of public spending on the service, its output grows more slowly and it may even fall. The effect on output may involve quantity, quality, or both. If the public buyer gives priority to quantity, then quality suffers (Ryan, 1992).

The politics of training in liberal democracies encourage the prioritization of quantity over quality. Four reasons may be distinguished. First, the electoral politics of public spending and taxation encourage governments to restrict public spending and reduce personal tax rates. Second, the greater visibility of quantity than quality in training programs means that a government can anticipate greater political rewards, for a given training budget, from making the program available to more eligible citizens than from offering a better service to fewer people. Third, in Europe at least, the goals of public programs involve social justice as well as efficiency, and entitlement-based participation means quantitatively large programs. Thus, the targets that have dominated training programs in the UK in the past decade have been primarily quantitative: for example, the target that all eligible young people have access to the Apprenticeships program by 2013 (DIUS, 2008). Finally, the career prospects of ministers tend to benefit from highly publicized policy innovations, whose presentation matters politically more than their content and implementation (Pierson, 1996; Keep, 2006).

Evidence of political constraints on training quality can be found in the decisions governments actually make when a choice must be made between quantity and quality. Both, the replacement of the Youth Training Scheme by the Modern Apprenticeship in the UK in the 1990s, and the subsequent introduction of requirements for training toward a technical certificate and basic skills in all MA programs, suggest the reverse prioritization: that is, quality over quantity. However, the detailed content and the implementation of such changes suggest otherwise, in terms of: the marked continuity in training methods and outcomes between successive programs; the lack of requirements for the skills and qualifications of training staff; the educational weakness of many of the technical certificates recognized for public support; and

the substantive failings of external inspection (Ryan and Unwin, 2001; Ryan *et al.*, 2007).

The quality problems of the training market may therefore reflect the wider difficulty of raising productivity and reducing costs in a labor-intensive public service, combined with fiscal pressure to restrict spending on it, and the political incentive to give quantity priority over quality when doing so.

Summary

The training market sees a range of providers, public and private, for profit and nonprofit, compete for contracts to provide training as part of publicly funded programs. It is characterized by a dominant public purchaser and fixed-price contracts.

Relative to traditional public administration, the training market strengthens economic incentives, with the introduction of the profit motive and competition. It promises increased efficiency, as the result of improved management, reduced labor costs, and increased innovation. Its potential to improve options for trainees and to make training more responsive to their needs is, however, limited.

A weakness of training markets is the difficulty, given asymmetric information, of ensuring acceptable quality under contractual relationships and economic motivation. In principle, the problem can be countered by reputation effects, external inspection, and nonprofit provision, but the power of all three mechanisms is limited.

Low service quality is also promoted by the technological stagnancy of training services, in conjunction with limits on public spending and political incentives to give priority to quantity over quality. Low quality may result more from political choices than from any technical impossibility of ensuring acceptable service quality under commercial contracting.

The implication is not, however, that traditional public administration should be preferred to quasi-markets. For vocational education at least, better results can be anticipated from joint administration by employers and the representatives of employees and educators, as in the national apprenticeship systems of continental Europe.

Glossary

Communities of practice – A term especially introduced in Lave and Wenger's *Situated Learning. Legitimate Peripheral Participation* (1991) meaning an activity system about which participants share understandings concerning what they are doing and what that means in their lives and for their communities.

Competence – The ability to apply learning outcomes adequately in a defined context (education, work, personal), or professional development.

Continuing professional development – Any kind of activity (education, training, development work, nonformal learning) which after initial education contributes to improve knowledge and skills and continuing personal or professional development.

Learning facilitator – Anyone who promotes the acquisition of knowledge and skills by establishing a favorable learning environment, including anyone exercising a teaching, training, supervision, or guidance function. The facilitator helps the learner develop knowledge and skills by providing guidelines, feedback, and advice throughout the learning process.

Learning outcomes – The set of knowledge, skills, and/or competences an individual has acquired and/or is able to demonstrate after completion of a learning process, either formal, nonformal, or informal.

Professionalization strategy – The concept or professionalization refers to two related processes. The first, internal, aspect concerns the development and consolidation, by a group of individuals, of the competences required to practice a profession. The second, external, refers to the claiming of a distinct social status as part of the division of labor in society. Both sides of the process are interrelated. The transmission of codified practices during initial training is part of the professionalization of the occupation and contributes toward its social recognition.

Teacher – A person whose function is to impart knowledge, know-how or skills to learner in an education or training institution. A teacher may fulfill several tasks such as organizing and carrying out training programs/courses and transmitting knowledge, whether generic or specific, theoretical

or practical. A teachers in a vocationally oriented institution may be referred to as a “trainer.”

Trainer – Anyone who fulfills one or more activities linked to the (theoretical or practical) training function, either in an institution for education and training, or at the workplace. Two categories of trainers exist: (i) professional trainers are training specialists whose job may coincide with that of the teacher in a VET establishment and (ii) part-time or occasional trainers are professionals in various fields who take on, in their normal duties, part-time training activity, either in-company or externally.

Vocational education and training (VET) – Education and training which aims to equip people with knowledge, skills, and competences required in particular occupations or more broadly on the labor market.

Introduction

The recruitment, training, and work of vocational education and training (VET) school teachers are core topics of vocational and business education and training. However, until today there is neither a requirement profile substantiated by theory and supported by empirical investigations nor a common job description for VET school teachers. What we know is that there is a great variety in the structure, status, and situation of the initial and continuing training and development systems for VET teachers and trainers. In this article, we first define the teachers in VET and then analyze major contextual factors and drivers of change influencing the educational and professional development needs of VET teachers and their new roles. We then examine initial teacher training for VET teachers and activities and trends in continuing professional development. In the final section, we consider future challenges for the VET teaching profession.

It is a complex task to give a global overview of the situation of VET teachers, the training of teachers, and the institutions in which they are educated and are working now. Studies of teachers from recent years do not make particular reference to the specific problems of teachers in vocational education. (These include the recent monitoring activities of the Organization for Economic Cooperation and Development (OECD) with regard to attracting,

developing and retaining teachers; the Working Group of the European Union (EU) on the qualifications of Teachers within the process Education 2010; the activities in the Asian context or the work of International Centre for Technical and Vocational Education and Training (UNEVOC) the comparative studies carried out by United Nations Educational, Scientific and Cultural Organization European Centre for Higher Education (UNESCO-CEPES) on institutional approaches to teacher education in Europe and in the Asia-Pacific Region (Battezzati *et al.*, 2004; Central Institute for Vocational Technical Education of the People's Republic of China, 2000; European Commission, Directorate-General for Education and Culture, and Working Group, Improving Education of Teachers and Trainers, 2003; Hopkins and Stern, 1996; Leney and The Lisbon-to-Copenhagen-to-Maastricht Consortium Partners, 2005; OECD, 2002; Morris and Williamson, 2000; Moon *et al.*, 2003). The significance of vocational learning is often overshadowed by the greater emphasis societies place on academic education and credentials. Not so much is, in fact, known about VET teachers; the last comprehensive international studies on VET teachers occurred more than 30 years ago (International Labour Organization, 1964; UNESCO, 1973; UNESCO's section for technical and vocational education, 1997). However, a study has been published (Grollmann and Rauner, 2007).

Another barrier is the difficulty related to comparative research. A general lesson from the history of comparative education is that “every system of education is shaped by its local, historical, economic, cultural and social context. . . . Education, in short, cannot be de-contextualized from its local culture . . .” (Crosley and Watson, 2003: 39). While we have overviews of VET TT systems and practices in a number of regions in the world (CEDEFOP, 2004–2007; ETF, 2005; etc.) – quite rich in data – they do not describe the societal background in any depth or detail. The main problem is the lack of contextualization and in-depth analysis of trends from a national perspective.

The low status of VET and the general problem of increasing the status of the teaching profession are a third factor. While vocational teachers and trainers are essential to supporting skill development in the workforce, they are not granted high status in this role. In industrialized countries, some two-thirds of the workforce that constitutes the backbone of each economy are intermediate-level workers and employees who have learned a substantial part of their occupational skills and knowledge through the support of teachers, trainers, and instructors from the domains of nonacademic technical vocational education and human resources development (cf. CEDEFOP, 1998). Given the basic importance of vocational training for economic success, it is significant that in many countries VET has failed to achieve the level of social recognition that is needed to establish VET teaching and training as a well-regarded profession that attracts

societal support, including attracting appropriate individuals to practice as vocational teachers. This is reinforced by the fact that teaching generally has always had problems in gaining professional recognition, and has even been referred to as a ‘semi-profession’ (Etzioni, 1969). The low professional status of teachers in VET is accompanied by a fragmentation of the profession through the variety of existing profiles and multiple ways of teacher training and recruitment.

With the increasing emphasis on lifelong learning, VET teachers (and trainers) can now be regarded as learning facilitators and VET teaching can gain acceptance as a core profession in the knowledge society. Improving the standing of teachers is, therefore, a significant lever for increasing the quality of vocational education, as acknowledged by many international and national organizations. The awareness of the roles of teachers and trainers as learning facilitators has markedly increased.

It is even becoming ‘high politics.’ In Helsinki on 5 December 2006, European Ministers of Education stated that “highly qualified teachers and trainers who undertake continuous professional development are essential to improve the quality of education and training systems.” However, VET teachers and trainers everywhere are getting older, their tasks more varied and complex, and they receive little support to cope with the changes and new demands made of them. In **Figure 1**, the European Centre for the Development of Vocational Training (CEDEFOP) captures well many of the new challenges for VET teachers and trainers in today's changing societies.

Who Are the VET Teachers?

In an analysis of the international landscape of VET, Rauner (1999) identified roughly four models of the school-to-work transition, based on the socioeconomic contexts, and producing a huge variety of functions of the educational day-to-day work distributed between different profiles of teaching and training. Job specialization has grown in all countries, albeit it is not well defined everywhere. Rauner identifies six clusters of teaching profiles within VET and, given the four models of school-to-work transition, this already leads to 24 different profiles of VET teachers, lecturers, and instructors. In reality, the picture will be even more complex as country in-depth studies would show. The global reality will be much more complex; given the vast number of different profiles and functions of VET teachers, this is indeed a very fragmented profession. (Grollmann (2007) identifies five different basic professional profiles of teachers, trainers and instructors in VET.)

The term VET teacher generally designates personnel in secondary level schools and VET colleges, regardless of the level of education.

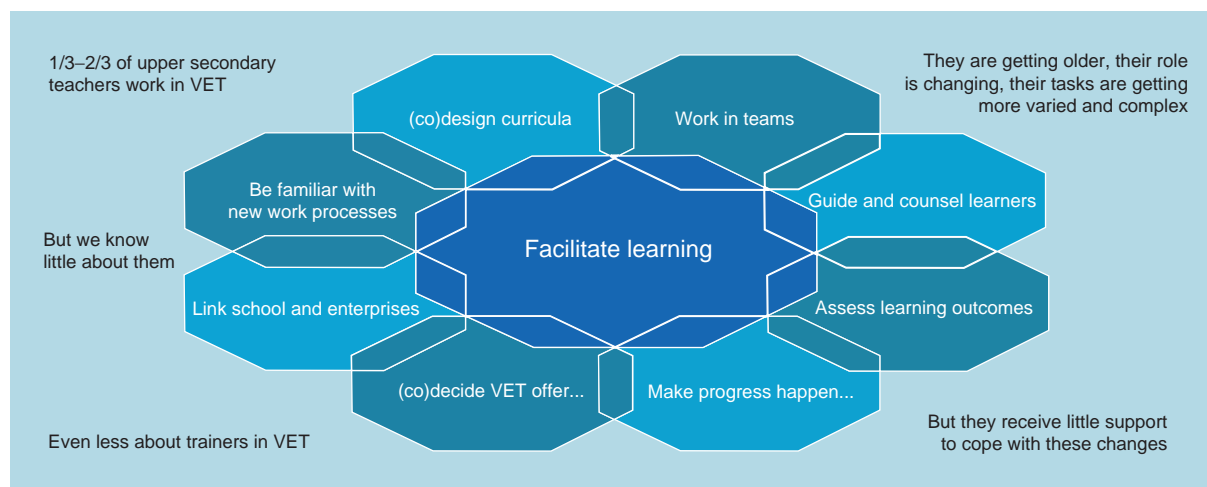

Figure 1 VET teachers and trainers: the forgotten change agents. From CEDEFOP, Conference outcomes: VET teachers and trainers: the forgotten change agents? CEDEFOP TTnet 9th Annual conference, Thessaloniki, 7–8 December 2006.

VET teachers:

1. Working context: public system, education system, Initial Vocational Education and Training (IVET).
2. Teaching content: theoretical part of VET.
3. Functions: general subject teachers, vocational subject teachers.

The term trainer normally refers to professionals involved in apprenticeship systems, on-the-job and off-the-job training and, more generally, in private sector training markets.

VET trainers:

1. Working context: private system, industry, and commerce sectors, Continuing Vocational Education and Training (CVET).
2. Teaching content: practical part of VET.
3. Functions: trainers, other learning facilitators.

Contextual Factors and Drivers of Change Influencing VET Teachers' Work

Educational reforms have been on the political agenda for many years. Earlier, several years passed between reforms but in this century each day seems to bring a new educational reform so there is no reason for calling it reforms anymore; what is going on can be called continuous change.

In education and VET there is a global movement toward standards. This approach assumes that the quality of education and productivity of labor can best be achieved by setting high performance standards for teaching and learning, and then measure to what extent the standards have been met. The Trends in International Mathematics and Science Study (TIMSS) and the Programme for International Student Assessment (PISA) are good examples of

some of the ingredients of this concept. The EU Open Method of Coordination in many ways reflects this.

Standardization seems (currently) to be the preferred approach, described by Hargreaves *et al.* (2001) as “a new official orthodoxy of educational reform,” very much inspired by the Anglo-Saxon community.

As Sahlberg (2004) points out, recent research in England and Wales, New Zealand, Australia, Japan, Singapore, and the USA indicates that standardized reforms may have drawbacks, for instance, de-professionalization of teachers' work and a more narrow focus on basic skills in core academic subjects, and less on how to seek information and use that information in problem-solving, etc. Over-standardization, therefore, does not seem to be the answer to challenges from the knowledge society, where people need to be able to acquire knowledge, use it, develop new knowledge, apply it to new situations, and share it.

Andreas Schleicher (2006) writes in The Lisbon Council Policy Brief that the most successful countries have something in common:

... they have all shifted policy away from control over the resources and content of education toward a focus on obtaining better outcomes. They have moved from “hit and miss” teaching practices to establishing universal high standards. They have shifted from uniformity in the system to embracing diversity and individualising learning. They have changed from a focus on provision to a focus on choice, and they have moved from a bureaucratic approach towards devolving responsibilities and enabling outcomes, from talking about equity to delivering equity. Most important, they have put the emphasis on creating a “knowledge-rich” (knowledge-rich means (in this context) that both national prescriptions and professional judgments are informed) education system, in which teachers and school principals act as partners and have the authority to act, the

necessary information to do so, and access to effective support systems to assist them in implementing change (Schleicher, 2004).

Such changes involve radical challenges for teachers and other professionals in VET. Two major policy elements (Ball, 1999) can be found in almost all countries. One is the insertion of the market form which is intended to subject education to the dynamics and culture of competition and business; the other is performativity. This seems to lead to a control system based on a so-called noninterventionary form of governance – the market decides what is necessary, and standards are set up in order to tell the institutions about good behavior. Governmental steering from a distance has been ever more common. In most cases, it has been combined with giving educational institutions more autonomy, authority, and accountability.

Some of the main drivers behind educational reforms are:

- Challenges from the knowledge society.
- The idea behind new public management and the efforts to change the public sector to make it more market oriented, customer related, performance based, competitive, flexible, and accountable.
- The constructivist approach, meaning that we all actually construct our own knowledge, and that the truth is what we believe in.
- The pressure from new groups of students with new and different expectations as to how to be treated in school – and how to learn.
- The never-ending story about information and communication technology (ICT) development and what it means to both teachers' and students' competence.
- Challenges from living in a global world and the subsequent need for understanding different languages, different cultures, etc.

It can be illustrated as shown in **Figure 2**.

Figure 2 Main drivers for education reforms.

These issues are shared globally. The discussions all over the world are more or less the same. In a new study of globalization Grewal (2008) analyzes the drivers for global change and catches these in his concept of network power. Networks are the means by which globalization proceeds. All networks have standards embedded in them. In theory we can choose among standards and become free. In practice, Grewal shows, our choices tend to narrow over time so that standards are imposed on us. Driving forces include the spread of the internet with its worldwide fiber-optic network and the growth of outsourcing. This generates the process of worldwide industrialization and intensifies worldwide interdependencies; the continuous flow of people, ideas, capital and goods ensures that a global knowledge-based economy emerges. With modern communications and the aggressive marketing of Western culture, the poor are now much better informed about how the other half lives. (In Giddens (2002) *Runaway World*, he gives an illustrative example of how an anthropologist friend of his studied village life in a remote area in central Africa. The day she arrived she was invited to a local home for an evening's entertainment. She expected to find out about the traditional pastimes of this isolated community. Instead, the occasion turned out to be a viewing of *Basic Instinct* on video, the film which at that point had not even reached the cinemas in London (p. 6).)

The challenge is how to cope with these changes in the specific national and cultural context. In the end, all educational reforms touch the teachers (and the students). At this crucial interface, they may have opinions differing from those of politicians and school leaders.

Today, more focus is put on the teacher as a facilitator, a person who will be able to organize learning for students, recognize students' prior learning, and cooperate with both students and colleagues (in teams?) and is supposed to work for both, students and country. Experience from countries already down that road shows that it is a very difficult process. At least two challenges are present. Teachers consider themselves (1) experts in their professional field, and (2) professionals, in the sense that they know what is best for the students, and therefore cannot be commanded and/or controlled by others (the management).

A teacher (as an expert) with a lot of experience in classroom teaching is able to act appropriately if something unexpected happens – immediate, adequate, and fast. But what happens if conditions change? If, for instance, teachers are now supposed to work as facilitators and in environments, based on principles from open learning or resource-based learning approaches? What will happen if teachers, due to a new reform, must cooperate with each other (in teams and across subjects), focus more on learning than on teaching, and accept that students should have much more influence on both form and content? Will they continue to use their original expertise

(from classroom-teaching)? And will that still be appropriate? In most cases the teachers' response to (the new) challenges will be inadequate. The teachers' options then would be to either (1) claim that the new conditions are bad for both teaching and learning or (2) accept to start as beginners in this new game, and to drop the idea of being experts. The first option is very difficult in relation to school leaders and policymakers, and the second one would be very difficult for the teachers themselves.

What is obvious everywhere is that the challenge needs to be solved by creating a new teacher professionalism involving new forms of relationship with colleagues, students, and society. This requires new and more comprehensive competences for both teachers and school leaders.

Initial Training for VET Teachers

Qualified VET teachers and trainers are in short supply in many countries. There are many problems related to the human resource base for VET and the VET teacher profession are almost everywhere, except maybe Germany, a young country. How could we best institutionalize initial teacher training and how do we recruit the right people into such programs? In small countries it is difficult to provide training in the many vocational specialties without underutilizing training capacity; this is today the case in the new republics of the former Soviet Union and former Yugoslavia. In most countries, we see challenges to ensure that the pedagogy part of VET teacher training is sufficiently relevant for the instruction of practical skills in the vocational specialty. Sufficient and relevant work experience from industry is also difficult to ensure when recruiting teacher candidates.

In general two traditions in VET teacher education have dominated: the school tradition where teacher training takes place in designated teacher-training institutions, and the academic tradition where teacher training takes place at universities.

Two main VET teacher types dominate:

The craftsman-turned-teacher. These teachers view themselves as skilled craftsmen; to be a teacher is only a secondary and, often, lately acquired part of

their professional identity. These teachers teach the practical or technical subjects in VET. In some countries, for example, the UK, the requirement of professional teacher training has been introduced only recently.

The professional VET teacher. Few countries have special professional educational courses aimed at becoming a VET teacher (e.g., Belgium, Germany, Hungary, the Netherlands, Norway, Poland, and Sweden). Students choose VET teaching as their career at the beginning of higher education itself, and to be a VET teacher is the primary and maybe only aspect of these teachers' professional identity.

There are many models of programs which give access to becoming a VET teacher. We will concentrate here on initial training for teachers of VET subjects; general subject teachers are educated in ordinary teacher education programs. To illustrate the scope of programs we will here compare highly different VET TT models in three Northern European neighboring, and in many ways, isomorphic countries, Denmark, Germany, and Norway which all have successful dual VET systems (Table 1).

This illuminates the scope of models. The Danish in-service tradition with a short pedagogical training course delivered as a sandwich program with a considerable part taking part in VET schools where candidates are employed (the craftsman-turned-teacher) versus the long university programs in Germany (the professional VET teacher). Norway has recently introduced 3-year programs in order to cope with challenges of the knowledge society.

Grollmann and Rauner (2007) in their comparative study describe four types of program content:

- A purely methodological training on teaching methods, for example, the teaching certificate in UK as a preparatory measure or the in-service courses in Denmark, the USA, Brazil, Japan, and (as one variety) in France. This is often connected to a situation based on the recruitment of practitioners of a certain field of occupational work.
- A consecutive concept based on a sequence of studying the subject matter (e.g., at the BA level) and obtaining an appropriate entry qualification to the education sector through acquiring general teaching skills in a

Table 1 Initial VET teacher training in Denmark, Norway, and Germany

	Where institutions	When pre/in-service	Whom access	How structure	How long duration	What curriculum
DE	University (many)	Preservice (young)	Abitur Work experience	University Practice ('Referendariat')	5 years 11/2 years	VET subject General subject Pedagogy
DK	Semi-academic institution (one)	In-service (mature)	Skilled worker 5 years of work experience	Sandwich course With Mentoring in schools	14 weeks (660 h)	Pedagogy Psychology Didactics
NO	Semi-academic institution (10)	Preservice (young)	Abitur Skilled worker	Study with School practice	3 years	VET subject General subjects Pedagogy

designated course program (typical in the USA). This concept can also be found in the Western Balkans and Turkey leading to a 4-year BA level degree.

- A model based on the concurrent study of a subject matter and educational sciences leading to a BA or an MA degree. Often the subject matter study is a reduced part of the ordinary business or engineering degree. Sometimes special vocational didactics are added. This is the model in the former Soviet Union and former Yugoslavia.
- A model based on an integrated conception of vocational disciplines where the subject matter is derived from the world of work and a model of competence development within this domain. This paradigm of vocational learning turned into teacher education is found in Northern German teacher education institutions and, to some extent, in Norway and some Chinese VET teacher education programs.

The UK has around 30% of VET delivered by providers without public institutional status; here teacher qualification requirements are limited to those who assess learner competence and with no parallel requirements for VET teachers. Also in the UK, with some parallels in Australia, there is a work-based alternative to school-based education; a host school or the teacher's own workplace can provide this training. In Albania (and in many other countries) neither pedagogical requirements nor courses to qualify VET teachers exist. In most of the southern European countries (e.g., Greece, Spain, France, Italy, Cyprus, Portugal, etc.), a state exam (*concours*) is the decisive point for becoming a teacher. Available courses are structured as specific preparation for this exam.

In Europe (Parsons *et al.*, forthcoming) a very complex patchwork of different stages of development exists, and there is no common tradition for VET teacher training. Structures diverge but there are common and enduring problems: aging, status, deregulation, limited career paths, and limited durability of employment. Entry requirements are rising across Europe on VET teachers who are increasingly becoming a graduatized workforce. A widespread emphasis is put on building and extending pedagogical skills but through a general education model which is rarely VET centered.

For Europe the common conclusion is one of convergence and divergence. The EU is pushing for member states to converge and this process of convergence is evident throughout Europe. At the same time, we see an adaptation process where the individual member states adapt the EU policies to national practices or interpret and transform them to suit national practices.

However, there are still a couple of unsolved problems which are found in most countries of the world.

Almost all studies identify two critical findings about VET teacher training (Rauner and Maclean, 2009):

- A relevance to practice of the specialized programs that is felt to be deficient. In almost all cases the practical experience as a skilled worker or engineer was seen as being of greater value for working as a teacher than studies in pedagogical sciences.
- The lack of any interlinking of the educational/sociological part of programs with the concrete professional and teaching situations, so that hardly any pedagogical competences relevant to working as a teacher were acquired during the studies to become a VET teacher.

Continuing Professional Development of VET Teachers

Throughout the world there is a shortage of in-service continuing development of VET teachers to keep updated on technological change. The concept of professionalization is closely linked to updating, upgrading and developing VET teachers' and trainers' competences so that they can meet the challenges facing their profession and act professionally in their daily work. In general, the continuing professional development (CPD) and in-service dimension of how VET practitioners stay qualified has received little attention in comparative analysis. In-service continuing training is generally a large and heterogeneous area with numerous offers of great variety and usually many different private/public profit/nonprofit providers.

Substantial differences exist between EU countries concerning in-service and continuing training and development (continuing professional development) for VET teachers. (CEDEFOP study on Training of VET teachers and trainers in Europe: a comparative perspective.) In many cases (e.g., Cyprus, Iceland, Ireland, Italy, Poland, and Slovenia), CPD is in principle voluntary, but teachers are expected to participate. In most of the new Eastern European EU countries CPD is laid down by law stipulating the minimum requirements to teachers' CPD within a certain period of time. CPD categories vary from obligatory in-service training, arrangements stemming from collective bargaining (Finland, Hungary), and CPD structures relying substantially on self-motivated in-service development. Where common themes are apparent, they seem to stress enhanced pedagogical training, teamworking, leadership, enhanced/updated subject knowledge, and preparation for advancement and on wider nonspecific professional skills. One component of CPD emerging in a number of EU countries is for post-qualification training in workplace-based technology and organization. Also in Germany and the UK among others, recent company-initiated initiatives have attempted to bridge the gap between theoretical vocational knowledge with skills use and new processes in industry and commerce.

In the CIS countries (of the former Soviet Union), the former Yugoslav countries, and among others. Turkey, continuing vocational training (CVT) is highly centralized and offered through a national catalog of training courses on offer. In these countries that are in transition, the CVT activity is extremely low; a foreign donor-led reform is ongoing in several countries to create a free market in CVT and establish accreditation systems for CVT providers.

The types of CVT span from on-the-job competence development in connection with implementing a reform to Master programs. A general trend is toward CPD in coaching, mentoring, and supervision as more student-oriented approaches have been introduced (e.g., in Austria, Belgium, Denmark, Norway, and the UK). This emphasizes the need for a diverse multifaceted provision for CPD that is focused on developing new competencies. In-service training for trainers in the on-the-job part of dual VET systems are regulated in countries like Austria, Germany, Hungary, and Slovenia; in Denmark there is a belief that learning organized in accordance with a production logic instead of a pedagogical logic is highly effective in a combination with formalized learning processes in school.

Continuing training of VET teachers is often criticized for not preparing teachers adequately to update their skills, and for not equipping them sufficiently to master new teaching methodologies. Much more than is usually apparent in studies of VET TT, it is the concrete conditions of work that primarily influence the understanding of vocational pedagogical tasks, the professional self-image, cooperation of teachers – in short, the essential dimensions of the process knowledge of vocational teachers. The impact of the learning environment within concrete working conditions of teachers in VET institutions is often overlooked. As contributors to CPD, comparative studies of those concrete working conditions and practices could be of great interest for understanding the reflected practitioners in VET.

An interesting response to this lacuna is found in Denmark which has a long tradition of local innovations seen as central for modernizing curricula and systems in VET. The vehicle is the Forsøgs- og Udviklingsarbejde (FoU)-scheme (innovation and development grant program) financing school-based projects led by teachers, and at the provider and cross-provider level. The Ministry of Education lays down overall reform priority areas stimulating and financing teacher-led school projects, with expertise to guide these projects from VET teaching expert consultants funded directly by government. These development projects are seen as important contributors in the continuing development of teachers in Denmark where the innovation of content, methods, and teacher competence development go hand in hand.

This is one of the few examples of practitioner-led change vehicles focusing on teachers as change agents, while in other countries comparable programs in the VET modernization agenda are fully policy led.

Funding of CPD is constrained everywhere. New and more cost-effective delivery methods are tested in a number of countries. In England a largely cascade-model for subject-based new learning methods has been implemented. In the Netherlands and Denmark, group and peer learning methods and communities of practice are starting to emerge as methods for reprofessionalization of VET teachers with some positive evidence of being both cost-effective and well received by teachers as a focus for reflective practice and for knowledge sharing. In Australia, CPD for VET teachers has become an important policy lever through a collaborative model to provide for a bottom-up approach to CVT (Dickie *et al.*, 2004).

Future Challenges

The Missing VET Didactics

There is no distinctive professional knowledge base in the pedagogy of VET learning and delivery. Many national systems which require a pedagogical foundation for VET practitioners continue to derive this from teacher training rooted in general education contexts. Also the demand for more learner-centered approaches in a vocational context calls for more specific and applied VET knowledge which is not always served well by current approaches. Universities in most cases lack the application and workplace experience to respond effectively.

The challenge is to combine the worlds of work and education and consequently different fields of science. VET teachers work in a more complex field compared to teachers in general education because their subjects, and thus their knowledge base, are characterized by a double theory/practice problem. They work in a field that lies between specialist theory and specialist work as well as between school practice and work and/or professional practice. This is a domain which is not really there but needs to be better conceptualized and developed. A research context which could help uncover the domain may be inspired by US research in connection with pedagogical content knowledge (PCK) (Shulman, 1986; Bauer and Grollmann, 2009).

The PCK approach represents a unique knowledge base of the teachers; it forms an amalgam from content-related (field-specific) and pedagogical knowledge and is interdisciplinary. The PCK strategy has concerned itself especially with how subject-related and curricular contents are transformed by teachers in the teaching activity itself. This inquiry into the professional knowhow of VET teachers would be worthwhile pursuing in the coming years.

Peer Learning and Communities of Practice

Communities of practice have started to emerge as vehicles in the reprofessionalization of VET teachers. There is some narrow but positive evidence that these are proving to be both cost effective and also well received and regarded by practitioners as a focus for reflective practice, a foundation for professionalism, and for sharing this with others in the professional field. This merits more attention through analysis of the various examples of innovation, both at policy, provider, and practitioner levels.

In most countries, still, the concept of CPD of teachers is only seen as continuing training of teachers provided by external delivery systems. CPD is a much more promising strategy; it is much cheaper and it reestablishes a social recognition of teachers as professionals and stakeholders of reform.

With the aim to establish another teacher professionalization strategy in Southeast Europe, the European Training Foundation (ETF) has launched a new teaching and learning project from 2007 to 2009. The 3-year ETF project aims at strengthening the national institutions which have a potential leverage for carrying forward ideas and projects in this field. The project will support VETCenters or other relevant institutions in order to enhance their capacity:

- to carry out continuous innovation and adaptations to changing conditions and increase the responsiveness of VET to local needs;
- to cope with the challenges of new policies through school-based development work, innovation of teaching and learning, and enhancing capabilities for international network learning and project cooperation; and
- to enhance their own and local school's expertise by actively taking part in knowledge-sharing based on horizontal learning processes.

The project is grounded in horizontal learning processes which are important tools for policy learning, and makes use of a principle of community of practice as a vehicle for network learning where participants (1) share a given practice, (2) are able and willing to learn together and (3) actually work together on improvements of practice, inventing new procedures, models, tools, etc. and share the results of their mutual work. Communities of practice are seen as useful tools both as an instrument for national learning activities and as a knowledge-sharing tool across countries. Shared learning activities will be based on the exchange of participants' own experience and the improvement of practice and competence will go hand in hand.

VET Teachers as Change Agents

In modern vocational education and training systems, teachers are, at the same time, professional educators

and key change agents. Continuing innovation and development has become a core task of a modern professional teacher. The professional expertise of teachers committed to change and modernization is also an important source of knowledge for policymakers leading the development and implementation of national policies. A key question therefore is: How to involve VET teachers actively in VET reform so that ownership will be better translated into quality learning in the classroom and professional expertise from teaching and learning processes can guide system reform?

Successful reform can only happen with engagement and commitment of teachers, if only because in the end, they will be the ones who will have to make it happen in their daily work with students and others. However, this is no longer simply a matter of establishing broad ownership and acceptance.

What makes the situation different today is that the new professional profile of teachers includes innovation and development as a key competence. They are no longer the executors of educational programs decided in detail by others but have to adapt learning processes and outcomes to the specific changing needs of their students and local labor market situations. Teachers are stakeholders in their capacity of educational professionals. This, in turn, reflects the fact that the current reforms in VET are very complex development processes, especially true for reforms in transition countries. Such reforms are not one-off events designed by external experts but ongoing change processes set within a broadly agreed reform agenda, which can be quite radical but that requires further operational detailing based on local innovation processes. It is because of this that teachers who are actively engaged in local innovation and experimentation are an important source of expertise for national policymakers; reform strategies have to build on engaging teachers working inside their school organizations. Such an understanding of reform puts policy learning, capacity building, and policy advice at both national and school levels in a new perspective and at the same time with considerable more urgency than before. Traditional top-down or bottom-up strategies are insufficient to make reforms work. Reform processes require a continuous interaction and dialog between national and local partners. There are therefore strong pressures to include teachers among the principal stakeholders in reform.

Changing Frameworks or Changing Actors?

There is an intense international debate about the lack of real substance per se in standards and national qualification frameworks. The focus only on learning outcomes is now perceived as too simplistic and has led to the belief that it really does not matter at all how people arrive at certain learning outcomes. It is questioned whether this

model sufficiently reflects the premise that rapidly changing and unstable labor markets ask for new kinds of competences enabling people to cope with increasing uncertainties. As a result there is a growing interest – also at the policy level – to pay more attention to the quality of learning processes, including the role that teachers play in helping people to learn. Learners and learning processes are back in the spotlight. VET schools and teachers and trainers have become key factors. Increasingly, the challenge to balance learning inputs, outcomes, and processes has international dimensions as well. The ETF Yearbook 2007 is placed within this broader context and the focus of the debate raised here is: How do we rebalance the tensions in VET systems between input and outcomes and how can a renewed focus on substance and learning processes be fed into VET reform policy?

We still need to find answers to this question.

Vocational Education and Training Workforce

VET System: VET Workforce

Vocational education and training (VET) is known by many names including vocational education, workforce education, industrial education, manual education, occupational education, further education, training, career education, and technical education. It is a large and diverse educational enterprise that spans both secondary and post-secondary education. Nevertheless, there are certain characteristics that are typically used to define VET and set it apart from traditional liberal arts education. Perhaps most significant is its purpose. Vocational education, by whatever name, has as its purpose the preparation of individuals for work. Historically, the purpose of vocational education has been to prepare individuals for entry-level jobs in occupations requiring less than a baccalaureate degree. More recently, however, vocational education has been reconceptualized into a broader preparation that includes academic as well as vocational and technical skills. Thus, vocational education has morphed into an enterprise that integrates occupational and academic knowledge, not only for entry-level work, but also for fully functioning in the world of work, for advancement, and for continuing education to keep up with the changing requirements of the workplace.

This article is divided into four distinct but interrelated sections: (1) historical roots of VET and the VET workforce; (2) VET faculty characteristics, qualifications, and credentials; (3) permanent/casual VET faculty; and (4) professional development for VET faculty.

Historical Roots of VET Workforce

One cannot understand the nature of the VET workforce without first understanding the history and competing philosophies that underpin contemporary vocational education. For centuries, there have been two types of education – education for work and education for culture. These two types of education have been separated by social class. Education for work was typically delivered through imitation and practical experience with tools, materials, and machines in the field, at home, or in the factory. Education for culture, on the other hand, was delivered through the medium of books, formal instruction in the home through tutors, and later through private and then public schools (Scott and Sarkees-Wircenski, 2001). It is only recently that educators and policymakers have begun to see that these two types of education are not so

distinct: indeed, except for the very elite and independently wealthy, all education is vocational education in that it prepares individuals for work. Nevertheless, there are still significant distinctions in the type of work implied by VET.

Perhaps the earliest vocational education occurred from father to son, mother to daughter as parents passed along to their children the skills by which they earned their living. However, vocational education became formalized when organized apprenticeships began. These apprenticeships were usually sponsored by guilds, particularly in England and France, and later in America. These guilds were composed of organized groups of craftsman who were among the earliest vocational instructors.

During the 1800s, schools were strictly divided by social class and the purpose of education for the wealthy classes was much different than it was for the working or indigent classes. Manual training, or handwork, became the centerpiece of vocational training for the lower classes. Germany was the center of the manual-arts movement and maintained elementary free and compulsory schooling, thus providing a secure foundation for industrial training. Rousseau was an early supporter of manual arts and believing that the manual arts could be seen as a means of mental training and an expanded view of vocational education. Pestalozzi built on Rousseau's thinking and insisted that children should be taught not only to think but also to do and that education should consist largely of manual labor. His ideas spread through Europe and into the United States throughout the nineteenth century (Gordon, 2003).

In the United States, by the late 1800s, industrialization had drastically changed the agrarian landscape of the previous century. While universal education was available up to the eighth grade for most students, the school curriculum was largely focused on preparing individuals for higher education in colleges and universities despite the fact that only a very small number even graduated high school. Thus, the manual-arts movement gained ascendancy as a social and economic issue: the belief that people who are trained to work for wages purchase goods and services and become contributing members of society. Pragmatism as a philosophical ideal became a part of faculty thinking, emphasizing the concrete and practical over the abstract. Education was seen more as a science, and the faculty were free to engage students in problem solving and concrete applications of their learning. John Dewey, a strong advocate of vocational education, came to symbolize early organized vocational

education in America, encouraging faculty to employ the project method of instruction which was being employed in some manual-training schools. He advocated methods of instruction that involved student interests, activity, or learning by doing, as well as group work and cooperation. These tenets were precursors of the emphasis in modern VET on collaboration, teamwork, and experiential learning for both children and adults. Innovative European VET recognizes that the development of professional competencies both for faculty and for students involve active experience. “In this context, learning is not committing to memory or fragmented and de-contextualized knowledge, but learning by doing” (Leney and Green, 2005: 269).

VET Faculty Characteristics, Qualifications, and Credentials

Viable VET programs require teachers who are competent in their occupational fields and competent in their pedagogy and teaching skills. While the list varies depending upon the compiler, the following disciplines are typically considered to be representative of vocational education at both the secondary and postsecondary level: agriculture, business, family and consumer sciences, health occupations, marketing, technology (including engineering technologies), trade, and industrial education.

Traditionally, a two-tier method has been utilized for the preparation of vocational faculty. Teachers in agriculture, business, and family and consumer sciences, for example, are primarily trained through baccalaureate degree programs. Public and private universities and colleges offer professional teacher-education programs, along with discipline-specific coursework. Most students are required to complete a student-teaching internship under the direction of an experienced teacher and mentor. Trade and industrial teachers, on the other hand, have been prepared largely through years of occupational experience coupled with minimal academic or professional-education courses. Teacher-certification requirements at the secondary level are changing to require a baccalaureate degree and certification of all teachers; however, at the postsecondary level there is still much more variance and dispute in the relative importance of experience versus formal education. While trade and industry faculty, health-occupations faculty, and those teaching in more than one specialty are less likely to have baccalaureate degrees, those whose teaching specialties included agriculture, business, technology, and family and consumer sciences, are more like their academic peers in terms of education and degree attainment.

The fact remains that overall VET faculty typically have fewer academic qualifications and more work experience than liberal-arts faculty. Historically, vocational faculty have maintained that real-world practical experience is a necessary precursor to teaching in some areas.

Educational attainment varies markedly depending upon the teaching specialty of the faculty member. This tendency for limited formal education is most apparent in the trades and industrial areas. For example, it would seem obvious that teachers who have never been auto mechanics, or welders, or plumbers, or electricians would have difficulty teaching these skills to students with any degree of credibility. However, studies over many years have indicated that there is no relationship between the number of years of experience and the effectiveness of teaching. The studies also suggest that extensive occupational experience does not confer extensive benefits on vocational teaching; nevertheless teaching is enhanced with some practical experience. Thus, VET faculty in the trades and industrial areas would do well to combine both formal education and knowledge of pedagogy with some practical, on-the-job experience for maximum effectiveness in the classroom.

Due to the wide variance in education and certification, as well as teacher shortages in secondary schools, a variety of alternative certification programs have been developed to encourage VET faculty into the classroom. Alternative routes to the profession include measures of occupation competency, professional experience, and completion of a baccalaureate degree in a relevant subject area without any formal professional-education courses. While some critics insist that alternatively certified teachers are inferior to traditionally certified teachers, others believe that providing alternative certification will attract competent and diverse candidates, as well as those equipped and willing to teach in urban schools, and will help alleviate the teacher shortage.

A large study involving 31 European nations revealed similar issues in the fragmented situation with regard to the education, training, and recruitment of VET professionals. The study suggested that closer cooperation between institution of VET teacher and trainer education and training across Europe, along with a closer connection between the community of practice of VET professionals, researchers, and policymakers would do a great deal to improve the professionalism and skills of VET teachers. Several countries indicated specific measures and goals to strengthen training for VET teachers including:

re-establishing the prestige of the teacher's profession (Bulgaria); enterprise experience for VET teachers during their careers (France); . . . introduction of the VET Teacher Training Certificate (Malta); a project of making teaching more attractive (Sweden); and special teacher training for teachers lacking qualifications (Sweden)” (Leney and Green, 2005: 267–268).

That same study emphasized the importance of faculty being able to provide an experience-based route into work-life hinged on the acquisition of key competencies which complement the more traditional teaching and

learning of technical skills. The study also indicates the centrality of being both a part of the labor market and having close ties and access to general and higher education. All these issues require constant vigilance and attention of VET faculty.

Understanding the challenges faced by contemporary VET faculty helps in developing curricular components for viable and useful teacher-preparation programs. Some of the areas in which future VET faculty will need strong competencies, regardless of their teaching specialties, include contextualized teaching and learning, articulation of secondary/postsecondary programs, alternative methods of student assessment, work-based learning which incorporates service learning, internships, cooperative education, and apprenticeships. They need to understand the importance of interpersonal relationships and so-called soft skills. Entrepreneurship education occupies an increasingly important niche in vocational education in as much as that is where many new jobs are created. Education for entrepreneurship is also seen as a key competence which merits a more prominent role in VET in Europe, Asia, and Africa as well. Understanding and teaching entrepreneurship involves not only discipline-based skills, but also skills in understanding capital acquisition, business plan development, and marketing. Perhaps most importantly, the contemporary VET faculty must be able to integrate academic and vocational education and understand the importance of their synergy.

VET faculty have to be well aware of the role of globalization and international business in their teaching. As Shaw (1999) maintains, there is no doubt that change and reform in European Union (EU) training and education systems will ultimately be driven by changes in the marketplace. Many of these changes in the workforce are driven by increasing globalization and have a direct impact on education and training systems and subsequently on VET faculty. Thus the need is strong to "ensure that larger portions of the workforce hold vocational qualification; ensure that VET processes are relevant to the needs of industry and commerce; and allow for and build in continuing education in order to meet changing skills and technology requirements" (Shaw, 1999: 140).

Similarly, in Finland, through the globalizing of industry, vocational education changed from an occupation focus into an organization focus. Occupational work became subsumed under the skills and competencies needed for flexible employability. Teachers became preoccupied with networking with various stakeholders and organizations rather than spending time with students. "Vocational pedagogy was substituted by training of skills, organizational and personnel development. Thus, the characteristic features of Finnish vocational education seem to lose their function. Vocational teachers are no more primarily proponents of occupation, but didactic-managerial experts" (Heikkinen, 2001: 242).

VET reform in Central Asia as a part of the post-Soviet economic transition has seen old, specialized training for declining industries replaced by a multiskilled labor force that is more able to respond to the emerging market economy. Initiatives to raise the status of teachers are necessarily coupled with an attempt to reduce teacher numbers and curriculum hours and develop more dynamic, student-centered learning. There is opportunity for VET if existing institutions will take the lead in responding to market forces and new business and industry (Howse, 2001).

In America, as in Europe and Asia, vocational education is in a transition period in which there is a perceptible shift from job-specific vocational preparation to a more generic approach, frequently labeled the new vocationalism. The new vocationalism posits that both secondary and postsecondary curricula should be more general and less job specific, allowing students more possible career options. It places strong emphasis on three core curriculum issues: (1) integration of academic and vocational education, (2) articulation of secondary and postsecondary programs, and (3) connections between school and the world of work (Rojewski, 2002). This connection between school and work is exemplified in the model of VET being delivered in the workplace with an increased emphasis on assessment rather than on teaching.

The new vocationalism also implies new demands on VET faculty, requiring them to become well versed in curriculum integration while assuming leadership in providing work-based learning activities such as job shadowing, internships, cooperative education, and school-based enterprises. They are expected to acquire new methods of pedagogy, new ways to assess student learning, new understanding of diverse populations, and a command of instructional technology. Faculty are expected to be fully engaged in these general practices while still maintaining content-area competencies. Further, many faculty have faced uncertainty about the future of their subject areas as their industrial area has either changed or contracted rapidly. New teaching areas have been introduced, including beauty (cosmetology), hospitality, and information technology (IT). Teachers have been required to change the way they taught because of the introduction of competency-based training and the need to develop courses that suit particular employers. Similar to what has transpired in the US, in Australia, alterations in the nature, status, and qualification requirements of the teaching workforce in the VET sector have led to changes in the settings in which VET is delivered, expansion in the market, and new initiatives in the qualifications for VET teachers. In short, the role of a vocational faculty member has become much more demanding and challenging than it once was. It is not sufficient today, as it once was, only to be proficient in a trade or profession.

As is the case with faculty in general, vocational instructors are aging. Many joined educational institutions

in the early boom years for vocational education in the 1970s and are nearing retirement. Particularly troublesome is the fact that vocational education teachers are in general older than their liberal-arts colleagues, though they are similar in years of teaching experience. This may be explained by the fact that many vocational-education teachers have substantial business or industry experience prior to entering the educational arena. The pattern is not unique to America; in Australia as well, the VET workforce is relatively old, with many teachers in their 40s and 50s (Smith, 2005). Whatever the reasons, the aging of vocational faculty and administrators is a policy issue for political and educational leaders. Consideration should be given to the types of incentives that might be employed to encourage young educators to engage in experiences and training that would lead them to become part of the secondary or postsecondary educational system as VET faculty.

Permanent/Casual Faculty in the VET Workforce

Part-time faculty, adjunct faculty, contingent workforce, casual faculty – however they are labeled, part-time faculty have become increasingly important, particularly in postsecondary education. Research has established that in the United States, part-time faculty comprise a substantial portion of higher education faculty and are a majority – nearly two-thirds – among community-college instructors. The community and technical college sector in America is the home of most VET faculty. Thus, many of the VET faculty are involved in education as a secondary pursuit to their full-time work in a trade or profession. In Australia, a majority of full-time teachers were used in VET programs, with a large complement of part-time staff who taught in addition to their regular jobs in trades and professions. Additionally, there are increasingly more part-timers and an extension of casualization and temporary-contract staff (Smith, 2005). Some of the same issues are present in the Central Asian republics of the former Soviet Union as they struggle with a reduction in the number of institutions and fewer full-time VET teachers. Financial realities dictate an emphasis on part-time or short courses and the expansion of private training outside VET, presenting yet additional uncertainty (Howse, 2001).

Given the budget pressures that postsecondary education confronts throughout the world, it is likely that casual faculty are a permanent part of the postsecondary educational landscape. Adjuncts are valued for their specialized knowledge and real-world experience and the close connection to business and industry. They also bring obvious economic benefits to an institution in as much as they are usually paid much less than permanent faculty. In most cases, they do not receive benefits, nor do they require office space or secretarial support. Adjunct faculty can be hired and fired at will and are usually only contracted for

one or two courses and for a single semester at a time. While they may not have as strong a pedagogical background as permanent faculty, many part-time faculty who are in the work-world bring a fresh and reality-based perspective to the classroom. They add diversity, enrichment, and scheduling flexibility to the institution. Those who currently work in a VET field – a business person, a realtor, a carpenter, or a nurse – can bring to the classroom contemporary experiences that are often lacking in full-time faculty. Further, contrary to conventional wisdom, most studies have shown that part-time faculty are as effective as full-time faculty, if student-learning outcomes are the measure. Students learn as much, perform as well, and are as likely to be retained when taught by part-time faculty as they do when taught by their full-time counterparts. Adjunct faculty have no more discipline problems; further, their student evaluations and the grades they give students are comparable to permanent faculty.

Nevertheless, it is true that adjunct faculty may not be as involved or knowledgeable about other important functions (such as financial aid, student services, library services, etc.). Thus, it is imperative that administrators be sensitive to the needs of adjunct faculty and be sure they have access to the same information and resources as do full-time faculty. That is particularly important if the part-time faculty teach in the evening or on weekends or at sites other than the main campus, when the full complement of services may not be available. It is the responsibility of management to recruit, evaluate, and retain successful part-time faculty. One way to support casual faculty is to provide a strong professional-development program tailored to the specific needs of part-time faculty. They need to understand what the institution expects of them through thorough orientation programs and ongoing support. Realizing that part-time faculty choose to teach for a variety of reasons, administrators need to be cognizant of the best ways to integrate them into the culture of the institution.

Professional Development for VET Faculty

Retention strategies are critical in maintaining a strong VET teaching corps at both the secondary and postsecondary levels. Research suggests the importance of retention strategies, particularly in the first 5 years of a new teacher's career. One strategy with documented success is the assignment of a support team to a new teacher. The team includes a subject-area peer teacher, an administrator, a staff person, and a teacher educator. Together, the team sees that the new teacher has the necessary resources and support to be successful.

Another strategy for supporting novice teachers at either the secondary or postsecondary level is the use of a mentoring system. Ideally, the mentor is a master

teacher in the discipline with a track record of good classroom management and positive relationships with students and peers. While mentoring programs are often looked at as a costly expense, considering the cost of recruiting and rehiring new teachers on a frequent basis, mentoring might be considered as a wise investment and fiscally efficient and effective.

When queried as to their needs regarding professional development, VET faculty responded that classroom management and working with special populations were areas in which they felt inadequately prepared (Ruhland and Bremer, 2003). As the demographics of the student population, particularly in Europe and in North America, are changing rapidly, with more variety in ethnicity, language, age, and academic preparation, VET faculty require additional support and assistance in meeting the needs of their new students.

VET faculty, more so than liberal arts faculty, need opportunities to return to the workplace for visits, internships, shadowing experiences, and industrial training. Particularly in fast-changing technology-based disciplines, it is imperative that faculty remain current within their teaching area and within the larger field of vocational and technical education. Thus, short-term leaves of absence should be made available, as well as opportunities to attend professional-association meetings and conferences. Where appropriate, back-to-industry experiences should be sought out and supported. Inservice training is often required for continuing licensure or certification in many fields, particularly in healthcare and in engineering technologies. Administration must be mindful of the time, cost, and commitment involved in maintaining vocational competency and provide appropriate support.

Administrators who are committed to providing professional-development opportunities for both permanent and adjunct faculty are often frustrated by the increasingly difficult challenge of bringing faculty together in one place at one time. The growth of the Internet has provided new avenues for bringing professional development, continuing education, and other educational opportunities to geographically dispersed and busy VET faculty. There is no need to tune in at a particular time or to drive to a specific location. Instead, learning can be asynchronous and accessed on the schedule of the faculty member. Professional-development opportunities are vital for VET faculty to continue to grow with their respective disciplines and to be well-prepared to provide competent, up-to-date leadership in the classroom, in the laboratories, and in the field.

Professional development can also play a significant role in upgrading the status and respect accorded VET faculty. In a study of 13 European partners, reform strategies were developed with the purpose of improving vocational education and its status relative to general education. A key element for reform was the improvement

of the status and qualifications of vocational teachers. Of the four strategies adopted, the one regarding the status and qualifications of vocational teachers was the most difficult to implement largely because of the great salary differentials between the private and public sectors. Nevertheless, opportunities for professional development and the standardization of qualifications for students and teachers surfaced as a common trans-European trend (Stenstrom and Lasonen 2004).

Summary

The roots of VET are both deep and broad. While the earliest vocational training took place within the family, vocational education was soon formalized through the guilds and apprenticeships. VET faculty have always been challenged to be not only competent, but also forward-thinking and on the cutting edge of their respective disciplines. While some faculty have been prepared for their roles through traditional college and university courses, others have brought extensive work experience. The increasing use of casual or part-time faculty has had both positive and negative effects on the profession. Often the part-timers bring valuable current experience to the classroom. However, with the budget pressures endemic in education, casual faculty are sometimes hired in place of, rather than as adjunct to, full-time faculty. Finally, if the VET workforce is to preserve its importance in the education and training of both young people and adults, it will be increasingly necessary for faculty to have continuing professional development experiences in order to maintain their currency and their credibility in the classroom, within the institution, and within the workplace. As the requirements of the workplace change and as academic and vocational enterprises become less distinct, the VET workforce will be constantly challenged to meet the needs of an increasingly diverse and globalized work environment.
